

# MySQL 5.6 Reference Manual

---

# MySQL 5.6 Reference Manual

## Abstract

This is the MySQL™ Reference Manual. It documents MySQL 5.6 through 5.6.12.

MySQL Cluster is currently not supported in MySQL 5.6. For information about MySQL Cluster, please see [MySQL Cluster NDB 7.2](#).

**MySQL 5.6 features.** This manual describes features that are not included in every edition of MySQL 5.6; such features may not be included in the edition of MySQL 5.6 licensed to you. If you have any questions about the features included in your edition of MySQL 5.6, refer to your MySQL 5.6 license agreement or contact your Oracle sales representative.

For release notes detailing the changes in each release, see the [MySQL 5.6 Release Notes](#).

For legal information, see the [Legal Notices](#).

Document generated on: 2013-04-16 (revision: 34905)

# Table of Contents

Preface and Legal Notices .....	xxi
1. General Information .....	1
1.1. About This Manual .....	2
1.2. Typographical and Syntax Conventions .....	2
1.3. Overview of the MySQL Database Management System .....	4
1.3.1. What is MySQL? .....	4
1.3.2. The Main Features of MySQL .....	6
1.3.3. History of MySQL .....	8
1.4. What Is New in MySQL 5.6 .....	9
1.5. MySQL Development History .....	17
1.6. MySQL Information Sources .....	18
1.6.1. MySQL Mailing Lists .....	18
1.6.2. MySQL Community Support at the MySQL Forums .....	20
1.6.3. MySQL Community Support on Internet Relay Chat (IRC) .....	21
1.6.4. MySQL Enterprise .....	21
1.7. How to Report Bugs or Problems .....	21
1.8. MySQL Standards Compliance .....	26
1.8.1. What Standards MySQL Follows .....	26
1.8.2. Selecting SQL Modes .....	26
1.8.3. Running MySQL in ANSI Mode .....	27
1.8.4. MySQL Extensions to Standard SQL .....	27
1.8.5. MySQL Differences from Standard SQL .....	30
1.8.6. How MySQL Deals with Constraints .....	34
1.9. Credits .....	38
1.9.1. Contributors to MySQL .....	38
1.9.2. Documenters and translators .....	42
1.9.3. Packages that support MySQL .....	44
1.9.4. Tools that were used to create MySQL .....	44
1.9.5. Supporters of MySQL .....	45
2. Installing and Upgrading MySQL .....	47
2.1. General Installation Guidance .....	49
2.1.1. Operating Systems Supported by MySQL Community Server .....	49
2.1.2. Choosing Which MySQL Distribution to Install .....	50
2.1.3. How to Get MySQL .....	53
2.1.4. Verifying Package Integrity Using MD5 Checksums or <a href="#">GnuPG</a> .....	54
2.1.5. Installation Layouts .....	62
2.1.6. Compiler-Specific Build Characteristics .....	62
2.2. Installing MySQL from Generic Binaries on Unix/Linux .....	62
2.3. Installing MySQL on Microsoft Windows .....	65
2.3.1. MySQL Installation Layout on Microsoft Windows .....	66
2.3.2. Choosing An Installation Package .....	67
2.3.3. Installing MySQL on Microsoft Windows Using MySQL Installer .....	67
2.3.4. Installing MySQL on Microsoft Windows Using a <a href="#">noinstall</a> Zip Archive .....	84
2.3.5. Troubleshooting a Microsoft Windows MySQL Server Installation .....	96
2.3.6. Upgrading MySQL on Windows .....	97
2.3.7. Windows Postinstallation Procedures .....	98
2.4. Installing MySQL on Mac OS X .....	100
2.4.1. General Notes on Installing MySQL on Mac OS X .....	100
2.4.2. Installing MySQL on Mac OS X Using Native Packages .....	101
2.4.3. Installing the MySQL Startup Item .....	104
2.4.4. Installing and Using the MySQL Preference Pane .....	107
2.4.5. Using the Bundled MySQL on Mac OS X Server .....	109
2.5. Installing MySQL on Linux .....	109
2.5.1. Installing MySQL from RPM Packages on Linux .....	110
2.5.2. Installing MySQL on Linux using Native Package Manager .....	114

2.6. Installing MySQL on Solaris and OpenSolaris .....	118
2.6.1. Installing MySQL on Solaris using a Solaris <code>PKG</code> .....	118
2.6.2. Installing MySQL on OpenSolaris using <code>IPS</code> .....	119
2.7. Installing MySQL on HP-UX .....	120
2.7.1. General Notes on Installing MySQL on HP-UX .....	120
2.7.2. Installing MySQL on HP-UX using <code>DEPOT</code> .....	121
2.8. Installing MySQL on FreeBSD .....	121
2.9. Installing MySQL from Source .....	122
2.9.1. MySQL Layout for Source Installation .....	124
2.9.2. Installing MySQL from a Standard Source Distribution .....	124
2.9.3. Installing MySQL from a Development Source Tree .....	127
2.9.4. MySQL Source-Configuration Options .....	129
2.9.5. Dealing with Problems Compiling MySQL .....	137
2.9.6. MySQL Configuration and Third-Party Tools .....	138
2.10. Postinstallation Setup and Testing .....	139
2.10.1. Unix Postinstallation Procedures .....	139
2.10.2. Securing the Initial MySQL Accounts .....	150
2.11. Upgrading or Downgrading MySQL .....	153
2.11.1. Upgrading MySQL .....	154
2.11.2. Downgrading MySQL .....	159
2.11.3. Checking Whether Tables or Indexes Must Be Rebuilt .....	161
2.11.4. Rebuilding or Repairing Tables or Indexes .....	163
2.11.5. Copying MySQL Databases to Another Machine .....	164
2.12. Environment Variables .....	165
2.13. Perl Installation Notes .....	167
2.13.1. Installing Perl on Unix .....	167
2.13.2. Installing ActiveState Perl on Windows .....	168
2.13.3. Problems Using the Perl <code>DBI/DBD</code> Interface .....	168
3. Tutorial .....	171
3.1. Connecting to and Disconnecting from the Server .....	171
3.2. Entering Queries .....	172
3.3. Creating and Using a Database .....	175
3.3.1. Creating and Selecting a Database .....	176
3.3.2. Creating a Table .....	177
3.3.3. Loading Data into a Table .....	178
3.3.4. Retrieving Information from a Table .....	179
3.4. Getting Information About Databases and Tables .....	191
3.5. Using <code>mysql</code> in Batch Mode .....	192
3.6. Examples of Common Queries .....	193
3.6.1. The Maximum Value for a Column .....	194
3.6.2. The Row Holding the Maximum of a Certain Column .....	194
3.6.3. Maximum of Column per Group .....	195
3.6.4. The Rows Holding the Group-wise Maximum of a Certain Column .....	195
3.6.5. Using User-Defined Variables .....	196
3.6.6. Using Foreign Keys .....	196
3.6.7. Searching on Two Keys .....	197
3.6.8. Calculating Visits Per Day .....	198
3.6.9. Using <code>AUTO_INCREMENT</code> .....	198
3.7. Using MySQL with Apache .....	200
4. MySQL Programs .....	203
4.1. Overview of MySQL Programs .....	204
4.2. Using MySQL Programs .....	208
4.2.1. Invoking MySQL Programs .....	208
4.2.2. Connecting to the MySQL Server .....	209
4.2.3. Specifying Program Options .....	212
4.2.4. Setting Environment Variables .....	224
4.3. MySQL Server and Server-Startup Programs .....	225
4.3.1. <code>mysqld</code> — The MySQL Server .....	225

4.3.2. <code>mysqld_safe</code> — MySQL Server Startup Script .....	225
4.3.3. <code>mysql.server</code> — MySQL Server Startup Script .....	230
4.3.4. <code>mysqld_multi</code> — Manage Multiple MySQL Servers .....	231
4.4. MySQL Installation-Related Programs .....	235
4.4.1. <code>comp_err</code> — Compile MySQL Error Message File .....	235
4.4.2. <code>mysqlbug</code> — Generate Bug Report .....	236
4.4.3. <code>mysql_install_db</code> — Initialize MySQL Data Directory .....	236
4.4.4. <code>mysql_plugin</code> — Configure MySQL Server Plugins .....	238
4.4.5. <code>mysql_secure_installation</code> — Improve MySQL Installation Security .....	240
4.4.6. <code>mysql_tzinfo_to_sql</code> — Load the Time Zone Tables .....	241
4.4.7. <code>mysql_upgrade</code> — Check and Upgrade MySQL Tables .....	241
4.5. MySQL Client Programs .....	244
4.5.1. <code>mysql</code> — The MySQL Command-Line Tool .....	244
4.5.2. <code>mysqladmin</code> — Client for Administering a MySQL Server .....	266
4.5.3. <code>mysqlcheck</code> — A Table Maintenance Program .....	272
4.5.4. <code>mysqldump</code> — A Database Backup Program .....	279
4.5.5. <code>mysqlimport</code> — A Data Import Program .....	297
4.5.6. <code>mysqlshow</code> — Display Database, Table, and Column Information .....	302
4.5.7. <code>mysqlslap</code> — Load Emulation Client .....	306
4.6. MySQL Administrative and Utility Programs .....	313
4.6.1. <code>innochecksum</code> — Offline InnoDB File Checksum Utility .....	313
4.6.2. <code>myisam_ftdump</code> — Display Full-Text Index information .....	314
4.6.3. <code>myisamchk</code> — MyISAM Table-Maintenance Utility .....	315
4.6.4. <code>myisamlog</code> — Display MyISAM Log File Contents .....	331
4.6.5. <code>myisampack</code> — Generate Compressed, Read-Only MyISAM Tables .....	332
4.6.6. <code>mysql_config_editor</code> — MySQL Configuration Utility .....	337
4.6.7. <code>mysqlaccess</code> — Client for Checking Access Privileges .....	343
4.6.8. <code>mysqlbinlog</code> — Utility for Processing Binary Log Files .....	345
4.6.9. <code>mysqldumpslow</code> — Summarize Slow Query Log Files .....	364
4.6.10. <code>mysqlhotcopy</code> — A Database Backup Program .....	365
4.6.11. <code>mysql_convert_table_format</code> — Convert Tables to Use a Given Storage Engine .....	368
4.6.12. <code>mysql_find_rows</code> — Extract SQL Statements from Files .....	369
4.6.13. <code>mysql_fix_extensions</code> — Normalize Table File Name Extensions .....	370
4.6.14. <code>mysql_setpermission</code> — Interactively Set Permissions in Grant Tables .....	370
4.6.15. <code>mysql_waitpid</code> — Kill Process and Wait for Its Termination .....	371
4.6.16. <code>mysql_zap</code> — Kill Processes That Match a Pattern .....	371
4.7. MySQL Program Development Utilities .....	372
4.7.1. <code>msql2mysql</code> — Convert mSQL Programs for Use with MySQL .....	372
4.7.2. <code>mysql_config</code> — Display Options for Compiling Clients .....	373
4.7.3. <code>my_print_defaults</code> — Display Options from Option Files .....	374
4.7.4. <code>resolve_stack_dump</code> — Resolve Numeric Stack Trace Dump to Symbols .....	375
4.8. Miscellaneous Programs .....	375
4.8.1. <code>perror</code> — Explain Error Codes .....	375
4.8.2. <code>replace</code> — A String-Replacement Utility .....	376
4.8.3. <code>resolveip</code> — Resolve Host name to IP Address or Vice Versa .....	377
5. MySQL Server Administration .....	379
5.1. The MySQL Server .....	380
5.1.1. Server Option and Variable Reference .....	380
5.1.2. Server Configuration Defaults .....	410
5.1.3. Server Command Options .....	412
5.1.4. Server System Variables .....	447
5.1.5. Using System Variables .....	564
5.1.6. Server Status Variables .....	576
5.1.7. Server SQL Modes .....	602
5.1.8. Server Plugins .....	609
5.1.9. IPv6 Support .....	613
5.1.10. Server-Side Help .....	617

5.1.11. Server Response to Signals .....	617
5.1.12. The Shutdown Process .....	618
5.2. MySQL Server Logs .....	619
5.2.1. Selecting General Query and Slow Query Log Output Destinations .....	620
5.2.2. The Error Log .....	622
5.2.3. The General Query Log .....	623
5.2.4. The Binary Log .....	624
5.2.5. The Slow Query Log .....	635
5.2.6. Server Log Maintenance .....	637
5.3. Managing Disk I/O and File Space for <a href="#">InnoDB</a> Tables .....	638
5.3.1. <a href="#">InnoDB</a> Disk I/O .....	638
5.3.2. File Space Management .....	639
5.3.3. <a href="#">InnoDB</a> Checkpoints .....	640
5.3.4. Defragmenting a Table .....	640
5.4. Creating and Using <a href="#">InnoDB</a> Tables and Indexes .....	640
5.4.1. Managing <a href="#">InnoDB</a> Tablespace .....	641
5.4.2. Grouping DML Operations with Transactions .....	645
5.4.3. Converting Tables from <a href="#">MyISAM</a> to <a href="#">InnoDB</a> .....	645
5.4.4. <a href="#">AUTO_INCREMENT</a> Handling in <a href="#">InnoDB</a> .....	650
5.4.5. <a href="#">InnoDB</a> and <a href="#">FOREIGN KEY</a> Constraints .....	655
5.4.6. Working with <a href="#">InnoDB</a> Compressed Tables .....	656
5.4.7. <a href="#">InnoDB</a> File-Format Management .....	667
5.4.8. How <a href="#">InnoDB</a> Stores Variable-Length Columns .....	672
5.5. Online DDL for <a href="#">InnoDB</a> Tables .....	674
5.5.1. Overview of Online DDL .....	674
5.5.2. Performance and Concurrency Considerations for Online DDL .....	679
5.5.3. SQL Syntax for Online DDL .....	681
5.5.4. Combining or Separating DDL Statements .....	682
5.5.5. Examples of Online DDL .....	682
5.5.6. Implementation Details of Online DDL .....	702
5.5.7. How Crash Recovery Works with Online DDL .....	703
5.5.8. DDL for Partitioned Tables .....	704
5.5.9. Limitations of Online DDL .....	704
5.6. Running Multiple MySQL Instances on One Machine .....	705
5.6.1. Setting Up Multiple Data Directories .....	706
5.6.2. Running Multiple MySQL Instances on Windows .....	707
5.6.3. Running Multiple MySQL Instances on Unix .....	710
5.6.4. Using Client Programs in a Multiple-Server Environment .....	711
5.7. Tracing <a href="#">mysqld</a> Using DTrace .....	711
5.7.1. <a href="#">mysqld</a> DTrace Probe Reference .....	713
6. Security .....	731
6.1. General Security Issues .....	732
6.1.1. Security Guidelines .....	732
6.1.2. Keeping Passwords Secure .....	733
6.1.3. Making MySQL Secure Against Attackers .....	746
6.1.4. Security-Related <a href="#">mysqld</a> Options and Variables .....	748
6.1.5. How to Run MySQL as a Normal User .....	748
6.1.6. Security Issues with <a href="#">LOAD DATA LOCAL</a> .....	749
6.1.7. Client Programming Security Guidelines .....	750
6.2. The MySQL Access Privilege System .....	751
6.2.1. Privileges Provided by MySQL .....	752
6.2.2. Privilege System Grant Tables .....	756
6.2.3. Specifying Account Names .....	762
6.2.4. Access Control, Stage 1: Connection Verification .....	763
6.2.5. Access Control, Stage 2: Request Verification .....	766
6.2.6. When Privilege Changes Take Effect .....	768
6.2.7. Causes of Access-Denied Errors .....	768
6.3. MySQL User Account Management .....	773

6.3.1. User Names and Passwords .....	773
6.3.2. Adding User Accounts .....	774
6.3.3. Removing User Accounts .....	778
6.3.4. Setting Account Resource Limits .....	778
6.3.5. Assigning Account Passwords .....	780
6.3.6. Password Expiration and Sandbox Mode .....	781
6.3.7. Pluggable Authentication .....	784
6.3.8. Proxy Users .....	803
6.3.9. Using SSL for Secure Connections .....	806
6.3.10. Connecting to MySQL Remotely from Windows with SSH .....	817
6.3.11. MySQL Enterprise Audit Log Plugin .....	817
6.3.12. SQL-Based MySQL Account Activity Auditing .....	827
7. Backup and Recovery .....	831
7.1. Backup and Recovery Types .....	832
7.2. Database Backup Methods .....	835
7.3. Example Backup and Recovery Strategy .....	837
7.3.1. Establishing a Backup Policy .....	838
7.3.2. Using Backups for Recovery .....	839
7.3.3. Backup Strategy Summary .....	840
7.4. Using <code>mysqldump</code> for Backups .....	840
7.4.1. Dumping Data in SQL Format with <code>mysqldump</code> .....	841
7.4.2. Reloading SQL-Format Backups .....	841
7.4.3. Dumping Data in Delimited-Text Format with <code>mysqldump</code> .....	842
7.4.4. Reloading Delimited-Text Format Backups .....	843
7.4.5. <code>mysqldump</code> Tips .....	844
7.5. Point-in-Time (Incremental) Recovery Using the Binary Log .....	845
7.5.1. Point-in-Time Recovery Using Event Times .....	847
7.5.2. Point-in-Time Recovery Using Event Positions .....	847
7.6. <code>MyISAM</code> Table Maintenance and Crash Recovery .....	848
7.6.1. Using <code>myisamchk</code> for Crash Recovery .....	848
7.6.2. How to Check <code>MyISAM</code> Tables for Errors .....	849
7.6.3. How to Repair <code>MyISAM</code> Tables .....	850
7.6.4. <code>MyISAM</code> Table Optimization .....	852
7.6.5. Setting Up a <code>MyISAM</code> Table Maintenance Schedule .....	853
8. Optimization .....	855
8.1. Optimization Overview .....	856
8.2. Optimizing SQL Statements .....	858
8.2.1. Optimizing <code>SELECT</code> Statements .....	858
8.2.2. Optimizing DML Statements .....	862
8.2.3. Optimizing Database Privileges .....	863
8.2.4. Optimizing <code>INFORMATION_SCHEMA</code> Queries .....	864
8.2.5. Other Optimization Tips .....	868
8.3. Optimization and Indexes .....	871
8.3.1. How MySQL Uses Indexes .....	871
8.3.2. Using Primary Keys .....	872
8.3.3. Using Foreign Keys .....	872
8.3.4. Column Indexes .....	872
8.3.5. Multiple-Column Indexes .....	873
8.3.6. Verifying Index Usage .....	875
8.3.7. <code>InnoDB</code> and <code>MyISAM</code> Index Statistics Collection .....	875
8.3.8. Comparison of B-Tree and Hash Indexes .....	876
8.4. Optimizing Database Structure .....	877
8.4.1. Optimizing Data Size .....	878
8.4.2. Optimizing MySQL Data Types .....	879
8.4.3. Optimizing for Many Tables .....	881
8.5. Optimizing for <code>InnoDB</code> Tables .....	883
8.5.1. Optimizing Storage Layout for <code>InnoDB</code> Tables .....	883
8.5.2. Optimizing <code>InnoDB</code> Transaction Management .....	884

8.5.3. Optimizing <code>InnoDB</code> Logging .....	885
8.5.4. Bulk Data Loading for <code>InnoDB</code> Tables .....	885
8.5.5. Optimizing <code>InnoDB</code> Queries .....	886
8.5.6. Optimizing <code>InnoDB</code> DDL Operations .....	886
8.5.7. Optimizing <code>InnoDB</code> Disk I/O .....	887
8.5.8. Optimizing <code>InnoDB</code> Configuration Variables .....	888
8.5.9. Optimizing <code>InnoDB</code> for Systems with Many Tables .....	889
8.6. Optimizing for <code>MyISAM</code> Tables .....	889
8.6.1. Optimizing <code>MyISAM</code> Queries .....	889
8.6.2. Bulk Data Loading for <code>MyISAM</code> Tables .....	891
8.6.3. Speed of <code>REPAIR TABLE</code> Statements .....	892
8.7. Optimizing for <code>MEMORY</code> Tables .....	893
8.8. Understanding the Query Execution Plan .....	894
8.8.1. Optimizing Queries with <code>EXPLAIN</code> .....	894
8.8.2. <code>EXPLAIN</code> Output Format .....	895
8.8.3. <code>EXPLAIN EXTENDED</code> Output Format .....	906
8.8.4. Estimating Query Performance .....	908
8.8.5. Controlling the Query Optimizer .....	908
8.9. Buffering and Caching .....	911
8.9.1. The <code>InnoDB</code> Buffer Pool .....	911
8.9.2. The <code>MyISAM</code> Key Cache .....	914
8.9.3. The MySQL Query Cache .....	918
8.9.4. Caching of Prepared Statements and Stored Programs .....	924
8.10. Optimizing Locking Operations .....	925
8.10.1. Internal Locking Methods .....	925
8.10.2. Table Locking Issues .....	927
8.10.3. Concurrent Inserts .....	929
8.10.4. Metadata Locking .....	929
8.10.5. External Locking .....	930
8.11. Optimizing the MySQL Server .....	931
8.11.1. System Factors and Startup Parameter Tuning .....	931
8.11.2. Tuning Server Parameters .....	932
8.11.3. Optimizing Disk I/O .....	939
8.11.4. Optimizing Memory Use .....	943
8.11.5. Optimizing Network Use .....	946
8.11.6. The Thread Pool Plugin .....	949
8.12. Measuring Performance (Benchmarking) .....	954
8.12.1. Measuring the Speed of Expressions and Functions .....	955
8.12.2. The MySQL Benchmark Suite .....	955
8.12.3. Using Your Own Benchmarks .....	956
8.12.4. Measuring Performance with <code>performance_schema</code> .....	956
8.12.5. Examining Thread Information .....	956
8.13. Internal Details of MySQL Optimizations .....	969
8.13.1. Range Optimization .....	970
8.13.2. Index Merge Optimization .....	973
8.13.3. Engine Condition Pushdown Optimization .....	976
8.13.4. Index Condition Pushdown Optimization .....	977
8.13.5. Use of Index Extensions .....	978
8.13.6. <code>IS NULL</code> Optimization .....	981
8.13.7. <code>LEFT JOIN</code> and <code>RIGHT JOIN</code> Optimization .....	981
8.13.8. Nested-Loop Join Algorithms .....	982
8.13.9. Nested Join Optimization .....	984
8.13.10. Outer Join Simplification .....	989
8.13.11. Multi-Range Read Optimization .....	991
8.13.12. Block Nested-Loop and Batched Key Access Joins .....	993
8.13.13. <code>ORDER BY</code> Optimization .....	995
8.13.14. <code>GROUP BY</code> Optimization .....	998
8.13.15. <code>DISTINCT</code> Optimization .....	1000

---

8.13.16. Subquery Optimization .....	1001
9. Language Structure .....	1011
9.1. Literal Values .....	1011
9.1.1. String Literals .....	1011
9.1.2. Number Literals .....	1013
9.1.3. Date and Time Literals .....	1014
9.1.4. Hexadecimal Literals .....	1016
9.1.5. Boolean Literals .....	1016
9.1.6. Bit-Field Literals .....	1016
9.1.7. <code>NULL</code> Values .....	1017
9.2. Schema Object Names .....	1017
9.2.1. Identifier Qualifiers .....	1019
9.2.2. Identifier Case Sensitivity .....	1020
9.2.3. Mapping of Identifiers to File Names .....	1021
9.2.4. Function Name Parsing and Resolution .....	1023
9.3. Reserved Words .....	1026
9.4. User-Defined Variables .....	1029
9.5. Expression Syntax .....	1032
9.6. Comment Syntax .....	1034
10. Globalization .....	1037
10.1. Character Set Support .....	1037
10.1.1. Character Sets and Collations in General .....	1038
10.1.2. Character Sets and Collations in MySQL .....	1039
10.1.3. Specifying Character Sets and Collations .....	1040
10.1.4. Connection Character Sets and Collations .....	1046
10.1.5. Configuring the Character Set and Collation for Applications .....	1049
10.1.6. Character Set for Error Messages .....	1050
10.1.7. Collation Issues .....	1051
10.1.8. String Repertoire .....	1060
10.1.9. Operations Affected by Character Set Support .....	1061
10.1.10. Unicode Support .....	1064
10.1.11. Upgrading from Previous to Current Unicode Support .....	1068
10.1.12. UTF-8 for Metadata .....	1070
10.1.13. Column Character Set Conversion .....	1071
10.1.14. Character Sets and Collations That MySQL Supports .....	1072
10.2. Setting the Error Message Language .....	1085
10.3. Adding a Character Set .....	1086
10.3.1. Character Definition Arrays .....	1088
10.3.2. String Collating Support for Complex Character Sets .....	1089
10.3.3. Multi-Byte Character Support for Complex Character Sets .....	1089
10.4. Adding a Collation to a Character Set .....	1089
10.4.1. Collation Implementation Types .....	1090
10.4.2. Choosing a Collation ID .....	1093
10.4.3. Adding a Simple Collation to an 8-Bit Character Set .....	1094
10.4.4. Adding a UCA Collation to a Unicode Character Set .....	1095
10.5. Character Set Configuration .....	1101
10.6. MySQL Server Time Zone Support .....	1102
10.6.1. Staying Current with Time Zone Changes .....	1104
10.6.2. Time Zone Leap Second Support .....	1105
10.7. MySQL Server Locale Support .....	1107
11. Data Types .....	1111
11.1. Data Type Overview .....	1112
11.1.1. Numeric Type Overview .....	1112
11.1.2. Date and Time Type Overview .....	1115
11.1.3. String Type Overview .....	1117
11.2. Numeric Types .....	1120
11.2.1. Integer Types (Exact Value) - <code>INTEGER</code> , <code>INT</code> , <code>SMALLINT</code> , <code>TINYINT</code> , <code>MEDIUMINT</code> , <code>BIGINT</code> .....	1121

---

11.2.2. Fixed-Point Types (Exact Value) - <code>DECIMAL</code> , <code>NUMERIC</code> .....	1121
11.2.3. Floating-Point Types (Approximate Value) - <code>FLOAT</code> , <code>DOUBLE</code> .....	1122
11.2.4. Bit-Value Type - <code>BIT</code> .....	1122
11.2.5. Numeric Type Attributes .....	1122
11.2.6. Out-of-Range and Overflow Handling .....	1123
11.3. Date and Time Types .....	1124
11.3.1. The <code>DATE</code> , <code>DATETIME</code> , and <code>TIMESTAMP</code> Types .....	1126
11.3.2. The <code>TIME</code> Type .....	1127
11.3.3. The <code>YEAR</code> Type .....	1128
11.3.4. <code>YEAR(2)</code> Limitations and Migrating to <code>YEAR(4)</code> .....	1128
11.3.5. Automatic Initialization and Updating for <code>TIMESTAMP</code> and <code>DATETIME</code> .....	1131
11.3.6. Fractional Seconds in Time Values .....	1134
11.3.7. Conversion Between Date and Time Types .....	1135
11.3.8. Two-Digit Years in Dates .....	1137
11.4. String Types .....	1137
11.4.1. The <code>CHAR</code> and <code>VARCHAR</code> Types .....	1137
11.4.2. The <code>BINARY</code> and <code>VARBINARY</code> Types .....	1139
11.4.3. The <code>BLOB</code> and <code>TEXT</code> Types .....	1140
11.4.4. The <code>ENUM</code> Type .....	1141
11.4.5. The <code>SET</code> Type .....	1144
11.5. Data Type Default Values .....	1146
11.6. Data Type Storage Requirements .....	1147
11.7. Choosing the Right Type for a Column .....	1151
11.8. Using Data Types from Other Database Engines .....	1151
12. Functions and Operators .....	1153
12.1. Function and Operator Reference .....	1154
12.2. Type Conversion in Expression Evaluation .....	1161
12.3. Operators .....	1164
12.3.1. Operator Precedence .....	1165
12.3.2. Comparison Functions and Operators .....	1165
12.3.3. Logical Operators .....	1171
12.3.4. Assignment Operators .....	1172
12.4. Control Flow Functions .....	1173
12.5. String Functions .....	1175
12.5.1. String Comparison Functions .....	1190
12.5.2. Regular Expressions .....	1193
12.6. Numeric Functions and Operators .....	1198
12.6.1. Arithmetic Operators .....	1199
12.6.2. Mathematical Functions .....	1201
12.7. Date and Time Functions .....	1209
12.8. What Calendar Is Used By MySQL? .....	1229
12.9. Full-Text Search Functions .....	1229
12.9.1. Natural Language Full-Text Searches .....	1231
12.9.2. Boolean Full-Text Searches .....	1234
12.9.3. Full-Text Searches with Query Expansion .....	1236
12.9.4. Full-Text Stopwords .....	1237
12.9.5. Full-Text Restrictions .....	1240
12.9.6. Fine-Tuning MySQL Full-Text Search .....	1241
12.9.7. Adding a Collation for Full-Text Indexing .....	1243
12.10. Cast Functions and Operators .....	1244
12.11. XML Functions .....	1247
12.12. Bit Functions .....	1257
12.13. Encryption and Compression Functions .....	1259
12.14. Information Functions .....	1265
12.15. GTID Functions .....	1273
12.16. Miscellaneous Functions .....	1274
12.17. Functions and Modifiers for Use with <code>GROUP BY</code> Clauses .....	1281
12.17.1. <code>GROUP BY</code> (Aggregate) Functions .....	1281

12.17.2. <code>GROUP BY</code> Modifiers .....	1285
12.17.3. MySQL Extensions to <code>GROUP BY</code> .....	1288
12.18. Spatial Extensions .....	1289
12.18.1. Introduction to MySQL Spatial Support .....	1289
12.18.2. The OpenGIS Geometry Model .....	1290
12.18.3. Supported Spatial Data Formats .....	1296
12.18.4. Creating a Spatially Enabled MySQL Database .....	1297
12.18.5. Spatial Analysis Functions .....	1302
12.18.6. Optimizing Spatial Analysis .....	1312
12.18.7. MySQL Conformance and Compatibility .....	1315
12.19. Precision Math .....	1315
12.19.1. Types of Numeric Values .....	1316
12.19.2. <code>DECIMAL</code> Data Type Changes .....	1316
12.19.3. Expression Handling .....	1317
12.19.4. Rounding Behavior .....	1319
12.19.5. Precision Math Examples .....	1319
13. SQL Statement Syntax .....	1325
13.1. Data Definition Statements .....	1326
13.1.1. <code>ALTER DATABASE</code> Syntax .....	1326
13.1.2. <code>ALTER EVENT</code> Syntax .....	1327
13.1.3. <code>ALTER FUNCTION</code> Syntax .....	1329
13.1.4. <code>ALTER PROCEDURE</code> Syntax .....	1329
13.1.5. <code>ALTER SERVER</code> Syntax .....	1329
13.1.6. <code>ALTER TABLE</code> Syntax .....	1330
13.1.7. <code>ALTER VIEW</code> Syntax .....	1343
13.1.8. <code>CREATE DATABASE</code> Syntax .....	1344
13.1.9. <code>CREATE EVENT</code> Syntax .....	1344
13.1.10. <code>CREATE FUNCTION</code> Syntax .....	1349
13.1.11. <code>CREATE INDEX</code> Syntax .....	1349
13.1.12. <code>CREATE PROCEDURE</code> and <code>CREATE FUNCTION</code> Syntax .....	1352
13.1.13. <code>CREATE SERVER</code> Syntax .....	1357
13.1.14. <code>CREATE TABLE</code> Syntax .....	1358
13.1.15. <code>CREATE TRIGGER</code> Syntax .....	1384
13.1.16. <code>CREATE VIEW</code> Syntax .....	1388
13.1.17. <code>DROP DATABASE</code> Syntax .....	1391
13.1.18. <code>DROP EVENT</code> Syntax .....	1392
13.1.19. <code>DROP FUNCTION</code> Syntax .....	1392
13.1.20. <code>DROP INDEX</code> Syntax .....	1392
13.1.21. <code>DROP PROCEDURE</code> and <code>DROP FUNCTION</code> Syntax .....	1393
13.1.22. <code>DROP SERVER</code> Syntax .....	1393
13.1.23. <code>DROP TABLE</code> Syntax .....	1393
13.1.24. <code>DROP TRIGGER</code> Syntax .....	1394
13.1.25. <code>DROP VIEW</code> Syntax .....	1394
13.1.26. <code>RENAME TABLE</code> Syntax .....	1394
13.1.27. <code>TRUNCATE TABLE</code> Syntax .....	1395
13.2. Data Manipulation Statements .....	1396
13.2.1. <code>CALL</code> Syntax .....	1396
13.2.2. <code>DELETE</code> Syntax .....	1398
13.2.3. <code>DO</code> Syntax .....	1402
13.2.4. <code>HANDLER</code> Syntax .....	1402
13.2.5. <code>INSERT</code> Syntax .....	1403
13.2.6. <code>LOAD DATA INFILE</code> Syntax .....	1412
13.2.7. <code>LOAD XML</code> Syntax .....	1420
13.2.8. <code>REPLACE</code> Syntax .....	1426
13.2.9. <code>SELECT</code> Syntax .....	1427
13.2.10. Subquery Syntax .....	1445
13.2.11. <code>UPDATE</code> Syntax .....	1455
13.3. MySQL Transactional and Locking Statements .....	1458

13.3.1. <code>START TRANSACTION</code> , <code>COMMIT</code> , and <code>ROLLBACK</code> Syntax .....	1458
13.3.2. Statements That Cannot Be Rolled Back .....	1460
13.3.3. Statements That Cause an Implicit Commit .....	1461
13.3.4. <code>SAVEPOINT</code> , <code>ROLLBACK TO SAVEPOINT</code> , and <code>RELEASE SAVEPOINT</code> Syntax .....	1462
13.3.5. <code>LOCK TABLES</code> and <code>UNLOCK TABLES</code> Syntax .....	1462
13.3.6. <code>SET TRANSACTION</code> Syntax .....	1468
13.3.7. XA Transactions .....	1470
13.4. Replication Statements .....	1474
13.4.1. SQL Statements for Controlling Master Servers .....	1474
13.4.2. SQL Statements for Controlling Slave Servers .....	1476
13.5. SQL Syntax for Prepared Statements .....	1486
13.5.1. <code>PREPARE</code> Syntax .....	1489
13.5.2. <code>EXECUTE</code> Syntax .....	1490
13.5.3. <code>DEALLOCATE PREPARE</code> Syntax .....	1490
13.6. MySQL Compound-Statement Syntax .....	1490
13.6.1. <code>BEGIN . . . END</code> Compound-Statement Syntax .....	1490
13.6.2. Statement Label Syntax .....	1491
13.6.3. <code>DECLARE</code> Syntax .....	1492
13.6.4. Variables in Stored Programs .....	1492
13.6.5. Flow Control Statements .....	1493
13.6.6. Cursors .....	1498
13.6.7. Condition Handling .....	1499
13.7. Database Administration Statements .....	1521
13.7.1. Account Management Statements .....	1521
13.7.2. Table Maintenance Statements .....	1536
13.7.3. Plugin and User-Defined Function Statements .....	1544
13.7.4. <code>SET</code> Syntax .....	1547
13.7.5. <code>SHOW</code> Syntax .....	1549
13.7.6. Other Administrative Statements .....	1588
13.8. MySQL Utility Statements .....	1596
13.8.1. <code>DESCRIBE</code> Syntax .....	1596
13.8.2. <code>EXPLAIN</code> Syntax .....	1596
13.8.3. <code>HELP</code> Syntax .....	1598
13.8.4. <code>USE</code> Syntax .....	1599
14. Storage Engines .....	1601
14.1. Setting the Storage Engine .....	1604
14.2. The <code>InnoDB</code> Storage Engine .....	1605
14.2.1. Getting Started with <code>InnoDB</code> Tables .....	1606
14.2.2. Administering <code>InnoDB</code> .....	1613
14.2.3. <code>InnoDB</code> Concepts and Architecture .....	1622
14.2.4. <code>InnoDB</code> Performance Tuning and Troubleshooting .....	1644
14.2.5. <code>InnoDB</code> Features for Flexibility, Ease of Use and Reliability .....	1686
14.2.6. <code>InnoDB</code> Startup Options and System Variables .....	1692
14.2.7. Limits on <code>InnoDB</code> Tables .....	1756
14.2.8. MySQL and the ACID Model .....	1759
14.2.9. <code>InnoDB</code> Integration with memcached .....	1761
14.3. The <code>MyISAM</code> Storage Engine .....	1787
14.3.1. <code>MyISAM</code> Startup Options .....	1789
14.3.2. Space Needed for Keys .....	1791
14.3.3. <code>MyISAM</code> Table Storage Formats .....	1791
14.3.4. <code>MyISAM</code> Table Problems .....	1794
14.4. The <code>MEMORY</code> Storage Engine .....	1795
14.5. The <code>CSV</code> Storage Engine .....	1799
14.5.1. Repairing and Checking CSV Tables .....	1800
14.5.2. CSV Limitations .....	1801
14.6. The <code>ARCHIVE</code> Storage Engine .....	1801
14.7. The <code>BLACKHOLE</code> Storage Engine .....	1802

14.8. The <code>MERGE</code> Storage Engine .....	1804
14.8.1. <code>MERGE</code> Table Advantages and Disadvantages .....	1806
14.8.2. <code>MERGE</code> Table Problems .....	1807
14.9. The <code>FEDERATED</code> Storage Engine .....	1809
14.9.1. <code>FEDERATED</code> Storage Engine Overview .....	1809
14.9.2. How to Create <code>FEDERATED</code> Tables .....	1810
14.9.3. <code>FEDERATED</code> Storage Engine Notes and Tips .....	1813
14.9.4. <code>FEDERATED</code> Storage Engine Resources .....	1814
14.10. The <code>EXAMPLE</code> Storage Engine .....	1814
14.11. Other Storage Engines .....	1815
14.12. Overview of MySQL Storage Engine Architecture .....	1815
14.12.1. Pluggable Storage Engine Architecture .....	1815
14.12.2. The Common Database Server Layer .....	1816
15. High Availability and Scalability .....	1819
15.1. Oracle VM Template for MySQL Enterprise Edition .....	1822
15.2. Overview of MySQL with DRBD/Pacemaker/Corosync/Oracle Linux .....	1822
15.3. Overview of MySQL with Windows Failover Clustering .....	1825
15.4. Using MySQL within an Amazon EC2 Instance .....	1827
15.4.1. Setting Up MySQL on an EC2 AMI .....	1828
15.4.2. EC2 Instance Limitations .....	1829
15.4.3. Deploying a MySQL Database Using EC2 .....	1829
15.5. Using ZFS Replication .....	1832
15.5.1. Using ZFS for File System Replication .....	1833
15.5.2. Configuring MySQL for ZFS Replication .....	1834
15.5.3. Handling MySQL Recovery with ZFS .....	1835
15.6. Using MySQL with <code>memcached</code> .....	1835
15.6.1. Installing <code>memcached</code> .....	1837
15.6.2. Using <code>memcached</code> .....	1838
15.6.3. Developing a <code>memcached</code> Application .....	1856
15.6.4. Getting <code>memcached</code> Statistics .....	1880
15.6.5. <code>memcached</code> FAQ .....	1888
15.7. MySQL Proxy .....	1891
15.7.1. MySQL Proxy Supported Platforms .....	1892
15.7.2. Installing MySQL Proxy .....	1892
15.7.3. MySQL Proxy Command Options .....	1895
15.7.4. MySQL Proxy Scripting .....	1904
15.7.5. Using MySQL Proxy .....	1918
15.7.6. MySQL Proxy FAQ .....	1923
16. Replication .....	1929
16.1. Replication Configuration .....	1930
16.1.1. How to Set Up Replication .....	1931
16.1.2. Replication Formats .....	1940
16.1.3. Replication with Global Transaction Identifiers .....	1947
16.1.4. Replication and Binary Logging Options and Variables .....	1955
16.1.5. Common Replication Administration Tasks .....	2024
16.2. Replication Implementation .....	2026
16.2.1. Replication Implementation Details .....	2027
16.2.2. Replication Relay and Status Logs .....	2028
16.2.3. How Servers Evaluate Replication Filtering Rules .....	2034
16.3. Replication Solutions .....	2040
16.3.1. Using Replication for Backups .....	2041
16.3.2. Using Replication with Different Master and Slave Storage Engines .....	2044
16.3.3. Using Replication for Scale-Out .....	2045
16.3.4. Replicating Different Databases to Different Slaves .....	2046
16.3.5. Improving Replication Performance .....	2047
16.3.6. Switching Masters During Failover .....	2048
16.3.7. Setting Up Replication Using SSL .....	2051
16.3.8. Semisynchronous Replication .....	2052

16.3.9. Delayed Replication .....	2057
16.4. Replication Notes and Tips .....	2057
16.4.1. Replication Features and Issues .....	2057
16.4.2. Replication Compatibility Between MySQL Versions .....	2080
16.4.3. Upgrading a Replication Setup .....	2081
16.4.4. Troubleshooting Replication .....	2082
16.4.5. How to Report Replication Bugs or Problems .....	2083
17. Partitioning .....	2085
17.1. Overview of Partitioning in MySQL .....	2086
17.2. Partitioning Types .....	2089
17.2.1. RANGE Partitioning .....	2091
17.2.2. LIST Partitioning .....	2094
17.2.3. COLUMNS Partitioning .....	2097
17.2.4. HASH Partitioning .....	2104
17.2.5. KEY Partitioning .....	2107
17.2.6. Subpartitioning .....	2108
17.2.7. How MySQL Partitioning Handles NULL .....	2111
17.3. Partition Management .....	2115
17.3.1. Management of RANGE and LIST Partitions .....	2116
17.3.2. Management of HASH and KEY Partitions .....	2121
17.3.3. Exchanging Partitions and Subpartitions with Tables .....	2122
17.3.4. Maintenance of Partitions .....	2127
17.3.5. Obtaining Information About Partitions .....	2128
17.4. Partition Pruning .....	2130
17.5. Partition Selection .....	2133
17.6. Restrictions and Limitations on Partitioning .....	2139
17.6.1. Partitioning Keys, Primary Keys, and Unique Keys .....	2144
17.6.2. Partitioning Limitations Relating to Storage Engines .....	2147
17.6.3. Partitioning Limitations Relating to Functions .....	2148
17.6.4. Partitioning and Locking .....	2149
18. Stored Programs and Views .....	2151
18.1. Defining Stored Programs .....	2152
18.2. Using Stored Routines (Procedures and Functions) .....	2153
18.2.1. Stored Routine Syntax .....	2153
18.2.2. Stored Routines and MySQL Privileges .....	2154
18.2.3. Stored Routine Metadata .....	2154
18.2.4. Stored Procedures, Functions, Triggers, and LAST_INSERT_ID() .....	2155
18.3. Using Triggers .....	2155
18.3.1. Trigger Syntax .....	2156
18.3.2. Trigger Metadata .....	2158
18.4. Using the Event Scheduler .....	2158
18.4.1. Event Scheduler Overview .....	2158
18.4.2. Event Scheduler Configuration .....	2159
18.4.3. Event Syntax .....	2161
18.4.4. Event Metadata .....	2161
18.4.5. Event Scheduler Status .....	2162
18.4.6. The Event Scheduler and MySQL Privileges .....	2163
18.5. Using Views .....	2165
18.5.1. View Syntax .....	2166
18.5.2. View Processing Algorithms .....	2166
18.5.3. Updatable and Insertable Views .....	2167
18.5.4. View Metadata .....	2169

19.30.4. The <code>INFORMATION_SCHEMA</code> <code>INNODB_TRX</code> Table .....	2207
19.30.5. The <code>INFORMATION_SCHEMA</code> <code>INNODB_LOCKS</code> Table .....	2209
19.30.6. The <code>INFORMATION_SCHEMA</code> <code>INNODB_LOCK_WAITS</code> Table .....	2210
19.30.7. The <code>INFORMATION_SCHEMA</code> <code>INNODB_SYS_TABLES</code> Table .....	2210
19.30.8. The <code>INFORMATION_SCHEMA</code> <code>INNODB_SYS_INDEXES</code> Table .....	2211
19.30.9. The <code>INFORMATION_SCHEMA</code> <code>INNODB_SYS_COLUMNS</code> Table .....	2212
19.30.10. The <code>INFORMATION_SCHEMA</code> <code>INNODB_SYS_FIELDS</code> Table .....	2212
19.30.11. The <code>INFORMATION_SCHEMA</code> <code>INNODB_SYS_FOREIGN</code> Table .....	2213
19.30.12. The <code>INFORMATION_SCHEMA</code> <code>INNODB_SYS_FOREIGN_COLS</code> Table .....	2213
19.30.13. The <code>INFORMATION_SCHEMA</code> <code>INNODB_SYS_TABLESTATS</code> View .....	2214
19.30.14. The <code>INFORMATION_SCHEMA</code> <code>INNODB_BUFFER_PAGE</code> Table .....	2214
19.30.15. The <code>INFORMATION_SCHEMA</code> <code>INNODB_BUFFER_PAGE_LRU</code> Table .....	2215
19.30.16. The <code>INFORMATION_SCHEMA</code> <code>INNODB_BUFFER_POOL_STATS</code> Table .....	2216
19.30.17. The <code>INFORMATION_SCHEMA</code> <code>INNODB_METRICS</code> Table .....	2217
19.30.18. The <code>INFORMATION_SCHEMA</code> <code>INNODB_FT_CONFIG</code> Table .....	2222
19.30.19. The <code>INFORMATION_SCHEMA</code> <code>INNODB_FT_DEFAULT_STOPWORD</code> Table .....	2223
19.30.20. The <code>INFORMATION_SCHEMA</code> <code>INNODB_FT_INDEX_TABLE</code> Table .....	2223
19.30.21. The <code>INFORMATION_SCHEMA</code> <code>INNODB_FT_INDEX_CACHE</code> Table .....	2224
19.30.22. The <code>INFORMATION_SCHEMA</code> <code>INNODB_FT_DELETED</code> Table .....	2224
19.30.23. The <code>INFORMATION_SCHEMA</code> <code>INNODB_FT_BEING_DELETED</code> Table .....	2225
19.31. Thread Pool <code>INFORMATION_SCHEMA</code> Tables .....	2225
19.31.1. The <code>INFORMATION_SCHEMA</code> <code>TP_THREAD_STATE</code> Table .....	2226

19.31.2. The <code>INFORMATION_SCHEMA TP_THREAD_GROUP_STATE</code> Table .....	2226
19.31.3. The <code>INFORMATION_SCHEMA TP_THREAD_GROUP_STATS</code> Table .....	2228
19.32. Extensions to <code>SHOW</code> Statements .....	2229
20. MySQL Performance Schema .....	2233
20.1. Performance Schema Quick Start .....	2234
20.2. Performance Schema Configuration .....	2240
20.2.1. Performance Schema Build Configuration .....	2240
20.2.2. Performance Schema Startup Configuration .....	2241
20.2.3. Performance Schema Runtime Configuration .....	2243
20.3. Performance Schema Queries .....	2258
20.4. Performance Schema Instrument Naming Conventions .....	2259
20.5. Performance Schema Status Monitoring .....	2261
20.6. Performance Schema Atom and Molecule Events .....	2264
20.7. Performance Schema Statement Digests .....	2264
20.8. Performance Schema General Table Characteristics .....	2266
20.9. Performance Schema Table Descriptions .....	2266
20.9.1. Performance Schema Setup Tables .....	2266
20.9.2. Performance Schema Instance Tables .....	2270
20.9.3. Performance Schema Wait Event Tables .....	2275
20.9.4. Performance Schema Stage Event Tables .....	2278
20.9.5. Performance Schema Statement Event Tables .....	2279
20.9.6. Performance Schema Connection Tables .....	2284
20.9.7. Performance Schema Connection Attribute Tables .....	2286
20.9.8. Performance Schema Summary Tables .....	2286
20.9.9. Performance Schema Miscellaneous Tables .....	2299
20.10. Performance Schema Option and Variable Reference .....	2305
20.11. Performance Schema Command Options .....	2306
20.12. Performance Schema System Variables .....	2307
20.13. Performance Schema Status Variables .....	2318
20.14. Performance Schema and Plugins .....	2319
20.15. Using the Performance Schema to Diagnose Problems .....	2319
21. Connectors and APIs .....	2321
21.1. MySQL Connector/ODBC .....	2326
21.1.1. Connector/ODBC Versions .....	2327
21.1.2. Connector/ODBC Introduction .....	2327
21.1.3. Connector/ODBC Installation .....	2330
21.1.4. Configuring Connector/ODBC .....	2341
21.1.5. Connector/ODBC Examples .....	2360
21.1.6. Connector/ODBC Reference .....	2386
21.1.7. Connector/ODBC Notes and Tips .....	2392
21.1.8. Connector/ODBC Support .....	2402
21.2. MySQL Connector/Net .....	2403
21.2.1. Connector/Net Versions .....	2404
21.2.2. Connector/Net Installation .....	2406
21.2.3. Connector/Net Visual Studio Integration .....	2414
21.2.4. Connector/Net Tutorials .....	2444
21.2.5. Connector/Net Programming .....	2484
21.2.6. Connector/Net Connection String Options Reference .....	2523
21.2.7. Connector/Net API Reference .....	2530
21.2.8. Connector/Net Support .....	2633
21.2.9. Connector/Net FAQ .....	2634
21.3. MySQL Connector/J .....	2635
21.3.1. Overview of MySQL Connector/J .....	2635
21.3.2. Connector/J Versions .....	2635
21.3.3. Connector/J Installation .....	2637
21.3.4. Connector/J Examples .....	2641
21.3.5. Connector/J (JDBC) Reference .....	2642
21.3.6. JDBC Concepts .....	2675

21.3.7. Connection Pooling with Connector/J .....	2684
21.3.8. Load Balancing with Connector/J .....	2687
21.3.9. Failover with Connector/J .....	2689
21.3.10. Using the Connector/J Interceptor Classes .....	2691
21.3.11. Using Connector/J with Tomcat .....	2691
21.3.12. Using Connector/J with JBoss .....	2693
21.3.13. Using Connector/J with Spring .....	2694
21.3.14. Using Connector/J with GlassFish .....	2698
21.3.15. Troubleshooting Connector/J Applications .....	2704
21.3.16. Connector/J Support .....	2712
21.4. MySQL Connector/C++ .....	2713
21.4.1. How to Get MySQL Connector/C++ .....	2715
21.4.2. Installing MySQL Connector/C++ from a Binary Distribution .....	2716
21.4.3. Installing MySQL Connector/C++ from Source .....	2718
21.4.4. Building MySQL Connector/C++ Windows Applications with Microsoft Visual Studio .....	2723
21.4.5. Building MySQL Connector/C++ Linux Applications with NetBeans .....	2731
21.4.6. MySQL Connector/C++ Getting Started: Usage Examples .....	2735
21.4.7. MySQL Connector/C++ Tutorials .....	2741
21.4.8. MySQL Connector/C++ Debug Tracing .....	2749
21.4.9. MySQL Connector/C++ Usage Notes .....	2750
21.4.10. MySQL Connector/C++ Known Bugs and Issues .....	2754
21.4.11. MySQL Connector/C++ Support .....	2755
21.5. MySQL Connector/C .....	2755
21.5.1. MySQL Connector/C Supported Platforms .....	2755
21.5.2. MySQL Connector/C Distribution Contents .....	2756
21.5.3. Obtaining MySQL Connector/C .....	2756
21.5.4. Installing MySQL Connector/C from a Binary Distribution .....	2756
21.5.5. Installing MySQL Connector/C from Source .....	2756
21.5.6. Testing MySQL Connector/C .....	2758
21.5.7. Building MySQL Connector/C Applications .....	2758
21.6. MySQL Connector/Python .....	2759
21.6.1. Guidelines for Python Developers .....	2759
21.6.2. Connector/Python Versions .....	2761
21.6.3. Connector/Python Installation .....	2761
21.6.4. Connector/Python Coding Examples .....	2762
21.6.5. Connector/Python Tutorials .....	2768
21.6.6. Connector/Python Connection Arguments .....	2769
21.6.7. Connector/Python API Reference .....	2772
21.6.8. Connector/Python FAQ .....	2790
21.7. libmysqld, the Embedded MySQL Server Library .....	2790
21.7.1. Compiling Programs with <a href="#">libmysqld</a> .....	2790
21.7.2. Restrictions When Using the Embedded MySQL Server .....	2791
21.7.3. Options with the Embedded Server .....	2791
21.7.4. Embedded Server Examples .....	2792
21.8. MySQL C API .....	2795
21.8.1. MySQL C API Implementations .....	2796
21.8.2. Example C API Client Programs .....	2797
21.8.3. Building and Running C API Client Programs .....	2797
21.8.4. C API Data Structures .....	2800
21.8.5. C API Function Overview .....	2805
21.8.6. C API Function Descriptions .....	2809
21.8.7. C API Prepared Statements .....	2859
21.8.8. C API Prepared Statement Data Structures .....	2859
21.8.9. C API Prepared Statement Function Overview .....	2865
21.8.10. C API Prepared Statement Function Descriptions .....	2868
21.8.11. C API Threaded Function Descriptions .....	2890
21.8.12. C API Embedded Server Function Descriptions .....	2892

21.8.13. C API Client Plugin Functions .....	2892
21.8.14. Common Questions and Problems When Using the C API .....	2895
21.8.15. Controlling Automatic Reconnection Behavior .....	2897
21.8.16. C API Support for Multiple Statement Execution .....	2898
21.8.17. C API Prepared Statement Problems .....	2900
21.8.18. C API Prepared Statement Handling of Date and Time Values .....	2900
21.8.19. C API Support for Prepared <code>CALL</code> Statements .....	2902
21.9. MySQL PHP API .....	2905
21.9.1. Overview of the MySQL PHP drivers .....	2906
21.9.2. Original MySQL API ( <code>Mysql</code> ) .....	2912
21.9.3. MySQL Improved Extension ( <code>Mysqli</code> ) .....	2982
21.9.4. MySQL Functions (PDO_MYSQL) ( <code>MySQL (PDO)</code> ) .....	3196
21.9.5. MySQL Native Driver ( <code>Mysqlnd</code> ) .....	3200
21.9.6. Mysqlnd replication and load balancing plugin ( <code>mysqlnd_ms</code> ) .....	3232
21.9.7. Mysqlnd query result cache plugin ( <code>mysqlnd_qc</code> ) .....	3333
21.9.8. Mysqlnd user handler plugin ( <code>mysqlnd_uh</code> ) .....	3384
21.9.9. Mysqlnd connection multiplexing plugin ( <code>mysqlnd_mux</code> ) .....	3467
21.9.10. Mysqlnd Memcache plugin ( <code>mysqlnd_memcache</code> ) .....	3471
21.9.11. Connector/PHP .....	3480
21.9.12. Common Problems with MySQL and PHP .....	3480
21.9.13. Enabling Both <code>mysql</code> and <code>mysqli</code> in PHP .....	3480
21.10. MySQL Perl API .....	3481
21.11. MySQL Python API .....	3482
21.12. MySQL Ruby APIs .....	3482
21.12.1. The MySQL/Ruby API .....	3482
21.12.2. The Ruby/MySQL API .....	3482
21.13. MySQL Tcl API .....	3482
21.14. MySQL Eiffel Wrapper .....	3482
22. Extending MySQL .....	3483
22.1. MySQL Internals .....	3483
22.1.1. MySQL Threads .....	3483
22.1.2. The MySQL Test Suite .....	3484
22.2. The MySQL Plugin API .....	3485
22.2.1. Plugin API Characteristics .....	3485
22.2.2. Plugin API Components .....	3486
22.2.3. Types of Plugins .....	3487
22.2.4. Writing Plugins .....	3490
22.2.5. MySQL Services for Plugins .....	3530
22.3. Adding New Functions to MySQL .....	3532
22.3.1. Features of the User-Defined Function Interface .....	3532
22.3.2. Adding a New User-Defined Function .....	3532
22.3.3. Adding a New Native Function .....	3542
22.4. Debugging and Porting MySQL .....	3543
22.4.1. Debugging a MySQL Server .....	3544
22.4.2. Debugging a MySQL Client .....	3550
22.4.3. The DEBUG Package .....	3550
23. MySQL Enterprise Edition .....	3553
23.1. MySQL Enterprise Monitor .....	3553
23.2. MySQL Enterprise Backup .....	3554
23.3. MySQL Enterprise Security .....	3554
23.4. MySQL Enterprise Audit .....	3555
23.5. MySQL Thread Pool .....	3555
24. MySQL Workbench .....	3557
25. MySQL for Excel .....	3559
25.1. Installing and Configuring .....	3559
25.2. Edit MySQL Data .....	3560
25.3. Import MySQL Data .....	3561
25.4. Append MySQL Data .....	3562

25.5. Export MySQL Data .....	3565
25.6. MySQL for Excel FAQ .....	3568

# Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, version 5.6, through release 5.6.12. Differences between minor versions of MySQL 5.6 are noted in the present text with reference to release numbers (5.6.x). For license information, see the [Legal Notices](#). This product may contain third-party code. For license information on third-party code, see [Appendix A, Licenses for Third-Party Components](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.6 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.5 Reference Manual](#) covers the 5.5 series of MySQL software releases.

## Legal Notices

Copyright © 1997, 2013, Oracle and/or its affiliates. All rights reserved.

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this software or related documentation is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, the following notice is applicable:

U.S. GOVERNMENT RIGHTS Programs, software, databases, and related documentation and technical data delivered to U.S. Government customers are "commercial computer software" or "commercial technical data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, duplication, disclosure, modification, and adaptation shall be subject to the restrictions and license terms set forth in the applicable Government contract, and, to the extent applicable by the terms of the Government contract, the additional rights set forth in FAR 52.227-19, Commercial Computer Software License (December 2007). Oracle USA, Inc., 500 Oracle Parkway, Redwood City, CA 94065.

This software is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications which may create a risk of personal injury. If you use this software in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure the safe use of this software. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software in dangerous applications.

Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used without Oracle's express written authorization. Other names may be trademarks of their respective owners.

This software and documentation may provide access to or information on content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services.

This document in any form, software or printed matter, contains proprietary information that is the exclusive property of Oracle. Your access to and use of this material is subject to the terms and conditions of your Oracle Software License and Service Agreement, which has been executed and with

which you agree to comply. This document and information contained herein may not be disclosed, copied, reproduced, or distributed to anyone outside Oracle without prior written consent of Oracle or as specifically provided below. This document is not part of your license agreement nor can it be incorporated into any contractual agreement with Oracle or its subsidiaries or affiliates.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

For more information on the terms of this license, or for details on how the MySQL documentation is built and produced, please visit [MySQL Contact & Questions](#).

For additional licensing information, including licenses for third-party libraries used by MySQL products, see [Preface and Legal Notices](#).

For help with using MySQL, please visit either the [MySQL Forums](#) or [MySQL Mailing Lists](#) where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML and PDF formats, see the [MySQL Documentation Library](#).

# Chapter 1. General Information

## Table of Contents

1.1. About This Manual .....	2
1.2. Typographical and Syntax Conventions .....	2
1.3. Overview of the MySQL Database Management System .....	4
1.3.1. What is MySQL? .....	4
1.3.2. The Main Features of MySQL .....	6
1.3.3. History of MySQL .....	8
1.4. What Is New in MySQL 5.6 .....	9
1.5. MySQL Development History .....	17
1.6. MySQL Information Sources .....	18
1.6.1. MySQL Mailing Lists .....	18
1.6.2. MySQL Community Support at the MySQL Forums .....	20
1.6.3. MySQL Community Support on Internet Relay Chat (IRC) .....	21
1.6.4. MySQL Enterprise .....	21
1.7. How to Report Bugs or Problems .....	21
1.8. MySQL Standards Compliance .....	26
1.8.1. What Standards MySQL Follows .....	26

The MySQL™ software delivers a very fast, multi-threaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle's express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (<http://www.fsf.org/licenses/>) or can purchase a standard commercial license from Oracle. See <http://www.mysql.com/company/legal/licensing/> for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion of MySQL Database Server capabilities, see [Section 1.3.2, “The Main Features of MySQL”](#).
- For an overview of new MySQL features, see [Section 1.4, “What Is New in MySQL 5.6”](#). For information about the changes in each version, see the [Release Notes](#).
- For installation instructions, see [Chapter 2, \*Installing and Upgrading MySQL\*](#). For information about upgrading MySQL, see [Section 2.11.1, “Upgrading MySQL”](#).
- For a tutorial introduction to the MySQL Database Server, see [Chapter 3, \*Tutorial\*](#).

- For information about configuring and administering MySQL Server, see [Chapter 5, MySQL Server Administration](#).
- For information about security in MySQL, see [Chapter 6, Security](#).
- For information about setting up replication servers, see [Chapter 16, Replication](#).
- For information about MySQL Enterprise, the commercial MySQL release with advanced features and management tools, see [Chapter 23, MySQL Enterprise Edition](#).
- For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see [Appendix B, MySQL 5.6 Frequently Asked Questions](#).
- For a history of new features and bugfixes, see the [Release Notes](#).

### Important

To report problems or bugs, please use the instructions at [Section 1.7, “How to Report Bugs or Problems”](#). If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert\\_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support.

## 1.1. About This Manual

This is the Reference Manual for the MySQL Database System, version 5.6, through release 5.6.12. Differences between minor versions of MySQL 5.6 are noted in the present text with reference to release numbers (5.6.x). For license information, see the [Legal Notices](#). This product may contain third-party code. For license information on third-party code, see [Appendix A, Licenses for Third-Party Components](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.6 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.5 Reference Manual](#) covers the 5.5 series of MySQL software releases.

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at <http://dev.mysql.com/doc/>. Other formats also are available there, including HTML, PDF, and EPUB versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see <http://docbook.org/>

If you have questions about using MySQL, you can ask them using our mailing lists or forums. See [Section 1.6.1, “MySQL Mailing Lists”](#), and [Section 1.6.2, “MySQL Community Support at the MySQL Forums”](#). If you have suggestions concerning additions or corrections to the manual itself, please send them to the <http://www.mysql.com/company/contact/>.

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Paul DuBois, Stefan Hinz, Philip Olson, John Russell, and Jon Stephens.

## 1.2. Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- *Text in this style* is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- *Text in this style* indicates input that you type in examples.
- *Text in this style* indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).
- *Text in this style* is used for variable input for which you should substitute a value of your own choosing.
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.
- *Text in this style* is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example:* “The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to”.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘%’ character.”

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, `root-shell>` is similar but should be executed as `root`, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csch`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses `db_name`, `tbl_name`, and `col_name`. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (“[” and “]”) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (“|”). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (“[” and “]”):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (“{” and “}”):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (...) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple `reset_option` values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

## 1.3. Overview of the MySQL Database Management System

### 1.3.1. What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL Web site (<http://www.mysql.com/>) provides the latest information about MySQL software.

- **MySQL is a database management system.**

A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible

programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**

Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), <http://www.fsf.org/licenses/>, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (<http://www.mysql.com/company/legal/licensing/>).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**

If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

You can find a performance comparison of MySQL Server with other database managers on our benchmark page. See [Section 8.12.2, “The MySQL Benchmark Suite”](#).

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**

The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**

MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

## 1.3.2. The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. See also [Section 1.5, “MySQL Development History”](#). In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 5.6: [MySQL 5.6 in a Nutshell](#)
- MySQL 5.5: [MySQL 5.5 in a Nutshell](#)
- MySQL 5.1: [MySQL 5.1 in a Nutshell](#)
- MySQL 5.0: [MySQL 5.0 in a Nutshell](#)

### Internals and Portability:

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See [Section 2.1.1, “Operating Systems Supported by MySQL Community Server”](#).
- For portability, uses [CMake](#) in MySQL 5.5 and up. Previous series use GNU Automake, Autoconf, and Libtool.
- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (<http://developer.kde.org/~sewardj/>).
- Uses multi-layered server design with independent modules.
- Designed to be fully multi-threaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.
- Uses very fast B-tree disk tables ([MyISAM](#)) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

### Data Types:

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, [FLOAT](#), [DOUBLE](#), [CHAR](#), [VARCHAR](#), [BINARY](#), [VARBINARY](#), [TEXT](#), [BLOB](#), [DATE](#), [TIME](#), [DATETIME](#), [TIMESTAMP](#), [YEAR](#), [SET](#), [ENUM](#), and OpenGIS spatial types. See [Chapter 11, Data Types](#).
- Fixed-length and variable-length string types.

## Statements and Functions:

- Full operator and function support in the `SELECT` list and `WHERE` clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
-> FROM citizen
-> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL `GROUP BY` and `ORDER BY` clauses. Support for group functions (`COUNT()` [1283], `AVG()` [1282], `STD()` [1284], `SUM()` [1285], `MAX()` [1284], `MIN()` [1284], and `GROUP_CONCAT()` [1283]).
- Support for `LEFT OUTER JOIN` and `RIGHT OUTER JOIN` with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.
- Support for MySQL-specific `SHOW` statements that retrieve information about databases, storage engines, tables, and indexes. MySQL 5.0 adds support for the `INFORMATION_SCHEMA` database, implemented according to standard SQL.
- An `EXPLAIN` statement to show how the optimizer resolves a query.
- Independence of function names from table or column names. For example, `ABS` is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "(" that follows it. See [Section 9.3, "Reserved Words"](#).
- You can refer to tables from different databases in the same statement.

## Security:

- A privilege and password system that is very flexible and secure, and that enables host-based verification.
- Password security by encryption of all password traffic when you connect to a server.

## Scalability and Limits:

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.
- Support for up to 64 indexes per table (32 before MySQL 4.1.2). Each index may consist of 1 to 16 columns or parts of columns. The maximum index width is 767 bytes for `InnoDB` tables, or 1000 for `MyISAM`; before MySQL 4.1.2, the limit is 500 bytes. An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

## Connectivity:

- Clients can connect to MySQL Server using several protocols:
  - Clients can connect using TCP/IP sockets on any platform.
  - On Windows systems in the NT family (NT, 2000, XP, 2003, or Vista), clients can connect using named pipes if the server is started with the `--enable-named-pipe` [421] option. In MySQL 4.1 and higher, Windows servers also support shared-memory connections if started with the `--shared-memory` [439] option. Clients can connect through shared memory by using the `--protocol=memory` option.
  - On Unix systems, clients can connect using Unix domain socket files.

- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See [Chapter 21, Connectors and APIs](#).
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See [Section 21.1, “MySQL Connector/ODBC”](#).
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See [Section 21.3, “MySQL Connector/J”](#).
- MySQL Connector/Net enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/Net is a fully managed ADO.NET driver written in 100% pure C#. See [Section 21.2, “MySQL Connector/Net”](#).

### Localization:

- The server can provide error messages to clients in many languages. See [Section 10.2, “Setting the Error Message Language”](#).
- Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names. Unicode support is available as of MySQL 4.1.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the chosen character set and collation (using `latin1` and Swedish collation by default). It is possible to change this when the MySQL server is started. To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.
- As of MySQL 4.1, the server time zone can be changed dynamically, and individual clients can specify their own time zone. [Section 10.6, “MySQL Server Time Zone Support”](#).

### Clients and Tools:

- MySQL includes several client and utility programs. These include both command-line programs such as `mysqldump` and `mysqladmin`, and graphical programs such as [MySQL Workbench](#).
- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on `MyISAM` tables. See [Chapter 4, MySQL Programs](#).
- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

### 1.3.3. History of MySQL

We started out with the intention of using the `mSQL` database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that `mSQL` was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as `mSQL`. This API was designed to enable third-party code that was written for use with `mSQL` to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose’s country of origin, Uganda.

## 1.4. What Is New in MySQL 5.6

This section summarizes what has been added to and removed from MySQL 5.6.

### Added Features

The following features have been added to MySQL 5.6:

- **Security improvements.** These security improvements were made:
  - MySQL now provides a method for storing authentication credentials encrypted in an option file named `.mylogin.cnf`. To create the file, use the `mysql_config_editor` utility. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to a MySQL server. `mysql_config_editor` writes the `.mylogin.cnf` file using encryption so the credentials are not stored as clear text, and its contents when decrypted by client programs are used only in memory. In this way, passwords can be stored in a file in non-clear text format and used later without ever needing to be exposed on the command line or in an environment variable. For more information, see [Section 4.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).
  - MySQL now supports stronger encryption for user account passwords, available through an authentication plugin named `sha256_password` that implements SHA-256 password hashing. This plugin is built in, so it is always available and need not be loaded explicitly. For more information, including instructions for creating accounts that use SHA-256 passwords, see [Section 6.3.7.2, “The SHA-256 Authentication Plugin”](#).
  - The `mysql.user` table now has a `password_expired` column. Its default value is 'N', but can be set to 'Y' with the new `ALTER USER` statement. After an account’s password has been expired, all operations performed in subsequent connections to the server using the account result in an error until the user issues a `SET PASSWORD` statement to establish a new account password. For more information, see [Section 13.7.1.1, “ALTER USER Syntax”](#).
  - MySQL now has provision for checking password security:
    - In statements that assign a password supplied as a cleartext value, the value is checked against the current password policy and rejected if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD [3714]` error). This affects the `CREATE USER`, `GRANT`, and `SET PASSWORD` statements. Passwords given as arguments to the `PASSWORD()` [\[1263\]](#) and `OLD_PASSWORD()` [\[1263\]](#) functions are checked as well.
    - The strength of potential passwords can be assessed using the new `VALIDATE_PASSWORD_STRENGTH()` [\[1265\]](#) SQL function, which takes a password argument and returns an integer from 0 (weak) to 100 (strong).

Both capabilities are implemented by the `validate_password` plugin. For more information, see [Section 6.1.2.6, “The Password Validation Plugin”](#).

- `mysql_upgrade` now produces a warning if it finds user accounts with passwords hashed with the older pre-4.1 hashing method. Such accounts should be updated to use more secure password hashing. See [Section 6.1.2.4, “Password Hashing in MySQL”](#)
- On Unix platforms, `mysql_install_db` supports a new option, `--random-passwords` [\[237\]](#), that provides for more secure MySQL installation. Invoking `mysql_install_db` with `--random-`

`passwords` [237] causes it to assign a random password to the MySQL `root` accounts, set the “password expired” flag for those accounts, and remove the anonymous-user MySQL accounts. For additional details, see [Section 4.4.3, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#).

- Logging has been modified so that passwords do not appear in plain text in statements written to the general query log, slow query log, and binary log. See [Section 6.1.2.3, “Passwords and Logging”](#).

The `mysql` client no longer logs to its history file statements that refer to passwords. See [Section 4.5.1.3, “mysql Logging”](#).

- `START SLAVE` syntax has been modified to permit connection parameters to be specified for connecting to the master. This provides an alternative to storing the password in the `master.info` file. See [Section 13.4.2.5, “START SLAVE Syntax”](#).
- **Changes to server defaults.** Beginning with MySQL 5.6.6, several MySQL Server parameter defaults differ from the defaults in previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for database administrators to change settings manually. For more information, see [Section 5.1.2.1, “Changes to Server Defaults”](#).
- **InnoDB enhancements.** These InnoDB enhancements were added:
  - You can create `FULLTEXT` indexes on InnoDB tables, and query them using the `MATCH( ) . . . AGAINST [1229]` syntax. This feature includes a new proximity search operator (`@`) and several new configuration options and `INFORMATION_SCHEMA` tables: See [Section 14.2.3.12.3, “FULLTEXT Indexes”](#) for more information.
  - Several `ALTER TABLE` operations can be performed without copying the table, without blocking inserts, updates, and deletes to the table, or both. These enhancements are known collectively as [online DDL](#). See [Section 5.5, “Online DDL for InnoDB Tables”](#) for details.
  - You have more flexibility to move around the `.ibd` files created in `file-per-table` mode to suit your storage devices and database servers. When creating a table, you can designate a location outside the MySQL data directory to hold the `.ibd` file, for example to put a busy table on an `SSD` device or a huge table on a high-capacity `HDD` device. You can export a table from one MySQL instance and import it in a different instance, without inconsistencies or mismatches caused by buffered data, in-progress transactions, and internal bookkeeping details such as the `space ID` and `LSN`. See [Section 14.2.4.2.34, “Improved Tablespace Management”](#) for details.
  - You can now set the InnoDB page size for uncompressed tables to 8KB or 4KB, as an alternative to the default 16KB. This setting is controlled by the `innodb_page_size [1740]` configuration option. You specify the size when creating the MySQL instance. All InnoDB tablespaces within an instance share the same page size. Smaller page sizes can help to avoid redundant or inefficient I/O for certain combinations of workload and storage devices, particularly `SSD` devices with small block sizes.
  - Improvements to the algorithms for [adaptive flushing](#) make I/O operations more efficient and consistent under a variety of `workloads`. The new algorithm and default configuration values are expected to improve performance and concurrency for most users. Advanced users can fine-tune their I/O responsiveness through several configuration options. See [Section 14.2.4.2.9, “Improvements to Buffer Pool Flushing”](#) for details.
  - You can code MySQL applications that access InnoDB tables through a NoSQL-style API. This feature uses the popular `memcached` daemon to relay requests such as `ADD`, `SET`, and `GET` for key-value pairs. These simple operations to store and retrieve data avoid the SQL overhead such as parsing and constructing a [query execution plan](#). You can access the same data through the NoSQL API and SQL. For example, you might use the NoSQL API for fast updates and lookups, and SQL for complex queries and compatibility with existing applications. See [Section 14.2.9, “InnoDB Integration with memcached”](#) for details.

- Optimizer statistics for [InnoDB](#) tables are gathered at more predictable intervals and can persist across server restarts, for improved [plan stability](#). You can also control the amount of sampling done for [InnoDB](#) indexes, to make the optimizer statistics more accurate and improve the query execution plan. See [Section 14.2.4.2.10, “Persistent Optimizer Statistics for InnoDB Tables”](#) for details.
- New optimizations apply to read-only [transactions](#), improving performance and concurrency for ad-hoc queries and report-generating applications. These optimizations are applied automatically when practical, or you can specify `START TRANSACTION READ ONLY` to ensure the transaction is read-only. See [Section 14.2.4.2.3, “Optimizations for Read-Only Transactions”](#) for details.
- You can move the [InnoDB undo log](#) out of the [system tablespace](#) into one or more separate [tablespaces](#). The I/O patterns for the undo log make these new tablespaces good candidates to move to SSD storage, while keeping the system tablespace on hard disk storage. For details, see [Section 14.2.4.2.4, “Separate Tablespaces for InnoDB Undo Logs”](#).
- The [InnoDB redo log](#) files now have a maximum combined size of 512GB, increased from 4GB. You can specify the larger values through the `innodb_log_file_size` [\[1732\]](#) option. The startup behavior now automatically handles the situation where the size of the existing redo log files does not match the size specified by `innodb_log_file_size` and `innodb_log_files_in_group` [\[1733\]](#).
- The `--innodb-read-only` [\[1743\]](#) option lets you run a MySQL server in read-only mode. You can access [InnoDB](#) tables on read-only media such as a DVD or CD, or set up a data warehouse with multiple instances all sharing the same data directory. See [Section 14.2.5.1, “Support for Read-Only Media”](#) for usage details.
- Several new [InnoDB](#)-related `INFORMATION_SCHEMA` tables provide information about the [InnoDB](#) buffer pool, metadata about tables, indexes, and foreign keys from the [InnoDB](#) data dictionary, and low-level information about performance metrics that complements the information from the Performance Schema tables.
- [InnoDB](#) now limits the memory used to hold table information when many tables are opened.
- [InnoDB](#) has several internal performance enhancements, including reducing contention by splitting the kernel mutex, moving flushing operations from the main thread to a separate thread, enabling multiple purge threads, and reducing contention for the buffer pool on large-memory systems.
- [InnoDB](#) uses a new, faster algorithm to detect [deadlocks](#). Information about all [InnoDB](#) deadlocks can be written to the MySQL server error log, to help diagnose application issues.
- To avoid a lengthy [warmup](#) period after restarting the server, particularly for instances with large [InnoDB buffer pools](#), you can reload pages into the buffer pool immediately after a restart. MySQL can dump a compact data file at shutdown, then consult that data file to find the [pages](#) to reload on the next restart. You can also manually dump or reload the buffer pool at any time, for example during benchmarking or after complex report-generation queries. See [Section 14.2.4.2.8, “Faster Restart by Preloading the InnoDB Buffer Pool”](#) for details.
- **Partitioning.** These table-partitioning enhancements were added:
  - The maximum number of partitions is increased to 8192. This number includes all partitions and all subpartitions of the table.
  - It is now possible to exchange a partition of a partitioned table or a subpartition of a subpartitioned table with a nonpartitioned table that otherwise has the same structure using the `ALTER TABLE ... EXCHANGE PARTITION` statement. This can be used, for example, to import and export partitions. For more information and examples, see [Section 17.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

- Explicit selection of one or more partitions or subpartitions is now supported for queries, as well as for many data modification statements, that act on partitioned tables. For example, assume a table `t` with some integer column `c` has 4 partitions named `p0`, `p1`, `p2`, and `p3`. Then the query `SELECT * FROM t PARTITION (p0, p1) WHERE c < 5` returns only those rows from partitions `p0` and `p1` for which `c` is less than 5.

The following statements support explicit partition selection:

- `SELECT`
- `DELETE`
- `INSERT`
- `REPLACE`
- `UPDATE`
- `LOAD DATA`.
- `LOAD XML`.

For syntax, see the descriptions of the individual statements. For additional information and examples, see [Section 17.5, “Partition Selection”](#).

- Partition lock pruning greatly improves performance of many DML and DDL statements acting on tables with many partitions by helping to eliminate locks on partitions that are not affected by these statements. Such statements include many `SELECT`, `SELECT ... PARTITION`, `UPDATE`, `REPLACE`, `INSERT`, as well as many other statements. For more information, including a complete listing of the statements whose performance has thus been improved, see [Section 17.6.4, “Partitioning and Locking”](#).
- **Performance Schema.** The Performance Schema includes several new features:
  - Instrumentation for table input and output. Instrumented operations include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete.
  - Event filtering by table, based on schema and/or table names.
  - Event filtering by thread. More information is collected for threads.
  - Summary tables for table and index I/O, and for table locks.
  - Instrumentation for statements and stages within statements.
  - Configuration of instruments and consumers at server startup, which previously was possible only at runtime.
- **Replication and logging.** These replication enhancements were added:
  - MySQL now supports transaction-based replication using *global transaction identifiers* (also known as “GTIDs”). This makes it possible to identify and track each transaction when it is committed on the originating server and as it is applied by any slaves.

Enabling of GTIDs in a replication setup is done primarily using the new `--gtid-mode` [2019] and `--enforce-gtid-consistency` [2018] server options. For information about additional options and variables introduced in support of GTIDs, see [Section 16.1.4.5, “Global Transaction ID Options and Variables”](#).

When using GTIDs it is not necessary to refer to log files or positions within those files when starting a new slave or failing over to a new master, which greatly simplifies these tasks. For more information about provisioning servers for GTID replication with or without referring to binary log files, see [Section 16.1.3.3, “Using GTIDs for Failover and Scaleout”](#).

GTID-based replication is completely transaction-based, which makes it simple to check the consistency of masters and slaves. If all transactions committed on a given master are also committed on a given slave, consistency between the two servers is guaranteed.

For more complete information about the implementation and use of GTIDs in MySQL Replication, see [Section 16.1.3, “Replication with Global Transaction Identifiers”](#).

- MySQL row-based replication now supports row image control. By logging only those columns required for uniquely identifying and executing changes on each row (as opposed to all columns) for each row change, it is possible to save disk space, network resources, and memory usage. You can determine whether full or minimal rows are logged by setting the `binlog_row_image` [2012] server system variable to one of the values `minimal` (log required columns only), `full` (log all columns), or `noblob` (log all columns except for unneeded `BLOB` or `TEXT` columns). See [System variables used with the binary log](#), for more information.
- Binary logs written and read by the MySQL Server are now crash-safe, because only complete events (or transactions) are logged or read back. By default, the server logs the length of the event as well as the event itself and uses this information to verify that the event was written correctly. You can also cause the server to write checksums for the events using CRC32 checksums by setting the `binlog_checksum` [2009] system variable. To cause the server to read checksums from the binary log, use the `master_verify_checksum` system variable. The `--slave-sql-verify-checksum` system variable causes the slave SQL thread to read checksums from the relay log.
- MySQL now supports logging of master connection information and of slave relay log information to tables as well as files. Use of these tables can be controlled independently, by the `--master-info-repository` [2000] and `--relay-log-info-repository` [2000] server options. Setting `--master-info-repository` [2000] to `TABLE` causes connection information to be logged in the `slave_master_info` table; setting `--relay-log-info-repository` [2000] to `TABLE` causes relay log information to be logged to the `slave_relay_log_info` table. Both of these tables are created automatically, in the `mysql` system database.

In order for replication to be crash-safe, the `slave_master_info` and `slave_relay_log_info` tables must each use a transactional storage engine, and beginning with MySQL 5.6.6, these tables are created using `InnoDB` for this reason. (Bug #13538891) If you are using a previous MySQL 5.6 release in which both of these tables use `MyISAM`, this means that, prior to starting replication, you must convert both of them to a transactional storage engine (such as `InnoDB`) if you wish for replication to be crash-safe. You can do this in such cases by means of the appropriate `ALTER TABLE ... ENGINE=...` statements. You should *not* attempt to change the storage engine used by either of these tables while replication is actually running.

**Note**

In order to guarantee crash safety on the slave, you must also run the slave with the `--relay-log-recovery` [1975] option enabled.

- `mysqlbinlog` now has the capability to back up a binary log in its original binary format. When invoked with the `--read-from-remote-server` [352] and `--raw` [352] options, `mysqlbinlog` connects to a server, requests the log files, and writes output files in the same format as the originals. See [Section 4.6.8.3, “Using `mysqlbinlog` to Back Up Binary Log Files”](#).

- MySQL now supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time. The default delay is 0 seconds. Use the new `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay.

Delayed replication can be used for purposes such as protecting against user mistakes on the master (a DBA can roll back a delayed slave to the time just before the disaster) or testing how the system behaves when there is a lag. See [Section 16.3.9, “Delayed Replication”](#).

- A replication slave having multiple network interfaces can now be caused to use only one of these (to the exclusion of the others) by using the `MASTER_BIND` option when issuing a `CHANGE MASTER TO` statement.
- The `log_bin_basename` [2015] system variable has been added. This variable contains the complete filename and path to the binary log file. Whereas the `log_bin` [2008] system variable shows only whether or not binary logging is enabled, `log_bin_basename` [2015] reflects the name set with the `--log-bin` [2002] server option.

Similarly, the `relay_log_basename` [1989] system variable shows the filename and complete path to the relay log file.

- MySQL Replication now supports parallel execution of transactions with multi-threading on the slave. When parallel execution is enabled, the slave SQL thread acts as the coordinator for a number of slave worker threads as determined by the value of the `slave_parallel_workers` [1993] server system variable. The current implementation of multi-threading on the slave assumes that data and updates are partitioned on a per-database basis, and that updates within a given database occur in the same relative order as they do on the master. However, it is not necessary to coordinate transactions between different databases. Transactions can then also be distributed per database, which means that a worker thread on the slave can process successive transactions on a given database without waiting for updates to other databases to complete.

Since transactions on different databases can occur in a different order on the slave than on the master, simply checking for the most recently executed transaction is not a guarantee that all previous transactions on the master have been executed on the slave. This has implications for logging and recovery when using a multi-threaded slave. For information about how to interpret binary logging information when using multi-threading on the slave, see [Section 13.7.5.35, “SHOW SLAVE STATUS Syntax”](#).

- **Optimizer enhancements.** These query optimizer improvements were implemented:
  - The optimizer now more efficiently handles queries (and subqueries) of the following form:

```
SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M,]N;
```

That type of query is common in web applications that display only a few rows from a larger result set. For example:

```
SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
```

The sort buffer has a size of `sort_buffer_size` [542]. If the sort elements for  $N$  rows are small enough to fit in the sort buffer ( $M+N$  rows if  $M$  was specified), the server can avoid using a merge file and perform the sort entirely in memory. For details, see [Section 8.2.1.3, “Optimizing LIMIT Queries”](#).

- The optimizer implements Disk-Sweep Multi-Range Read. Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are

sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data. For more information, see [Section 8.13.11](#), “Multi-Range Read Optimization”.

- The optimizer implements Index Condition Pushdown (ICP), an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the `WHERE` condition for the rows. With ICP enabled, and if parts of the `WHERE` condition can be evaluated by using only fields from the index, the MySQL server pushes this part of the `WHERE` condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is base row be read. ICP can reduce the number of accesses the storage engine has to do against the base table and the number of accesses the MySQL server has to do against the storage engine. For more information, see [Section 8.13.4](#), “Index Condition Pushdown Optimization”.
- The `EXPLAIN` statement now provides execution plan information for `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements. Previously, `EXPLAIN` provided information only for `SELECT` statements. In addition, the `EXPLAIN` statement now can produce output in JSON format. See [Section 13.8.2](#), “`EXPLAIN` Syntax”.
- The optimizer more efficiently handles subqueries in the `FROM` clause (that is, derived tables). Materialization of subqueries in the `FROM` clause is postponed until their contents are needed during query execution, which improves performance. In addition, during query execution, the optimizer may add an index to a derived table to speed up row retrieval from it. For more information, see [Section 8.13.16.3](#), “Optimizing Subqueries in the `FROM` Clause (Derived Tables)”.
- The optimizer uses semi-join and materialization strategies to optimize subquery execution. See [Section 8.13.16.1](#), “Optimizing Subqueries with Semi-Join Transformations”, and [Section 8.13.16.2](#), “Optimizing Subqueries with Subquery Materialization”.
- A Batched Key Access (BKA) join algorithm is now available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semi-join operations, including nested outer joins and nested semi-joins. Benefits of BKA include improved join performance due to more efficient table scanning. For more information, see [Section 8.13.12](#), “Block Nested-Loop and Batched Key Access Joins”.
- The optimizer now has a tracing capability, primarily for use by developers. The interface is provided by a set of `optimizer_trace_xxx` system variables and the `INFORMATION_SCHEMA.OPTIMIZER_TRACE` table. For details, see [MySQL Internals: Tracing the Optimizer](#).
- **Condition handling.** MySQL now supports the `GET DIAGNOSTICS` statement. `GET DIAGNOSTICS` provides applications a standardized way to obtain information from the diagnostics area, such as whether the previous SQL statement produced an exception and what it was. For more information, see [Section 13.6.7.3](#), “`GET DIAGNOSTICS` Syntax”.

In addition, several deficiencies in condition handler processing rules were corrected so that MySQL behavior is more like standard SQL:

- Block scope is used in determining which handler to select. Previously, a stored program was treated as having a single scope for handler selection.
- Condition precedence is more accurately resolved.
- Diagnostics area clearing has changed. Bug #55843 caused handled conditions to be cleared from the diagnostics area before activating the handler. This made condition information unavailable within the handler. Now condition information is available to the handler, which can inspect it with the `GET DIAGNOSTICS` statement. The condition information is cleared when the handler exits, if it has not already been cleared during handler execution.

- Previously, handlers were activated as soon as a condition occurred. Now they are not activated until the statement in which the condition occurred finishes execution, at which point the most appropriate handler is chosen. This can make a difference for statements that raise multiple conditions, if a condition raised later during statement execution has higher precedence than an earlier condition and there are handlers in the same scope for both conditions. Previously, the handler for the first condition raised would be chosen, even if it had a lower precedence than other handlers. Now the handler for the condition with highest precedence is chosen, even if it is not the first condition raised by the statement.

For more information, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

- **Data types.** These data type changes have been implemented:
  - MySQL now permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 11.3.6, “Fractional Seconds in Time Values”](#).
  - Previously, at most one `TIMESTAMP` column per table could be automatically initialized or updated to the current date and time. This restriction has been lifted. Any `TIMESTAMP` column definition can have any combination of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses. In addition, these clauses now can be used with `DATETIME` column definitions. For more information, see [Section 11.3.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”](#).
  - In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types in terms of default value and assignment of automatic initialization and update attributes. These behaviors remain the default but now are deprecated, and can be turned off by enabling the `explicit_defaults_for_timestamp` [481] system variable at server startup. See [Section 11.3.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”](#), and [Section 5.1.4, “Server System Variables”](#).
  - The `YEAR(2)` data type is now deprecated. `YEAR(2)` columns in existing tables are treated as before, but `YEAR(2)` in new or altered tables are converted to `YEAR(4)`. For more information, see [Section 11.3.4, “`YEAR\(2\)` Limitations and Migrating to `YEAR\(4\)`”](#).
- **Host cache.** MySQL now provides more information about the causes of errors that occur when clients connect to the server, as well as improved access to the host cache, which contains client IP address and host name information and is used to avoid DNS lookups. These changes have been implemented:
  - New `Connection_errors_xxx` [587] status variables provide information about connection errors that do not apply to specific client IP addresses.
  - Counters have been added to the host cache to track errors that do apply to specific IP addresses, and a new `host_cache` Performance Schema table exposes the contents of the host cache so that it can be examined using `SELECT` statements. Access to host cache contents makes it possible to answer questions such as how many hosts are cached, what kinds of connection errors are occurring for which hosts, or how close host error counts are to reaching the `max_connect_errors` [502] system variable limit.
  - The host cache size now is configurable using the `host_cache_size` [487] system variable.

For more information, see [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#), and [Section 20.9.9.1, “The `host\_cache` Table”](#).

- **OpenGIS.** The OpenGIS specification defines functions that test the relationship between two geometry values. MySQL originally implemented these functions such that they used object bounding rectangles and returned the same result as the corresponding MBR-based functions. Corresponding versions are now available that use precise object shapes. These versions are named with an `ST_` prefix. For example, `Contains()` [1311] uses object bounding

rectangles, whereas `ST_Contains()` [1310] uses object shapes. For more information, see [Section 12.18.5.4.2, “Functions That Test Spatial Relationships Between Geometries”](#).

## Removed Features

The following constructs are obsolete and have been removed in MySQL 5.6. Where alternatives are shown, applications should be updated to use them.

- The `--log` server option and the `log` system variable. Instead, use the `--general_log` [485] option to enable the general query log and the `--general_log_file=file_name` [486] option to set the general query log file name.
- The `--log-slow-queries` server option and the `log_slow_queries` system variable. Instead, use the `--slow_query_log` [541] option to enable the slow query log and the `--slow_query_log_file=file_name` [541] option to set the slow query log file name.
- The `--one-thread` server option. Use `--thread_handling=no-threads` [553] instead.
- The `--safe-mode` server option.
- The `--skip-thread-priority` server option.
- The `--table-cache` server option. Use the `table_open_cache` [551] system variable instead.
- The `--init-rpl-role` and `--rpl-recovery-rank` options, the `rpl_recovery_rank` system variable, and the `Rpl_status` status variable.
- The `engine_condition_pushdown` system variable. Use the `engine_condition_pushdown` flag of the `optimizer_switch` [520] variable instead.
- The `have_csv`, `have_innodb`, `have_ndbcluster`, and `have_partitioning` system variables. Use `SHOW ENGINES` instead.
- The `sql_big_tables` system variable. Use `big_tables` [466] instead.
- The `sql_low_priority_updates` system variable. Use `low_priority_updates` [500] instead.
- The `sql_max_join_size` system variable. Use `max_join_size` [505] instead.
- The `max_long_data_size` system variable. Use `max_allowed_packet` [502] instead.
- The `FLUSH MASTER` and `FLUSH SLAVE` statements. Use the `RESET MASTER` and `RESET SLAVE` statements instead.
- The `SLAVE START` and `SLAVE STOP` statements. Use The `START SLAVE` and `STOP SLAVE` statements.
- The `SHOW AUTHORS` and `SHOW CONTRIBUTORS` statements.
- The `OPTION` and `ONE_SHOT` modifiers for the `SET` statement.
- It is explicitly disallowed to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). It remains permissible to assign `DEFAULT` to system variables, as before.

## 1.5. MySQL Development History

This section describes the general MySQL development history, provides an overview about features that have been implemented in previous series and that are new in MySQL 5.6, the release series covered in this manual. The maturity level this release series is general availability. Information about maturity levels can be found in [Section 2.1.2.1, “Choosing Which Version of MySQL to Install”](#).

Before upgrading from one release series to the next, please see the notes in [Section 2.11.1](#), “Upgrading MySQL”.

The most requested features and the versions in which they were implemented are summarized in the following table.

Feature	MySQL Series
Unions	4.0
Subqueries	4.1
R-trees	4.1 (for the <a href="#">MyISAM</a> storage engine)
Stored procedures and functions	5.0
Views	5.0
Cursors	5.0
XA transactions	5.0
Triggers	5.0 and 5.1
Event scheduler	5.1
Partitioning	5.1
Pluggable storage engine API	5.1
Plugin API	5.1
Row-based replication	5.1
Server log tables	5.1
Scalability and performance improvements	5.1 (with InnoDB Plugin)
DTrace support	5.5
Semisynchronous replication	5.5
SIGNAL/RESIGNAL support in stored routines	5.5
Performance Schema	5.5
Supplementary Unicode characters	5.5

## 1.6. MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as the MySQL mailing lists and user forums, and Internet Relay Chat.

### 1.6.1. MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit <http://lists.mysql.com/>. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from [lists.mysql.com](http://lists.mysql.com) to your site are propagated to the local

list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

To have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the `List-ID:` or `Delivered-To:` headers to identify list messages.

The MySQL mailing lists are as follows:

- [announce](#)

The list for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- [mysql](#)

The main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- [bugs](#)

The list for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See [Section 1.7, “How to Report Bugs or Problems”](#).

- [internals](#)

The list for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- [mysqldoc](#)

The list for people who work on the MySQL documentation.

- [benchmarks](#)

The list for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, file system, disk system, and so on.

- [packagers](#)

The list for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- [java](#)

The list for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- [win32](#)

The list for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- [myodbc](#)

The list for all topics concerning connecting to the MySQL server with ODBC.

- [gui-tools](#)

The list for all topics concerning MySQL graphical user interface tools such as MySQL Workbench.

- [cluster](#)

The list for discussion of MySQL Cluster.

- [dotnet](#)

The list for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/Net.

- [plusplus](#)

The list for all topics concerning programming with the C++ API for MySQL.

- [perl](#)

The list for all topics concerning Perl support for MySQL with `DBD: :mysql`.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from Oracle. This puts you in direct contact with MySQL developers.

The following MySQL mailing lists are in languages other than English. These lists are not operated by Oracle.

- [<mysql-france-subscribe@yahoogroups.com>](mailto:mysql-france-subscribe@yahoogroups.com)

A French mailing list.

- [<list@tinc.net>](mailto:list@tinc.net)

A Korean mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

- [<mysql-de-request@lists.4t2.com>](mailto:mysql-de-request@lists.4t2.com)

A German mailing list. To subscribe, email `subscribe mysql-de your@email.address` to this list. You can find information about this mailing list at <http://www.4t2.com/mysql/>.

- [<mysql-br-request@listas.linkway.com.br>](mailto:mysql-br-request@listas.linkway.com.br)

A Portuguese mailing list. To subscribe, email `subscribe mysql-br your@email.address` to this list.

- [<mysql-alta@elistas.net>](mailto:mysql-alta@elistas.net)

A Spanish mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

### 1.6.1.1. Guidelines for Using the Mailing Lists

Please do not post mail messages from your browser with HTML mode turned on. Many users do not read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Do not feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

### 1.6.2. MySQL Community Support at the MySQL Forums

The forums at <http://forums.mysql.com> are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

### 1.6.3. MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

**freenode** (see <http://www.freenode.net/> for servers)

- `#mysql` is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.

If you are looking for IRC client software to connect to an IRC network, take a look at **xChat** (<http://www.xchat.org/>). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at <http://www.silverex.org/download/>).

### 1.6.4. MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:

- MySQL Enterprise Server
- MySQL Enterprise Monitor
- Monthly Rapid Updates and Quarterly Service Packs
- MySQL Knowledge Base
- 24x7 Technical and Consultative Support

MySQL Enterprise is available in multiple tiers, giving you the flexibility to choose the level of service that best matches your needs. For more information, see [MySQL Enterprise](#).

## 1.7. How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at <http://dev.mysql.com/doc/>. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the

release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.

- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

- For solutions to some common problems, see [Section C.5, "Problems and Common Errors"](#).
- Search the bugs database at <http://bugs.mysql.com/> to see whether the bug has been reported and fixed.
- Search the MySQL mailing list archives at <http://lists.mysql.com/>. See [Section 1.6.1, "MySQL Mailing Lists"](#).
- You can also use <http://www.mysql.com/search/> to search all the Web pages (including the manual) that are located at the MySQL Web site.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at <http://bugs.mysql.com/> that are corrected for a given release are noted in the release notes.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert\\_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support at <http://support.oracle.com/>.

To discuss problems with other users, you can use one of the MySQL mailing lists. [Section 1.6.1, "MySQL Mailing Lists"](#).

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test <script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See [MySQL Internals: Porting to Other Systems](#).

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem

and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See [Section 21.1.8.2, “How to Report Connector/ODBC Problems or Bugs”](#).

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` [254] option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.0.19). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.
- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.
- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See [MySQL Internals: Porting to Other Systems](#).
- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of

any table in a database. The information helps us create a situation matching the one that you have experienced.

- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` [545] system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` [545] value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ...\G
<output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ...\G
<output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...;
<A short version of the output from SELECT,
including the time taken to run the query>
mysql> SHOW STATUS;
<output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`. After you initiate a bug report for our bugs database at <http://bugs.mysql.com/>, click the Files tab in the bug report for instructions on uploading the archive to the bugs database.
- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.
- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the

information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.

- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD: :mysql` modules, include the version numbers for Perl, `DBI`, and `DBD: :mysql`.
- If your question is related to the privilege system, please include the output of `mysqlaccess`, the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should first run `mysqlaccess`. After this, execute `mysqladmin reload version` and try to connect with the program that gives you trouble. `mysqlaccess` can be found in the `bin` directory under your MySQL installation directory.
- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.
- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.
- If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:
  - The `InnoDB` crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with `InnoDB` tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery [1722]` option enabled so that you can dump the affected tables.
  - For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See [Chapter 5, MySQL Server Administration](#).

If you are running Windows, please verify the value of `lower_case_table_names [501]` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in [Section 9.2.2, “Identifier Case Sensitivity”](#).

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See [Section 5.2.2, “The Error Log”](#). Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See [Section C.5.1, “How to Determine What Is Causing a Problem”](#).
- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software thoroughly tested and should work without

problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See [Section 2.1.2, “Choosing Which MySQL Distribution to Install”](#).

## 1.8. MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, “SQL:2003” refers to the standard released in 2003, and “SQL:2008” refers to the most recent version of the standard, released in 2008. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See [Section 13.2.4, “HANDLER Syntax”](#).

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

Currently, we are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports high-availability database clustering using the `NDBCLUSTER` storage engine. See [MySQL Cluster NDB 7.2](#).

We implement XML functionality which supports most of the W3C XPath standard. See [Section 12.11, “XML Functions”](#).

### 1.8.1. What Standards MySQL Follows

Our aim is to support the full ANSI/ISO SQL standard, but without making concessions to speed and quality of the code.

ODBC levels 0 to 3.51.

### 1.8.2. Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differentially for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

SQL modes control aspects of server operation such as what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="mode_value"` [\[442\]](#) option. You can also change the mode at runtime by setting the `sql_mode` [\[545\]](#) system variable with a `SET [GLOBAL|SESSION] sql_mode='mode_value'` statement.

For more information on setting the SQL mode, see [Section 5.1.7, “Server SQL Modes”](#).

### 1.8.3. Running MySQL in ANSI Mode

You can tell `mysqld` to run in ANSI mode with the `--ansi` [413] startup option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

You can achieve the same effect at runtime by executing these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` [545] system variable to `'ANSI'` enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@global.sql_mode;
-> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` [413] is not quite the same as setting the SQL mode to `'ANSI'`. The `--ansi` [413] option affects the SQL mode and also sets the transaction isolation level. Setting the SQL mode to `'ANSI'` has no effect on the isolation level.

See [Section 5.1.3, “Server Command Options”](#), and [Section 1.8.2, “Selecting SQL Modes”](#).

### 1.8.4. MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably won't find in other SQL DBMSs. Be warned that if you use them, your code won't be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:

- Database and table names are case sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See [Section 9.2.2, “Identifier Case Sensitivity”](#).
- You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the `MyISAM` storage engine. For example, it is possible to rename a `MyISAM` table

by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

- General language syntax
  - By default, strings can be enclosed by either “`”` or “`'`”, not just by “`'`”. (If the [ANSI\\_QUOTES \[603\]](#) SQL mode is enabled, strings can be enclosed only by “`'`” and the server interprets strings enclosed by “`”` as identifiers.)
  - “`\`” is the escape character in strings.
  - In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.
- SQL statement syntax
  - The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
  - The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See [Section 13.1.8, “CREATE DATABASE Syntax”](#), [Section 13.1.17, “DROP DATABASE Syntax”](#), and [Section 13.1.1, “ALTER DATABASE Syntax”](#).
  - The `DO` statement.
  - `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
  - The `FLUSH` and `RESET` statements.
  - The `SET` statement. See [Section 13.7.4, “SET Syntax”](#).
  - The `SHOW` statement. See [Section 13.7.5, “SHOW Syntax”](#). The information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See [Chapter 19, \*INFORMATION\\_SCHEMA Tables\*](#).
  - Use of `LOAD DATA INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).
  - Use of `RENAME TABLE`. See [Section 13.1.26, “RENAME TABLE Syntax”](#).
  - Use of `REPLACE` instead of `DELETE` plus `INSERT`. See [Section 13.2.8, “REPLACE Syntax”](#).
  - Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX, IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See [Section 13.1.6, “ALTER TABLE Syntax”](#).
  - Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See [Section 13.1.14, “CREATE TABLE Syntax”](#).
  - Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.
  - Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.
  - The capability of dropping multiple tables with a single `DROP TABLE` statement.
  - The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.
  - `INSERT INTO tbl_name SET col_name = ...` syntax.
  - The `DELAYED` clause of the `INSERT` and `REPLACE` statements.

- The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.
- Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See [Section 13.2.9](#), “`SELECT` Syntax”.
- Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.
- You don't need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See [Section 12.17](#), “`Functions and Modifiers for Use with GROUP BY Clauses`”.
- You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.
- The ability to set variables in a statement with the `:=` assignment operator. See [Section 9.4](#), “`User-Defined Variables`”.
- Data types
  - The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.
  - The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.
- Functions and operators
  - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
  - MySQL Server understands the `||` [1172] and `&&` [1171] operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` [1172] and `OR` [1172] are synonyms, as are `&&` [1171] and `AND` [1171]. Because of this nice syntax, MySQL Server doesn't support the standard SQL `||` [1172] operator for string concatenation; use `CONCAT()` [1178] instead. Because `CONCAT()` [1178] takes any number of arguments, it is easy to convert use of the `||` [1172] operator to MySQL Server.
  - Use of `COUNT(DISTINCT value_list)` [1283] where `value_list` has more than one element.
  - String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is `latin1` (cp1252 West European) by default. If you don't like this, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
  - The `%` [1205] operator is a synonym for `MOD()` [1205]. That is, `N % M` is equivalent to `MOD(N,M)` [1205]. `%` [1205] is supported for C programmers and for compatibility with PostgreSQL.
  - The `=` [1166], `<>` [1167], `<=` [1167], `<` [1167], `>=` [1167], `>` [1167], `<<` [1258], `>>` [1258], `<=>` [1167], `AND` [1171], `OR` [1172], or `LIKE` [1190] operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```
- The `LAST_INSERT_ID()` [1269] function returns the most recent `AUTO_INCREMENT` value. See [Section 12.14](#), “`Information Functions`”.
- `LIKE` [1190] is permitted on numeric values.
- The `REGEXP` [1193] and `NOT REGEXP` [1193] extended regular expression operators.

- `CONCAT()` [1178] or `CHAR()` [1177] with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)
- The `BIT_COUNT()` [1259], `CASE` [1174], `ELT()` [1179], `FROM_DAYS()` [1218], `FORMAT()` [1180], `IF()` [1174], `PASSWORD()` [1263], `ENCRYPT()` [1262], `MD5()` [1263], `ENCODE()` [1262], `DECODE()` [1261], `PERIOD_ADD()` [1221], `PERIOD_DIFF()` [1221], `TO_DAYS()` [1225], and `WEEKDAY()` [1228] functions.
- Use of `TRIM()` [1186] to trim substrings. Standard SQL supports removal of single characters only.
- The `GROUP BY` functions `STD()` [1284], `BIT_OR()` [1282], `BIT_AND()` [1282], `BIT_XOR()` [1283], and `GROUP_CONCAT()` [1283]. See [Section 12.17, “Functions and Modifiers for Use with GROUP BY Clauses”](#).

## 1.8.5. MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see [Section 13.7.1.6, “REVOKE Syntax”](#).
- The `CAST()` [1245] function does not support cast to `REAL` or `BIGINT`. See [Section 12.10, “Cast Functions and Operators”](#).

### 1.8.5.1. SELECT INTO TABLE Differences

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See [Section 13.2.5.1, “INSERT ... SELECT Syntax”](#). For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).

### 1.8.5.2. UPDATE Differences

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

### 1.8.5.3. Transaction and Atomic Operation Differences

MySQL Server (version 3.23-max and all versions 4.0 and above) supports transactions with the `InnoDB` transactional storage engine. In MySQL 5.5 and up, newly created tables use `InnoDB` by default, as explained in [Section 14.2.1.1, “InnoDB as the Default MySQL Storage Engine”](#). By default, `InnoDB` provides *full* ACID compliance; see [Section 14.2.8, “MySQL and the ACID Model”](#) for ways

that you can adjust settings to balance ACID compliance with raw performance. For information about [InnoDB](#) differences from standard SQL with regard to treatment of transaction errors, see [Section 14.2.3.14, “InnoDB Error Handling”](#).

The nontransactional storage engines in MySQL Server (such as [MyISAM](#)) follow a different paradigm for data integrity called “atomic operations”. [MyISAM](#) tables effectively always operate in `autocommit = 1` [464] mode. Because changed data is written to disk one statement at a time, it is harder to guarantee the consistency of a sequence of related DML operations, which could be interrupted partway through. Thus, this mode is suitable for read-mostly workloads. In transactional terms, while each specific update is running, no other user can interfere with it, there can never be an automatic rollback, and there are no dirty reads. However, these features apply to single operations, not related updates that succeed or fail as a unit. Workarounds such as the `LOCK TABLES` statement limit concurrent write access to nontransactional tables.

You can choose which paradigm to use, even for different tables within the same application: transactional features for reliability combined with high performance, or atomic operations for non-critical, read-mostly data (for example, on replication slave servers).

Transactional storage engines such as [InnoDB](#) offer many significant features to support high reliability for heavy read/write workloads. As a result, transactional tables can have higher memory and disk space requirements, and more CPU overhead. MySQL Server's modular design enables the concurrent use of different storage engines to suit different requirements and deliver optimum performance in all situations.

## Workarounds for Reliability with Non-Transactional Tables

But how do you use the features of MySQL Server to maintain integrity even with the nontransactional [MyISAM](#) tables, and how do these features compare with the transactional storage engines?

- If your applications are written in a way that is dependent on being able to call `ROLLBACK` rather than `COMMIT` in critical situations, transactions are more convenient. Transactions also ensure that unfinished updates or corrupting activities are not committed to the database; the server is given the opportunity to do an automatic rollback and your database is saved.

If you use nontransactional tables, you must resolve potential problems at the application level by including checks before updates and by running scripts that check the databases for inconsistencies and automatically repair or warn if such an inconsistency occurs. You can normally fix tables with no data integrity loss by using the MySQL log or even adding one extra log.

- Sometimes, critical transactional updates can be rewritten to be atomic. Multiple DML operations can be done with `LOCK TABLES` or atomic updates, ensuring that there are no deadlocks by limiting concurrent write access. If you obtain a `READ LOCAL` lock (as opposed to a write lock) for a table that enables concurrent inserts at the end of the table, reads are permitted, as are inserts by other clients. The newly inserted records are not be seen by the client that has the read lock until it releases the lock. With `INSERT DELAYED`, you can write inserts that go into a local queue until the locks are released, without having the client wait for the insert to complete. See [Section 8.10.3, “Concurrent Inserts”](#), and [Section 13.2.5.2, “INSERT DELAYED Syntax”](#).
- To be safe with MySQL Server, regardless of what kinds of tables you use, make regular backups and have binary logging turned on. It is always good to have backups, regardless of which database system you use.

Following are some techniques for working with nontransactional tables:

- Loops that need transactions normally can be coded with the help of `LOCK TABLES`, and you don't need cursors to update records on the fly.
- To avoid using `ROLLBACK`, you can employ the following strategy:
  1. Use `LOCK TABLES` to lock all the tables you want to access.

2. Test the conditions that must be true before performing the update.
3. Update if the conditions are satisfied.
4. Use `UNLOCK TABLES` to release your locks.

#### Note

This solution does not handle the situation when someone kills the threads in the middle of an update. In that case, all locks are released but some of the updates may not have been executed.

- You can also use functions to update records in a single operation, using the following techniques:
  - Modify columns relative to their current value. This makes the update correct even if another client has changed the column values in the meantime.
  - Update only those columns that actually have changed. This is a good database practice in general.
- When managing unique identifiers, you can avoid statements such as `LOCK TABLES` or `ROLLBACK` by using an `AUTO_INCREMENT` column and either the `LAST_INSERT_ID()` [1269] SQL function or the `mysql_insert_id()` C API function. See [Section 12.14, “Information Functions”](#), and [Section 21.8.6.37, “mysql\\_insert\\_id\(\)”](#).

For situations that require row-level locking, use `InnoDB` tables. Otherwise, with `MyISAM` tables, you can use a flag column in the table and do something like the following:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID;
```

MySQL returns 1 for the number of affected rows if the row was found and `row_flag` wasn't 1 in the original row. You can think of this as though MySQL Server changed the preceding statement to:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID AND row_flag <> 1;
```

### 1.8.5.4. Foreign Key Differences

The `InnoDB` storage engine supports checking of foreign key constraints, including `CASCADE`, `ON DELETE`, and `ON UPDATE`. See [Section 5.4.5, “InnoDB and FOREIGN KEY Constraints”](#).

For storage engines other than `InnoDB`, MySQL Server parses the `FOREIGN KEY` syntax in `CREATE TABLE` statements, but does not use or store it. In the future, the implementation will be extended to store this information in the table specification file so that it may be retrieved by `mysqldump` and ODBC. At a later stage, foreign key constraints will be implemented for `MyISAM` tables as well.

Foreign key enforcement offers several benefits to database developers:

- Assuming proper design of the relationships, foreign key constraints make it more difficult for a programmer to introduce an inconsistency into the database.
- Centralized checking of constraints by the database server makes it unnecessary to perform these checks on the application side. This eliminates the possibility that different applications may not all check the constraints in the same way.
- Using cascading updates and deletes can simplify the application code.
- Properly designed foreign key rules aid in documenting relationships between tables.

Do keep in mind that these benefits come at the cost of additional overhead for the database server to perform the necessary checks. Additional checking by the server affects performance, which for some applications may be sufficiently undesirable as to be avoided if possible. (Some major commercial applications have coded the foreign key logic at the application level for this reason.)

MySQL gives database developers the choice of which approach to use. If you don't need foreign keys and want to avoid the overhead associated with enforcing referential integrity, you can choose another storage engine instead, such as [MyISAM](#). (For example, the [MyISAM](#) storage engine offers very fast performance for applications that perform only [INSERT](#) and [SELECT](#) operations. In this case, the table has no holes in the middle and the inserts can be performed concurrently with retrievals. See [Section 8.10.3, "Concurrent Inserts"](#).)

If you choose not to take advantage of referential integrity checks, keep the following considerations in mind:

- In the absence of server-side foreign key relationship checking, the application itself must handle relationship issues. For example, it must take care to insert rows into tables in the proper order, and to avoid creating orphaned child records. It must also be able to recover from errors that occur in the middle of multiple-record insert operations.
- If [ON DELETE](#) is the only referential integrity capability an application needs, you can achieve a similar effect as of MySQL Server 4.0 by using multiple-table [DELETE](#) statements to delete rows from many tables with a single statement. See [Section 13.2.2, "DELETE Syntax"](#).
- A workaround for the lack of [ON DELETE](#) is to add the appropriate [DELETE](#) statements to your application when you delete records from a table that has a foreign key. In practice, this is often as quick as using foreign keys and is more portable.

Be aware that the use of foreign keys can sometimes lead to problems:

- Foreign key support addresses many referential integrity issues, but it is still necessary to design key relationships carefully to avoid circular rules or incorrect combinations of cascading deletes.
- It is not uncommon for a DBA to create a topology of relationships that makes it difficult to restore individual tables from a backup. (MySQL alleviates this difficulty by enabling you to temporarily disable foreign key checks when reloading a table that depends on other tables. See [Section 5.4.5, "InnoDB and FOREIGN KEY Constraints"](#). As of MySQL 4.1.1, [mysqldump](#) generates dump files that take advantage of this capability automatically when they are reloaded.)

Foreign keys in SQL are used to check and enforce referential integrity, not to join tables. If you want to get results from multiple tables from a [SELECT](#) statement, you do this by performing a join between them:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.id;
```

See [Section 13.2.9.2, "JOIN Syntax"](#), and [Section 3.6.6, "Using Foreign Keys"](#).

The [FOREIGN KEY](#) syntax without [ON DELETE . . .](#) is often used by ODBC applications to produce automatic [WHERE](#) clauses.

### 1.8.5.5. '--' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in [Section 9.6, "Comment Syntax"](#).

Standard SQL uses `--` as a start-comment sequence. MySQL Server uses `#` as the start comment character. MySQL Server 3.23.3 and up also supports a variant of the `--` comment style. That is, the `--` start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a valid expression in SQL, but “--” is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with “--” can have serious consequences.

Using our implementation requires a space following the “--” for it to be recognized as a start-comment sequence in MySQL Server 3.23.3 and newer. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with “--”.

The following information is relevant only if you are running a MySQL version earlier than 3.23.3:

If you have an SQL script in a text file that contains “--” comments, you should use the `replace` utility as follows to convert the comments to use “#” characters before executing the script:

```
shell> replace " --" " #" < text-file-with-funny-comments.sql \
| mysql db_name
```

That is safer than executing the script in the usual way:

```
shell> mysql db_name < text-file-with-funny-comments.sql
```

You can also edit the script file “in place” to change the “--” comments to “#” comments:

```
shell> replace " --" " #" -- text-file-with-funny-comments.sql
```

Change them back with this command:

```
shell> replace " #" " --" -- text-file-with-funny-comments.sql
```

See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

## 1.8.6. How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See [Section 5.1.7, “Server SQL Modes”](#).

The following sections describe how MySQL Server handles different types of constraints.

### 1.8.6.1. PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occurs for data-change statements (such as `INSERT` or `UPDATE`) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as `InnoDB`, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an `IGNORE` keyword for `INSERT`, `UPDATE`, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using ([Section 13.2.5, “INSERT Syntax”](#), [Section 13.2.11, “UPDATE Syntax”](#), and so forth).

You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. You can also use the `SHOW WARNINGS` statement. See [Section 21.8.6.35, “mysql\\_info\(\)”](#), and [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

Currently, only `InnoDB` tables support foreign keys. See [Section 5.4.5, “InnoDB and FOREIGN KEY Constraints”](#).

### 1.8.6.2. FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and [foreign key constraints](#) help keep this spread-out data consistent.

MySQL supports `ON UPDATE` and `ON DELETE` foreign key references in `CREATE TABLE` and `ALTER TABLE` statements. The available referential actions are `RESTRICT` (the default), `CASCADE`, `SET NULL`, and `NO ACTION`.

`SET DEFAULT` is also supported by the MySQL Server but is currently rejected as invalid by `InnoDB`. Since MySQL does not support deferred constraint checking, `NO ACTION` is treated as `RESTRICT`. For the exact syntax supported by MySQL for foreign keys, see [Section 13.1.14.2, “Using FOREIGN KEY Constraints”](#).

`MATCH FULL`, `MATCH PARTIAL`, and `MATCH SIMPLE` are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any `ON DELETE` or `ON UPDATE` clause used in the same statement. `MATCH` options do not have any other effect in MySQL, which in effect enforces `MATCH SIMPLE` semantics full-time.

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created.

You can obtain information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
> FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
> WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

TABLE_SCHEMA	TABLE_NAME	COLUMN_NAME	CONSTRAINT_NAME
fk1	myuser	myuser_id	f
fk1	product_order	customer_id	f2
fk1	product_order	product_id	f1

```
3 rows in set (0.01 sec)
```

Information about foreign keys on `InnoDB` tables can also be found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, in the `INFORMATION_SCHEMA` database.

Currently, only `InnoDB` tables support foreign keys. See [Section 5.4.5, “InnoDB and FOREIGN KEY Constraints”](#), for information specific to foreign key support in `InnoDB`.

## Deviations from SQL Standards

MySQL's implementation of foreign keys differs from the SQL standard in the following key respects:

- If there are several rows in the parent table that have the same referenced key value, [InnoDB](#) acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a [RESTRICT](#) type constraint, and there is a child row with several parent rows, [InnoDB](#) does not permit the deletion of any of those parent rows.

[InnoDB](#) performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

- A [FOREIGN KEY](#) constraint that references a non-[UNIQUE](#) key is not standard SQL but rather an [InnoDB](#) extension.
- If [ON UPDATE CASCADE](#) or [ON UPDATE SET NULL](#) recurses to update the *same table* it has previously updated during the same cascade, it acts like [RESTRICT](#). This means that you cannot use self-referential [ON UPDATE CASCADE](#) or [ON UPDATE SET NULL](#) operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential [ON DELETE SET NULL](#), on the other hand, is possible, as is a self-referential [ON DELETE CASCADE](#). Cascading operations may not be nested more than 15 levels deep.
- In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, [InnoDB](#) sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.

For information how [InnoDB](#) foreign keys differ from the SQL standard, see [Section 5.4.5, “InnoDB and FOREIGN KEY Constraints”](#).

### 1.8.6.3. Constraints on Invalid Data

By default, MySQL is forgiving of invalid or improper data values and coerces them to valid values for data entry. However, you can change the server SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. See [Section 5.1.7, “Server SQL Modes”](#).

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a [NULL](#) into a [NOT NULL](#) column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.
- If you try to store a string that doesn't start with a number into a numeric column, MySQL Server stores 0.
- Invalid values for [ENUM](#) and [SET](#) columns are handled as described in [Section 1.8.6.4, “ENUM and SET Constraints”](#).
- MySQL enables you to store certain incorrect date values into [DATE](#) and [DATETIME](#) columns (such as '2000-02-31' or '2000-02-00'). The idea is that it is not the job of the SQL server to validate

dates. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value '0000-00-00' is stored in the column instead.

- If you try to store `NULL` into a column that doesn't take `NULL` values, an error occurs for single-row `INSERT` statements. For multiple-row `INSERT` statements or for `INSERT INTO ... SELECT` statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string ( ' ' ) for string types, and the “zero” value for date and time types. Implicit default values are discussed in [Section 11.5, “Data Type Default Values”](#).
- If an `INSERT` statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit `DEFAULT` clause. If the definition has no such `DEFAULT` clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules in nonstrict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

In MySQL 5.0.2 and up, you can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` [\[607\]](#) or `STRICT_ALL_TABLES` [\[607\]](#) SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

`STRICT_TRANS_TABLES` [\[607\]](#) enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.
- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES` [\[607\]](#), a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable `STRICT_ALL_TABLES` [\[607\]](#). This is the same as `STRICT_TRANS_TABLES` [\[607\]](#) except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` [\[607\]](#) if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only valid values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

#### 1.8.6.4. `ENUM` and `SET` Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See [Section 11.4.4, “The `ENUM` Type”](#), and [Section 11.4.5, “The `SET` Type”](#). However, before MySQL 5.0.2, `ENUM` and `SET` columns do not provide true constraints on entry of invalid data:

- [ENUM](#) columns always have a default value. If you specify no default value, then it is [NULL](#) for columns that can have [NULL](#), otherwise it is the first enumeration value in the column definition.
- If you insert an incorrect value into an [ENUM](#) column or if you force a value into an [ENUM](#) column with [IGNORE](#), it is set to the reserved enumeration value of 0, which is displayed as an empty string in string context.
- If you insert an incorrect value into a [SET](#) column, the incorrect value is ignored. For example, if the column can contain the values 'a', 'b', and 'c', an attempt to assign 'a,x,b,y' results in a value of 'a,b'.

As of MySQL 5.0.2, you can configure the server to use strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#). With strict mode enabled, the definition of a [ENUM](#) or [SET](#) column does act as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An [ENUM](#) value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as [ENUM\('a','b','c'\)](#), values such as '', 'd', or 'ax' are invalid and are rejected.
- A [SET](#) value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as [SET\('a','b','c'\)](#), values such as 'd' or 'a,b,c,d' are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use [INSERT IGNORE](#) or [UPDATE IGNORE](#). In this case, a warning is generated rather than an error. For [ENUM](#), the value is inserted as the error member (0). For [SET](#), the value is inserted as given except that any invalid substrings are deleted. For example, 'a,x,b,y' results in a value of 'a,b'.

## 1.9. Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

### 1.9.1. Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the [MySQL server](#) and the [MySQL manual](#), we wish to recognize those who have made contributions of one kind or another to the [MySQL distribution](#). Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola <[qwerg@mbbox.vol.it](mailto:qwerg@mbbox.vol.it)> or <[qwerg@tin.it](mailto:qwerg@tin.it)>

The initial port to Win32/NT.

- Per Eric Olsson

For constructive criticism and real testing of the dynamic record format.

- Irena Pancirov <[irena@mail.yacc.it](mailto:irena@mail.yacc.it)>

Win32 port with Borland compiler. [mysqlshutdown.exe](#) and [mysqlwatch.exe](#).

- David J. Hughes

For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with [mSQL](#), but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. [mysqladmin](#) and [mysql](#) client are programs that were largely influenced by their [mSQL](#) counterparts. We have put a lot of effort into making the MySQL syntax a superset of [mSQL](#). Many of the API's ideas are borrowed from [mSQL](#) to make it easy to port free [mSQL](#) programs to the MySQL API. The MySQL software doesn't contain any code from [mSQL](#). Two files in the distribution ([client/insert\\_test.c](#) and [client/select\\_test.c](#)) are based

on the corresponding (noncopyrighted) files in the `mSQL` distribution, but are modified as examples showing the changes necessary to convert code from `mSQL` to MySQL Server. (`mSQL` is copyrighted David J. Hughes.)

- Patrick Lynch

For helping us acquire <http://www.mysql.com/>.

- Fred Lindberg

For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko <[igor@frog.kiev.ua](mailto:igor@frog.kiev.ua)>

`mysqldump` (previously `msqldump`, but ported and enhanced by Monty).

- Yuri Dario

For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

Author of `mysqlhotcopy`.

- Zarko Mocnik <[zarko.mocnik@dem.si](mailto:zarko.mocnik@dem.si)>

Sorting for Slovenian language.

- "TAMITO" <[tommy@valley.ne.jp](mailto:tommy@valley.ne.jp)>

The `_MB` character set macros and the `ujis` and `sjis` character sets.

- Joshua Chamas <[joshua@chamas.com](mailto:joshua@chamas.com)>

Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier <[Yves.Carlier@rug.ac.be](mailto:Yves.Carlier@rug.ac.be)>

`mysqlaccess`, a program to show the access rights for a user.

- Rhys Jones <[rhys@wales.com](mailto:rhys@wales.com)> (And GWE Technologies Limited)

For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU <[X.Zhu@brad.ac.uk](mailto:X.Zhu@brad.ac.uk)>

Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <[pixel@organic.com](mailto:pixel@organic.com)>

For setting up a searchable mailing list archive at his site.

- Rick Mehalick <[Rick\\_Mehalick@i-o.com](mailto:Rick_Mehalick@i-o.com)>

For `xmysql`, a graphical X client for MySQL Server.

- Doug Sisk <[sisk@wix.com](mailto:sisk@wix.com)>

For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. <[axeld@vial.ethz.ch](mailto:axeld@vial.ethz.ch)>

For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive <[toni@readysoft.es](mailto:toni@readysoft.es)>

For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth <[jay@pathways.sde.state.sc.us](mailto:jay@pathways.sde.state.sc.us)>

For providing RPM versions for MySQL 3.21.

- David Sacerdote <[davids@secnet.com](mailto:davids@secnet.com)>

Ideas for secure checking of DNS host names.

- Wei-Jou Chen <[jou@nematic.ieo.nctu.edu.tw](mailto:jou@nematic.ieo.nctu.edu.tw)>

Some support for Chinese(BIG5) characters.

- Wei He <[hewei@mail.ied.ac.cn](mailto:hewei@mail.ied.ac.cn)>

A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora <[adelton@fi.muni.cz](mailto:adelton@fi.muni.cz)>

Czech sorting order.

- Albert Chin-A-Young.  
Configure updates for Tru64, large file support and better TCP wrappers support.
- John Birrell  
Emulation of `pthread_mutex()` for OS/2.
- Benjamin Pflugmann  
Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.
- Jocelyn Fournier  
Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).
- Marc Liyanage  
Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X packages.
- Robert Rutherford  
Providing invaluable information and feedback about the QNX port.
- Previous developers of NDB Cluster  
Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataulah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.
- Google Inc.  
We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <[jehamby@lightside](mailto:jehamby@lightside)>, <[psmith@BayNetworks.com](mailto:psmith@BayNetworks.com)>, <[duane@connect.com.au](mailto:duane@connect.com.au)>, Ted Deppner <[ted@psyber.com](mailto:ted@psyber.com)>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

## 1.9.2. Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois  
Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.
- Kim Aldale  
Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <[mke@terrapin.turbolift.com](mailto:mke@terrapin.turbolift.com)>

For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded (<http://mysql.hitstar.com/>) versions were based. [Personal home page at linuxdb.yeah.net](http://linuxdb.yeah.net).

- Jay Flaherty <[fty@mediapulse.com](mailto:fty@mediapulse.com)>

Big parts of the Perl [DBI/DBD](#) section in the manual.

- Timur I. Bakeyev <[root@timur.tatarstan.ru](mailto:root@timur.tatarstan.ru)>

Russian error messages.

- <[brenno@dewinter.com](mailto:brenno@dewinter.com)> & Filippo Grassilli <[phil@hyppo.com](mailto:phil@hyppo.com)>

Italian error messages.

- Dirk Munzinger <[dirk@trinity.saar.de](mailto:dirk@trinity.saar.de)>

German error messages.

- Billik Stefan <[billik@sun.uniag.sk](mailto:billik@sun.uniag.sk)>

Slovak error messages.

- Stefan Saroiu <[tzoompy@cs.washington.edu](mailto:tzoompy@cs.washington.edu)>

Romanian error messages.

- Peter Feher

Hungarian error messages.

- Roberto M. Serqueira

Portuguese error messages.

- Carsten H. Pedersen

Danish error messages.

- Arjen Lentz

Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

### 1.9.3. Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at <http://solutions.mysql.com/software/>.

- Tim Bunce, Alligator Descartes

For the `DBD` (Perl) interface.

- Andreas Koenig <[a.koenig@mind.de](mailto:a.koenig@mind.de)>

For the Perl interface for MySQL Server.

- Jochen Wiedmann <[wiedmann@neckar-alb.de](mailto:wiedmann@neckar-alb.de)>

For maintaining the Perl `DBD::mysql` module.

- Eugene Chan <[eugene@acenet.com.sg](mailto:eugene@acenet.com.sg)>

For porting PHP for MySQL Server.

- Georg Richter

MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.

- Giovanni Maruzzelli <[maruzz@matrice.it](mailto:maruzz@matrice.it)>

For porting iODBC (Unix ODBC).

- Xavier Leroy <[Xavier.Leroy@inria.fr](mailto:Xavier.Leroy@inria.fr)>

The author of LinuxThreads (used by the MySQL Server on Linux).

### 1.9.4. Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

From whom we got an excellent compiler (`gcc`), an excellent debugger (`gdb`) and the `libc` library (from which we have borrowed `strto.c` to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

For a really great editor/environment.

- Julian Seward

Author of [valgrind](#), an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

For [DDD](#) (The Data Display Debugger) which is an excellent graphical front end to [gdb](#).

## 1.9.5. Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the [MySQL server](#) and the [MySQL manual](#), we wish to recognize the following companies, which helped us finance the development of the [MySQL server](#), such as by paying us for developing a new feature or giving us hardware for development of the [MySQL server](#).

- VA Linux / Andover.net

Funded replication.

- NuSphere

Editing of the MySQL manual.

- Stork Design studio

The MySQL Web site in use between 1998-2000.

- Intel

Contributed to development on Windows and Linux platforms.

- Compaq

Contributed to Development on Linux/Alpha.

- SWSOft

Development on the embedded [mysqld](#) version.

- FutureQuest

The `--skip-show-database` [\[441\]](#) option.

---

# Chapter 2. Installing and Upgrading MySQL

## Table of Contents

2.1. General Installation Guidance .....	49
2.1.1. Operating Systems Supported by MySQL Community Server .....	49
2.1.2. Choosing Which MySQL Distribution to Install .....	50
2.1.3. How to Get MySQL .....	53
2.1.4. Verifying Package Integrity Using MD5 Checksums or <a href="#">GnuPG</a> .....	54
2.1.5. Installation Layouts .....	62
2.1.6. Compiler-Specific Build Characteristics .....	62
2.2. Installing MySQL from Generic Binaries on Unix/Linux .....	62
2.3. Installing MySQL on Microsoft Windows .....	65
2.3.1. MySQL Installation Layout on Microsoft Windows .....	66
2.3.2. Choosing An Installation Package .....	67
2.3.3. Installing MySQL on Microsoft Windows Using MySQL Installer .....	67
2.3.4. Installing MySQL on Microsoft Windows Using a <a href="#">noinstall</a> Zip Archive .....	84
2.3.5. Troubleshooting a Microsoft Windows MySQL Server Installation .....	96
2.3.6. Upgrading MySQL on Windows .....	97
2.3.7. Windows Postinstallation Procedures .....	98
2.4. Installing MySQL on Mac OS X .....	100
2.4.1. General Notes on Installing MySQL on Mac OS X .....	100
2.4.2. Installing MySQL on Mac OS X Using Native Packages .....	101
2.4.3. Installing the MySQL Startup Item .....	104
2.4.4. Installing and Using the MySQL Preference Pane .....	107
2.4.5. Using the Bundled MySQL on Mac OS X Server .....	109
2.5. Installing MySQL on Linux .....	109
2.5.1. Installing MySQL from RPM Packages on Linux .....	110
2.5.2. Installing MySQL on Linux using Native Package Manager .....	114
2.6. Installing MySQL on Solaris and OpenSolaris .....	118
2.6.1. Installing MySQL on Solaris using a Solaris <a href="#">PKG</a> .....	118
2.6.2. Installing MySQL on OpenSolaris using IPS .....	119
2.7. Installing MySQL on HP-UX .....	120
2.7.1. General Notes on Installing MySQL on HP-UX .....	120
2.7.2. Installing MySQL on HP-UX using DEPOT .....	121
2.8. Installing MySQL on FreeBSD .....	121
2.9. Installing MySQL from Source .....	122
2.9.1. MySQL Layout for Source Installation .....	124
2.9.2. Installing MySQL from a Standard Source Distribution .....	124
2.9.3. Installing MySQL from a Development Source Tree .....	127
2.9.4. MySQL Source-Configuration Options .....	129
2.9.5. Dealing with Problems Compiling MySQL .....	137
2.9.6. MySQL Configuration and Third-Party Tools .....	138
2.10. Postinstallation Setup and Testing .....	139
2.10.1. Unix Postinstallation Procedures .....	139
2.10.2. Securing the Initial MySQL Accounts .....	150
2.11. Upgrading or Downgrading MySQL .....	153
2.11.1. Upgrading MySQL .....	154
2.11.2. Downgrading MySQL .....	159
2.11.3. Checking Whether Tables or Indexes Must Be Rebuilt .....	161
2.11.4. Rebuilding or Repairing Tables or Indexes .....	163
2.11.5. Copying MySQL Databases to Another Machine .....	164
2.12. Environment Variables .....	165
2.13. Perl Installation Notes .....	167
2.13.1. Installing Perl on Unix .....	167
2.13.2. Installing ActiveState Perl on Windows .....	168

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see [Section 2.11.1, "Upgrading MySQL"](#), for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, you may wish to read [Section B.8, "MySQL 5.6 FAQ: Migration"](#), which contains answers to some common questions concerning migration issues.

Installation of MySQL generally follows the steps outlined here:

**1. Determine whether MySQL runs and is supported on your platform.**

Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation:

**2. Choose which distribution to install.**

Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. We also provide public access to our current source tree for those who want to see our most recent developments and help us test new code. To determine which version and type of distribution you should use, see [Section 2.1.2, "Choosing Which MySQL Distribution to Install"](#).

**3. Download the distribution that you want to install.**

For instructions, see [Section 2.1.3, "How to Get MySQL"](#). To verify the integrity of the distribution, use the instructions in [Section 2.1.4, "Verifying Package Integrity Using MD5 Checksums or GnuPG"](#).

**4. Install the distribution.**

To install MySQL from a binary distribution, use the instructions in [Section 2.2, "Installing MySQL from Generic Binaries on Unix/Linux"](#).

To install MySQL from a source distribution or from the current development source tree, use the instructions in [Section 2.9, "Installing MySQL from Source"](#).

**5. Perform any necessary postinstallation setup.**

After installing MySQL, read [Section 2.10, "Postinstallation Setup and Testing"](#). This section contains important information about making sure the MySQL server is working properly. It also describes how to secure the initial MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

**6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See [Section 2.13, "Perl Installation Notes"](#).**

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux, FreeBSD**

For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a `.tar.gz` package), see [Section 2.2, "Installing MySQL from Generic Binaries on Unix/Linux"](#).

For information on building MySQL entirely from the source code distributions or the source code repositories, see [Section 2.9, “Installing MySQL from Source”](#)

For specific platform help on installation, configuration, and building from source see the corresponding platform section:

- Linux, including notes on distribution specific methods, see [Section 2.5, “Installing MySQL on Linux”](#).
- Solaris and OpenSolaris, including PKG and IPS formats, see [Section 2.6, “Installing MySQL on Solaris and OpenSolaris”](#).
- IBM AIX, see [Section 2.6, “Installing MySQL on Solaris and OpenSolaris”](#).
- Hewlett-Packard HP-UX, including the DEPOT package format, see [Section 2.7, “Installing MySQL on HP-UX”](#).
- FreeBSD, see [Section 2.8, “Installing MySQL on FreeBSD”](#).

- **Microsoft Windows**

For instructions on installing MySQL on Microsoft Windows, using either a Zipped binary or an MSI package, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

For details and instructions on building MySQL from source code using Microsoft Visual Studio, see [Section 2.9, “Installing MySQL from Source”](#).

- **Mac OS X**

For installation on Mac OS X, including using both the binary package and native PKG formats, see [Section 2.4, “Installing MySQL on Mac OS X”](#).

For information on making use of the MySQL Startup Item to automatically start and stop MySQL, see [Section 2.4.3, “Installing the MySQL Startup Item”](#).

For information on the MySQL Preference Pane, see [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

## 2.1. General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#) or the corresponding section for your platform if available. To build MySQL from source, use the instructions in [Section 2.9, “Installing MySQL from Source”](#).

### 2.1.1. Operating Systems Supported by MySQL Community Server

This section lists the operating systems on which MySQL Community Server is known to run.

#### Important

Oracle Corporation does not necessarily provide official support for all the platforms listed in this section. For information about those platforms that are officially supported, see <http://www.mysql.com/support/supportedplatforms.html> on the MySQL Web site.

We use `CMake`, so it is possible to port MySQL to all modern systems that have a C++ compiler and a working implementation of POSIX threads. (Thread support is needed for the server. To compile only the client code, the only requirement is a C++ compiler.)

MySQL has been reported to compile successfully on the following combinations of operating system and thread package.

- FreeBSD 5.x and up with native threads. See [Section 2.8, “Installing MySQL on FreeBSD”](#).
- HP-UX 11.x with the native threads. See [Section 2.7, “Installing MySQL on HP-UX”](#).
- Linux. Builds on all recent Linux distributions based on the 2.6 kernel. See [Section 2.5, “Installing MySQL on Linux”](#).
- Mac OS X. See [Section 2.4, “Installing MySQL on Mac OS X”](#).
- Solaris 2.8 on SPARC and x86, including support for native threads. See [Section 2.6, “Installing MySQL on Solaris and OpenSolaris”](#).
- Windows XP, Windows Vista, Windows Server 2003, and Windows Server 2008. See [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

MySQL has also been known to run on other systems in the past. See [Section 2.1, “General Installation Guidance”](#). Some porting effort might be required for current versions of MySQL on these systems.

Not all platforms are equally well-suited for running MySQL. How well a certain platform is suited for a high-load mission-critical MySQL server is determined by the following factors:

- General stability of the thread library. A platform may have an excellent reputation otherwise, but MySQL is only as stable as the thread library it calls, even if everything else is perfect.
- The capability of the kernel and the thread library to take advantage of symmetric multi-processor (SMP) systems. In other words, when a process creates a thread, it should be possible for that thread to run on a CPU different from the original process.
- The capability of the kernel and the thread library to run many threads that acquire and release a mutex over a short critical region frequently without excessive context switches. If the implementation of `pthread_mutex_lock()` is too anxious to yield CPU time, this hurts MySQL tremendously. If this issue is not taken care of, adding extra CPUs actually makes MySQL slower.
- General file system stability and performance.
- Table size. If your tables are large, performance is affected by the ability of the file system to deal with large files and dealing with them efficiently.
- Our level of expertise here at Oracle Corporation with the platform. If we know a platform well, we enable platform-specific optimizations and fixes at compile time. We can also provide advice on configuring your system optimally for MySQL.
- The amount of testing we have done internally for similar configurations.
- The number of users that have run MySQL successfully on the platform in similar configurations. If this number is high, the likelihood of encountering platform-specific surprises is much smaller.

### 2.1.2. Choosing Which MySQL Distribution to Install

When preparing to install MySQL, you should decide which version to use. MySQL development occurs in several release series, and you can pick the one that best fits your needs. After deciding which version to install, you can choose a distribution format. Releases are available in binary or source format.

#### 2.1.2.1. Choosing Which Version of MySQL to Install

The first decision to make is whether you want to use a production (stable) release or a development release. In the MySQL development process, multiple release series co-exist, each at a different stage of maturity.

## Production Releases

- MySQL 5.6: Latest General Availability (Production) release
- MySQL 5.5: Previous General Availability (Production) release
- MySQL 5.1: Older General Availability (Production) release
- MySQL 5.0: Older Production release nearing the end of the product lifecycle

MySQL 4.1, 4.0, and 3.23 are old releases that are no longer supported.

See <http://www.mysql.com/about/legal/lifecycle/> for information about support policies and schedules.

Normally, if you are beginning to use MySQL for the first time or trying to port it to some system for which there is no binary distribution, use the most recent General Availability series listed in the preceding descriptions. All MySQL releases, even those from development series, are checked with the MySQL benchmarks and an extensive test suite before being issued.

If you are running an older system and want to upgrade, but do not want to take the chance of having a nonseamless upgrade, you should upgrade to the latest version in the same release series you are using (where only the last part of the version number is newer than yours). We have tried to fix only fatal bugs and make only small, relatively “safe” changes to that version.

If you want to use new features not present in the production release series, you can use a version from a development series. Be aware that development releases are not as stable as production releases.

We do not use a complete code freeze because this prevents us from making bugfixes and other fixes that must be done. We may add small things that should not affect anything that currently works in a production release. Naturally, relevant bugfixes from an earlier series propagate to later series.

If you want to use the very latest sources containing all current patches and bugfixes, you can use one of our source code repositories (see [Section 2.9.3, “Installing MySQL from a Development Source Tree”](#)). These are not “releases” as such, but are available as previews of the code on which future releases are to be based.

The naming scheme in MySQL 5.6 uses release names that consist of three numbers and a suffix; for example, **mysql-5.6.1-m1**. The numbers within the release name are interpreted as follows:

- The first number (**5**) is the major version and describes the file format. All MySQL 5 releases have the same file format.
- The second number (**6**) is the release level. Taken together, the major version and release level constitute the release series number.
- The third number (**1**) is the version number within the release series. This is incremented for each new release. Usually you want the latest version for the series you have chosen.

For each minor update, the last number in the version string is incremented. When there are major new features or minor incompatibilities with previous versions, the second number in the version string is incremented. When the file format changes, the first number is increased.

Release names also include a suffix to indicate the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **mN** (for example, **m1**, **m2**, **m3**, ...) indicate a milestone number. MySQL development uses a milestone model, in which each milestone proceeds through a small number of versions with a tight focus on a small subset of thoroughly tested features. Following the releases for one milestone, development proceeds with another small number of releases that focuses on the next small set of

features, also thoroughly tested. Features within milestone releases may be considered to be of pre-production quality.

- **rc** indicates a Release Candidate. Release candidates are believed to be stable, having passed all of MySQL's internal testing, and with all known fatal runtime bugs fixed. However, the release has not been in widespread use long enough to know for sure that all bugs have been identified. Only minor fixes are added.
- If there is no suffix, it indicates that the release is a General Availability (GA) or Production release. GA releases are stable, having successfully passed through all earlier release stages and are believed to be reliable, free of serious bugs, and suitable for use in production systems. Only critical bugfixes are applied to the release.

All releases of MySQL are run through our standard tests and benchmarks to ensure that they are relatively safe to use. Because the standard tests are extended over time to check for all previously found bugs, the test suite keeps getting better.

All releases have been tested at least with these tools:

- **An internal test suite.** The `mysql-test` directory contains an extensive set of test cases. We run these tests for every server binary. See [Section 22.1.2, "The MySQL Test Suite"](#), for more information about this test suite.
- **The MySQL benchmark suite.** This suite runs a range of common queries. It is also a test to determine whether the latest batch of optimizations actually made the code faster. See [Section 8.12.2, "The MySQL Benchmark Suite"](#).

We also perform additional integration and nonfunctional testing of the latest MySQL version in our internal production environment. Integration testing is done with different connectors, storage engines, replication modes, backup, partitioning, stored programs, and so forth in various combinations. Additional nonfunctional testing is done in areas of performance, concurrency, stress, high volume, upgrade and downgrade.

### 2.1.2.2. Choosing a Distribution Format

After choosing which version of MySQL to install, you should decide whether to use a binary distribution or a source distribution. In most cases, you should probably use a binary distribution, if one exists for your platform. Binary distributions are available in native format for many platforms, such as RPM files for Linux or PKG package installers for Mac OS X or Solaris. Distributions also are available as Zip archives or compressed `tar` files.

Reasons to choose a binary distribution include the following:

- Binary distributions generally are easier to install than source distributions.
- To satisfy different user requirements, we provide several servers in binary distributions. `mysqld` is an optimized server that is a smaller, faster binary. `mysqld-debug` is compiled with debugging support.

Each of these servers is compiled from the same source distribution, though with different configuration options. All native MySQL clients can connect to servers from either MySQL version.

Under some circumstances, you may be better off installing MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` to ensure that features are available that might not be included in the standard binary distributions. Here is a list of the most common extra options that you may want to use to ensure feature availability:

- `-DWITH_LIBWRAP=1` [136] for TCP wrappers support.
- `-DWITH_ZLIB={system|bundled}` [137] for features that depend on compression
- `-DWITH_DEBUG=1` [136] for debugging support
- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.
- You want to use the latest sources from one of the Bazaar repositories to have access to all current bugfixes. For example, if you have found a bug and reported it to the MySQL development team, the bugfix is committed to the source repository and you can access it there. The bugfix does not appear in a release until a release actually is issued.
- You want to read (or modify) the C and C++ code that makes up MySQL. For this purpose, you should get a source distribution, because the source code is always the ultimate manual.
- Source distributions contain more tests and examples than binary distributions.

### 2.1.2.3. How and When Updates Are Released

MySQL is evolving quite rapidly and we want to share new developments with other MySQL users. We try to produce a new release whenever we have new and useful features that others also seem to have a need for.

We also try to help users who request features that are easy to implement. We take note of what our licensed users want, and we especially take note of what our support customers want and try to help them in this regard.

No one is *required* to download a new release. The [Release Notes](#) help you determine whether the new release has something you really want.

We use the following policy when updating MySQL:

- Enterprise Server releases are meant to appear every 18 months, supplemented by quarterly service packs and monthly rapid updates. Community Server releases are meant to appear 2 to 3 times per year.
- Releases are issued within each series. For each release, the last number in the version is one more than the previous release within the same series.
- Binary distributions for some platforms are made by us for major releases. Other people may make binary distributions for other systems, but probably less frequently.
- We make fixes available as soon as we have identified and corrected small or noncritical but annoying bugs. The fixes are available in source form immediately from our public Bazaar repositories, and are included in the next release.
- If by any chance a security vulnerability or critical bug is found in a release, our policy is to fix it in a new release as soon as possible. (We would like other companies to do this, too!)

### 2.1.3. How to Get MySQL

Check our downloads page at <http://dev.mysql.com/downloads/> for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see <http://dev.mysql.com/downloads/mirrors.html>. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

To obtain the latest development source, see [Section 2.9.3, “Installing MySQL from a Development Source Tree”](#).

## 2.1.4. Verifying Package Integrity Using MD5 Checksums or GnuPG

After you have downloaded the MySQL package that suits your needs and before you attempt to install it, you should make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using [GnuPG](#), the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

### 2.1.4.1. Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product, and you will compare it against the MD5 checksum of the file (product) that you download.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named `md5sum`, or it may be named `md5`, and some operating systems do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can also download the source code from <http://www.gnu.org/software/textutils/>. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the `md5` command line utility is available from <http://www.fourmilab.ch/md5/>. `winMd5Sum` is a graphical MD5 checking tool that can be obtained from <http://www.nullriver.com/index/products/winmd5sum>. Our Microsoft Windows examples will assume the name `md5.exe`.

Linux and Microsoft Windows examples:

```
shell> md5sum mysql-standard-5.6.12-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-5.6.12-linux-i686.tar.gz
```

```
shell> md5.exe mysql-installer-community-5.6.12.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-5.6.12.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

#### Note

Make sure to verify the checksum of the *archive file* (for example, the `.zip`, `.tar.gz`, or `.msi` file) and not of the files that are contained inside of the archive. In other words, verify the file before extracting its contents.

### 2.1.4.2. Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using [MD5 checksums](#), but requires more work.

We sign MySQL downloadable packages with [GnuPG](#) (GNU Privacy Guard). [GnuPG](#) is an Open Source alternative to the well-known Pretty Good Privacy ([PGP](#)) by Phil Zimmermann. See <http://www.gnupg.org/> for more information about [GnuPG](#) and how to obtain and install it on your system.

Most Linux distributions ship with [GnuPG](#) installed by default. For more information about [GnuPG](#), see <http://www.openpgp.org/>.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from <http://pgp.mit.edu/>. The key that you want to obtain is named [mysql-build@oss.oracle.com](mailto:mysql-build@oss.oracle.com). Alternatively, you can cut and paste the key directly from the following text:

```

4fUUmwCbByr2+bBEN/L2B0cnw9Z/QFWuhRMAoKVgCFm5fadQ3Afi+UQ1AcOphrnJ
=Eto8
-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
gpg: key 5072E1F5: public key "MySQL Release Engineering
<mysql-build@oss.oracle.com>" imported
gpg: Total number processed: 1
gpg: imported: 1
gpg: no ultimately trusted keys found
```

You can also download the key from the public keyserver using the public key id, `5072E1F5`:

```
shell> gpg --recv-keys 5072E1F5
gpg: requesting key 5072E1F5 from hkp server keys.gnupg.net
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
1 new user ID
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
53 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg: new user IDs: 1
gpg: new signatures: 53
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> rpm --import mysql_pubkey.asc
```

If you experience problems or require RPM specific information, see [Section 2.1.4.4, "Signature Checking Using RPM"](#).

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

**Table 2.1. MySQL Package and Signature Files for Source files**

File Type	File Name
Distribution file	<code>mysql-standard-5.6.12-linux-i686.tar.gz</code>
Signature file	<code>mysql-standard-5.6.12-linux-i686.tar.gz.asc</code>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

If the downloaded package is valid, you will see a "Good signature" similar to:

```
shell> gpg --verify mysql-standard-5.6.12-linux-i686.tar.gz.asc
gpg: Signature made Tue 01 Feb 2011 02:38:30 AM CST using DSA key ID 5072E1F5
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
```

The `Good signature` message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

```
shell> gpg --verify mysql-standard-5.6.12-linux-i686.tar.gz.asc
gpg: Signature made Wed 23 Jan 2013 02:25:45 AM PST using DSA key ID 5072E1F5
gpg: checking the trustdb
gpg: no ultimately trusted keys found
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: A4A9 4068 76FC BD3C 4567 70C8 8C71 8D3B 5072 E1F5
```

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- *gpg: no ultimately trusted keys found*: This means that the specific key is not "ultimately trusted" by you or your web of trust, which is okay for the purposes of verifying file signatures.
- *WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.*: This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

See the GPG documentation for more information on how to work with public keys.

### 2.1.4.3. Signature Checking Using [Gpg4win](#) for Windows

The [Section 2.1.4.2, "Signature Checking Using GnuPG"](#) section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a GUI tool like [Gpg4win](#). You may use a different tool but our examples are based on Gpg4win, and utilize its bundled [Kleopatra](#) GUI.

Download and install Gpg4win, and then load Kleopatra. The dialog should look similar to:

Figure 2.1. Initial screen after loading Kleopatra

Next, add the MySQL Release Engineering certificate. Do this by clicking **File**, **Lookup Certificates on Server**. Type "Mysql Release Engineering" into the search box and press **Search**.

Figure 2.2. Finding the MySQL Release Engineering certificate

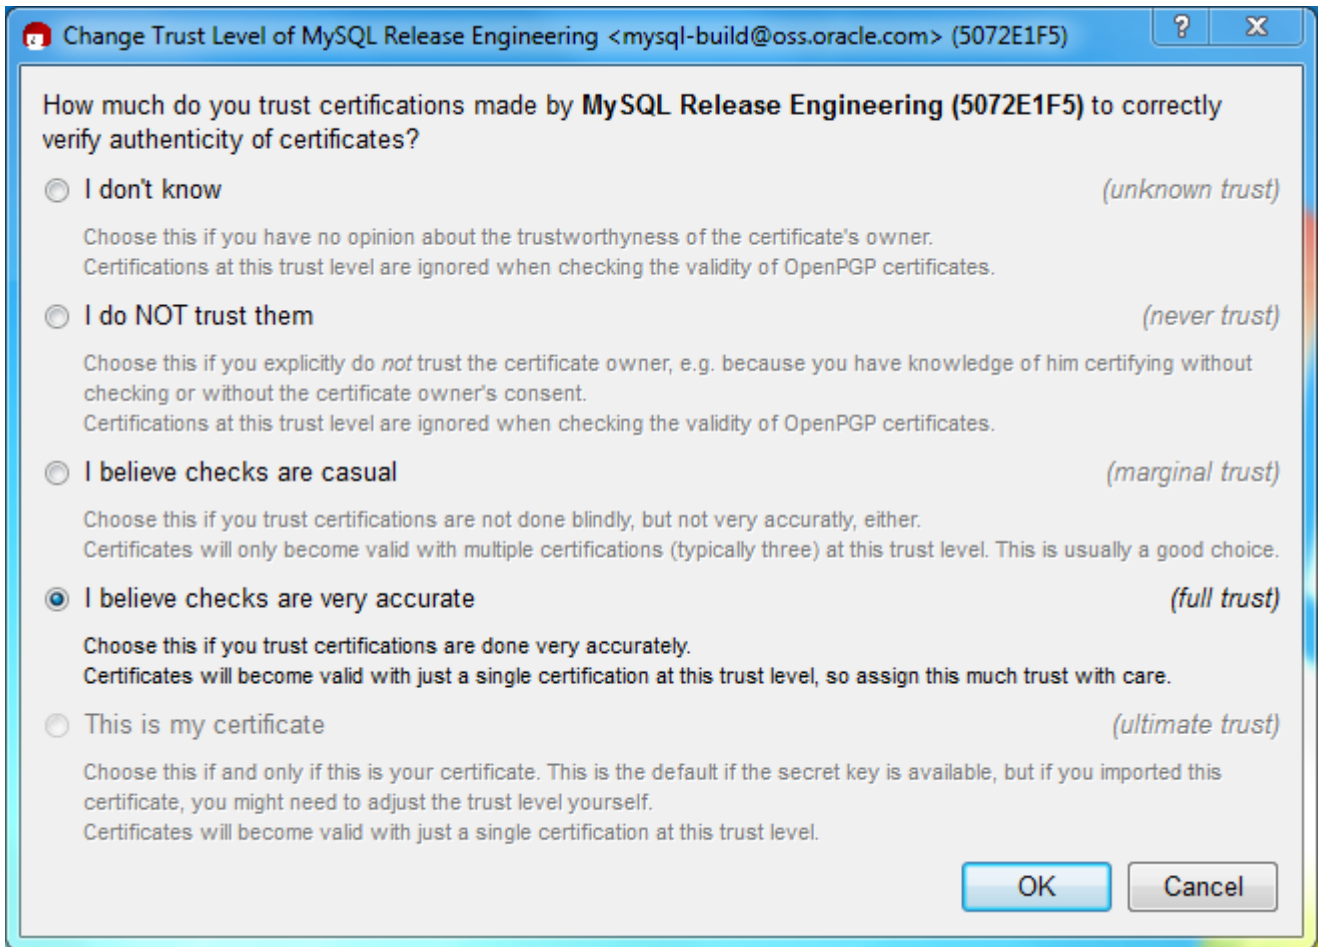

Select the "MySQL Release Engineering" certificate. The Fingerprint and Key-ID must be "5072E1F5", or choose **Details...** to confirm the certificate is valid. Now, import it by clicking **Import**. An import dialog will be displayed, choose **Okay**, and this certificate will now be listed under the **Imported Certificates** tab.

Next, configure the trust level for our certificate. Select our certificate, then from the main menu select **Certificates**, **Change Owner Trust...**. We suggest choosing **I believe checks are very accurate** for our

certificate, as otherwise you might not be able to verify our signature. Select **I believe checks are very accurate** and then press **OK**.

**Figure 2.3. Changing the Trust level**

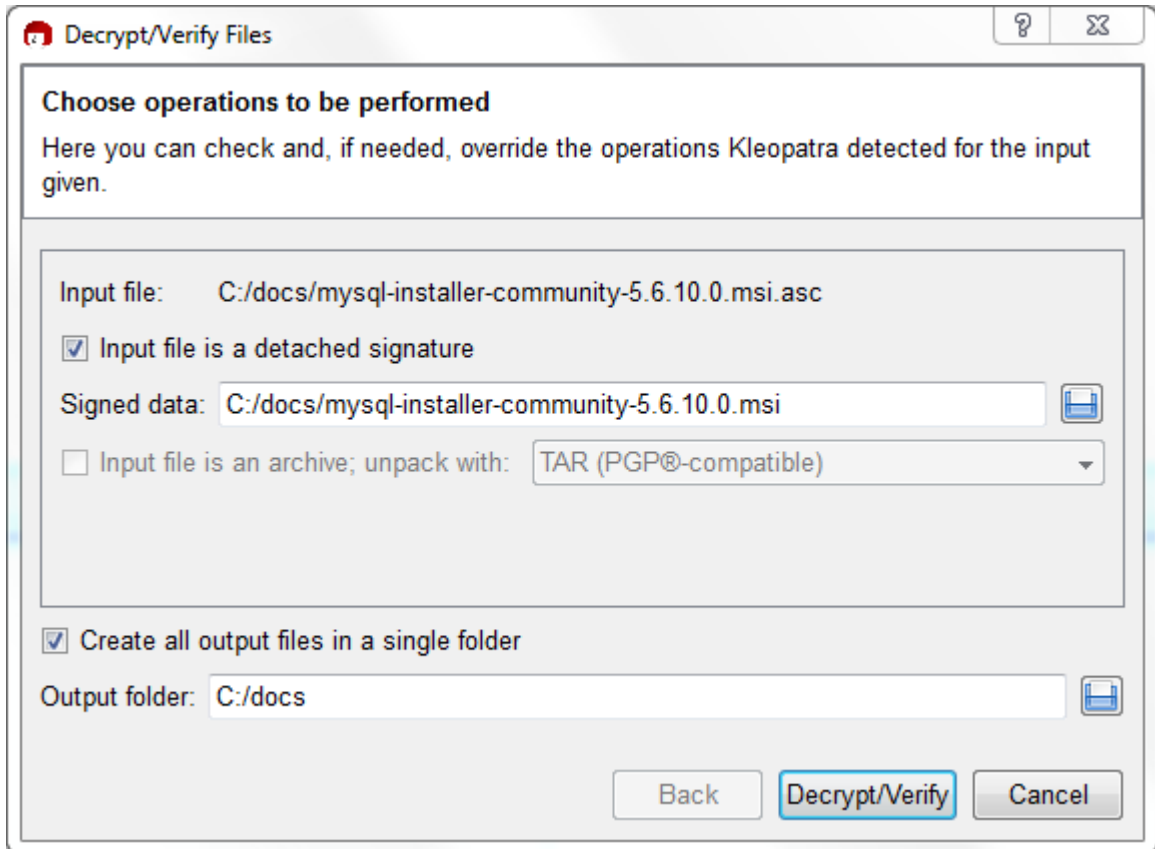

Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended `.asc` extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the `.asc` file with this signature.

**Table 2.2. MySQL Package and Signature Files for MySQL Installer for Microsoft Windows**

File Type	File Name
Distribution file	<code>mysql-installer-community-5.6.12.msi</code>
Signature file	<code>mysql-installer-community-5.6.12.msi.asc</code>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Either drag and drop the signature (`.asc`) file into Kleopatra, or load the dialog from **File**, **Decrypt/Verify Files...**, and then choose either the `.msi` or `.asc` file.

**Figure 2.4. The Decrypt/Verify Files dialog**

Click **Decrypt/Verify** to check the file. The two most common results will look like the following, and although the yellow warning looks problematic, the following means that the file check passed with success. You may now run this installer.

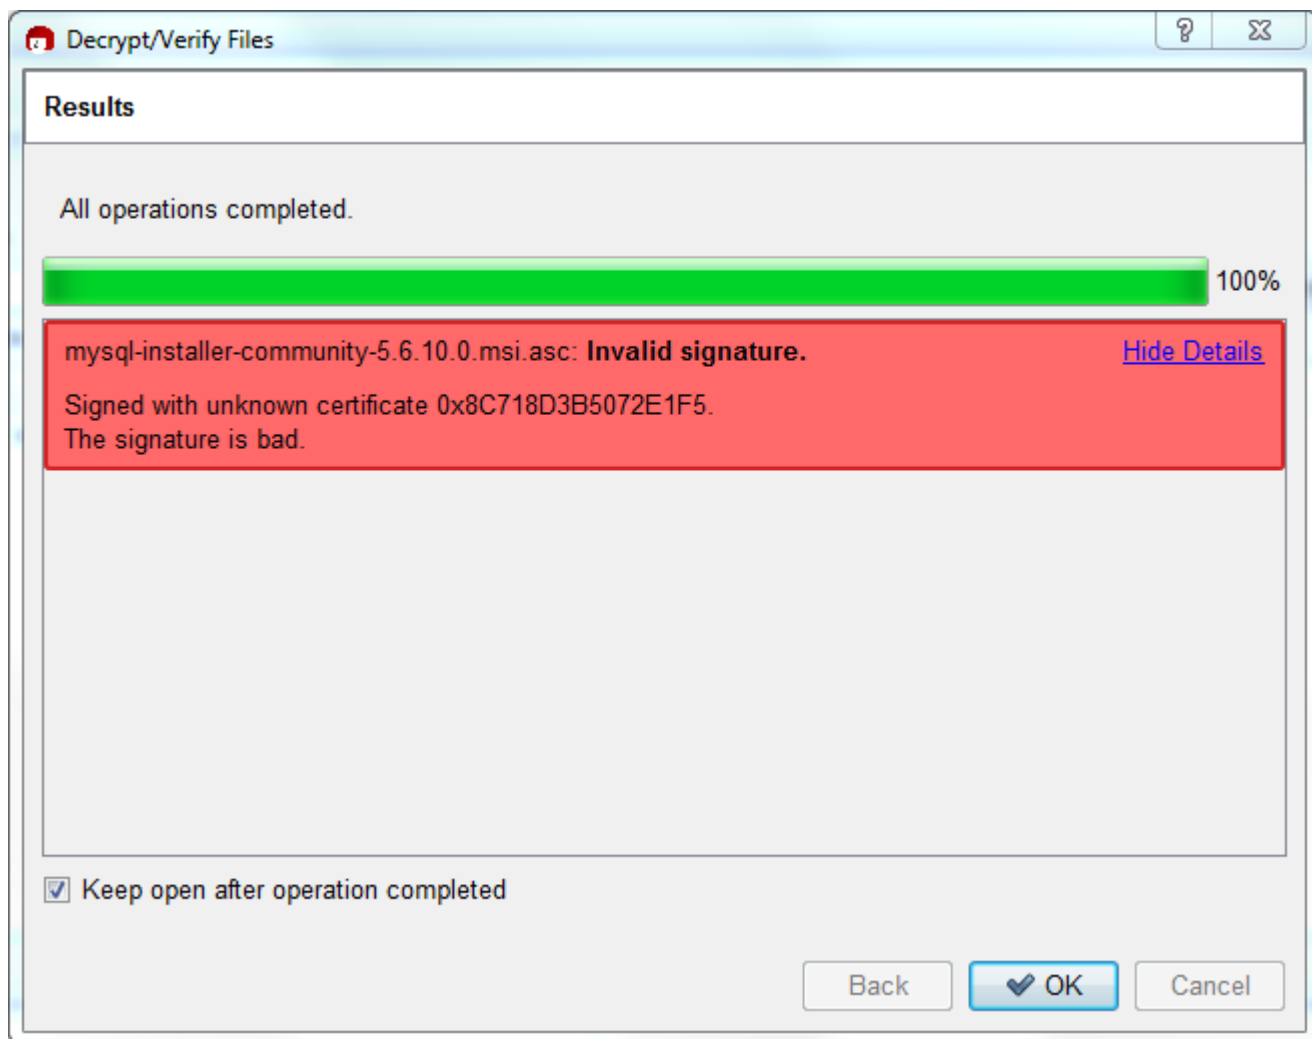

Figure 2.5. The Decrypt/Verify Results: Good

Seeing a red "The signature is bad" error means the file is invalid. Do not execute the MSI file if you see this error.

Figure 2.6. The Decrypt/Verify Results: Bad

The [Section 2.1.4.2, “Signature Checking Using GnuPG”](#) section explains why you probably don't see a green `Good signature` result.

#### 2.1.4.4. Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-5.6.12-0.glibc23.i386.rpm
MySQL-server-5.6.12-0.glibc23.i386.rpm: md5 gpg OK
```

#### Note

If you are using RPM 4.1 and it complains about `(GPG) NOT OK (MISSING KEYS: GPG#5072e1f5)`, even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use `rpm --import` to import the key. For example:

```
shell> gpg --export -a 5072elf5 > 5072elf5.asc
shell> rpm --import 5072elf5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you can use this manual page:

```
shell> rpm --import http://dev.mysql.com/doc/refman/5.6/en/checking-gpg-signature.html
```

If you need to obtain the MySQL public key, see [Section 2.1.4.2, “Signature Checking Using GnuPG”](#).

## 2.1.5. Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

- [Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”](#)
- [Section 2.9.1, “MySQL Layout for Source Installation”](#)
- [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)
- [Table 2.9, “MySQL Installation Layout for Linux RPM”](#)
- [Table 2.6, “MySQL Installation Layout on Mac OS X”](#)

## 2.1.6. Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

### `icc` (Intel C++ Compiler) Builds

A server built with `icc` has these characteristics:

- SSL support is not included.

## 2.2. Installing MySQL from Generic Binaries on Unix/Linux

Oracle provides a set of binary distributions of MySQL. These include binary distributions in the form of compressed `tar` files (files with a `.tar.gz` extension) for a number of platforms, as well as binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed `tar` file binary distribution. For other platform-specific package formats, see the other platform-specific sections. For example, for Windows distributions, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

To obtain MySQL, see [Section 2.1.3, “How to Get MySQL”](#).

MySQL compressed `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.gz`, where `VERSION` is a number (for example, `5.6.12`), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

To install MySQL from a compressed `tar` file binary distribution, your system must have GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from <http://www.gnu.org/software/tar/>.

### Warning

If you have previously installed MySQL using your operating system native package management system, such as `yum` or `apt-get`, you may experience problems installing using a native binary. Make sure your previous MySQL previous installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check the existence of configuration files such as `/etc/my.cnf` or the `/etc/mysql` directory have been deleted.

If you run into problems and need to file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

On Unix, to install a compressed `tar` file binary distribution, unpack it at the installation location you choose (typically `/usr/local/mysql`). This creates the directories shown in the following table.

**Table 2.3. MySQL Installation Layout for Generic Unix/Linux Binary Package**

Directory	Contents of Directory
<code>bin</code>	Client programs and the <code>mysqld</code> server
<code>data</code>	Log files, databases
<code>docs</code>	Manual in Info format
<code>man</code>	Unix manual pages
<code>include</code>	Include (header) files
<code>lib</code>	Libraries
<code>scripts</code>	<code>mysql_install_db</code>
<code>share</code>	Miscellaneous support files, including error messages, sample configuration files, SQL for database installation
<code>sql-bench</code>	Benchmarks

Debug versions of the `mysqld` binary are available as `mysqld-debug`. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. For more information on compiling from source, see [Section 2.9, “Installing MySQL from Source”](#).

To install and use a MySQL binary distribution, the basic command sequence looks like this:

```
shell> groupadd mysql
shell> useradd -r -g mysql mysql
shell> cd /usr/local
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
# Next command is optional
shell> cp support-files/my-medium.cnf /etc/my.cnf
shell> bin/mysqld_safe --user=mysql &
```

```
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```

A more detailed version of the preceding description for installing a binary distribution follows.

### Note

This procedure assumes that you have `root` (administrator) access to your system. Alternatively, you can prefix each command using the `sudo` (Linux) or `pfexec` (OpenSolaris) command.

The procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.10, “Postinstallation Setup and Testing”](#).

## Create a `mysql` User and Group

If your system does not already have a user and group for `mysqld` to run as, you may need to create one. The following commands add the `mysql` group and the `mysql` user. You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following instructions. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

```
shell> groupadd mysql
shell> useradd -r -g mysql mysql
```

### Note

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` option to create a user that does not have login permissions to your server host. Omit this option to permit logins for the user (or if your `useradd` does not support the option).

## Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```
shell> cd /usr/local
```

Obtain a distribution file using the instructions in [Section 2.1.3, “How to Get MySQL”](#). For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. Then create a symbolic link to that directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `tar` command creates a directory named `mysql-VERSION-OS`. The `ln` command makes a symbolic link to that directory. This enables you to refer more easily to the installation directory as `/usr/local/mysql`.

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it. Replace the preceding `tar` command with the following alternative command to uncompress and extract the distribution:

```
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
```

## Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see [Section 2.10, “Postinstallation Setup and Testing”](#).

### Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

## 2.3. Installing MySQL on Microsoft Windows

MySQL for Microsoft Windows is available in a number of different forms. A Microsoft Windows operating system such as Windows Vista, Windows 7, Windows 8, Windows Server 2008, or Windows Server 2012. Both 32-bit and 64-bit versions are supported. For supported platform information, see <http://www.mysql.com/support/supportedplatforms/database.html>.

In addition to running MySQL as a standard application, you can also run the MySQL server as a Windows service. By using a service you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the `Service Control Manager`. Once installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations within the Windows version of MySQL, see [Section E.10.6, “Windows Platform Limitations”](#).

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

- If you plan to connect to the MySQL server using ODBC, you need a Connector/ODBC driver. For more information, including installation and configuration instructions, see [Section 21.1, “MySQL Connector/ODBC”](#). But note that MySQL Installer will install and configure Connector/ODBC for you.
- If you plan to use MySQL server with .NET applications, you need the Connector/Net driver. For more information, including installation and configuration instructions, see [Section 21.2, “MySQL Connector/Net”](#). But note that MySQL Installer will install and configure Connector/NET for you.

MySQL distributions for Windows can be downloaded from <http://dev.mysql.com/downloads/>. See [Section 2.1.3, “How to Get MySQL”](#).

MySQL for Windows is available in several distribution formats, detailed below. Generally speaking, you should use MySQL Installer. It is simpler to use than the ZIP file, and you need no additional tools to get MySQL up and running. MySQL Installer will automatically install MySQL Server, install additional MySQL products, create an options file, starts the server, and allow you to create default user accounts. For more information on choosing a package, see [Section 2.3.2, “Choosing An Installation Package”](#).

- MySQL Installer. It includes MySQL Server and additional MySQL products including MySQL Workbench, MySQL Notifier, and MySQL for Excel. And MySQL Installer can also be used to upgrade these product in the future.

For instructions on installing MySQL using MySQL Installer, see [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).

- Standard binary distribution format packaged as a Zip file containing all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

For instructions on installing MySQL using the Zip file, see [Section 2.3.4, “Installing MySQL on Microsoft Windows Using a `noinstall` Zip Archive”](#).

- The source distribution contains all the code and support files for building the executables using the Visual Studio compiler system.

For instructions on building MySQL from source on Windows, see [Section 2.9, “Installing MySQL from Source”](#).

**MySQL on Windows considerations:**

- **Large Table Support**

If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See [Section 13.1.14, “CREATE TABLE Syntax”](#).

- **MySQL and Virus Checking Software**

Using virus scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software mis-identifying the contents of the files as containing spam. This is because of the fingerprinting mechanism used by the virus scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (`datadir` [472]) being used to store your MySQL table data. There is usually a system built into the virus scanning software to permit certain directories to be specifically ignored during virus scanning.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, you should configure a separate temporary directory for MySQL temporary files and add this to the virus scanning exclusion list. To do this, add a configuration option for the `tmpdir` [446] parameter to your `my.ini` configuration file. For more information, see [Section 2.3.4.2, “Creating an Option File”](#).

## 2.3.1. MySQL Installation Layout on Microsoft Windows

For MySQL 5.6 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.6`. Some Windows users prefer to install in `C:\mysql`, the directory that formerly was used as the default. However, the layout of the subdirectories remains the same.

All of the files are located within this parent directory, using the structure shown in the following table.

**Table 2.4. MySQL Installation Layout for Windows**

Directory	Contents of Directory
<code>bin</code>	Client programs and the <code>mysqld</code> server
<code>C:\Documents and Settings\All Users\Application Data\MySQL</code>	Log files, databases (Windows XP, Windows Server 2003)
<code>C:\ProgramData\MySQL</code>	Log files, databases (Windows 7, Windows Server 2008, and newer)
<code>examples</code>	Example programs and scripts
<code>include</code>	Include (header) files

Directory	Contents of Directory
<code>lib</code>	Libraries
<code>scripts</code>	Utility scripts
<code>share</code>	Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation

If you install MySQL using the MySQL Installer, this package creates and sets up the data directory that the installed server will use, but also creates a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using this package, the template data directory can be copied to set up additional MySQL instances. See [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

## 2.3.2. Choosing An Installation Package

For MySQL 5.6, there are installation package formats to choose from when installing MySQL on Windows:

- **MySQL Installer:** This package has a file name similar to `mysql-installer-community-5.6.12.0.msi` or `mysql-installer-commercial-5.6.12.0.msi`, and utilizes MSI's to automatically install MySQL server and other products. It will download and apply updates to itself, and for each of the installed products. It also configures the additional non-server products.

The installed products are configurable, and this includes: documentation with samples and examples, connectors (such as C, C++, J, NET, and ODBC), MySQL Workbench, MySQL Notifier for Microsoft Windows, MySQL for Excel, and the MySQL Server with its components.

MySQL Installer will run on all Windows platforms that are [supported by MySQL](#). Note: because MySQL is not a native component of Windows and depends on .NET, it will not work on minimal installation options like the "Server Core" version of Windows Server 2008.

For instructions on installing MySQL using MySQL Installer, see [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).

- **The Noinstall Archive:** This package has a file name similar to `mysql-5.6.12-win32.zip` or `mysql-5.6.12-winx64.zip`, and contains all the files found in the Complete install package, with the exception of the GUI. This package does not include an automated installer, and must be manually installed and configured.

Your choice of install package affects the installation process you must follow. If you choose to use MySQL Installer, see [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#). If you choose to install a Noinstall archive, see [Section 2.3.4, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”](#).

## 2.3.3. Installing MySQL on Microsoft Windows Using MySQL Installer

MySQL Installer is an application that simplifies the installation and updating process for a wide range of MySQL products, including [MySQL Notifier for Microsoft Windows](#), [MySQL Workbench](#), and [MySQL for Excel](#). From this central application, you can see which MySQL products are already installed, configure them, and update or remove them if necessary. The installer can also install plugins, documentation, tutorials, and example databases. The MySQL Installer is only available for Microsoft Windows, and includes both a GUI and command-line interface.

### Community edition

Download the community edition of MySQL Installer at <http://dev.mysql.com/downloads/installer/>. It will install the community version of all MySQL products.

## Commercial edition

Download the commercial edition of MySQL Installer at either [My Oracle Support \(MOS\)](#) or <https://edelivery.oracle.com/>. It will install the commercial version of all MySQL products, including Workbench SE. It also integrates with your MOS account, so enter in your MOS credentials to automatically receive updates for your commercial MySQL products.

For release notes detailing the changes in each release of MySQL Installer, see [MySQL Installer Release Notes](#).

MySQL Installer is compatible with pre-existing installations, and adds them to its list of installed components. And while the MySQL Installer is bundled with a specific version of MySQL Server, a single MySQL Installer instance can install and manage multiple MySQL Server versions. For example, a single MySQL Installer instance can install versions 5.1, 5.5, and 5.6. It can also manage either commercial or community editions of the MySQL Server.

### Note

A single host can not have both community and commercial editions of MySQL Server installed. For example, if you want both MySQL Server 5.5 and 5.6 installed on a single host, then both must be the same commercial or community edition.

MySQL Installer handles the initial configuration and setup of the applications. For example:

1. It will create MySQL Server connections in MySQL Workbench.
2. It creates the configuration file (`my.ini`) that is used to configure the MySQL Server. The values written to this file are influenced by choices you make during the installation process.
3. It imports example databases.
4. It creates MySQL Server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin. It optionally creates a Windows user named `MysqISys` with limited privileges, which would then run the MySQL Server.

This feature is only available during the initial installation of the MySQL Server, and not during future updates. User accounts may also be added with MySQL Workbench.

5. If the "Advanced Configuration" option is checked, then the **Logging Options** are also configured. This includes defining file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

MySQL Installer can optionally check for updated components and download them for you automatically.

### 2.3.3.1. MySQL Installer GUI

After installation of the GUI version, the installer will have add its own Start Menu item under MySQL.

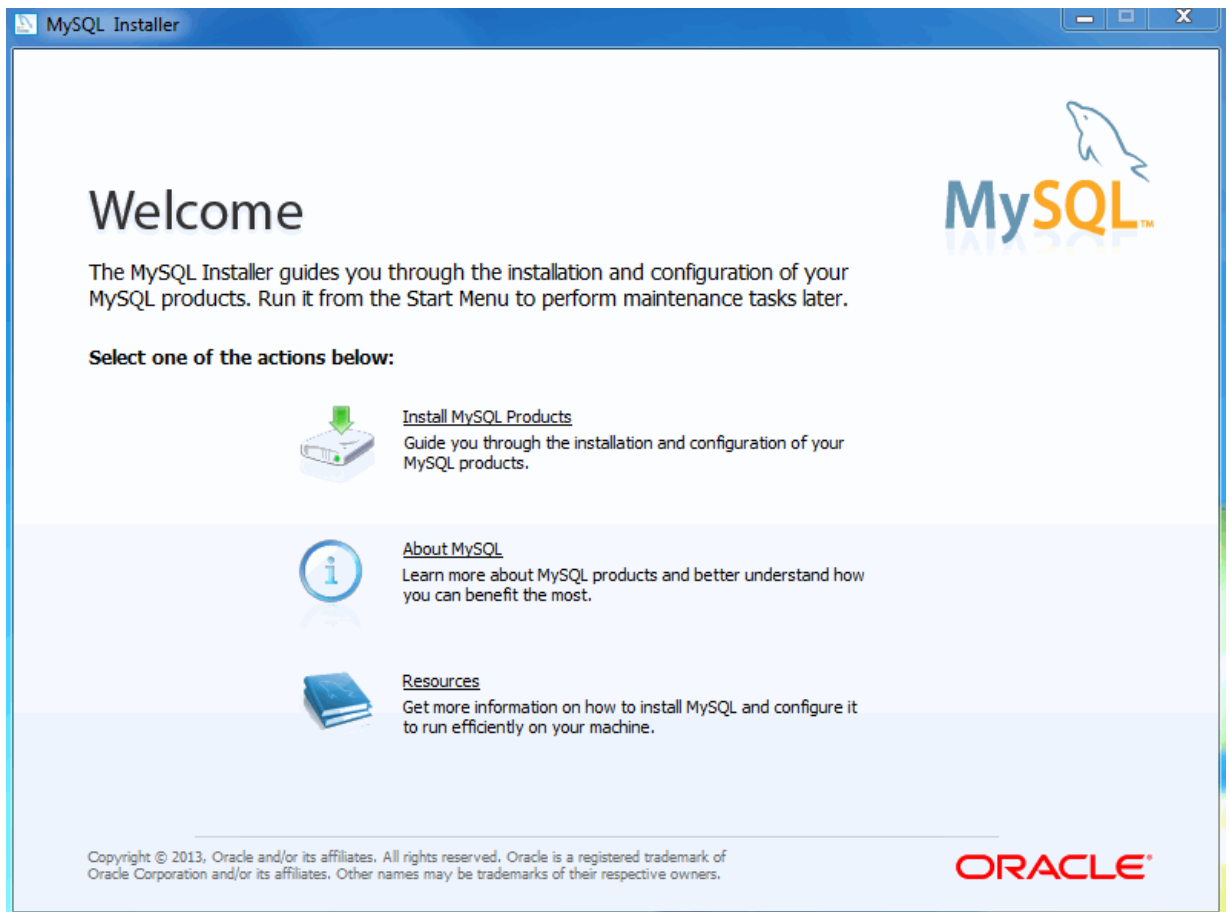

### Note

Files that are generated by MySQL Installer grant full permissions to the user that executes MySQL Installer, including `my.ini`. This does not apply to files and directories for specific products such as the MySQL Server data directory in `ProgramData`, that is owned by `SYSTEM`.

After the installer itself has been installed and started, the following screen is displayed:

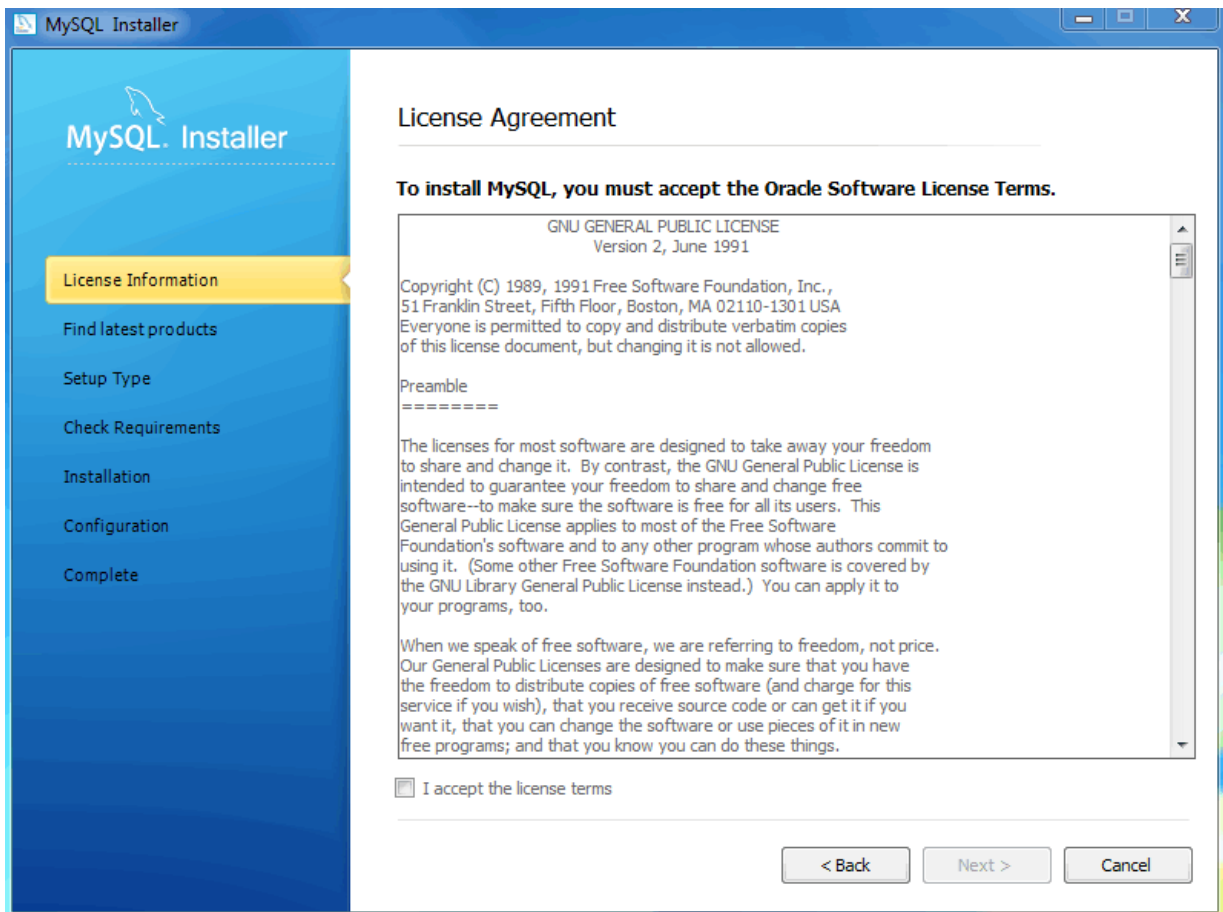

Figure 2.7. MySQL Installer - Welcome Screen

There are three main options:

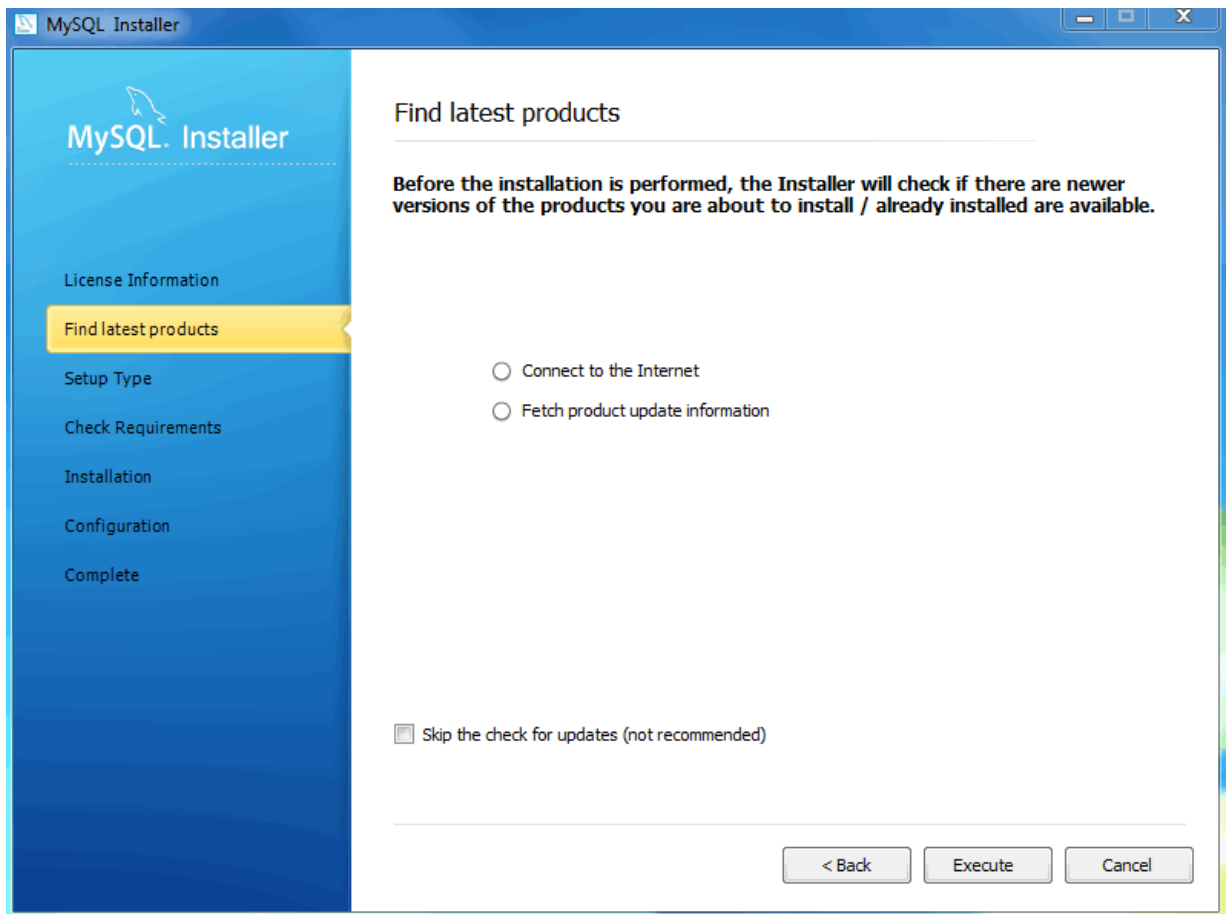

1. Install MySQL Products - The Installation Wizard.
2. About MySQL - Learn about MySQL products and features.
3. Resources - Information to help install and configure MySQL.

To **Install MySQL Products** after executing MySQL Installer for the first time, you must accept the license agreement before proceeding with the installation process.

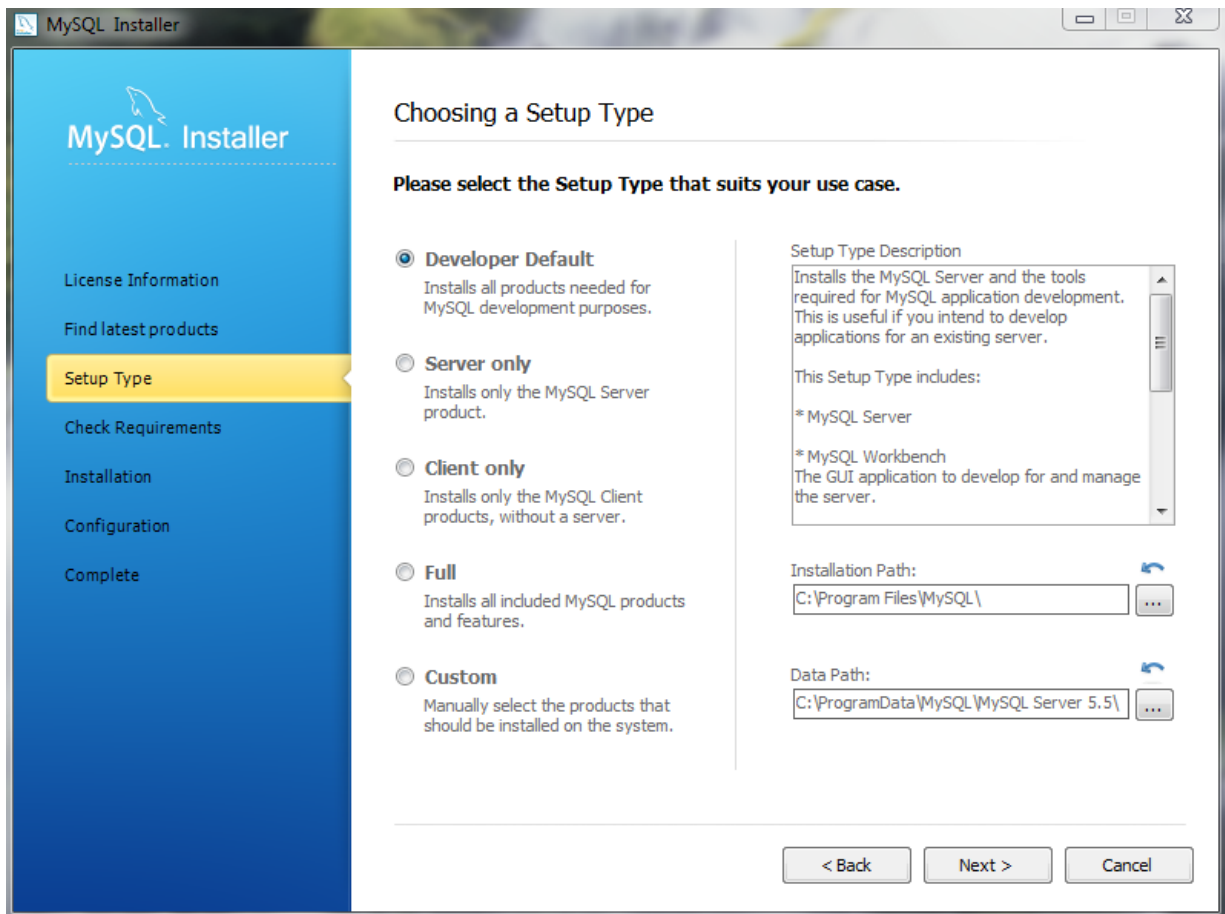

**Figure 2.8. MySQL Installer - License Agreement**

If you are connected to the Internet, then the Installer will search for the latest MySQL components and add them to the installation bundle. Click **Connect to the Internet** to complete this step, or otherwise check the **Skip** checkbox and then **Continue**.

**Figure 2.9. MySQL Installer - Find latest products**

If you chose "Connect to the Internet," the next page will show the progress of MySQL Installer's search for available updates. When the search is complete (or if you opted to skip the search), you will be taken to the **Choose Setup Type** page:

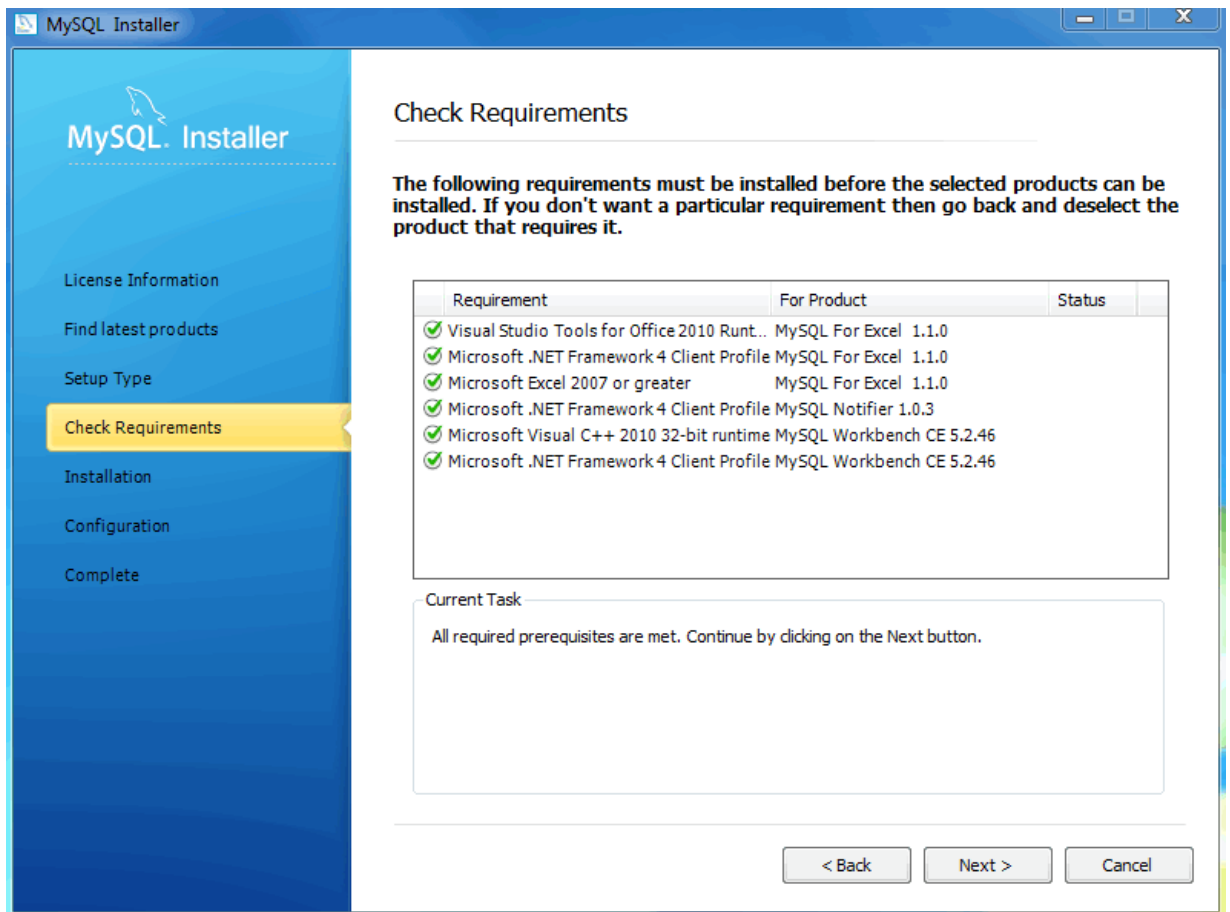

**Figure 2.10. MySQL Installer - Choosing a Setup Type**

Determine the option most compatible with your preferences by reading the **Setup Type Description** descriptions.

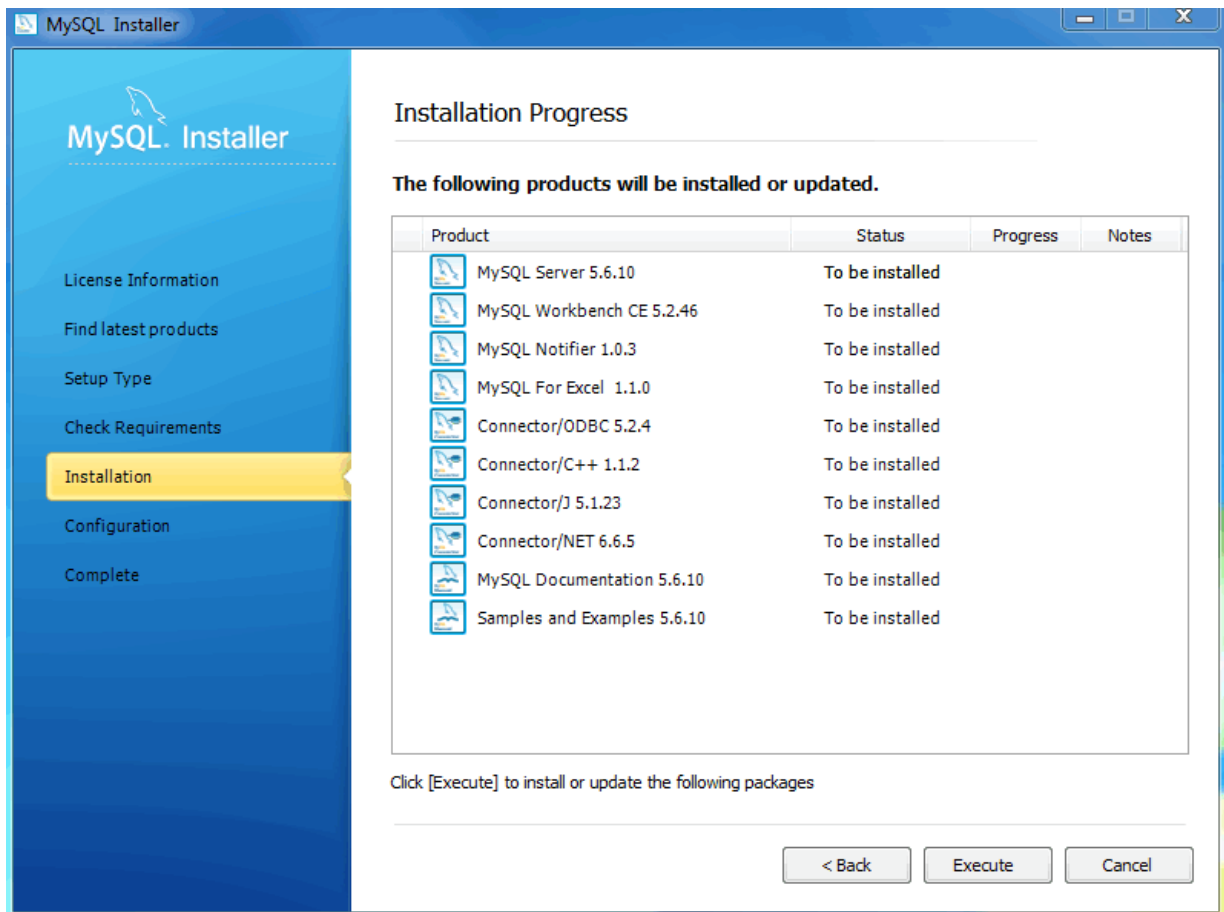

The Installation and Data paths are also defined here, and a caution flag will notify you if the data path you define already exists.

After you select a setup type, the MySQL Installer will check your system for the necessary external requirements and download then install missing components onto your system.

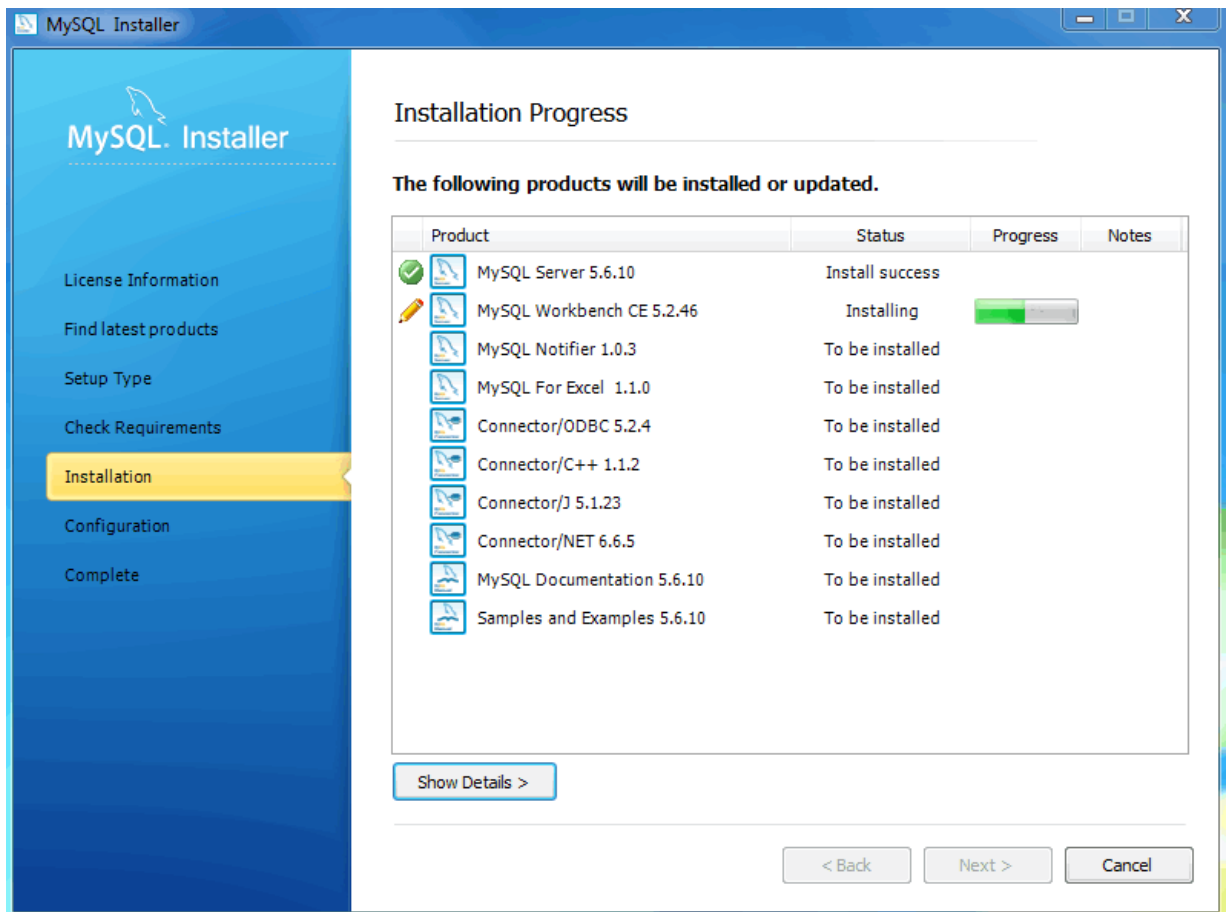

**Figure 2.11. MySQL Installer - Check Requirements**

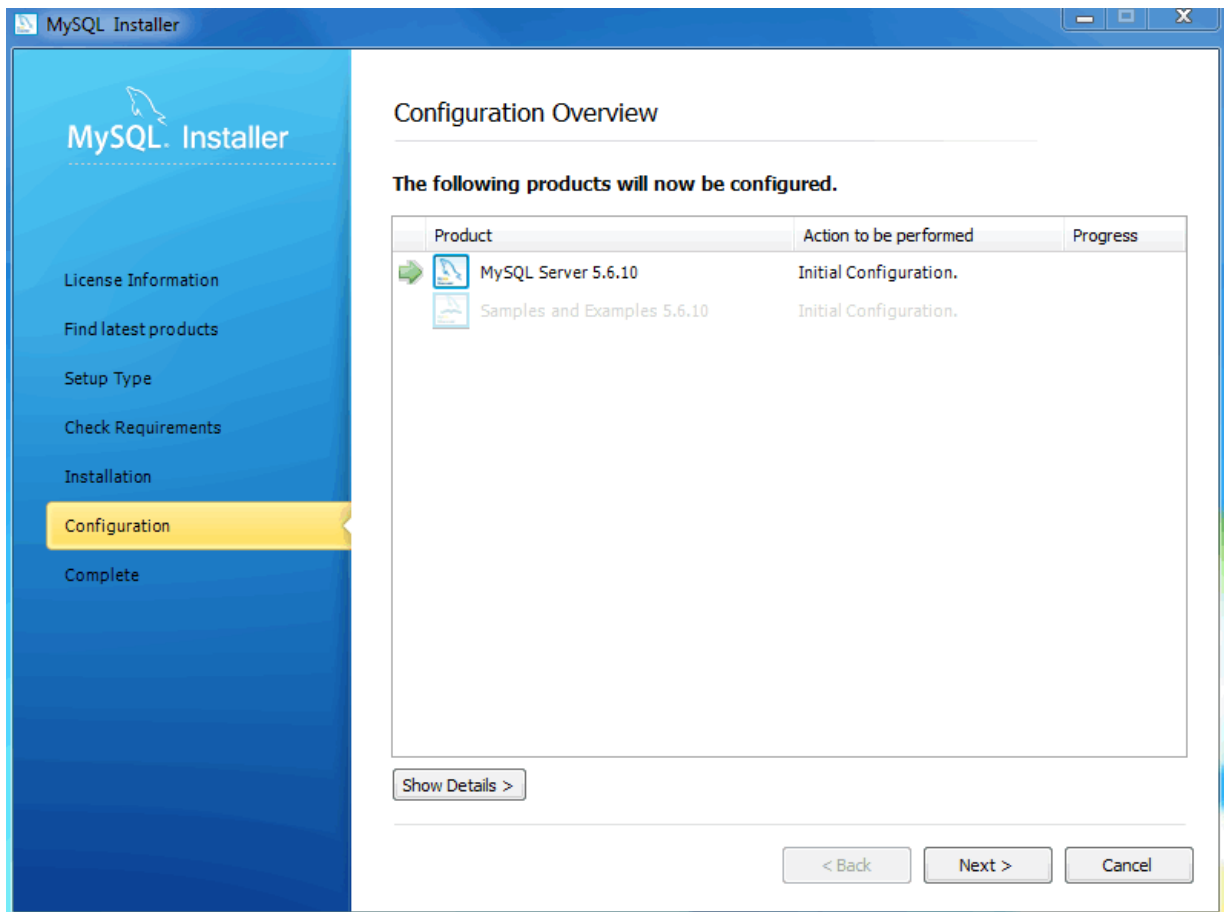

The next window lists the MySQL products that are scheduled to be installed:

**Figure 2.12. MySQL Installer - Installation Progress**

As components are installed, you'll see their status change from "to be installed" to "install success."

**Figure 2.13. MySQL Installer - Installation Progress status**

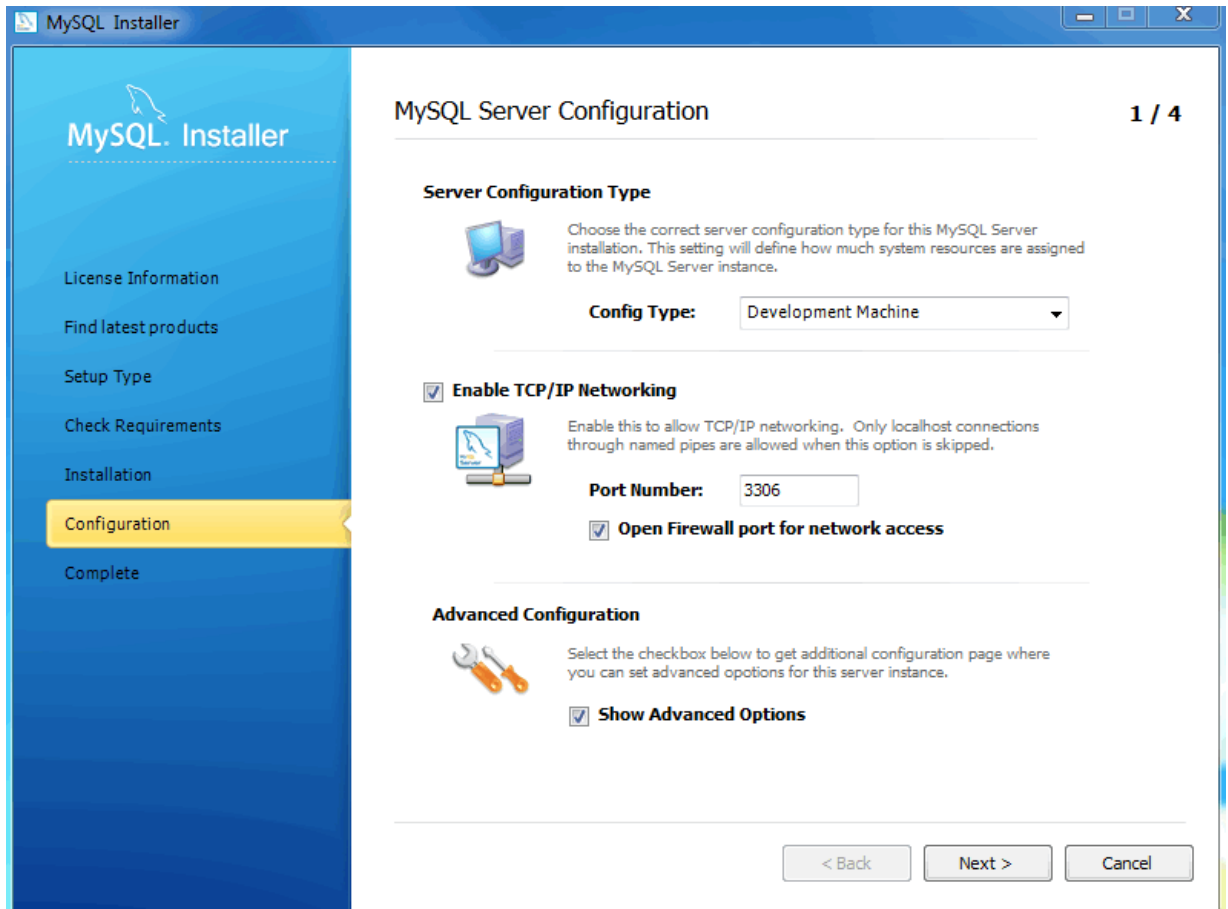

After all components are installed, the next step involves configuring the products. The [Configuration Overview](#) window displays the progress and then loads a configuration window if it is required.

**Figure 2.14. MySQL Installer - Configuration Overview**

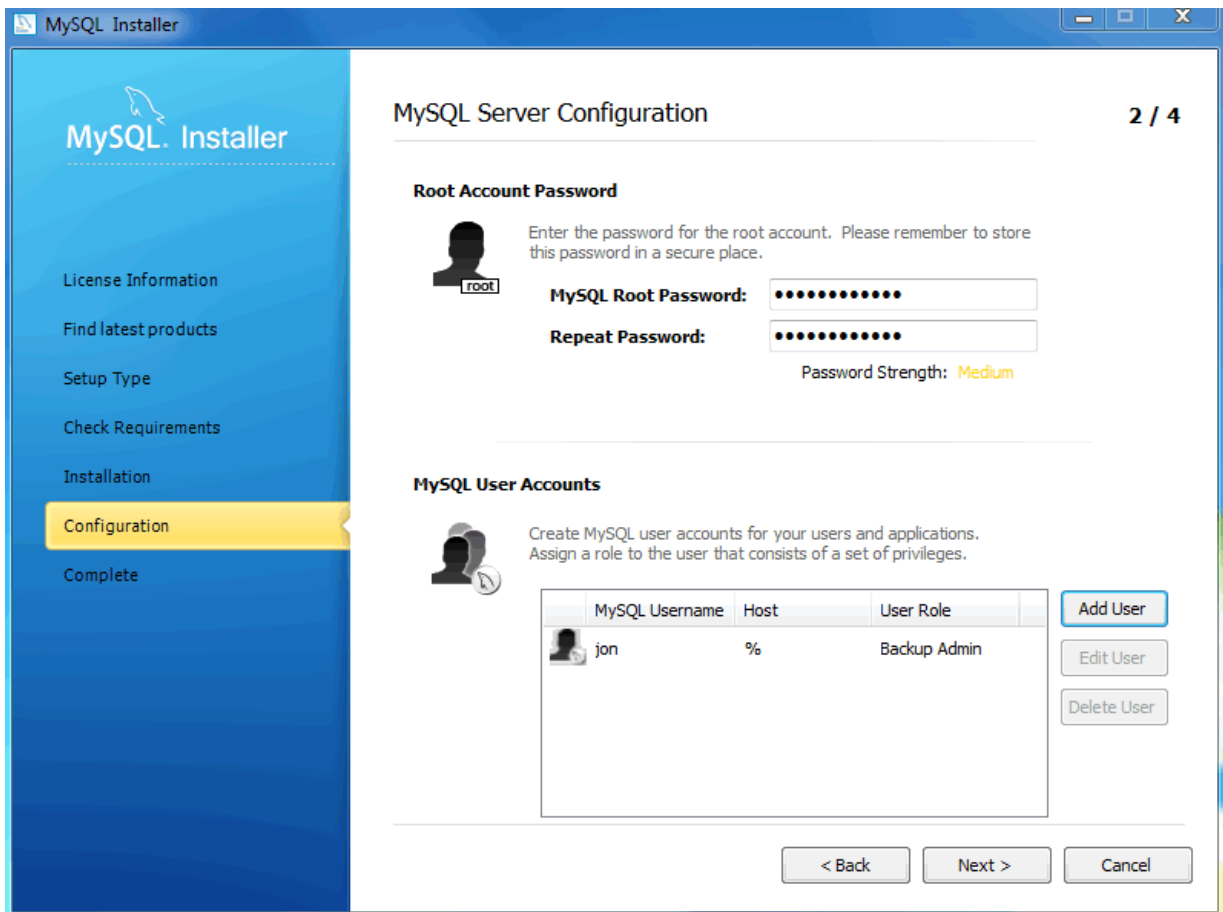

The ideal MySQL Server configuration depends on your intended use, as explained in the next window. Choose the description that most closely applies to your machine.

You may enable TCP/IP Networking here as otherwise only localhost connections are allowed.

Checking the "Advanced Configuration" option provides additional **Logging Options** to configure. This includes defining file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

**Figure 2.15. MySQL Installer - MySQL Server Configuration: Define platform, networking, and logging options**

Next, choose your account information. Defining a root password is required, whereas it's optional to create additional users. There are several different predefined user roles that each have different permission levels. For example, a "DB Admin" will have more privileges than a "DB Designer."

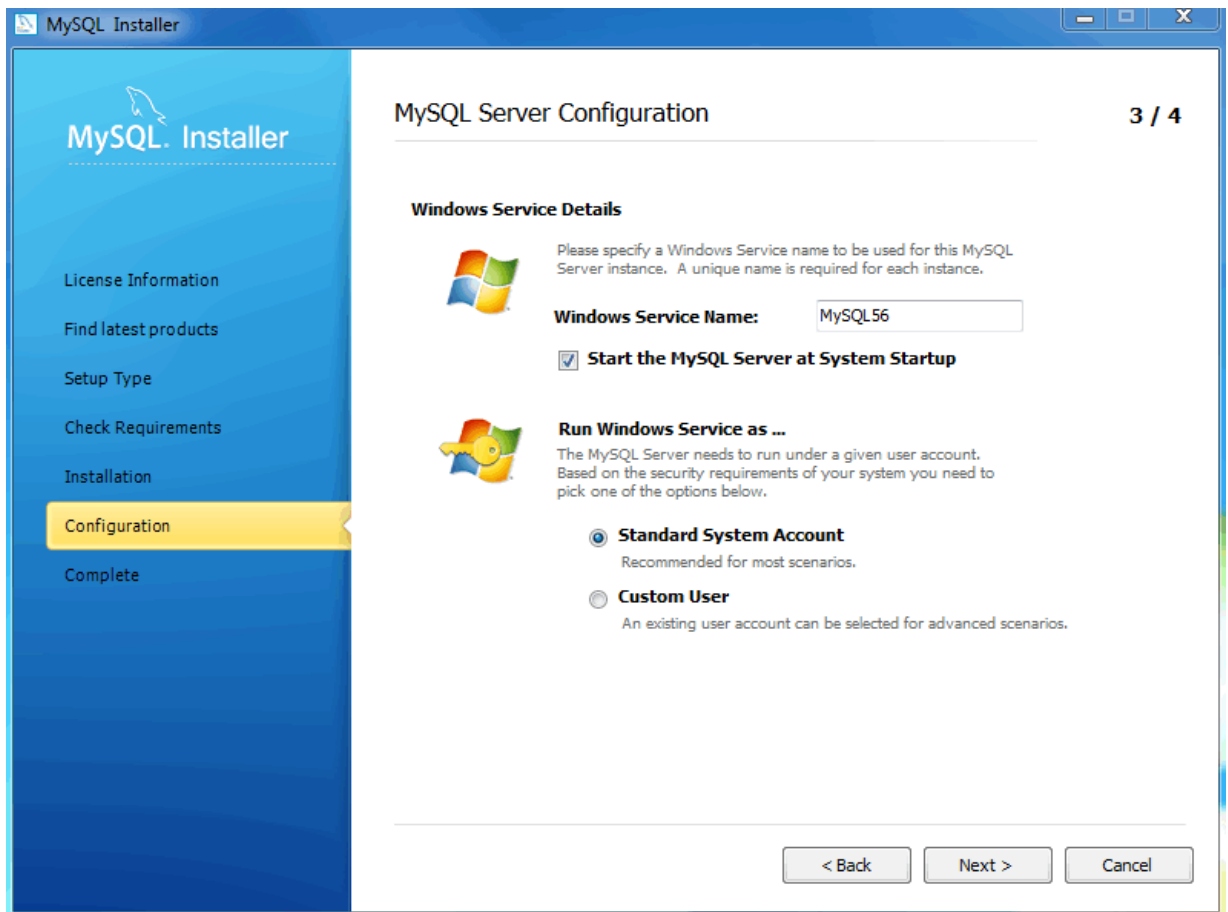

**Figure 2.16. MySQL Installer - MySQL Server Configuration: User accounts****Note**

If the MySQL Server is already installed, then the [Current Root Password](#) will also be needed.

Next, configure the **Windows Service Details**. This includes the service name, how the MySQL Server should be loaded at startup, and how the Windows Service for MySQL Server will be run.

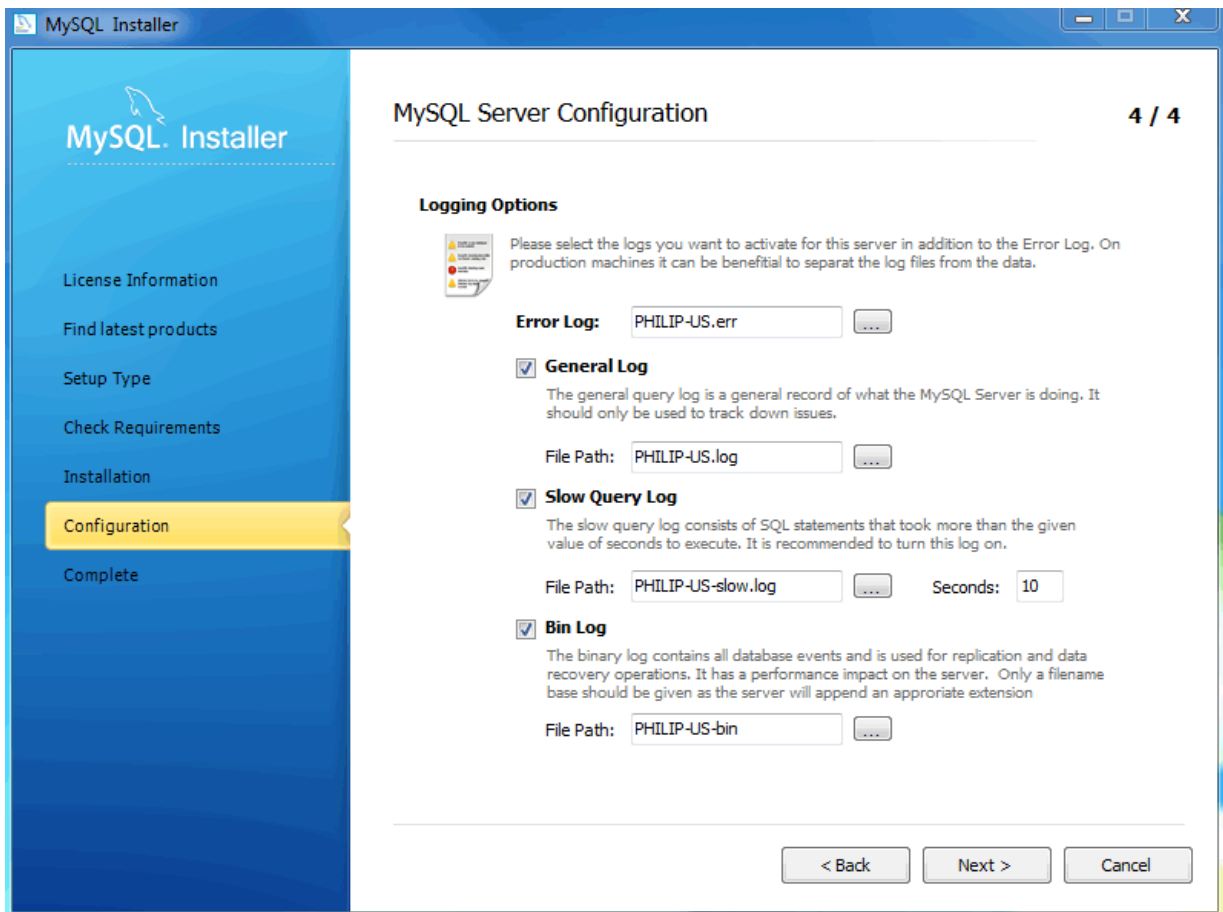

Figure 2.17. MySQL Installer - MySQL Server Configuration: Windows service details

**Note**

When configuring **Run Windows Services as ...** using a **Custom User**, the custom user must have privileges to log on to Windows as a service. And the **Next** button will be disabled until this user is given these user rights.

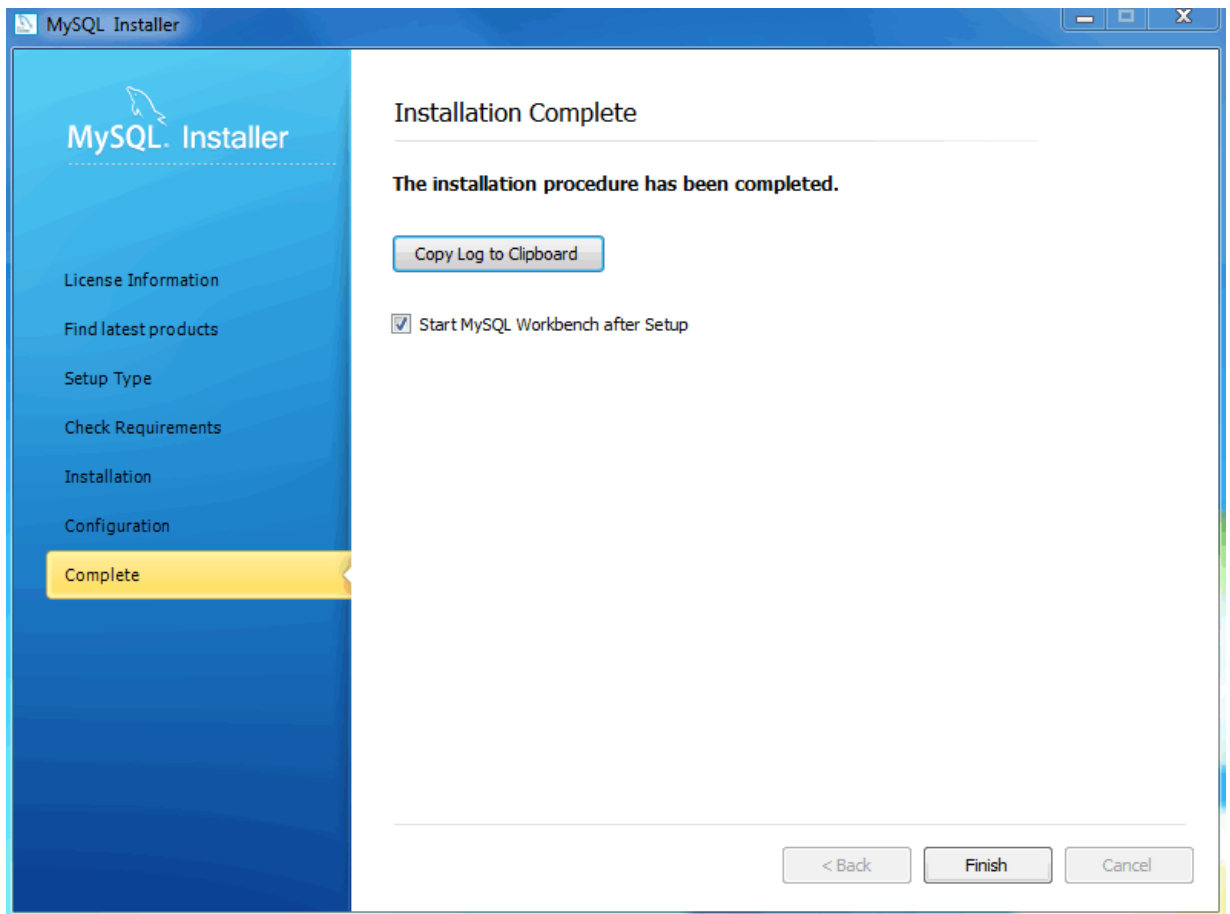

On Microsoft Windows 7, this is configured by loading the [Start Menu](#), [Control Panel](#), [Administrative Tools](#), [Local Security Policy](#), [Local Policies](#), [User Rights Assignment](#), then [Log On As A Service](#). Choose [Add User or Group](#) here to add the custom user, and then **OK**, **OK** to save.

The final configuration step is available if the **Advanced Configuration** option was checked, and it includes configuration options related to log file names:

**Figure 2.18. MySQL Installer - MySQL Server Configuration: Logging options**

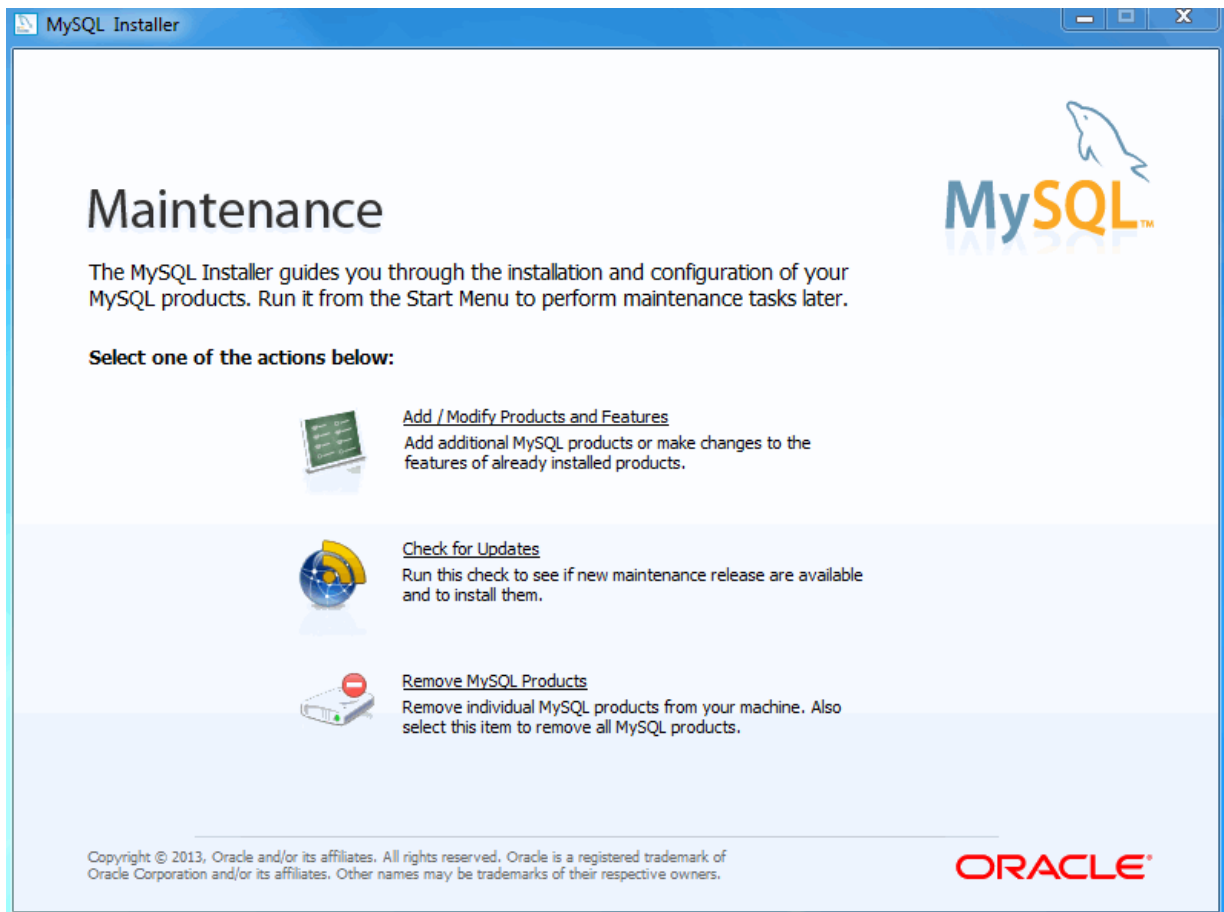

After the MySQL Installer configuration process is completed, you may save the installation log, and then load MySQL Workbench if the **Start MySQL Workbench after Setup** option is checked:

**Figure 2.19. MySQL Installer - Installation Complete**

You can now open MySQL Installer from the Microsoft Windows Start menu under the [MySQL](#) group, which will load the MySQL Installer [Maintenance Screen](#). This is used to add, update, and remove features.

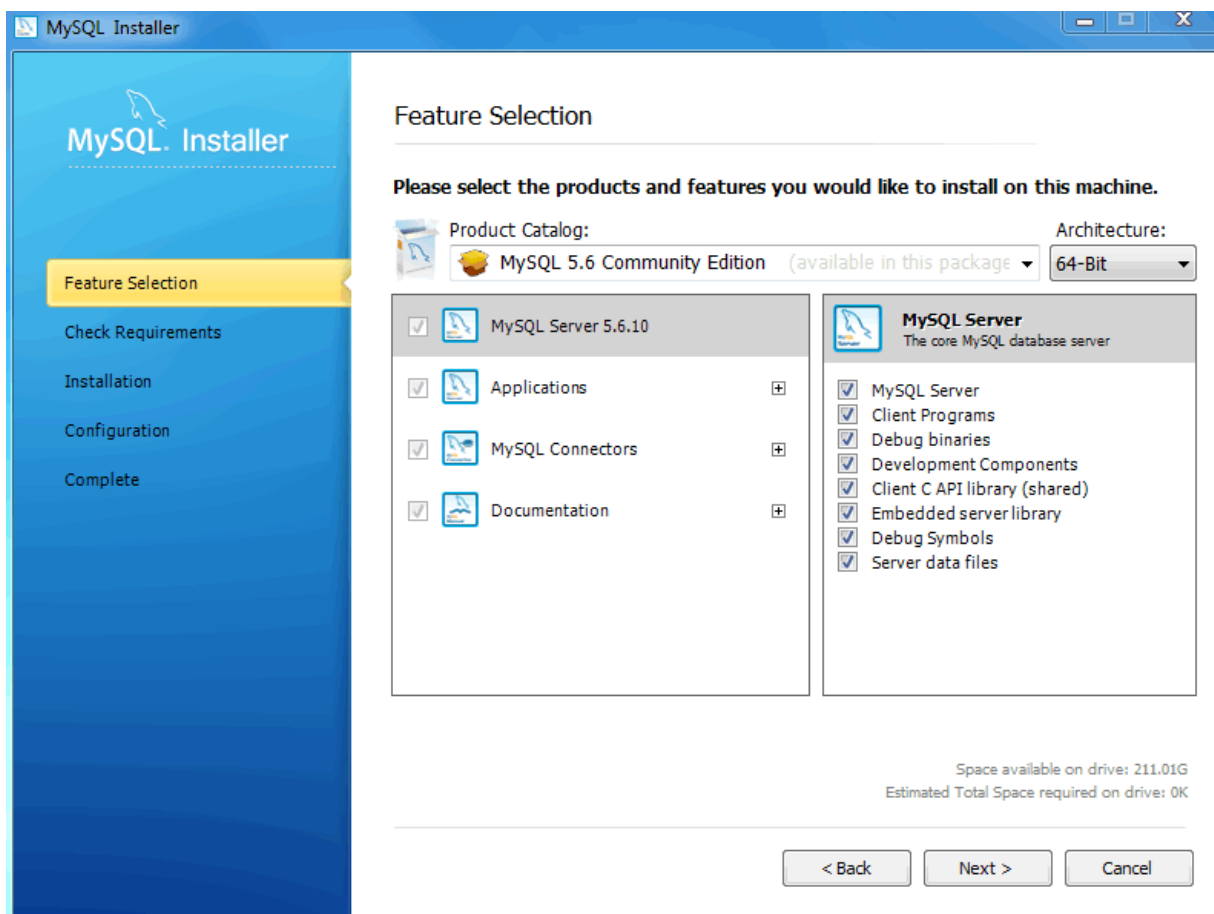

Figure 2.20. MySQL Installer - Maintenance Screen

**Note**

An [Update Screen](#) screen is shown if MySQL Installer is used on a machine with older products installed, as opposed to the [Maintenance Screen](#) shown above. However, the functionality remains the same.

**Add/Modify Products and Features** will list all installed and available MySQL products.

**Figure 2.21. MySQL Installer - Add/Modify Products and Features**

The installation is now complete. MySQL Server should be running, and most MySQL products installed and available for use.

See also the MySQL Workbench documentation (<http://dev.mysql.com/doc/workbench/en/>).

### 2.3.3.2. MySQL Installer Console

`MySQLInstallerConsole` provides functionality similar to the GUI version of MySQL Installer, but from the command-line. It is installed when MySQL Installer is initially executed, and then available within the `MySQL Installer` directory. Typically that is in `C:\Program Files (x86)\MySQL\MySQL Installer\`, and the console must be executed with administrative privileges.

To use, invoke the Command Prompt with administrative privileges by choosing Start, Accessories, then right-click on Command Prompt and choose Run as administrator. And from the command-line, optionally change the directory to where `MySQLInstallerConsole` is located:

```
C:\> cd "C:\Program Files (x86)\MySQL\MySQL Installer"
```

`MySQLInstallerConsole` supports the following options, which are specified on the command line:

- `--help`, `-h`, or `-?`

Displays a help message with usage examples, and then exits.

```
C:\> MySQLInstallerConsole --help
```

- `--updates` (or `-u`)

Checks for new products before any further action is taken. Disabled by default.

- `--nowait`

Skips the final pause when the program finishes. Otherwise, a "Press Enter to continue." dialogue is generated. It is used in conjunction with other options.

- `--catalog=catalog_name` (or `-c`)

Sets the default catalog. Use `--list` to view a list of available catalogs.

- `--type=installation_type` (or `-t`)

Sets the installation type.

The possible values for `installation_type` are: `developer`, `server`, `client`, `full`, and `custom`.

- `--action=action_name`

The action being performed.

The possible values are: `install`, `remove`, `upgrade`, `list`, and `status`.

- **install**: Installs a product or products, as defined by `--products`
- **upgrade**: Upgrades a product or products, as defined by `--products`.
- **remove**: Removes a product or products, as defined by `--products`.
- **list**: Lists the product manifest, both installed and available products.
- **status**: Shows the status after another action is performed.

- `--product=product_name[:feature1],[feature2], [...]` (or `-p`)

Set the feature list of a product. Use `--list` to view available products, or pass in `--product=*` (an asterisk) to install all available products.

- `--config=product_name:passwd=root_password[;parameter1=value],[;parameter2=value], ...`

The configuration parameters for the most recently listed products.

- `--user=product_name:name=username,host:hostname,role=rolename,password=password` or `--user=product_name:name=username,host:hostname,role=rolename,tokens=tokens`

Creates a new user.

Requires: `name`, `host`, `role`, and the `password` or `tokens`. Tokens are separated by pipe ("|") characters.

### 2.3.4. Installing MySQL on Microsoft Windows Using a `noinstall` Zip Archive

Users who are installing from the `noinstall` package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory
2. Create an option file

3. Choose a MySQL server type
4. Start the MySQL server
5. Secure the default user accounts

This process is described in the sections that follow.

### 2.3.4.1. Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to [Section 2.3.6, “Upgrading MySQL on Windows”](#), before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. The MySQL Installer installs MySQL under `C:\Program Files\MySQL`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See [Section 2.3.4.2, “Creating an Option File”](#).
4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

### 2.3.4.2. Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 5.6` and `C:\Program Files\MySQL\MySQL Server 5.6\data`).
- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see [Section 4.2.3.3, “Using Option Files”](#)). The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

#### Note

When using the MySQL Installer to install MySQL Server, it will create the `my.ini` at the default location. And as of MySQL Server 5.5.27, the user running MySQL Installer is granted full permissions to this new `my.ini`.

In other words, be sure that the MySQL Server user has permission to read the `my.ini` file.

You can also make use of the example option files included with your MySQL distribution; see [Section 5.1.2, “Server Configuration Defaults”](#).

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

The rules for use of backslash in option file values are given in [Section 4.2.3.3, “Using Option Files”](#).

The data directory is located within the `AppData` directory for the user running MySQL.

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\Program Files\MySQL\MySQL Server 5.6\data`) to `E:\mydata`.
2. Use a `--datadir [418]` option to specify the new data directory location each time you start the server.

### 2.3.4.3. Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 5.6.

Binary	Description
<code>mysqld</code>	Optimized binary with named-pipe support
<code>mysqld-debug</code>	Like <code>mysqld</code> , but compiled with full debugging and automatic memory allocation checking

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 5.6 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows support named pipes as indicated in the following list. However, the default is to use TCP/IP regardless of platform. (Named pipes are slower than TCP/IP in many Windows configurations.)

Named pipes are enabled only if you start the server with the `--enable-named-pipe [421]` option. It is necessary to use this option explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used.

### 2.3.4.4. Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `Noinstall` version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

#### Note

The MySQL server will automatically start after using the MySQL Installer, and the [MySQL Notifier for Microsoft Windows](#) GUI can be used to start/stop/restart at any time.

The examples in these sections assume that MySQL is installed under the default location of `C:\Program Files\MySQL\MySQL Server 5.6`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `--shared-memory` [439] option. Clients can connect through shared memory by using the `--protocol=MEMORY` [211] option.

For information about which server binary to run, see [Section 2.3.4.3, “Selecting a MySQL Server Type”](#).

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --console
```

For a server that includes `InnoDB` support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25 InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.6.12' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` [417] option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 5.6\data` by default). The error log is the file with the `.err` extension, and may be set using the `--log-error` [427] option.

**Note**

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

### 2.3.4.5. Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

**Note**

The [MySQL Notifier for Microsoft Windows](#) GUI can also be used to start/stop/restart the MySQL server.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin" -u root shutdown
```

**Note**

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the `C:\Program Files\MySQL\MySQL Server 5.6\data` directory. It is the file with a suffix of `.err`, or may be specified by passing in the `--log-error` [427] option. Alternatively, you can try to start the server as `mysqld --console`; in this case, you may get some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with the `--standalone` [440] and `--debug` [418] options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See [MySQL Internals: Porting to Other Systems](#).

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

### 2.3.4.6. MySQL Notifier for Microsoft Windows

The MySQL Notifier for Microsoft Windows is a tool that allows you to monitor and adjust the status of your local MySQL Server instances through an indicator that resides in the system tray. The MySQL Notifier for Microsoft Windows also gives quick access to several MySQL GUI tools (such as MySQL Workbench) through its context menu.

The MySQL Notifier for Microsoft Windows is installed by MySQL Installer, and (by default) will start-up when Microsoft Windows is started.

#### Note

To install, download and execute the [MySQL Installer](#), be sure the MySQL Notifier for Microsoft Windows product is selected, then proceed with the installation. See the [MySQL Installer manual](#) for additional details.

For release notes detailing the changes in each release of MySQL Notifier for Microsoft Windows, see [MySQL Notifier Release Notes](#).

Visit the [MySQL Notifier forum](#) for additional MySQL Notifier for Microsoft Windows help and support.

Features include:

- Start, Stop, and Restart instances of the MySQL Server.
- Automatically detects (and adds) new MySQL Server services. These are listed under [Manage Services](#), and may also be configured.
- The Tray icon changes, depending on the status. It's green if all monitored MySQL Server instances are running, or red if at least one service is stopped.
- Links to other applications like MySQL Workbench, Windows Installer, and the MySQL Utilities. For example, choosing [Configure Instance](#) will load the MySQL Workbench Server Administration window for that particular instance.
- If MySQL Workbench is also installed, then the [Configure Instance](#) and [SQL Editor](#) options are available.

The MySQL Notifier for Microsoft Windows resides in the system tray and provides visual status information for your MySQL Server instances. A green icon is displayed at the top left corner of the tray icon if the current MySQL Server is running, or a red icon if the service is stopped.

The MySQL Notifier for Microsoft Windows automatically adds discovered MySQL Services on the local machine, and each service is saved and configurable. By default, the **Automatically add new services that match this pattern** option is enabled and set to `.*mysql\d.*`. Related **Notifications Options** include being notified when new services are either discovered or experience status changes, and are also enabled by default. And uninstalling a service will also remove the service from the MySQL Notifier for Microsoft Windows.

Clicking the system tray icon will reveal several options, as seen in the screenshots below:

The Service Instance menu is the main MySQL Notifier for Microsoft Windows window, and allows you to Stop, Start, and Restart the MySQL Server.

**Figure 2.22. MySQL Notifier for Microsoft Windows Service Instance menu**

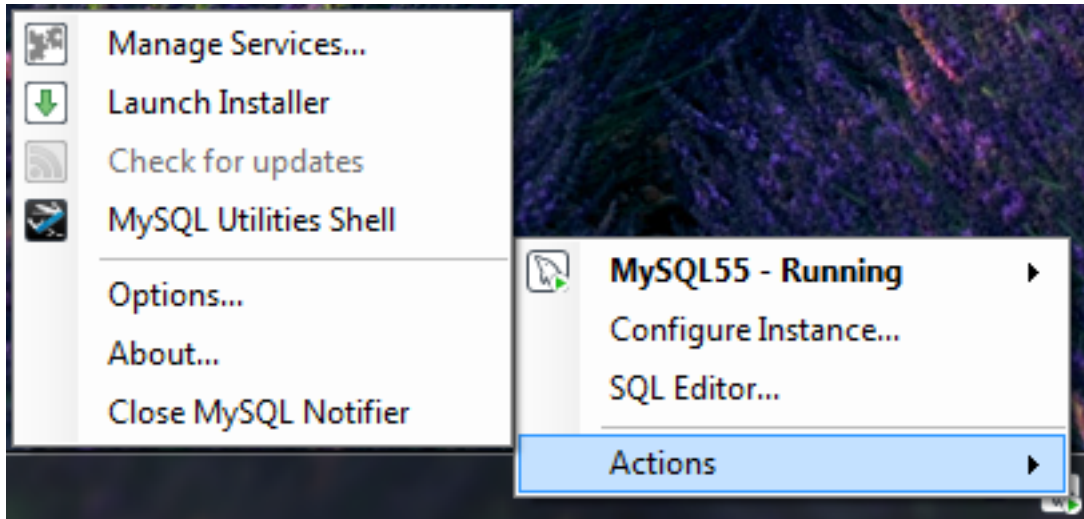

The Actions menu actions include several links to external applications (if they are installed).

**Note**

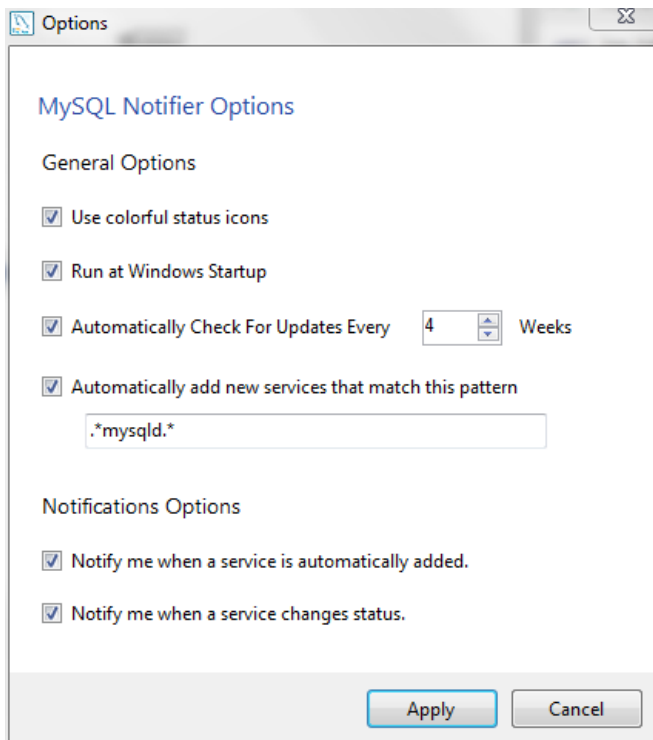

The main menu will not show the Actions menu when there are no services being monitored by MySQL Notifier for Microsoft Windows.

**Figure 2.23. MySQL Notifier for Microsoft Windows Actions menu**

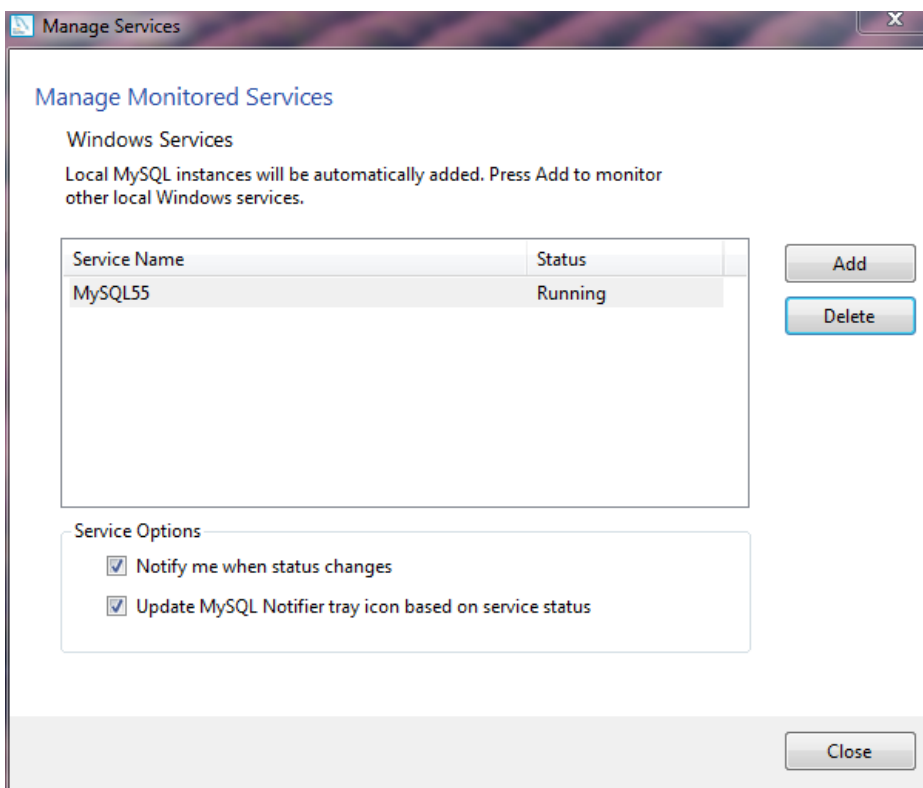

The Actions, Options menu configures MySQL Notifier for Microsoft Windows and includes options to:

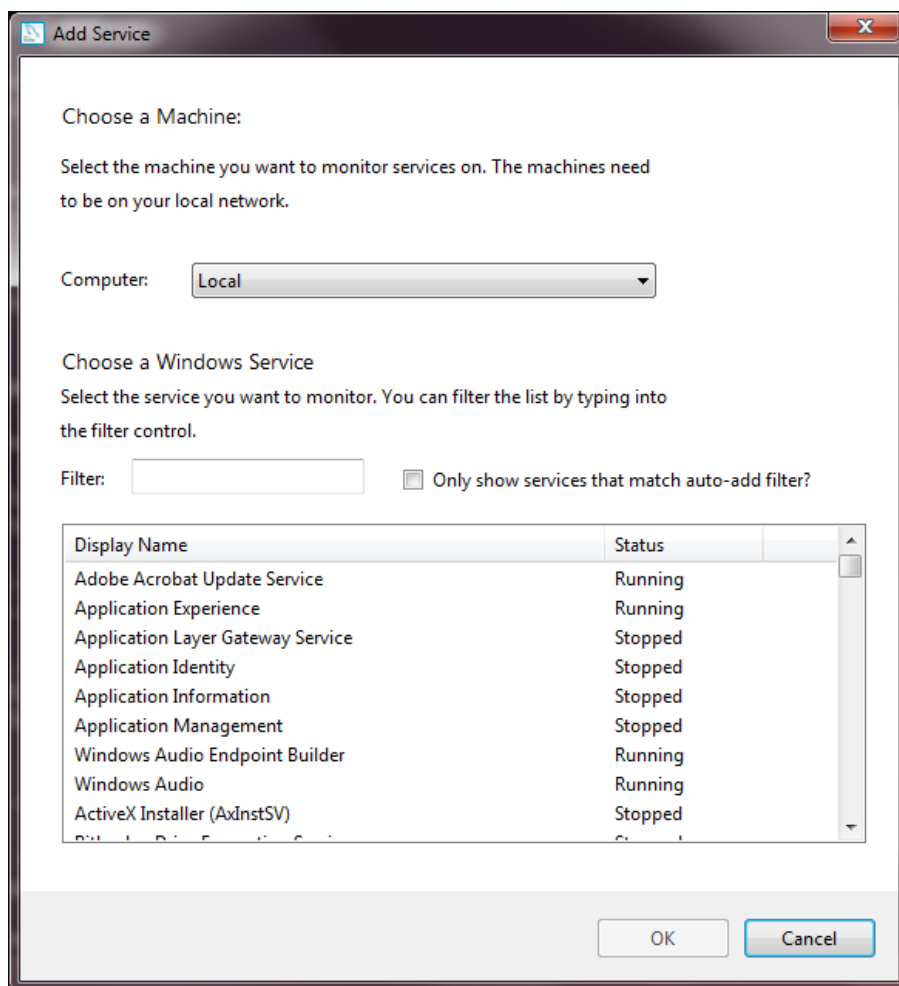

- **Use colorful status icons:** Enables a colorful style of icons for the tray of the MySQL Notifier for Microsoft Windows.
- **Run at Windows Startup:** Allows the application to be loaded when Microsoft Windows starts.
- **Automatically Check For Updates Every # Weeks:** Checks for a new version of MySQL Notifier for Microsoft Windows, and runs this check every # weeks.
- **Automatically add new services that match this pattern:** A custom regular expression that filters the monitored services, and also filters the list of the Microsoft Windows services for the **Add New Service** dialog.
- **Notify me when a service is automatically added:** Will display a notification from the taskbar when a newly discovered service is added to the monitored services list.
- **Notify me when a service changes status:** Will display a notification from the taskbar when a monitored service changes its status.

**Figure 2.24. MySQL Notifier for Microsoft Windows Options menu**

The **Actions**, **Manage Services** menu allows you to configure the monitored services.

**Figure 2.25. MySQL Notifier for Microsoft Windows Service Instance menu**

Adding a service (after clicking **Add** in the **Manage Services** window) allows you to select a running Microsoft Windows service, and configure MySQL Notifier for Microsoft Windows to monitor it. Add a new service by clicking service name from the list, then **OK** to accept. Multiple services may be selected.

**Figure 2.26. MySQL Notifier for Microsoft Windows Adding a new services**

### 2.3.4.7. Customizing the PATH for MySQL Tools

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
- Under **System Variables**, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\bin`)

#### Note

There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply

the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

#### Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

### 2.3.4.8. Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

#### Note

The [MySQL Notifier for Microsoft Windows](#) GUI can also be used to monitor the status of the MySQL service.

The `Services` utility (the Windows [Service Control Manager](#)) can be found in the Windows Control Panel (under Administrative Tools on Windows 2000, XP, Vista, and Server 2003). To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin"  
-u root shutdown
```

#### Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the [System Properties](#) menu that appears, and click the [Environment Variables](#) button.

- Under **System Variables**, select Path, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\bin`), Note that there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

### Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.
- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name [219]` to specify the name of an option file from which the server should read options when it starts.

The use of a single option other than `--defaults-file [219]` is possible but discouraged. `--defaults-file [219]` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

- You can also specify a `--local-service` option following the service name. This causes the server to run using the `LocalService` Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file [219]` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the a service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.
- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.
- If the service-installation command specifies a `--defaults-file [219]` option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld"  
--install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` [219] option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` [219] option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

You can also specify options as Start parameters in the Windows `Services` utility before you start the MySQL service.

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the `Services` utility, or by using a `NET START MySQL` command. The `NET` command is not case sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the `Services` utility, the `NET STOP MySQL` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --install-manual
```

To remove a server that is installed as a service, first stop it if it is running by executing `NET STOP MySQL`. Then use the `--remove` [437] option to remove it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see [Section 2.3.4.5, "Starting MySQL from the Windows Command Line"](#).

If you encounter difficulties during installation, see [Section 2.3.5, "Troubleshooting a Microsoft Windows MySQL Server Installation"](#).

### 2.3.4.9. Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqlshow"  
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqlshow" -u root mysql  
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin" version status proc  
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` [440] option and use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables.

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` [211] or `--protocol=PIPE` [211] option, or by specifying `.` (period) as the host name. Use the `--socket` [211] option to specify the name of the pipe if you do not want to use the default pipe name.

Note that if you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then you must use the appropriate `-u` and `-p` options with the commands shown above to connect with the MySQL Server. See [Section 4.2.2, "Connecting to the MySQL Server"](#).

For more information about `mysqlshow`, see [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

## 2.3.5. Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. This section helps you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the [error log](#). The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the [data directory](#) specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 5.6\data`, or `C:\ProgramData\Mysql` on Windows 7 and Windows Server 2008. The `C:\ProgramData` directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see [Section 5.2.2, “The Error Log”](#).

For information regarding possible errors, also consult the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

The following examples show other common error messages you might encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, it displays these messages:

```
System error 1067 has occurred.
Fatal error: Can't open and lock privilege tables:
Table 'mysql.user' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 5.6` and `C:\Program Files\MySQL\MySQL Server 5.6\data`, respectively).

This situation can occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, old and new configuration files might conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 5.6`, ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. Put the `my.ini` file in your Windows directory, typically `C:\WINDOWS`. To determine its exact location from the value of the `WINDIR` environment variable, issue the following command from the command prompt:

```
C:\> echo %WINDIR%
```

You can create or modify an option file with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\MySQL\\MySQL Server 5.6
```

```
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

The rules for use of backslash in option file values are given in [Section 4.2.3.3, “Using Option Files”](#).

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See [Section 2.3.4.2, “Creating an Option File”](#).

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Installer, you might see this error:

```
Error: Cannot create Windows service for MySQL. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command line:

```
C:\> sc delete mysql
[SC] DeleteService SUCCESS
```

If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from <http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp> and use the `delsrv mysql` syntax.

## 2.3.6. Upgrading MySQL on Windows

This section lists some of the steps to take when upgrading MySQL on Windows.

1. Review [Section 2.11.1, “Upgrading MySQL”](#), for additional information on upgrading MySQL that is not specific to Windows.
2. Always back up your current MySQL installation before performing an upgrade. See [Section 7.2, “Database Backup Methods”](#).
3. Download the latest Windows distribution of MySQL from <http://dev.mysql.com/downloads/>.
4. Before upgrading MySQL, stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

```
C:\> NET STOP MySQL
```

If you are not running the MySQL server as a service, use `mysqladmin` to stop it. For example, before upgrading from MySQL 5.5 to 5.6, use `mysqladmin` from MySQL 5.5 as follows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqladmin" -u root shutdown
```

### Note

If the MySQL `root` user account has a password, invoke `mysqladmin` with the `-p` option and supply the password when prompted.

5. Before upgrading to MySQL 5.6 from a version previous to 4.1.5, or from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must first manually remove the previous installation and MySQL service (if the server is installed as a service).

To remove the MySQL service, use the following command:

```
C:\> C:\mysql\bin\mysqld --remove
```

**If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.**

6. If you are using the MySQL Installer, start it as described in [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).
7. If you are installing MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql5`. Overwriting the existing installation is recommended.
8. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).)
9. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.
10. As Administrator, run `mysql_upgrade` to check your tables, attempt to repair them if necessary, and update your grant tables if they have changed so that you can take advantage of any new capabilities. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).
11. If you encounter errors, see [Section 2.3.5, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

## 2.3.7. Windows Postinstallation Procedures

GUI tools exist that perform most of the tasks described below, including:

- [MySQL Installer](#): Used to install and upgrade MySQL products.
- [MySQL Workbench](#): Manages the MySQL server and edits SQL queries.
- [MySQL Notifier](#): Starts, stops, or restarts the MySQL server, and monitors its status.
- [MySQL for Excel](#): Edits MySQL data with Microsoft Excel.

On Windows, you need not create the data directory and the grant tables. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory. Regarding passwords, if you installed MySQL using the MySQL Installer, you may have already assigned passwords to the accounts. (See [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).) Otherwise, use the password-assignment procedure given in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

Before setting up passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see [Section 2.3.4.4, “Starting the Server for the First Time”](#)), and then issue the following commands to verify that you can retrieve information from the server. You may need to specify directory different from `C:\mysql\bin` on the command line. If you used the MySQL Installer, the default directory is `C:\Program Files\MySQL\MySQL Server 5.6`, and the `mysql` and `mysqlshow` client programs are in `C:\Program Files\MySQL\MySQL Server 5.6\bin`. See [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#), for more information.

Use `mysqlshow` to see what databases exist:

```
C:\> C:\mysql\bin\mysqlshow
+-----+
|          |
| Databases |
|          |
```

```
+-----+
| information_schema |
| mysql              |
| test               |
+-----+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`. In most cases, the `test` database will also be installed automatically.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you installed using MySQL Installer, then the `root` user will have been created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You will also need to use the `-u root` and `-p` options if you have already secured the initial MySQL accounts.) With `-p`, you will be prompted for the `root` password. For example:

```
C:\> C:\mysql\bin\mysqlshow -u root -p
Enter password: (enter root password here)
+-----+
|      Databases      |
+-----+
| information_schema  |
| mysql              |
| test               |
+-----+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> C:\mysql\bin\mysqlshow mysql
Database: mysql
+-----+
|      Tables        |
+-----+
| columns_priv      |
| db                 |
| event              |
| func               |
| help_category     |
| help_keyword      |
| help_relation     |
| help_topic        |
| host               |
| plugin             |
| proc               |
| procs_priv        |
| servers            |
| tables_priv       |
| time_zone          |
| time_zone_leap_second |
| time_zone_name    |
| time_zone_transition |
| time_zone_transition_type |
| user               |
+-----+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> C:\mysql\bin\mysql -e "SELECT Host,Db,User FROM mysql.db"
+-----+-----+-----+
| host | db   | user |
+-----+-----+-----+
| %    | test |      |
| %    | test_% |    |
+-----+-----+-----+
```

For more information about `mysqlshow` and `mysql`, see [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#), and [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

If you are running a version of Windows that supports services, you can set up the MySQL server to run automatically when Windows starts. See [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

## 2.4. Installing MySQL on Mac OS X

MySQL for Mac OS X is available in a number of different forms:

- Native Package Installer format, which uses the native Mac OS X installer to walk you through the installation of MySQL. For more information, see [Section 2.4.2, “Installing MySQL on Mac OS X Using Native Packages”](#). You can use the package installer with Mac OS X 10.3 and later, and the package is available for both PowerPC and Intel architectures, and 32-bit and 64-bit architectures. There is no Universal Binary available using the package installation method. The user you use to perform the installation must have administrator privileges.
- Tar package format, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you will need to open a `Terminal` window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#). You can use the package installer with Mac OS X 10.3 and later, and available for both PowerPC and Intel architectures, and both 32-bit and 64-bit architectures. A Universal Binary, incorporating both Power PC and Intel architectures and 32-bit and 64-bit binaries is available.

In addition to the core installation, the Package Installer also includes [Section 2.4.3, “Installing the MySQL Startup Item”](#) and [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#), both of which simplify the management of your installation.

- Mac OS X server includes a version of MySQL as standard. If you want to use a more recent version than that supplied with the Mac OS X server release, you can make use of the package or tar formats. For more information on using the MySQL bundled with Mac OS X, see [Section 2.4.5, “Using the Bundled MySQL on Mac OS X Server”](#).

For additional information on using MySQL on Mac OS X, see [Section 2.4.1, “General Notes on Installing MySQL on Mac OS X”](#).

### 2.4.1. General Notes on Installing MySQL on Mac OS X

You should keep the following issues and notes in mind:

- The default location for the MySQL Unix socket is different on Mac OS X and Mac OS X Server depending on the installation type you chose. The following table shows the default locations by installation type.

**Table 2.5. MySQL Unix Socket Locations on Mac OS X by Installation Type**

Installation Type	Socket Location
Package Installer from MySQL	<code>/tmp/mysql.sock</code>
Tarball from MySQL	<code>/tmp/mysql.sock</code>
MySQL Bundled with Mac OS X Server	<code>/var/mysql/mysql.sock</code>

To prevent issues, you should either change the configuration of the socket used within your application (for example, changing `php.ini`), or you should configure the socket location using a MySQL configuration file and the `socket [442]` option. For more information, see [Section 5.1.3, “Server Command Options”](#).

- You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. On Mac OS X 10.4 and lower you can do this by using the `Netinfo Manager` application, located within the `Utilities` folder within the `Applications` folder. On Mac OS X 10.5 and later you

can do this through the [Directory Utility](#). From Mac OS X 10.5 and later (including Mac OS X Server 10.5) the `mysql` should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.

- Due to a bug in the Mac OS X package installer, you may see this error message in the destination disk selection dialog:

```
You cannot install this software on this disk. (null)
```

If this error occurs, click the [Go Back](#) button once to return to the previous screen. Then click [Continue](#) to advance to the destination disk selection again, and you should be able to choose the destination disk correctly. We have reported this bug to Apple and it is investigating this problem.

- If you get an “insecure startup item disabled” error when MySQL launches, use the following procedure. Adjust the pathnames appropriately for your system.

1. Modify the `mysql.script` using this command (enter it on a single line):

```
shell> sudo /Applications/TextEdit.app/Contents/MacOS/TextEdit  
/usr/local/mysql/support-files/mysql.server
```

2. Locate the option file that defines the `basedir` value and modify it to contain these lines:

```
basedir=/usr/local/mysql  
datadir=/usr/local/mysql/data
```

In the `/Library/StartupItems/MySQLCOM/` directory, make the following group ID changes from `staff` to `wheel`:

```
shell> sudo chgrp wheel MySQLCOM StartupParameters.plist
```

3. Start the server from System Preferences or Terminal.app.

- Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You will need to either copy the `data` directory from the old version to the new version, or alternatively specify an alternative `datadir` value to set location of the data directory.
- You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql  
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql  
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see [Section 4.2.1](#), “[Invoking MySQL Programs](#)”.

- After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

## 2.4.2. Installing MySQL on Mac OS X Using Native Packages

You can install MySQL on Mac OS X 10.3.x (“Panther”) or newer using a Mac OS X binary package in PKG format instead of the binary tarball distribution. Please note that older versions of Mac OS X (for example, 10.1.x or 10.2.x) are *not* supported by this package.

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

#### Note

Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on Mac OS X Server) or `mysqladmin shutdown` on the command line.

When installing from the package version, you should also install the MySQL Preference Pane, which will enable you to control the startup and execution of your MySQL server from System Preferences. For more information, see [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

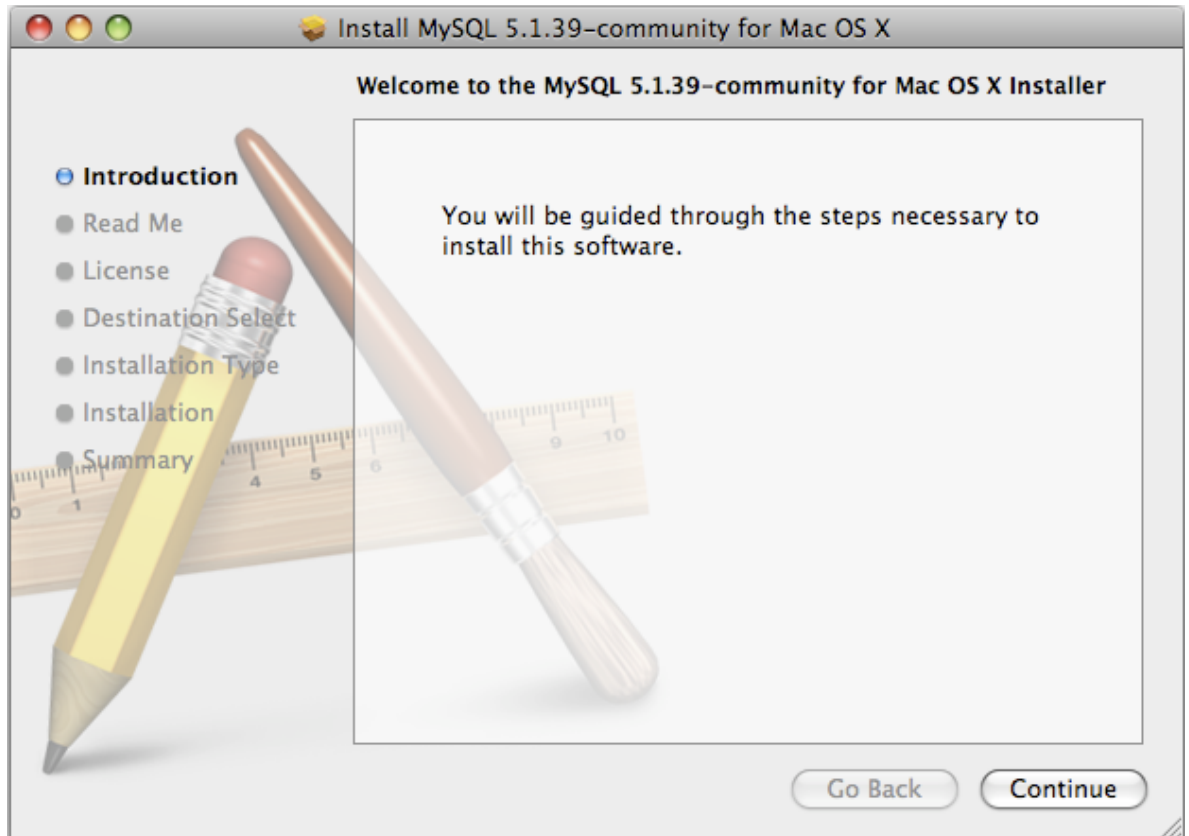

When installing using the package installer, the files are installed into a directory within `/usr/local` matching the name of the installation version and platform. For example, the installer file `mysql-5.1.39-osx10.5-x86_64.pkg` installs MySQL into `/usr/local/mysql-5.1.39-osx10.5-x86_64`. The following table shows the layout of the installation directory.

**Table 2.6. MySQL Installation Layout on Mac OS X**

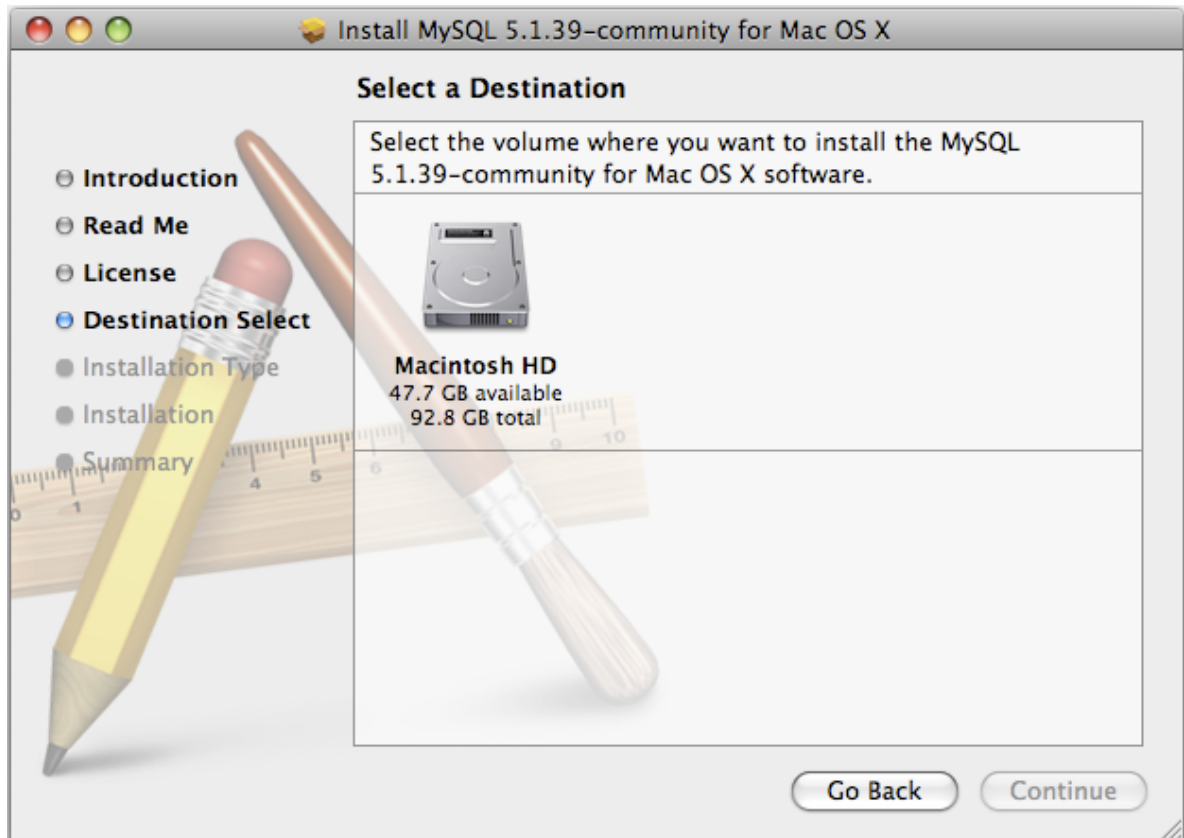

Directory	Contents of Directory
<code>bin</code>	Client programs and the <code>mysqld</code> server
<code>data</code>	Log files, databases
<code>docs</code>	Manual in Info format
<code>include</code>	Include (header) files
<code>lib</code>	Libraries
<code>man</code>	Unix manual pages
<code>mysql-test</code>	MySQL test suite
<code>scripts</code>	<code>mysql_install_db</code>
<code>share</code>	Miscellaneous support files, including error messages, sample configuration files, SQL for database installation
<code>sql-bench</code>	Benchmarks
<code>support-files</code>	Scripts and sample configuration files
<code>/tmp/mysql.sock</code>	Location of the MySQL Unix socket

During the package installer process, a symbolic link from `/usr/local/mysql` to the version/platform specific directory created during installation will be created automatically.

1. Download and open the MySQL package installer, which is provided on a disk image (`.dmg`) that includes the main MySQL installation package, the `MySQLStartupItem.pkg` installation package, and the `MySQL.prefPane`. Double-click the disk image to open it.
2. Double-click the MySQL installer package. It will be named according to the version of MySQL you have downloaded. For example, if you have downloaded MySQL 5.1.39, double-click `mysql-5.1.39-osx10.5-x86.pkg`.
3. You will be presented with the opening installer dialog. Click **Continue** to begin installation.

4. A copy of the installation instructions and other important information relevant to this installation are displayed. Click **Continue** .
5. If you have downloaded the community version of MySQL, you will be shown a copy of the relevant GNU General Public License. Click **Continue** .
6. Select the drive you want to use to install the MySQL Startup Item. The drive must have a valid, bootable, Mac OS X operating system installed. Click **Continue**.

7. You will be asked to confirm the details of the installation, including the space required for the installation. To change the drive on which the startup item is installed, click either **Go Back** or **Change Install Location...**. To install the startup item, click **Install**.
8. Once the installation has been completed successfully, you will be shown an **Install Succeeded** message.

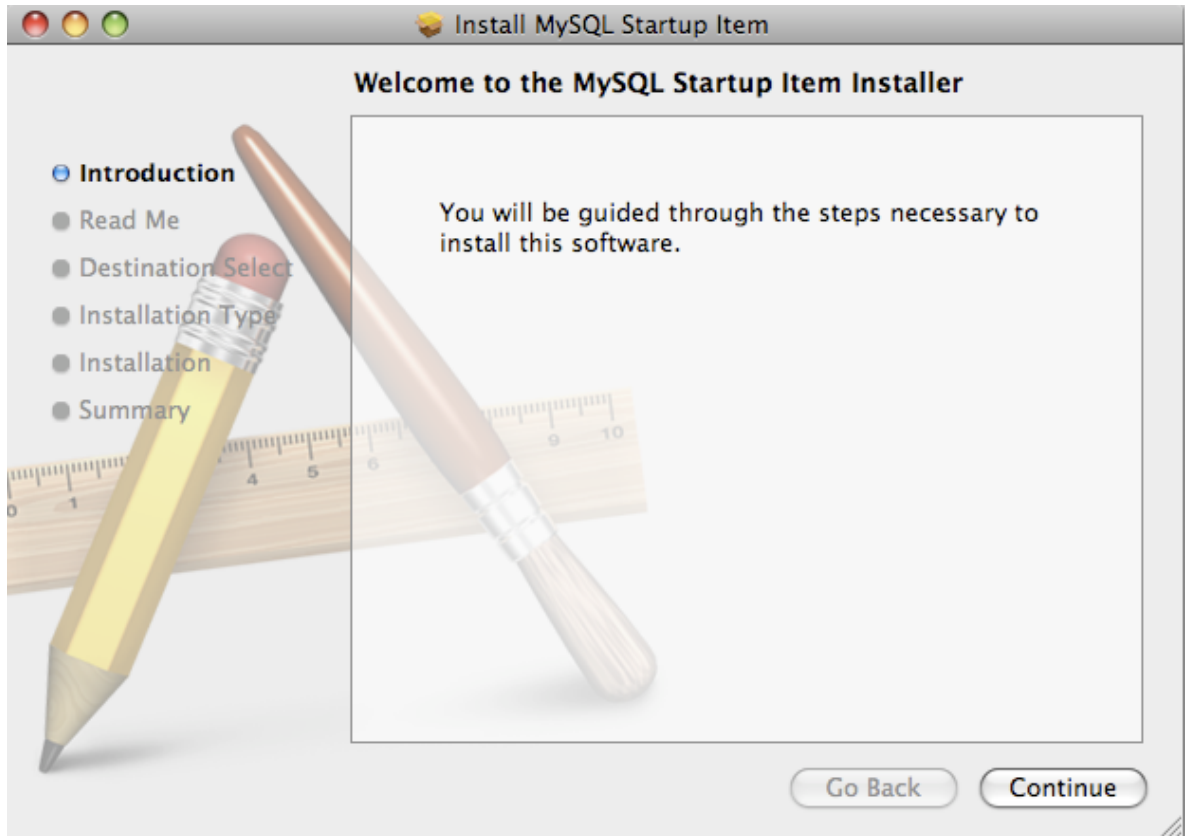

For convenience, you may also want to install the startup item and preference pane. See [Section 2.4.3, “Installing the MySQL Startup Item”](#), and [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

### 2.4.3. Installing the MySQL Startup Item

The MySQL Installation Package includes a startup item that can be used to automatically start and stop MySQL.

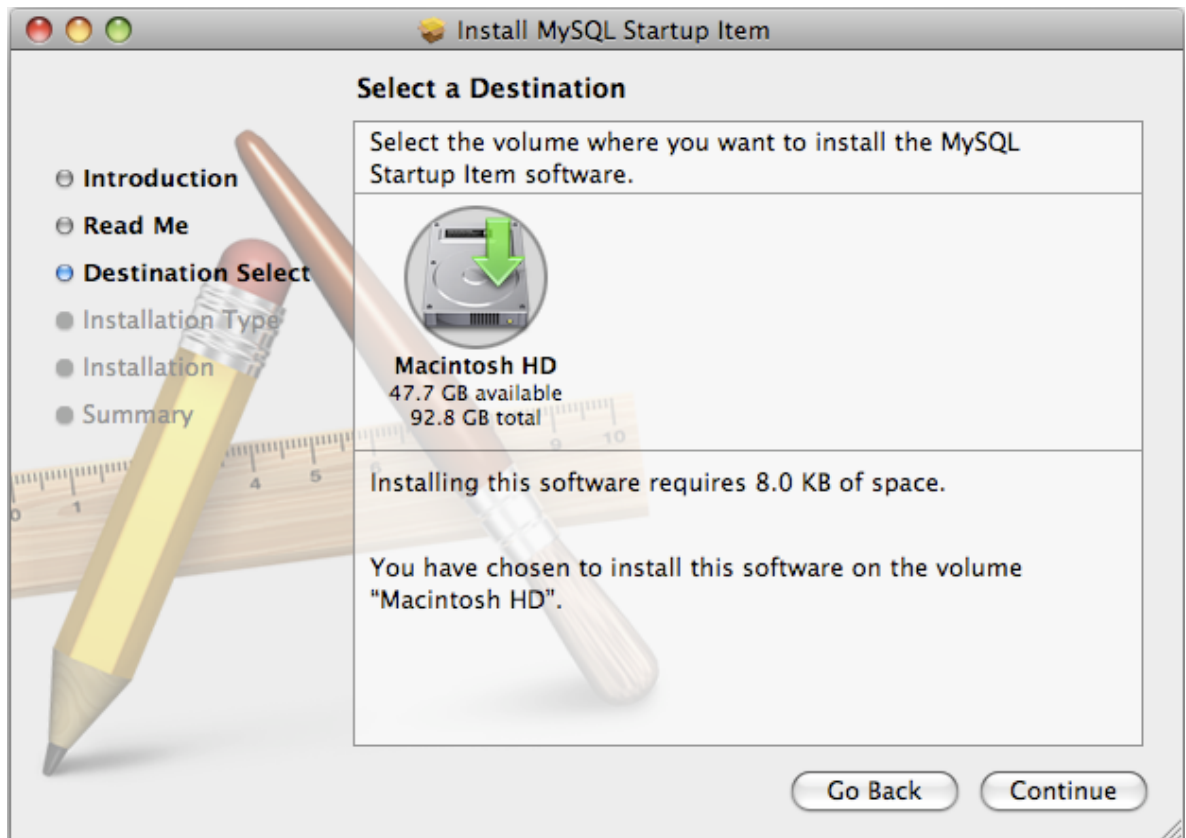

To install the MySQL Startup Item:

1. Download and open the MySQL package installer, which is provided on a disk image (`.dmg`) that includes the main MySQL installation package, the `MySQLStartupItem.pkg` installation package, and the `MySQL.prefPane`. Double-click the disk image to open it.
2. Double-click the `MySQLStartItem.pkg` file to start the installation process.
3. You will be presented with the **Install MySQL Startup Item** dialog.

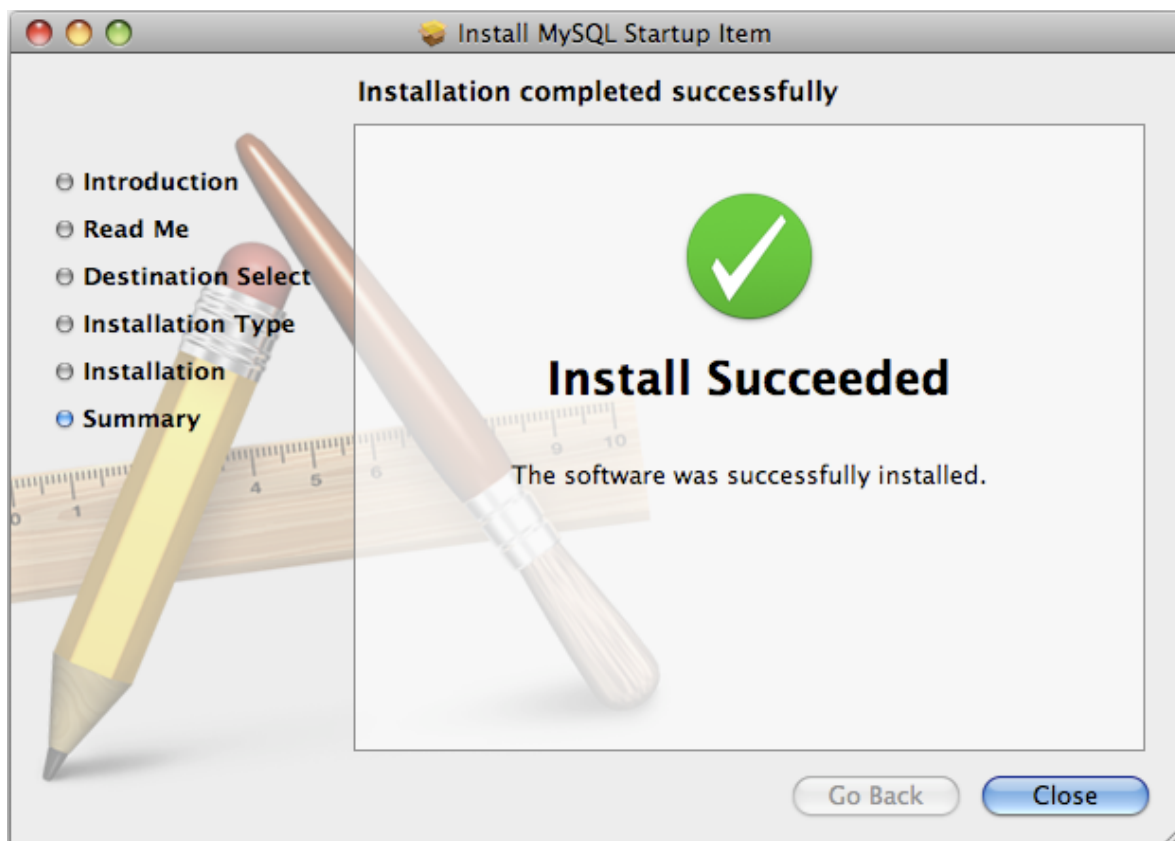

Click **Continue** to continue the installation process.

4. A copy of the installation instructions and other important information relevant to this installation are displayed. Click **Continue** .
5. Select the drive you want to use to install the MySQL Startup Item. The drive must have a valid, bootable, Mac OS X operating system installed. Click **Continue**.

6. You will be asked to confirm the details of the installation. To change the drive on which the startup item is installed, click either **Go Back** or **Change Install Location...**. To install the startup item, click **Install**.
7. Once the installation has been completed successfully, you will be shown an **Install Succeeded** message.

The Startup Item for MySQL is installed into `/Library/StartupItems/MySQLCOM`. The Startup Item installation adds a variable `MYSQLCOM=-YES-` to the system configuration file `/etc/hostconfig`. If you want to disable the automatic startup of MySQL, change this variable to `MYSQLCOM=-NO-`.

After the installation, you can start and stop MySQL by running the following commands in a terminal window. You must have administrator privileges to perform these tasks, and you may be prompted for your password.

If you have installed the Startup Item, use this command to start the server:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM start
```

If you have installed the Startup Item, use this command to stop the server:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM stop
```

## 2.4.4. Installing and Using the MySQL Preference Pane

The MySQL Package installer disk image also includes a custom MySQL Preference Pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

To install the MySQL Preference Pane:

1. Download and open the MySQL package installer package, which is provided on a disk image (`.dmg`) that includes the main MySQL installation package, the `MySQLStartupItem.pkg` installation package, and the `MySQL.prefPane`. Double-click the disk image to open it.
2. Double-click the `MySQL.prefPane`. The MySQL System Preferences will open.
3. If this is the first time you have installed the preference pane, you will be asked to confirm installation and whether you want to install the preference pane for all users, or only the current user. To install the preference pane for all users you will need administrator privileges. If necessary, you will be prompted for the username and password for a user with administrator privileges.

4. If you already have the MySQL Preference Pane installed, you will be asked to confirm whether you want to overwrite the existing MySQL Preference Pane.

#### Note

The MySQL Preference Pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL Preference Pane has been installed, you can control your MySQL server instance using the preference pane. To use the preference pane, open the **System Preferences...** from the Apple menu. Select the MySQL preference pane by clicking the MySQL logo within the **Other** section of the preference panes list.

The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

- **To start MySQL using the preference pane:**

Click **Start MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to start the MySQL server.

- **To stop MySQL using the preference pane:**

Click **Stop MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to stop the MySQL server.

- **To automatically start the MySQL server when the system boots:**

Check the check box next to **Automatically Start MySQL Server on Startup**.

- **To disable automatic MySQL server startup when the system boots:**

Uncheck the check box next to **Automatically Start MySQL Server on Startup**.

You can close the **System Preferences...** window once you have completed your settings.

## 2.4.5. Using the Bundled MySQL on Mac OS X Server

If you are running Mac OS X Server, a version of MySQL should already be installed. The following table shows the versions of MySQL that ship with Mac OS X Server versions.

**Table 2.7. MySQL Versions Preinstalled with Mac OS X Server**

Mac OS X Server Version	MySQL Version
10.2-10.2.2	3.23.51
10.2.3-10.2.6	3.23.53
10.3	4.0.14
10.3.2	4.0.16
10.4.0	4.1.10a
10.5.0	5.0.45
10.6.0	5.0.82

The following table shows the installation layout of MySQL on Mac OS X Server.

**Table 2.8. MySQL Directory Layout for Preinstalled MySQL Installations on Mac OS X Server**

Directory	Contents of Directory
<code>/usr/bin</code>	Client programs
<code>/var/mysql</code>	Log files, databases
<code>/usr/libexec</code>	The <code>mysqld</code> server
<code>/usr/share/man</code>	Unix manual pages
<code>/usr/share/mysql/mysql-test</code>	MySQL test suite
<code>/usr/share/mysql</code>	Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation
<code>/var/mysql/mysql.sock</code>	Location of the MySQL Unix socket

### Additional Resources

- For more information on managing the bundled MySQL instance in Mac OS X Server 10.5, see [Mac OS X Server: Web Technologies Administration For Version 10.5 Leopard](#).
- For more information on managing the bundled MySQL instance in Mac OS X Server 10.6, see [Mac OS X Server: Web Technologies Administration Version 10.6 Snow Leopard](#).
- The MySQL server bundled with Mac OS X Server does not include the MySQL client libraries and header files required to access and use MySQL from a third-party driver, such as Perl DBI or PHP. For more information on obtaining and installing MySQL libraries, see [Mac OS X Server version 10.5: MySQL libraries available for download](#). Alternatively, you can ignore the bundled MySQL server and install MySQL from the package or tarball installation.

## 2.5. Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. The recommended method is to use one of the distributions from Oracle. If you choose this method, there are three options available:

- Installing from a generic binary package in `.tar.gz` format. See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#) for more information.

- Extracting and compiling MySQL from a source distribution. For detailed instructions, see [Section 2.9, “Installing MySQL from Source”](#).
- Installing using a pre-compiled RPM package. For more information on using the RPM solution, see [Section 2.5.1, “Installing MySQL from RPM Packages on Linux”](#).

As an alternative, you can use the native package manager within your Linux distribution to automatically download and install MySQL for you. Native package installations can take of the download and dependencies required to run MySQL, but the MySQL version will often be some way behind the currently available release. You will also normally be unable to install developmental releases, as these are not usually made available in the native repository. For more information on using the native package installers, see [Section 2.5.2, “Installing MySQL on Linux using Native Package Manager”](#).

#### Note

For many Linux installations, you will want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, `mysql.server`, can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).

## 2.5.1. Installing MySQL from RPM Packages on Linux

#### Note

To install or upgrade to MySQL 5.6.11, be sure to read the special instructions at the end of this section.

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages. The RPMs that we provide to the community should work on all versions of Linux that support RPM packages and use `glibc` 2.3. To obtain RPM packages, see [Section 2.1.3, “How to Get MySQL”](#).

For non-RPM Linux distributions, you can install MySQL using a `.tar.gz` package. See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

Installations created from our Linux RPM distributions result in files under the following system directories.

**Table 2.9. MySQL Installation Layout for Linux RPM**

Directory	Contents of Directory
<code>/usr/bin</code>	Client programs and scripts
<code>/usr/sbin</code>	The <code>mysqld</code> server
<code>/var/lib/mysql</code>	Log files, databases
<code>/usr/share/info</code>	Manual in Info format
<code>/usr/share/man</code>	Unix manual pages
<code>/usr/include/mysql</code>	Include (header) files
<code>/usr/lib/mysql</code>	Libraries
<code>/usr/share/mysql</code>	Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation
<code>/usr/share/sql-bench</code>	Benchmarks

**Note**

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by us in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead. Because of these differences, RPM packages built by us check whether such RPMs built by other vendors are installed. If so, the RPM does not install and produces a message explaining this.

In most cases, you need to install only the `MySQL-server` and `MySQL-client` packages to get a functional MySQL installation. The other packages are not required for a standard installation.

As of MySQL 5.6.8, new RPM install operations (not upgrades) invoke `mysql_install_db` with the `--random-passwords` option that provides for more secure MySQL installation. Invoking `mysql_install_db` with `--random-passwords` [237] causes it to assign a random password to the MySQL `root` accounts, set the “password expired” flag for those accounts, and remove the anonymous-user MySQL accounts. It will be necessary after installation to start the server, connect as `root` using the password written to the `$HOME/.mysql_secret` file, and assign a new `root` password. Until this is done, `root` cannot do anything else. This must be done for each `root` account you intend to use. To change the password, you can use the `SET PASSWORD` statement (for example, with the `mysql` client). You can also use `mysqladmin` or `mysql_secure_installation`. For additional details, see [Section 4.4.3, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#). (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

**RPMs for MySQL Cluster.** Standard MySQL server RPMs built by MySQL do not provide support for the `NDBCLUSTER` storage engine.

**Important**

When upgrading a MySQL Cluster RPM installation, you must upgrade *all* installed RPMs, including the `Server` and `Client` RPMs.

For more information about installing MySQL Cluster from RPMs, see [MySQL Cluster Installation and Upgrades](#).

For upgrades, if your installation was originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

If you get a dependency failure when trying to install MySQL packages (for example, `error: removing these packages would break dependencies: libmysqlclient.so.10 is needed by ...`), you should also install the `MySQL-shared-compat` package, which includes the shared libraries for older releases for backward compatibility.

The RPM packages shown in the following list are available. The names shown here use a suffix of `.glibc23.i386.rpm`, but particular packages can have different suffixes, described later.

- `MySQL-server-VERSION.glibc23.i386.rpm`

The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine.

- `MySQL-client-VERSION.glibc23.i386.rpm`

The standard MySQL client programs. You probably always want to install this package.

- `MySQL-devel-VERSION.glibc23.i386.rpm`

The libraries and include files that are needed if you want to compile other MySQL clients, such as the Perl modules.

- [MySQL-shared-VERSION.glibc23.i386.rpm](#)

This package contains the shared libraries (`libmysqlclient.so*`) that certain languages and applications need to dynamically load and use MySQL. It contains single-threaded and thread-safe libraries.

- [MySQL-shared-compat-VERSION.glibc23.i386.rpm](#)

This package includes the shared libraries for older releases, but not the libraries for the current release. It contains single-threaded and thread-safe libraries. Install this package if you have applications installed that are dynamically linked against older versions of MySQL but you want to upgrade to the current version without breaking the library dependencies.

As of MySQL 5.6.5, the [MySQL-shared-compat](#) RPM package enables users of Red Hat-provided `mysql-*5.1` RPM packages to migrate to Oracle-provided `MySQL-*5.5` packages. [MySQL-shared-compat](#) replaces the Red Hat `mysql-libs` package by replacing `libmysqlclient.so` files of the latter package, thus satisfying dependencies of other packages on `mysql-libs`. This change affects only users of Red Hat (or Red Hat-compatible) RPM packages. Nothing is different for users of Oracle RPM packages.

- [MySQL-embedded-VERSION.glibc23.i386.rpm](#)

The embedded MySQL server library.

- [MySQL-test-VERSION.glibc23.i386.rpm](#)

This package includes the MySQL test suite.

- [MySQL-VERSION.src.rpm](#)

This contains the source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, Alpha or SPARC).

The suffix of RPM package names (following the `VERSION` value) has the following syntax:

```
.PLATFORM.CPU.rpm
```

The `PLATFORM` and `CPU` values indicate the type of system for which the package is built. `PLATFORM` indicates the platform and `CPU` indicates the processor type or family.

All packages are dynamically linked against `glibc` 2.3. The `PLATFORM` value indicates whether the package is platform independent or intended for a specific platform, as shown in the following table.

**Table 2.10. MySQL Linux Installation Packages**

<code>PLATFORM</code> Value	Intended Use
<code>glibc23</code>	Platform independent, should run on any Linux distribution that supports <code>glibc</code> 2.3
<code>rhel4, rhel5</code>	Red Hat Enterprise Linux 4 or 5
<code>e16</code>	Enterprise Linux 6
<code>sles10, sles11</code>	SuSE Linux Enterprise Server 10 or 11

In MySQL 5.6, only `glibc23` packages are available currently.

The `CPU` value indicates the processor type or family for which the package is built.

**Table 2.11. MySQL Installation Packages for Linux CPU Identifier**

<code>CPU</code> Value	Intended Processor Type or Family
<code>i386, i586, i686</code>	Pentium processor or better, 32 bit
<code>x86_64</code>	64-bit x86 processor

CPU Value	Intended Processor Type or Family
ia64	Itanium (IA-64) processor

To see all files in an RPM package (for example, a `MySQL-server` RPM), run a command like this:

```
shell> rpm -qpl MySQL-server-VERSION.glibc23.i386.rpm
```

To perform a standard minimal installation, install the server and client RPMs:

```
shell> rpm -i MySQL-server-VERSION.glibc23.i386.rpm
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

To install only the client programs, install just the client RPM:

```
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. If you would like to learn more about this feature, see [Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

The server RPM places data under the `/var/lib/mysql` directory. The RPM also creates a login account for a user named `mysql` (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in `/etc/init.d/` to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you do not lose it when you install a newer RPM.) See [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#), for more information on how MySQL can be started automatically on system startup.

In MySQL 5.6, during a new installation, the server boot scripts are installed, but the MySQL server is not started at the end of the installation, since the status of the server during an unattended installation is not known.

In MySQL 5.6, during an upgrade installation using the RPM packages, if the MySQL server is running when the upgrade occurs, the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. If the MySQL server is not already running when the RPM upgrade occurs, the MySQL server is not started at the end of the installation.

If something goes wrong, you can find more information in the binary installation section. See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

#### Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

During RPM installation, a user named `mysql` and a group named `mysql` are created on the system. This is done using the `useradd`, `groupadd`, and `usermod` commands. Those commands require appropriate administrative privileges, which is required for locally managed users and groups (as listed in the `/etc/passwd` and `/etc/group` files) by the RPM installation process being run by `root`.

If you log in as the `mysql` user, you may find that MySQL displays “Invalid (old?) table or database name” errors that mention `.mysqlgui`, `lost+found`, `.mysqlgui`, `.bash_history`, `.fonts.cache-1`, `.lesshtst`, `.mysql_history`, `.profile`, `.viminfo`, and similar files created by MySQL or operating system utilities. You can safely ignore these error messages or remove the files or directories that cause them if you do not need them.

For nonlocal user management (LDAP, NIS, and so forth), the administrative tools may require additional authentication (such as a password), and will fail if the installing user does not provide this authentication. Even if they fail, the RPM installation will not abort but succeed, and this is intentional. If they failed, some of the intended transfer of ownership may be missing, and it is recommended that the system administrator then manually ensures some appropriate user and group exists and manually transfers ownership following the actions in the RPM spec file.

In MySQL 5.6.11, the RPM spec file has been updated, which has the following consequences:

- For a non-upgrade installation (no existing MySQL version installed), it is possible to install MySQL using `yum`.
- For upgrades, it is necessary to clean up any earlier MySQL installations. In effect, the update is performed by removing the old installations and installing the new one.

Additional details follow.

For a non-upgrade installation of MySQL 5.6.11, it is possible to install using `yum`:

```
shell> yum install MySQL-server-NEWVERSION.glibc23.i386.rpm
```

For upgrades to MySQL 5.6.11, the upgrade is performed by removing the old installation and installing the new one. To do this, use the following procedure:

1. Remove the existing 5.6.X installation. `OLDVERSION` is the version to remove.

```
shell> rpm -e MySQL-server-OLDVERSION.glibc23.i386.rpm
```

Repeat this step for all installed MySQL RPMs.

2. Install the new version. `NEWVERSION` is the version to install.

```
shell> rpm -ivh MySQL-server-NEWVERSION.glibc23.i386.rpm
```

Alternatively, the removal and installation can be done using `yum`:

```
shell> yum remove MySQL-server-OLDVERSION.glibc23.i386.rpm
shell> yum install MySQL-server-NEWVERSION.glibc23.i386.rpm
```

## 2.5.2. Installing MySQL on Linux using Native Package Manager

Many Linux distributions include a version of the MySQL server, client tools, and development components into the standard package management system built into distributions such as Fedora, Debian, Ubuntu, and Gentoo. This section provides basic instructions for installing MySQL using these systems.

### Important

Native package installations can take care of the download and dependencies required to run MySQL, but the MySQL version will often be some way behind the currently available release. You will also normally be unable to install developmental releases, as these are not usually made available in the native repository.

Distribution specific instructions are shown below:

- **Red Hat Linux, Fedora, CentOS**

For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

To install, use the `yum` command to specify the packages that you want to install. For example:

```
root-shell> yum install mysql mysql-server mysql-libs mysql-server
Loaded plugins: presto, refresh-packagekit
Setting up Install Process
Resolving Dependencies
--> Running transaction check
----> Package mysql.x86_64 0:5.1.48-2.fc13 set to be updated
----> Package mysql-libs.x86_64 0:5.1.48-2.fc13 set to be updated
----> Package mysql-server.x86_64 0:5.1.48-2.fc13 set to be updated
```

```
--> Processing Dependency: perl-DBD-MySQL for package: mysql-server-5.1.48-2.fc13.x86_64
--> Running transaction check
---> Package perl-DBD-MySQL.x86_64 0:4.017-1.fc13 set to be updated
--> Finished Dependency Resolution

  Installing      : mysql-libs-5.1.48-2.fc13.x86_64          1/4
  Installing      : mysql-5.1.48-2.fc13.x86_64             2/4
  Installing      : perl-DBD-MySQL-4.017-1.fc13.x86_64     3/4
  Installing      : mysql-server-5.1.48-2.fc13.x86_64     4/4

Installed:
mysql.x86_64 0:5.1.48-2.fc13          mysql-libs.x86_64 0:5.1.48-2.fc13
mysql-server.x86_64 0:5.1.48-2.fc13

Dependency Installed:
perl-DBD-MySQL.x86_64 0:4.017-1.fc13

Complete!
```

MySQL and the MySQL server should now be installed. A sample configuration file is installed into `/etc/my.cnf`. An init script, to start and stop the server, will have been installed into `/etc/init.d/mysql`. To start the MySQL server use `service`:

```
root-shell> service mysqld start
```

To enable the server to be started and stopped automatically during boot, use `chkconfig`:

```
root-shell> chkconfig --levels 235 mysqld on
```

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables will have been automatically created for you, if they do not already exist. You should, however, run `mysql_secure_installation` to set the root passwords on your server.

- **Debian, Ubuntu, Kubuntu**

On Debian and related distributions, there are two packages, `mysql-client` and `mysql-server`, for the client and server components respectively. You should specify an explicit version, for example `mysql-client-5.1`, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the `apt-get` command, specifying the packages that you want to install.

### Note

Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

```
root-shell> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
  linux-headers-2.6.28-11 linux-headers-2.6.28-11-generic
Use 'apt-get autoremove' to remove them.
The following extra packages will be installed:
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-common postfix
Suggested packages:
  dbshell libipc-sharedcache-perl tinyca procmail postfix-mysql postfix-pgsql
  postfix-ldap postfix-pcre sasl2-bin resolvconf postfix-cdb
The following NEW packages will be installed:
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-client-5.1 mysql-common mysql-server-5.1 postfix

### Note

The `apt-get` command will install a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.

During installation, the initial database will be created, and you will be prompted for the MySQL root password (and confirmation). A configuration file will have been created in `/etc/mysql/my.cnf`. An init script will have been created in `/etc/init.d/mysql`.

The server will already be started. You can manually start and stop the server using:

```
root-shell> service mysql [start|stop]
```

The service will automatically be added to the 2, 3 and 4 run levels, with stop scripts in the single, shutdown and restart levels.

### • Gentoo Linux

As a source-based distribution, installing MySQL on Gentoo involves downloading the source, patching the Gentoo specifics, and then compiling the MySQL server and installing it. This process is handled automatically by the `emerge` command. Depending on the version of MySQL that you want to install, you may need to unmask the specific version that you want for your chosen platform.

The MySQL server and client tools are provided within a single package, `dev-db/mysql`. You can obtain a list of the versions available to install by looking at the portage directory for the package:

```
root-shell> ls /usr/portage/dev-db/mysql/mysql-5.1*
mysql-5.1.39-r1.ebuild
mysql-5.1.44-r1.ebuild
mysql-5.1.44-r2.ebuild
mysql-5.1.44-r3.ebuild
mysql-5.1.44.ebuild
mysql-5.1.45-r1.ebuild
mysql-5.1.45.ebuild
mysql-5.1.46.ebuild
```

To install a specific MySQL version, you must specify the entire atom. For example:

```
root-shell> emerge =dev-db/mysql-5.1.46
```

A simpler alternative is to use the `virtual/mysql-5.1` package, which will install the latest version:

```
root-shell> emerge =virtual/mysql-5.1
```

If the package is masked (because it is not tested or certified for the current platform), use the `ACCEPT_KEYWORDS` environment variable. For example:

```
root-shell> ACCEPT_KEYWORDS="~x86" emerge =virtual/mysql-5.1
```

After installation, you should create a new database using `mysql_install_db`, and set the password for the root user on MySQL. You can use the configuration interface to set the password and create the initial database:

```
root-shell> emerge --config =dev-db/mysql-5.1.46
```

A sample configuration file will have been created for you in `/etc/mysql/my.cnf`, and an init script will have been created in `/etc/init.d/mysql`.

To enable MySQL to start automatically at the normal (default) run levels, you can use:

```
root-shell> rc-update add mysql default
```

## 2.6. Installing MySQL on Solaris and OpenSolaris

MySQL on Solaris and OpenSolaris is available in a number of different formats.

- For information on installing using the native Solaris `PKG` format, see [Section 2.6.1, “Installing MySQL on Solaris using a Solaris `PKG`”](#).
- On OpenSolaris, the standard package repositories include MySQL packages specially built for OpenSolaris that include entries for the Service Management Framework (SMF) to enable control of the installation using the SMF administration commands. For more information, see [Section 2.6.2, “Installing MySQL on OpenSolaris using IPS”](#).
- To use a standard `tar` binary installation, use the notes provided in [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#). Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, <http://dev.mysql.com/downloads/mysql/5.6.html>.

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

```
groupadd mysql
useradd -g mysql mysql
```

- If you install MySQL using a binary tarball distribution on Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution. In Solaris 10 and OpenSolaris `gtar` is normally located in `/usr/sfw/bin/gtar`, but may not be included in the default path definition.

- When using Solaris 10 for x86\_64, you should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the `InnoDB` storage engine on this platform.
- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.
- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` [\[465\]](#) option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they will be generated using the mode 600 and owned by the superuser.

### 2.6.1. Installing MySQL on Solaris using a Solaris `PKG`

You can install MySQL on Solaris and OpenSolaris using a binary package using the native Solaris `PKG` format instead of the binary tarball distribution.

To use this package, download the corresponding `mysql-VERSION-solaris10-PLATFORM.pkg.gz` file, then decompress it. For example:

```
shell> gunzip mysql-5.6.12-solaris10-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```
shell> pkgadd -d mysql-5.6.12-solaris10-x86_64.pkg

The following packages are available:
 1  mysql      MySQL Community Server (GPL)
      (i86pc) 5.6.12

Select package(s) you wish to process (or 'all' to process
all packages). (default: all) [?,??,q]:
```

The `PKG` installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

The default installation directory is `/opt/mysql`. You can only change the root path of the installation when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use the binary `tar` file.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
shell> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
shell> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
shell> mysqladmin shutdown
shell> pkgrm mysql
shell> pkgadd -d mysql-5.6.12-solaris10-x86_64.pkg
shell> mysqld_safe &
shell> mysql_upgrade
```

You should check the notes in [Section 2.11, “Upgrading or Downgrading MySQL”](#) before performing any upgrade.

## 2.6.2. Installing MySQL on OpenSolaris using IPS

OpenSolaris includes standard packages for MySQL in the core repository. The MySQL packages are based on a specific release of MySQL and updated periodically. For the latest release you must use either the native Solaris `PKG`, `tar`, or source installations. The native OpenSolaris packages include SMF files so that you can easily control your MySQL installation, including automatic startup and recovery, using the native service management tools.

To install MySQL on OpenSolaris, use the `pkg` command. You will need to be logged in as root, or use the `pfexec` tool, as shown in the example below:

```
shell> pfexec pkg install SUNWmysql156
```

The package set installs three individual packages, `SUNWmysql156lib`, which contains the MySQL client libraries; `SUNWmysql156r` which contains the root components, including SMF and configuration

files; and `SUNWmysql56u` which contains the scripts, binary tools and other files. You can install these packages individually if you only need the corresponding components.

The MySQL files are installed into `/usr/mysql` which symbolic links for the sub directories (`bin`, `lib`, etc.) to a version specific directory. For MySQL 5.6, the full installation is located in `/usr/mysql/5.6`. The default data directory is `/var/mysql/5.6/data`. The configuration file is installed in `/etc/mysql/5.6/my.cnf`. This layout permits multiple versions of MySQL to be installed, without overwriting the data and binaries from other versions.

Once installed, you must run `mysql_install_db` to initialize the database, and use the `mysql_secure_installation` to secure your installation.

## Using SMF to manage your MySQL installation

Once installed, you can start and stop your MySQL server using the installed SMF configuration. The service name is `mysql`, or if you have multiple versions installed, you should use the full version name, for example `mysql:version_56`. To start and enable MySQL to be started at boot time:

```
shell> svcadm enable mysql
```

To disable MySQL from starting during boot time, and shut the MySQL server down if it is running, use:

```
shell> svcadm disable mysql
```

To restart MySQL, for example after a configuration file changes, use the `restart` option:

```
shell> svcadm restart mysql
```

You can also use SMF to configure the data directory and enable full 64-bit mode. For example, to set the data directory used by MySQL:

```
shell> svccfg
svc:> select mysql:version_56
svc:/application/database/mysql:version_56> setprop mysql/data=/data0/mysql
```

By default, the 32-bit binaries are used. To enable the 64-bit server on 64-bit platforms, set the `enable_64bit` parameter. For example:

```
svc:/application/database/mysql:version_56> setprop mysql/enable_64bit=1
```

You need to refresh the SMF after settings these options:

```
shell> svcadm refresh mysql
```

## 2.7. Installing MySQL on HP-UX

MySQL for HP-UX is available in a number of different forms:

- Using a DEPOT distribution provided at <http://dev.mysql.com/downloads/>. Please read the [general notes on HP-UX installation](#) before continuing. For more information on DEPOT installations, see [Section 2.7.2, "Installing MySQL on HP-UX using DEPOT"](#).
- Using a binary tarball distribution provided at <http://dev.mysql.com/downloads/>. Please read the [general notes on HP-UX installation](#) before continuing. For more information on binary installations, see [Section 2.2, "Installing MySQL from Generic Binaries on Unix/Linux"](#).

### 2.7.1. General Notes on Installing MySQL on HP-UX

Some additional notes on installing and using MySQL on HP-UX:

- If you install MySQL using a binary tarball distribution on HP-UX, you may run into trouble even before you get the MySQL distribution unpacked, as the HP-UX `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

- Because of some critical bugs in the standard HP-UX libraries, you should install the following patches before trying to run MySQL on HP-UX 11.0:

```
PHKL_22840 Streams cumulative
PHNE_22397 ARPA cumulative
```

This solves the problem of getting `EWOULDBLOCK` from `recv()` and `EBADF` from `accept()` in threaded applications.

## 2.7.2. Installing MySQL on HP-UX using DEPOT

The HP-UX DEPOT format packages can be installed using the `swinstall` command. You should install the `ncurses` and `zlib` libraries before installing the MySQL DEPOT package. You can use the free software `depothelper` tool to install these packages and any dependencies for you automatically.

To install using the MySQL DEPOT packages, follow this guide:

1. Download the MySQL DEPOT package from <http://dev.mysql.com/downloads/>. You must decompress the package before installation:

```
root-shell> gunzip mysql-5.1.48-hpux11.31-ia64-64bit.depot.gz
```

2. Install the DEPOT package using `swinstall`:

```
root-shell> swinstall -s mysql-5.1.49-hpux11.31-ia64-64bit.depot
```

MySQL will be installed into a directory matching the depot package name, within `/usr/local`. For convenience, you may want to create a symbolic link to the installed directory, for example:

```
root-shell> ln -s mysql-5.1.49-hpux11.31-ia64-64bit mysql
```

3. Your package is now installed. You should complete the configuration of MySQL by creating a user and group:

```
root-shell> /usr/sbin/groupadd mysql
root-shell> /usr/sbin/useradd -g mysql -d /var/lib/mysql/ -s /bin/false mysql
```

4. Create the standard database using the new user/group you have created, and set the permissions:

```
root-shell> cd /usr/local/
root-shell> scripts/mysql_install_db --user=mysql
root-shell> chown -R root .
root-shell> chown -R mysql data
```

5. Finally, secure your new installation by setting the root passwords, and then start your MySQL server using the `mysql` user:

```
root-shell> mysql_secure_installation
root-shell> mysqld_safe --user=mysql &
```

## 2.8. Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.

You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at <http://www.freebsd.org/>. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.

- The ability to use `pkg_info -L` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

To install using the ports system:

```
# cd /usr/ports/databases/mysql51-server
# make
...
# cd /usr/ports/databases/mysql51-client
# make
...
```

The standard port installation places the server into `/usr/local/libexec/mysqld`, with the startup script for the MySQL server placed in `/usr/local/etc/rc.d/mysql-server`.

Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

```
# cd /usr/ports/databases/mysql51-server
# make deinstall
...
# cd /usr/ports/databases/mysql51-client
# make deinstall
...
```

- If you get problems with the current date in MySQL, setting the `TZ` variable should help. See [Section 2.12, “Environment Variables”](#).

## 2.9. Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see [Section 2.1.1, “Operating Systems Supported by MySQL Community Server”](#).

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

### Source Installation Methods

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see [Section 2.1.3, “How to Get MySQL”](#). For instructions on building from a standard distribution, see [Section 2.9.2, “Installing MySQL from a Standard Source Distribution”](#).

Standard distributions are available as compressed `tar` files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or `mysql-VERSION.rpm`, where `VERSION` is a number like `5.6.12`. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

- Use a MySQL development tree. Development trees have not necessarily received the same level of testing as standard release distributions, so this installation method is usually required only if you

need the most recent code changes. For information on building from one of the development trees, see [Section 2.9.3, “Installing MySQL from a Development Source Tree”](#).

## Source Installation System Requirements

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, your system must have the following tools, regardless of installation method:

- [CMake](#), which is used as the build framework on all platforms. [CMake](#) can be downloaded from <http://www.cmake.org>.
- A good [make](#) program. Although some platforms come with their own [make](#) implementations, it is highly recommended that you use GNU [make](#) 3.75 or newer. It may already be available on your system as [gmake](#). GNU [make](#) is available from <http://www.gnu.org/software/make/>.
- A working ANSI C++ compiler. GCC 4.2.1 or later, Sun Studio 10 or later, Visual Studio 2008 or later, and many current vendor-supplied compilers are known to work.
- Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you can use a version such as ActiveState Perl.

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

- For a [.tar.gz](#) compressed [tar](#) file: GNU [gunzip](#) to uncompress the distribution and a reasonable [tar](#) to unpack it. If your [tar](#) program supports the [z](#) option, it can both uncompress and unpack the file.

GNU [tar](#) is known to work. The standard [tar](#) provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU [tar](#), or if available, use a preinstalled version of GNU [tar](#). Usually this is available as [gnutar](#), [gtar](#), or as [tar](#) within a GNU or Free Software directory, such as [/usr/sfw/bin](#) or [/usr/local/bin](#). GNU [tar](#) is available from <http://www.gnu.org/software/tar/>.

- For a [.zip](#) Zip archive: [WinZip](#) or another tool that can read [.zip](#) files.
- For an [.rpm](#) RPM package: The [rpmbuild](#) program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- To obtain the source tree, you must have Bazaar installed. The [Bazaar VCS Web site](#) has instructions for downloading and installing Bazaar on different platforms. Bazaar is supported on any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows, or Mac OS X host.
- [bison](#) is needed to generate [sql\\_yacc.cc](#) from [sql\\_yacc.yy](#). You should use the latest version of [bison](#) where possible. Versions 1.75 and 2.1 are known to work. There have been reported problems with [bison](#) 1.875. If you experience problems, upgrade to a later, rather than earlier, version.

[bison](#) is available from <http://www.gnu.org/software/bison/>. [bison](#) for Windows can be downloaded from <http://gnuwin32.sourceforge.net/packages/bison.htm>. Download the package labeled “Complete package, excluding sources”. On Windows, the default location for [bison](#) is the [C:\Program Files\GnuWin32](#) directory. Some utilities may fail to find [bison](#) because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space; for example [C:\GnuWin32](#).

- On OpenSolaris and Solaris Express, `m4` must be installed in addition to `bison`. `m4` is available from <http://www.gnu.org/software/m4/>.

#### Note

If you have to install any programs, modify your `PATH` environment variable to include any directories in which the programs are located. See [Section 4.2.4, “Setting Environment Variables”](#).

If you run into problems and need to file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

## 2.9.1. MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under `/usr/local/mysql`. The component locations under the installation directory are the same as for binary distributions. See [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#), and [Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”](#). To configure installation locations different from the defaults, use the options described at [Section 2.9.4, “MySQL Source-Configuration Options”](#).

## 2.9.2. Installing MySQL from a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at [Section 2.9, “Installing MySQL from Source”](#).
2. Obtain a distribution file using the instructions in [Section 2.1.3, “How to Get MySQL”](#).
3. Configure, build, and install the distribution using the instructions in this section.
4. Perform postinstallation procedures using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

In MySQL 5.6, `CMake` is used as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using `CMake` to build MySQL, see [How to Build MySQL Server with CMake](#).

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in [Section 2.5.1, “Installing MySQL from RPM Packages on Linux”](#).

The sequence for installation from a compressed `tar` file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#)), except that it is used on all platforms and includes steps to configure and compile the distribution. For example, with a compressed `tar` file source distribution on Unix, the basic installation command sequence looks like this:

```
# Preconfiguration setup
shell> groupadd mysql
shell> useradd -r -g mysql mysql
# Beginning of source-build specific instructions
shell> tar zxvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> cmake .
shell> make
shell> make install
# End of source-build specific instructions
# Postinstallation setup
shell> cd /usr/local/mysql
```

```

shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
# Next command is optional
shell> cp support-files/my-medium.cnf /etc/my.cnf
shell> bin/mysqld_safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server

```

A more detailed version of the source-build specific instructions is shown following.

#### Note

The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.10](#), “Postinstallation Setup and Testing”, for postinstallation setup and testing.

## Perform Preconfiguration Setup

On Unix, set up the `mysql` user and group that will be used to run and execute the MySQL server and own the database directory. For details, see [Creating a `mysql` System User and Group](#), in [Section 2.2](#), “Installing MySQL from Generic Binaries on Unix/Linux”. Then perform the following steps as the `mysql` user, except as noted.

## Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in [Section 2.1.3](#), “How to Get MySQL”.

Unpack the distribution into the current directory:

- To unpack a compressed `tar` file, `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxvf mysql-VERSION.tar.gz
```

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it:

```
shell> gunzip < mysql-VERSION.tar.gz | tar xvf -
```

Alternatively, `CMake` can uncompress and unpack the distribution:

```
shell> cmake -E tar zxvf mysql-VERSION.tar.gz
```

- To unpack a Zip archive, use `WinZip` or another tool that can read `.zip` files.

Unpacking the distribution file creates a directory named `mysql-VERSION`.

## Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

Configure the source directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake .
```

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
shell> cmake . -G "Visual Studio 9 2008"
```

```
shell> cmake . -G "Visual Studio 9 2008 Win64"
```

On Mac OS X, to use the Xcode IDE:

```
shell> cmake . -G Xcode
```

When you run `cmake`, you might want to add options to the command line. Here are some examples:

- `-DBUILD_CONFIG=mysql_release` [131]: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.
- `-DCMAKE_INSTALL_PREFIX=dir_name` [132]: Configure the distribution for installation under a particular location.
- `-DCPACK_MONOLITHIC_INSTALL=1` [131]: Cause `make package` to generate a single installation file rather than multiple files.
- `-DWITH_DEBUG=1` [136]: Build the distribution with debugging support.

For a more extensive list of options, see [Section 2.9.4, “MySQL Source-Configuration Options”](#).

To list the configuration options, use one of the following commands:

```
shell> cmake . -L # overview
shell> cmake . -LH # overview with help text
shell> cmake . -LAH # all params with help text
shell> ccmake . # interactive display
```

If `CMake` fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands on Unix before re-running `CMake`:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build out of the source tree (as described later), the `CMakeCache.txt` file and all built files are in the build directory, so you can remove that directory to object files and cached configuration information.

If you are going to send mail to a MySQL mailing list to ask for configuration assistance, first check the files in the `CMakeFiles` directory for useful information about the failure. To file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

## Build the Distribution

On Unix:

```
shell> make
shell> make VERBOSE=1
```

The second command sets `VERBOSE` to show the commands for each compiled source.

Use `gmake` instead on systems where you are using GNU `make` and it has been installed as `gmake`.

On Windows:

```
shell> devenv MySQL.sln /build RelWithDebInfo
```

It is possible to build out of the source tree to keep the tree clean. If the top-level source directory is named `mysql-src` under your current working directory, you can build in a directory named `build` at the same level like this:

```
shell> mkdir build
shell> cd build
shell> cmake ../mysql-src
```

If you have gotten to the compilation stage, but the distribution does not build, see [Section 2.9.5, “Dealing with Problems Compiling MySQL”](#), for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a `command not found` error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

## Install the Distribution

On Unix:

```
shell> make install
```

This installs the files under the configured installation directory (by default, `/usr/local/mysql`). You might need to run the command as `root`.

To install in a specific directory, add a `DESTDIR` parameter to the command line:

```
shell> make install DESTDIR="/opt/mysql"
```

Alternatively, generate installation package files that you can install where you like:

```
shell> make package
```

This operation produces one or more `.tar.gz` files that can be installed like generic binary distribution packages. See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#). If you run `CMake` with `-DCPACK_MONOLITHIC_INSTALL=1` [131], the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a `.zip` archive installation package:

```
shell> devenv MySQL.sln /build RelWithDebInfo /project initial_database
shell> devenv MySQL.sln /build RelWithDebInfo /project package
```

You can install the resulting `.zip` archive where you like. See [Section 2.3.4, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”](#).

## Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see [Section 2.10, “Postinstallation Setup and Testing”](#).

### Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

## 2.9.3. Installing MySQL from a Development Source Tree

This section discusses how to install MySQL from the latest development source code. Development trees have not necessarily received the same level of testing as standard release distributions, so this installation method is usually required only if you need the most recent code changes. Do not use a development tree for production systems. If your goal is simply to get MySQL up and running on your system, you should use a standard release distribution (either a binary or source distribution). See [Section 2.1.3, “How to Get MySQL”](#).

MySQL development projects are hosted on [Launchpad](#). MySQL projects, including MySQL Server, MySQL Workbench, and others are available from the [Oracle/MySQL Engineering](#) page. For the repositories related only to MySQL Server, see the [MySQL Server](#) page.

To install MySQL from a development source tree, your system must satisfy the tool requirements listed at [Section 2.9, “Installing MySQL from Source”](#), including the requirements for Bazaar and `bison`.

To create a local branch of the MySQL development tree on your machine, use this procedure:

1. To obtain a copy of the MySQL source code, you must create a new Bazaar branch. If you do not already have a Bazaar repository directory set up, you must initialize a new directory:

```
shell> mkdir mysql-server
shell> bzz init-repo --trees mysql-server
```

This is a one-time operation.

2. Assuming that you have an initialized repository directory, you can branch from the public MySQL server repositories to create a local source tree. To create a branch of a specific version:

```
shell> cd mysql-server
shell> bzz branch lp:mysql-server/5.6 mysql-5.6
```

This is a one-time operation per source tree. You can branch the source trees for several versions of MySQL under the `mysql-server` directory.

3. The initial download will take some time to complete, depending on the speed of your connection. Please be patient. Once you have downloaded the first tree, additional trees should take significantly less time to download.
4. When building from the Bazaar branch, you may want to create a copy of your active branch so that you can make configuration and other changes without affecting the original branch contents. You can achieve this by branching from the original branch:

```
shell> bzz branch mysql-5.6 mysql-5.6-build
```

5. To obtain changes made after you have set up the branch initially, update it using the `pull` option periodically. Use this command in the top-level directory of the local copy:

```
shell> bzz pull
```

To examine the changeset comments for the tree, use the `log` option to `bzz`:

```
shell> bzz log
```

You can also browse changesets, comments, and source code online at the Launchpad [MySQL Server](#) page.

If you see diffs (changes) or code that you have a question about, do not hesitate to send email to the MySQL [internals](#) mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#). If you think you have a better idea on how to do something, send an email message to the list with a patch.

After you have the local branch, you can build MySQL server from the source code. For information, see [Section 2.9.2, “Installing MySQL from a Standard Source Distribution”](#), except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run `CMake` with values for the `CMAKE_INSTALL_PREFIX` [132], `MYSQL_TCP_PORT` [135], and `MYSQL_UNIX_ADDR` [135] options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See [Section 22.1.2, “The MySQL Test Suite”](#).

## 2.9.4. MySQL Source-Configuration Options

The `CMake` program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the `CMake` command line. For information about options supported by `CMake`, run either of these commands in the top-level source directory:

```
shell> cmake . -LH
shell> ccmake .
```

You can also affect `CMake` using certain environment variables. See [Section 2.12, “Environment Variables”](#).

The following table shows the available `CMake` options. In the `Default` column, `PREFIX` stands for the value of the `CMAKE_INSTALL_PREFIX` [132] option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

**Table 2.12. MySQL Source-Configuration Option Reference (CMake)**

Formats	Description	Default	Introduced	Removed
<code>BUILD_CONFIG</code> [131]	Use same build options as official releases			
<code>CMAKE_BUILD_TYPE</code> [131]	Type of build to produce	<code>RelWithDebInfo</code>		
<code>CMAKE_INSTALL_PREFIX</code> [132]	Installation base directory	<code>/usr/local/mysql</code>		
<code>COMPILATION_COMMENT</code> [134]	Comment about compilation environment			
<code>CPACK_MONOLITHIC_INSTALLATION</code> [133]	Whether package build produces single file	<code>OFF</code>		
<code>DEFAULT_CHARSET</code> [134]	The default server character set	<code>latin1</code>		
<code>DEFAULT_COLLATION</code> [134]	The default server collation	<code>latin1_swedish_ci</code>		
<code>ENABLE_DEBUG_SYNC</code> [134]	Whether to enable Debug Sync support	<code>ON</code>		
<code>ENABLE_DOWNLOADS</code> [135]	Whether to download optional files	<code>OFF</code>		
<code>ENABLE_DTRACE</code> [135]	Whether to include DTrace support			
<code>ENABLE_GCOV</code> [135]	Whether to include gcov support		5.6.3	
<code>ENABLE_GPROF</code> [135]	Enable gprof (optimized Linux builds only)	<code>OFF</code>	5.6.6	
<code>ENABLED_LOCAL_INFILE</code> [135]	Whether to enable LOCAL for LOAD DATA INFILE	<code>OFF</code>		
<code>ENABLED_PROFILING</code> [135]	Whether to enable query profiling code	<code>ON</code>		

MySQL Source-Configuration Options

Formats	Description	Default	Introduced	Removed
<a href="#">IGNORE_AIO_CHECK [135]</a>	With -DBUILD_CONFIG=mysql_release, ignore libaio check	OFF	5.6.1	
<a href="#">INSTALL_BINDIR [132]</a>	User executables directory	PREFIX/bin		
<a href="#">INSTALL_DOCDIR [132]</a>	Documentation directory	PREFIX/docs		
<a href="#">INSTALL_DOCREADMEDIR [132]</a>	README file directory	PREFIX

<a href="#">MYSQL_PROJECT_NAME [135]</a>	Windows/Mac OS X project name	3306	5.6.5	
<a href="#">MYSQL_TCP_PORT [135]</a>	TCP/IP port number	3306		
<a href="#">MYSQL_UNIX_ADDR [135]</a>	Unix socket file	/tmp/mysql.sock		
<a href="#">ODBC_INCLUDES [133]</a>	ODBC includes directory			
<a href="#">ODBC_LIB_DIR [133]</a>	ODBC library directory			
<a href="#">OPTIMIZER_TRACE [133]</a>	Whether to support optimizer tracing		5.6.3	
<a href="#">SYSCONFDIR [133]</a>	Option file directory			
<a href="#">WITH_DEBUG [136]</a>	Whether to include debugging support	OFF		
<a href="#">WITH_DEFAULT_COMPILER_OPTIONS [136]</a>	Whether to use default compiler options	ON	5.6.6	
<a href="#">WITH_DEFAULT_FEATURE_SET [135]</a>	Whether to use default feature set	ON	5.6.6	

Formats	Description	Default	Introduced	Removed
<a href="#">WITH_EMBEDDED_SERVER [136]</a>	Whether to build embedded server	OFF		
<a href="#">WITH_xxx_STORAGE_ENGINE [136]</a>	Compile storage engine xxx statically into server			
<a href="#">WITH_EXTRA_CHARSETS [136]</a>	Which extra character sets to include	all		
<a href="#">WITH_LIBEDIT [136]</a>	Use bundled libedit library	ON		
<a href="#">WITH_LIBWRAP [136]</a>	Whether to include libwrap (TCP wrappers) support	OFF		
<a href="#">WITH_READLINE [136]</a>	Use bundled readline library	OFF		5.6.5
<a href="#">WITH_SSL [136]</a>	Type of SSL support	no		
<a href="#">WITH_UNIXODBC [137]</a>	Enable unixODBC support	OFF		
<a href="#">WITH_ZLIB [137]</a>	Type of zlib support	system		
<a href="#">WITHOUT_xxx_STORAGE_ENGINE [136]</a>	Exclude storage engine xxx from build			

The following sections provide more information about [CMake](#) options.

- [General Options](#)
- [Installation Layout Options](#)
- [Feature Options](#)
- [Compiler Flags](#)

For boolean options, the value may be specified as 1 or [ON](#) to enable the option, or as 0 or [OFF](#) to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the [CMAKE\\_INSTALL\\_PREFIX \[132\]](#), [MYSQL\\_TCP\\_PORT \[135\]](#), and [MYSQL\\_UNIX\\_ADDR \[135\]](#) options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the [--basedir \[414\]](#), [--port \[437\]](#), and [--socket \[442\]](#) options for `mysqld`. Where applicable, configuration option descriptions indicate the corresponding `mysqld` startup option.

## General Options

- `-DBUILD_CONFIG=mysql_release`

This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- `-DCMAKE_BUILD_TYPE=type`

The type of build to produce:

- `RelWithDebInfo`: Enable optimizations and generate debugging information. This is the default MySQL build type.
- `Debug`: Disable optimizations and generate debugging information. This build type is also used if the [WITH\\_DEBUG \[136\]](#) option is enabled. That is, `-DWITH_DEBUG=1 [136]` has the same effect as `-DCMAKE_BUILD_TYPE=Debug [131]`.
- `-DCPACK_MONOLITHIC_INSTALL=bool`

This option affects whether the `make package` operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

## Installation Layout Options

The `CMAKE_INSTALL_PREFIX` [132] option indicates the base installation directory. Other options with names of the form `INSTALL_XXX` that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

- `-DCMAKE_INSTALL_PREFIX=dir_name`

The installation base directory.

This value can be set at server startup with the `--basedir` [414] option.

- `-DINSTALL_BINDIR=dir_name`

Where to install user programs.

- `-DINSTALL_DOCDIR=dir_name`

Where to install documentation.

- `-DINSTALL_DOCREADMEDIR=dir_name`

Where to install `README` files.

- `-DINSTALL_INCLUDEDIR=dir_name`

Where to install header files.

- `-DINSTALL_INFODIR=dir_name`

Where to install Info files.

- `-DINSTALL_LAYOUT=name`

Select a predefined installation layout:

- `STANDALONE`: Same layout as used for `.tar.gz` and `.zip` packages. This is the default.
- `RPM`: Layout similar to RPM packages.
- `SVR4`: Solaris package layout.
- `DEB`: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
shell> cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

- `-DINSTALL_LIBDIR=dir_name`

Where to install library files.

- `-DINSTALL_MANDIR=dir_name`

Where to install manual pages.

- `-DINSTALL_MYSQLSHAREDIR=dir_name`

Where to install shared data files.

- `-DINSTALL_MYSQLTESTDIR=dir_name`

Where to install the `mysql-test` directory. As of MySQL 5.6.12, to suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_MYSQLTESTDIR= [133]`).

- `-DINSTALL_PLUGINDIR=dir_name`

The location of the plugin directory.

This value can be set at server startup with the `--plugin_dir [525]` option.

- `-DINSTALL_SBINDIR=dir_name`

Where to install the `mysqld` server.

- `-DINSTALL_SCRIPTDIR=dir_name`

Where to install `mysql_install_db`.

- `-DINSTALL_SHAREDIR=dir_name`

Where to install `aclocal/mysql.m4`.

- `-DINSTALL_SQLBENCHDIR=dir_name`

Where to install the `sql-bench` directory. To suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_SQLBENCHDIR= [133]`).

- `-DINSTALL_SUPPORTFILESDIR=dir_name`

Where to install extra support files.

- `-DMYSQL_DATADIR=dir_name`

The location of the MySQL data directory.

This value can be set at server startup with the `--datadir [418]` option.

- `-DOPTIMIZER_TRACE=bool`

Whether to support optimizer tracing. See [MySQL Internals: Tracing the Optimizer](#). This option was added in MySQL 5.6.3.

- `-DSYSCONFDIR=dir_name`

The default `my.cnf` option file directory.

This location cannot be set at server startup, but you can start the server with a given option file using the `--defaults-file=file_name [219]` option, where `file_name` is the full path name to the file.

- `-DODBC_INCLUDES=dir_name`

The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

- `-DODBC_LIB_DIR=dir_name`

The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

## Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the `INSTALL PLUGIN` statement or the `--plugin-load` [435] option before it can be used). Some plugins might not support static or dynamic building.

The `MyISAM`, `MERGE`, `MEMORY`, and `CSV` engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use `-DWITH_engine_STORAGE_ENGINE=1`. Some permissible *engine* values are `ARCHIVE`, `BLACKHOLE`, `EXAMPLE`, `FEDERATED`, `INNOBASE` (InnoDB), `PARTITION` (partitioning support), and `PERFSCHEMA` (Performance Schema). Examples:

```
-DWITH_INNOBASE_STORAGE_ENGINE=1
-DWITH_ARCHIVE_STORAGE_ENGINE=1
-DWITH_BLACKHOLE_STORAGE_ENGINE=1
-DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

To exclude a storage engine from the build, use `-DWITHOUT_engine_STORAGE_ENGINE=1`. Examples:

```
-DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
-DWITHOUT_FEDERATED_STORAGE_ENGINE=1
-DWITHOUT_PARTITION_STORAGE_ENGINE=1
```

If neither `-DWITH_engine_STORAGE_ENGINE` nor `-DWITHOUT_engine_STORAGE_ENGINE` are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

## Feature Options

- `-DCOMPILATION_COMMENT=string`

A descriptive comment about the compilation environment.

- `-DDEFAULT_CHARSET=charset_name`

The server character set. By default, MySQL uses the `latin1` (cp1252 West European) character set.

*charset\_name* may be one of `binary`, `armscii8`, `ascii`, `big5`, `cp1250`, `cp1251`, `cp1256`, `cp1257`, `cp850`, `cp852`, `cp866`, `cp932`, `dec8`, `eucjms`, `euckr`, `gb2312`, `gbk`, `geostd8`, `greek`, `hebrew`, `hp8`, `keybcs2`, `koi8r`, `koi8u`, `latin1`, `latin2`, `latin5`, `latin7`, `macce`, `macroman`, `sjis`, `swe7`, `tis620`, `ucs2`, `ujis`, `utf8`, `utf8mb4`, `utf16`, `utf16le`, `utf32`. The permissible character sets are listed in the `cmake/character_sets.cmake` file as the value of `CHARSETS_AVAILABLE`.

This value can be set at server startup with the `--character_set_server` [468] option.

- `-DDEFAULT_COLLATION=collation_name`

The server collation. By default, MySQL uses `latin1_swedish_ci`. Use the `SHOW COLLATION` statement to determine which collations are available for each character set.

This value can be set at server startup with the `--collation_server` [470] option.

- `-DENABLE_DEBUG_SYNC=bool`

Whether to compile the Debug Sync facility into the server. This facility is used for testing and debugging. This option is enabled by default, but has no effect unless MySQL is configured with debugging enabled. If debugging is enabled and you want to disable Debug Sync, use `-DENABLE_DEBUG_SYNC=0` [134].

When compiled in, Debug Sync is disabled by default at runtime. To enable it, start `mysqld` with the `--debug-sync-timeout=N` [419] option, where *N* is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) *N* becomes the default timeout for individual synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `-DENABLE_DOWNLOADS=bool`

Whether to download optional files. For example, with this option enabled, `CMake` downloads the Google Test distribution that is used by the test suite to run unit tests.

- `-DENABLE_DTRACE=bool`

Whether to include support for DTrace probes. For information about DTrace, see [Section 5.7, “Tracing `mysqld` Using DTrace”](#)

- `-DENABLE_GCOV=bool`

Whether to include gcov support (Linux only).

- `-DENABLE_GPROF=bool`

Whether to enable `gprof` (optimized Linux builds only). This option was added in MySQL 5.6.6.

- `-DENABLED_LOCAL_INFILE=bool`

Whether to enable `LOCAL` capability in the client library for `LOAD DATA INFILE`.

This option controls client-side `LOCAL` capability, but the capability can be set on the server side at server startup with the `--local-infile` [496] option. See [Section 6.1.6, “Security Issues with `LOAD DATA LOCAL`”](#).

- `-DENABLED_PROFILING=bool`

Whether to enable query profiling code (for the `SHOW PROFILE` and `SHOW PROFILES` statements).

- `-DIGNORE_AIO_CHECK=bool`

If the `-DBUILD_CONFIG=mysql_release` [131] option is given on Linux, the `libaio` library must be linked in by default. If you do not have `libaio` or do not want to install it, you can suppress the check for it by specifying `-DIGNORE_AIO_CHECK=1` [135]. This option was added in MySQL 5.6.1.

- `-DMYSQL_MAINTAINER_MODE=bool`

Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors.

- `-DMYSQL_PROJECT_NAME=name`

For Windows or Mac OS X, the project name to incorporate into the project file name. This option was added in MySQL 5.6.5.

- `-DMYSQL_TCP_PORT=port_num`

The port number on which the server listens for TCP/IP connections. The default is 3306.

This value can be set at server startup with the `--port` [437] option.

- `-DMYSQL_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`.

This value can be set at server startup with the `--socket` [442] option.

- `-DWITH_DEBUG=bool`

Whether to include debugging support.

Configuring MySQL with debugging support enables you to use the `--debug="d,parser_debug"` [418] option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

- `-DWITH_DEFAULT_COMPILER_OPTIONS=bool`

Whether to use the flags from `cmake/build_configurations/compiler_options.cmake`. This option was added in MySQL 5.6.6.

- `-DWITH_DEFAULT_FEATURE_SET=bool`

Whether to use the flags from `cmake/build_configurations/feature_set.cmake`. This option was added in MySQL 5.6.6.

- `-DWITH_EMBEDDED_SERVER=bool`

Whether to build the `libmysqld` embedded server library.

- `-DWITH_EXTRA_CHARSETS=name`

Which extra character sets to include:

- `all`: All character sets. This is the default.
- `complex`: Complex character sets.
- `none`: No extra character sets.

- `-DWITH_LIBEDIT=bool`

Whether to use the `libedit` library bundled with the distribution.

- `-DWITH_LIBWRAP=bool`

Whether to include `libwrap` (TCP wrappers) support.

- `-DWITH_READLINE=bool`

Whether to use the `readline` library bundled with the distribution. This option was removed in MySQL 5.6.5 because `readline` is no longer bundled.

- `-DWITH_SSL=ssl_type`

The type of SSL support to include, if any:

- `no`: No SSL support. This is the default before MySQL 5.6.6. As of 5.6.6, this is no longer a permitted value and the default is `bundled`.
- `yes`: Use the system SSL library if present, else the library bundled with the distribution.
- `bundled`: Use the SSL library bundled with the distribution. This is the default as of MySQL 5.6.6.
- `system`: Use the system SSL library.

- `path_name`: As of MySQL 5.6.7, it is permitted to specify the path name to the OpenSSL installation to use. This can be useful instead of a value of `system` when CMake detects an older or incorrect installed OpenSSL version. (Another permitted way to do the same thing is to set the `CMAKE_PREFIX_PATH` option to `path_name`.)

For information about using SSL support, see [Section 6.3.9, “Using SSL for Secure Connections”](#).

- `-DWITH_ZLIB=zlib_type`

Some features require that the server be built with compression library support, such as the `COMPRESS()` [1261] and `UNCOMPRESS()` [1265] functions, and compression of the client/server protocol. The `WITH_ZLIB` [137] indicates the source of `zlib` support:

- `bundled`: Use the `zlib` library bundled with the distribution.
- `system`: Use the system `zlib` library. This is the default.
- `-DWITH_UNIXODBC=1`

Enables unixODBC support, for Connector/ODBC.

## Compiler Flags

To specify compiler flags, set the `CFLAGS` and `CXXFLAGS` environment variables before running CMake. Example:

```
shell> CFLAGS=-DHAVE_EMBEDDED_PRIVILEGE_CONTROL
shell> CXXFLAGS=-DHAVE_EMBEDDED_PRIVILEGE_CONTROL
shell> export CFLAGS CXXFLAGS
shell> cmake [options]
```

The following flags control configuration features:

- `HAVE_EMBEDDED_PRIVILEGE_CONTROL`

By default, authentication for connections to the embedded server is disabled. To enable connection authentication, define this flag.

## 2.9.5. Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If CMake is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When CMake starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run CMake, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands on Unix before re-running CMake:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build out of the source tree, remove and recreate your build directory before re-running CMake. For instructions on building outside of the source tree, see [How to Build MySQL Server with CMake](#).

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

- To define flags to be used by your C or C++ compilers, specify them using the `CFLAGS` and `CXXFLAGS` environment variables. You can also specify the compiler names this way using `CC` and `CXX`. For example:

```
shell> CC=gcc
shell> CFLAGS=-O3
shell> CXX=g++
shell> CXXFLAGS=-O3
shell> export CC CFLAGS CXX CXXFLAGS
```

To see what flags you might need to specify, invoke `mysql_config` with the `--cflags` [373] and `--cxxflags` [373] options.

- If compilation fails, check whether the `MYSQL_MAINTAINER_MODE` [135] option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.
- If your compile fails with errors such as any of the following, you must upgrade your version of `make` to GNU `make`:

```
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome `make` programs.

GNU `make` 3.75 is known to work.

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install `bison` (the GNU version of `yacc`) and use that instead.

Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

For information about acquiring or updating tools, see the system requirements in [Section 2.9, "Installing MySQL from Source"](#).

## 2.9.6. MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the `VERSION` file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is 5.5.8, the file looks like this:

```
MYSQL_VERSION_MAJOR=5
```

```
MYSQL_VERSION_MINOR=5
MYSQL_VERSION_PATCH=8
MYSQL_VERSION_EXTRA=
```

If the source is not for a General Availability (GA) release, the `MYSQL_VERSION_EXTRA` value will be nonempty. For example, the value for a Release Candidate release would look like this:

```
MYSQL_VERSION_EXTRA=rc
```

To construct a five-digit number from the version components, use this formula:

```
MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH
```

## 2.10. Postinstallation Setup and Testing

After installing MySQL, there are some issues that you should address. For example, on Unix, you should initialize the data directory and create the MySQL grant tables. On all platforms, an important security concern is that the initial accounts in the grant tables have no passwords. You should assign passwords to prevent unauthorized access to the MySQL server. Optionally, you can create time zone tables to enable recognition of named time zones.

The following sections include postinstallation procedures that are specific to Windows systems and to Unix systems. Another section, [Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”](#), applies to all platforms; it describes what to do if you have trouble getting the server to start. [Section 2.10.2, “Securing the Initial MySQL Accounts”](#), also applies to all platforms. You should follow its instructions to make sure that you have properly protected your MySQL accounts by assigning passwords to them.

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in [Section 6.2, “The MySQL Access Privilege System”](#), and [Section 6.3, “MySQL User Account Management”](#).

### 2.10.1. Unix Postinstallation Procedures

After installing MySQL on Unix, you must initialize the grant tables, start the server, and make sure that the server works satisfactorily. You may also wish to arrange for the server to be started and stopped automatically when your system starts and stops. You should also assign passwords to the accounts in the grant tables.

On Unix, the grant tables are set up by the `mysql_install_db` program. For some installation methods, this program is run for you automatically if an existing database cannot be found.

- If you install MySQL on Linux using RPM distributions, the server RPM runs `mysql_install_db`.
- Using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux and others, the `mysql_install_db` command is run for you.
- If you install MySQL on Mac OS X using a PKG distribution, the installer runs `mysql_install_db`.

For other platforms and installation types, including generic binary and source installs, you will need to run `mysql_install_db` yourself.

The following procedure describes how to initialize the grant tables (if that has not previously been done) and start the server. It also suggests some commands that you can use to test whether the server is accessible and working properly. For information about starting and stopping the server automatically, see [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).

After you complete the procedure and have the server running, you should assign passwords to the accounts created by `mysql_install_db` and perhaps restrict access to test databases. For instructions, see [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

In the examples shown here, the server runs under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server. For information

about creating the account, see [Creating a `mysql` System User and Group](#), in [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

1. Change location into the top-level directory of your MySQL installation, represented here by `BASEDIR`:

```
shell> cd BASEDIR
```

`BASEDIR` is the installation directory for your MySQL instance. It is likely to be something like `/usr/local/mysql` or `/usr/local`. The following steps assume that you have changed location to this directory.

You will find several files and subdirectories in the `BASEDIR` directory. The most important for installation purposes are the `bin` and `scripts` subdirectories:

- The `bin` directory contains client programs and the server. You should add the full path name of this directory to your `PATH` environment variable so that your shell finds the MySQL programs properly. See [Section 2.12, “Environment Variables”](#).
  - The `scripts` directory contains the `mysql_install_db` script used to initialize the `mysql` database containing the grant tables that store the server access permissions.
2. If necessary, ensure that the distribution contents are accessible to `mysql`. If you installed the distribution as `mysql`, no further action is required. If you installed the distribution as `root`, its contents will be owned by `root`. Change its ownership to `mysql` by executing the following commands as `root` in the installation directory. The first command changes the owner attribute of the files to the `mysql` user. The second changes the group attribute to the `mysql` group.

```
shell> chown -R mysql .
shell> chgrp -R mysql .
```

3. If necessary, run the `mysql_install_db` program to set up the initial MySQL grant tables containing the privileges that determine how users are permitted to connect to the server. You will need to do this if you used a distribution type for which the installation procedure does not run the program for you.

```
shell> scripts/mysql_install_db --user=mysql
```

Typically, `mysql_install_db` needs to be run only the first time you install MySQL, so you can skip this step if you are upgrading an existing installation. However, `mysql_install_db` does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

It might be necessary to specify other options such as `--basedir` [\[237\]](#) or `--datadir` [\[237\]](#) if `mysql_install_db` does not identify the correct locations for the installation directory or data directory. For example:

```
shell> scripts/mysql_install_db --user=mysql \
    --basedir=/opt/mysql/mysql \
    --datadir=/opt/mysql/mysql/data
```

The `mysql_install_db` script creates the server's data directory with `mysql` as the owner. Under the data directory, it creates directories for the `mysql` database that holds the grant tables and the `test` database that you can use to test MySQL. The script also creates privilege table entries for `root` and anonymous-user accounts. The accounts have no passwords initially. [Section 2.10.2, “Securing the Initial MySQL Accounts”](#), describes the initial privileges. Briefly, these privileges permit the MySQL `root` user to do anything, and permit anybody to create or use databases with a name of `test` or starting with `test_`. See [Section 6.2, “The MySQL Access Privilege System”](#), for a complete listing and description of the grant tables.

For a more secure installation, invoke `mysql_install_db` with the `--random-passwords` option. This causes it to assign a random password to the MySQL `root` accounts, set the “password expired” flag for those accounts, and remove the anonymous-user MySQL accounts. For

additional details, see [Section 4.4.3, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#). (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this if you run `mysql_install_db` as `root`, include the `--user [238]` option as shown. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user [238]` option from the command.

If you do not want to have the `test` database, you can remove it after starting the server, using the instructions in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

If you have trouble with `mysql_install_db` at this point, see [Section 2.10.1.1, “Problems Running mysql\\_install\\_db”](#).

- Most of the MySQL installation can be owned by `root` if you like. The exception is that the data directory must be owned by `mysql`. To accomplish this, run the following commands as `root` in the installation directory:

```
shell> chown -R root .
shell> chown -R mysql data
```

- If the plugin directory (the directory named by the `plugin_dir [525]` system variable) is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir [525]` read only to the server or by setting `--secure-file-priv [438]` to a directory where `SELECT` writes can be made safely.
- If you installed MySQL using a source distribution, you may want to optionally copy one of the provided configuration files from the `support-files` directory into your `/etc` directory. There are different sample configuration files for different use cases, server types, and CPU and RAM configurations. If you want to use one of these standard files, you should copy it to `/etc/my.cnf`, or `/etc/mysql/my.cnf` and edit and check the configuration before starting your MySQL server for the first time.

If you do not copy one of the standard configuration files, the MySQL server will be started with the default settings.

If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `mysql.server` script itself, and in [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).

- Start the MySQL server:

```
shell> bin/mysqld_safe --user=mysql &
```

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this if you run `mysqld_safe` as `root`, include the `--user [229]` option as shown. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user [229]` option from the command.

For further instructions for running MySQL as an unprivileged user, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If you neglected to create the grant tables by running `mysql_install_db` before proceeding to this step, the following message appears in the error log file when you start the server:

```
mysqld: Can't find file: 'host.frm'
```

This error also occurs if you run `mysql_install_db` as `root` without the `--user` [238] option. Remove the `data` directory and run `mysql_install_db` with the `--user` [238] option as described previously.

If you have other problems starting the server, see [Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”](#). For more information about `mysqld_safe`, see [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).

- Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin Ver 14.12 Distrib 5.6.12, for pc-linux-gnu on i686
...

Server version          5.6.12
Protocol version        10
Connection              Localhost via UNIX socket
UNIX socket             /var/lib/mysql/mysql.sock
Uptime:                 14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` [270] option.

- Verify that you can shut down the server:

```
shell> bin/mysqladmin -u root shutdown
```

- Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql &
```

If `mysqld_safe` fails, see [Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”](#).

- Run some simple tests to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
shell> bin/mysqlshow
+-----+
|          Databases          |
+-----+
| information_schema |
| mysql              |
| test               |
+-----+

shell> bin/mysqlshow mysql
Database: mysql
+-----+
|          Tables          |
+-----+
| columns_priv |
| db           |
| event       |
| func        |
```

```

| help_category

+-----+

shell> bin/mysql -e "SELECT Host,Db,User FROM db" mysql
+-----+-----+-----+
| host | db      | user |
+-----+-----+-----+
| %    | test   |      |
| %    | test_% |      |
+-----+-----+-----+

```

12. There is a benchmark suite in the `sql-bench` directory (under the MySQL installation directory) that you can use to compare how MySQL performs on different platforms. The benchmark suite is written in Perl. It requires the Perl DBI module that provides a database-independent interface to the various databases, and some other additional Perl modules:

```

DBI
DBD::mysql
Data::Dumper
Data::ShowTable

```

These modules can be obtained from CPAN (<http://www.cpan.org/>). See also [Section 2.13.1](#), “Installing Perl on Unix”.

The `sql-bench/Results` directory contains the results from many runs against different databases and platforms. To run all tests, execute these commands:

```

shell> cd sql-bench
shell> perl run-all-tests

```

If you do not have the `sql-bench` directory, you probably installed MySQL using RPM files other than the source RPM. (The source RPM includes the `sql-bench` benchmark directory.) In this case, you must first install the benchmark suite before you can use it. There are separate benchmark RPM files named `mysql-bench-VERSION.i386.rpm` that contain benchmark code and data.

If you have a source distribution, there are also tests in its `tests` subdirectory that you can run. For example, to run `auto_increment.tst`, execute this command from the top-level directory of your source distribution:

```

shell> mysql -vfv test < ./tests/auto_increment.tst

```

The expected result of the test can be found in the `./tests/auto_increment.res` file.

13. At this point, you should have the server running. However, none of the initial MySQL accounts have a password, and the server permits permissive access to test databases. To tighten security, follow the instructions in [Section 2.10.2](#), “Securing the Initial MySQL Accounts”.

The MySQL 5.6 installation procedure creates time zone tables in the `mysql` database but does not populate them. To do so, use the instructions in [Section 10.6](#), “MySQL Server Time Zone Support”.

To make it more convenient to invoke programs installed in the `bin` directory under the installation directory, you can add that directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. See [Section 4.2.4, “Setting Environment Variables”](#).

You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl modules. See [Section 4.6.14, “mysql\\_setpermission — Interactively Set Permissions in Grant Tables”](#). For Perl module installation instructions, see [Section 2.13, “Perl Installation Notes”](#).

If you would like to use `mysqlaccess` and have the MySQL distribution in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `bin/mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL = '/usr/local/bin/mysql'; # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a [Broken pipe](#) error will occur when you run `mysqlaccess`.

### 2.10.1.1. Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` script is to generate new MySQL privilege tables. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

If you want to re-create your privilege tables, first stop the `mysqld` server if it is running. Then rename the `mysql` directory under the data directory to save it, and then run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
shell> mv data/mysql data/mysql.old
shell> scripts/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

```
Starting mysqld daemon with databases from XXXXXX
mysqld ended
```

In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message and should indicate why `mysqld` did not start. If you do not understand what happened, include the log when you post a bug report. See [Section 1.7, “How to Report Bugs or Problems”](#).

- **There is a `mysqld` process running**

This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once (when you install MySQL the first time).

- **Installing a second `mysqld` server does not work when one server is running**

This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

```
Can't start server: Bind on TCP/IP port:
Address already in use
```

```
Can't start server: Bind on unix socket...
```

For instructions on setting up multiple servers, see [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

- **You do not have write access to the `/tmp` directory**

If you do not have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory) or the `TMP_DIR` environment variable, if it has been set, an error occurs when you run `mysql_install_db` or the `mysqld` server.

You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where `some_tmp_dir` is the full path name to some directory for which you have write permission:

```
shell> TMPDIR=/some_tmp_dir/
shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
shell> export TMPDIR MYSQL_UNIX_PORT
```

Then you should be able to run `mysql_install_db` and start the server with these commands:

```
shell> scripts/mysql_install_db --user=mysql
shell> bin/mysqld_safe --user=mysql &
```

If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

See [Section C.5.4.5, “How to Protect or Change the MySQL Unix Socket File”](#), and [Section 2.12, “Environment Variables”](#).

There are some alternatives to running the `mysql_install_db` script provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, you can modify `mysql_install_db` before you run it. However, it is preferable to use `GRANT` and `REVOKE` to change the privileges *after* the grant tables have been set up. In other words, you can run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the necessary `GRANT` and `REVOKE` statements.

If you want to install MySQL on several machines with the same privileges, you can put the `GRANT` and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

```
shell> scripts/mysql_install_db --user=mysql
shell> bin/mysql -u root < your_script_file
```

By doing this, you can avoid having to issue the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you are just learning how to use `GRANT` and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

To re-create the grant tables, remove all the `.frm`, `.MYI`, and `.MYD` files in the `mysql` database directory. Then run the `mysql_install_db` script again.

- You can start `mysqld` manually using the `--skip-grant-tables` [\[439\]](#) option and add the privilege information yourself using `mysql`:

```
shell> bin/mysqld_safe --user=mysql --skip-grant-tables &
shell> bin/mysql mysql
```

From `mysql`, manually execute the SQL commands contained in `mysql_install_db`. Make sure that you run `mysqladmin flush-privileges` or `mysqladmin reload` afterward to tell the server to reload the grant tables.

Note that by not using `mysql_install_db`, you not only have to populate the grant tables manually, you also have to create them first.

### 2.10.1.2. Starting and Stopping MySQL Automatically

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.
- Run the MySQL server as a Windows service. The service can be set to start the server automatically when Windows starts, or as a manual service that you start on request. For instructions, see [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).
- Invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. This script is used on Unix and Unix-like systems. See [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).
- Invoke `mysql.server`. This script is used primarily at system startup and shutdown on systems that use System V-style run directories (that is, `/etc/init.d` and run-level specific directories), where it usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See [Section 4.3.3, “mysql.server — MySQL Server Startup Script”](#).
- On Mac OS X, install a separate MySQL Startup Item package to enable the automatic startup of MySQL on system startup. The Startup Item starts the server by invoking `mysql.server`. See [Section 2.4.3, “Installing the MySQL Startup Item”](#), for details. A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences, see [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).
- Use the Solaris/OpenSolaris service management framework (SMF) system to initiate and control MySQL startup. For more information, see [Section 2.6.2, “Installing MySQL on OpenSolaris using IPS”](#).

The `mysqld_safe` and `mysql.server` scripts, Windows server, Solaris/OpenSolaris SMF, and the Mac OS X Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

To start or stop the server manually using the `mysql.server` script, invoke it with `start` or `stop` arguments:

```
shell> mysql.server start
shell> mysql.server stop
```

Before `mysql.server` starts the server, it changes location to the MySQL installation directory, and then invokes `mysqld_safe`. If you want the server to run as some specific user, add an appropriate `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file, as shown later in this section. (It is possible that you will need to edit `mysql.server` if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you need to add start and stop commands to the appropriate places in your `/etc/rc*` files.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), or a native Linux package installation, the `mysql.server` script may be installed in the `/etc/init.d` directory with the name `mysql`. See [Section 2.5.1, “Installing MySQL from RPM Packages on Linux”](#), for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. The script can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree.

To install `mysql.server` manually, copy it to the `/etc/init.d` directory with the name `mysql`, and then make it executable. Do this by changing location into the appropriate directory where `mysql.server` is located and executing these commands:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

#### Note

Older Red Hat systems use the `/etc/rc.d/init.d` directory rather than `/etc/init.d`. Adjust the preceding commands accordingly. Alternatively, first create `/etc/init.d` as a symbolic link that points to `/etc/rc.d/init.d`:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. The `rc(8)` manual page states that scripts in this directory are executed only if their basename matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored. In other words, on FreeBSD, you should install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, you could append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `/etc/my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the following options: `basedir`, `datadir`, and `pid-file`. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

The following table shows which option groups the server and each startup script read from option files.

**Table 2.13. MySQL Startup scripts and supported server option groups**

Script	Option Groups
<code>mysqld</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld-major_version]</code>
<code>mysqld_safe</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld_safe]</code>
<code>mysql.server</code>	<code>[mysqld]</code> , <code>[mysql.server]</code> , <code>[server]</code>

`[mysqld-major_version]` means that groups with names like `[mysqld-5.5]` and `[mysqld-5.6]` are read by servers having versions 5.5.x, 5.6.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead when using MySQL 5.6.

For more information on MySQL configuration files and their structure and contents, see [Section 4.2.3.3, “Using Option Files”](#).

### 2.10.1.3. Starting and Troubleshooting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server on Unix. If you are using Windows, see [Section 2.3.5, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

If you have problems starting the server, here are some things to try:

- Check the [error log](#) to see why the server does not start. Log files are located in the [data directory](#) (typically `C:\Program Files\MySQL\MySQL Server 5.6\data` on Windows, `/usr/local/mysql/data` for a Unix binary distribution, and `/usr/local/var` for a Unix source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. On Unix, use `tail` to display them:

```
shell> tail host_name.err
shell> tail host_name.log
```

- Specify any special options needed by the storage engines you are using. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables ([InnoDB](#), [NDB](#)), be sure that you have them configured the way you want before starting the server. If you are using [InnoDB](#) tables, see [Section 14.2.1.2, “Configuring InnoDB”](#) for guidelines and [Section 14.2.6, “InnoDB Startup Options and System Variables”](#) for option syntax.

Although storage engines use default values for options that you omit, Oracle recommends that you review the available options and specify explicit values for any options whose defaults are not appropriate for your installation.

- Make sure that the server knows where to find the [data directory](#). The `mysqld` server uses this directory as its current directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The default data directory location is hardcoded when the server is compiled. To determine what the default path settings are, invoke `mysqld` with the `--verbose` [\[447\]](#) and `--help` [\[413\]](#) options. If the data directory is located somewhere else on your system, specify that location with the `--datadir` [\[418\]](#) option to `mysqld` or `mysqld_safe`, on the command line or in an option file. Otherwise, the server will not work properly. As an alternative to the `--datadir` [\[418\]](#) option, you can specify `mysqld` the location of the base directory under which MySQL is installed with the `--basedir` [\[414\]](#), and `mysqld` looks for the `data` directory there.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` [\[447\]](#) and `--help` [\[413\]](#) options. For example, if you change location into the directory

where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` [418] as well, but `--verbose` [447] and `--help` [413] must be the last options.

Once you determine the path settings you want, start the server without `--verbose` [447] and `--help` [413].

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

- Make sure that the server can access the [data directory](#). The ownership and permissions of the data directory and its contents must allow the server to read and modify them.

If you get [Errcode 13](#) (which means [Permission denied](#)) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

On Unix, change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

Even with correct ownership, MySQL might fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

- Verify that the network interfaces the server wants to use are available.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in [Section 5.6, "Running Multiple MySQL Instances on One Machine"](#).)

If no other server is running, execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote`

`host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. Track down what program this is and disable it, or tell `mysqld` to listen to a different port with the `--port [437]` option. In this case, specify the same non-default port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1 localhost
```

- If you cannot get `mysqld` to start, try to make a trace file to find the problem by using the `--debug [418]` option. See [MySQL Internals: Porting to Other Systems](#).

## 2.10.2. Securing the Initial MySQL Accounts

Part of the MySQL installation process is to set up the `mysql` database that contains the grant tables:

- Windows distributions contain preinitialized grant tables.
- On Unix, the `mysql_install_db` program populates the grant tables. Some installation methods run this program for you. Others require that you execute it manually. For details, see [Section 2.10.1, “Unix Postinstallation Procedures”](#).

The `mysql.user` grant table defines the initial MySQL user accounts and their access privileges:

- Some accounts have the user name `root`. These are superuser accounts that have all privileges and can do anything. The initial `root` account passwords are empty, so anyone can connect to the MySQL server as `root` *without a password* and be granted all privileges.
- On Windows, `root` accounts are created that permit connections from the local host only. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, or the IPv6 address `::1`. If the user selects the **Enable root access from remote machines** option during installation, the Windows installer creates another `root` account that permits connections from any host.
- On Unix, each `root` account permits connections from the local host. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, the IPv6 address `::1`, or the actual host name or IP address.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve [440]` option, so the `127.0.0.1` account is useful in that case. The `::1` account is used for IPv6 connections.

- Some accounts are for anonymous users. These have an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.
- On Windows, there is one anonymous account that permits connections from the local host. Connections can be made by specifying a host name of `localhost`.
- On Unix, each anonymous account permits connections from the local host. Connections can be made by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP address for the other.

To display which accounts exist in the `mysql.user` table and check whether their passwords are empty, use the following statement:

```
mysql> SELECT User, Host, Password FROM mysql.user;
+-----+-----+-----+
| User | Host | Password |
+-----+-----+-----+
```

root	localhost		
root	myhost.example.com		
root	127.0.0.1		
root	::1		
	localhost		
	myhost.example.com		

This output indicates that there are several `root` and anonymous-user accounts, none of which have passwords. The output might differ on your system, but the presence of accounts with empty passwords means that your MySQL installation is unprotected until you do something about it:

- You should assign a password to each MySQL `root` account.
- If you want to prevent clients from connecting as anonymous users without a password, you should either assign a password to each anonymous account or else remove the accounts.

In addition, the `mysql.db` table contains rows that permit all accounts to access the `test` database and other databases with names that start with `test_`. This is true even for accounts that otherwise have no special privileges such as the default anonymous accounts. This is convenient for testing but inadvisable on production servers. Administrators who want database access restricted only to accounts that have permissions granted explicitly for that purpose should remove these `mysql.db` table rows.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the `root` accounts, then for the anonymous accounts. The instructions also cover how to remove the anonymous accounts, should you prefer not to permit anonymous access at all, and describe how to remove permissive access to test databases. Replace `newpwd` in the examples with the password that you want to use. Replace `host_name` with the name of the server host. You can determine this name from the output of the preceding `SELECT` statement. For the output shown, `host_name` is `myhost.example.com`.

#### Note

For additional information about setting passwords, see [Section 6.3.5, “Assigning Account Passwords”](#). If you forget your `root` password after setting it, see [Section C.5.4.1, “How to Reset the Root Password”](#).

You might want to defer setting the passwords until later, to avoid the need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

To set up additional accounts, see [Section 6.3.2, “Adding User Accounts”](#).

## Assigning `root` Account Passwords

The `root` account passwords can be set several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement
- Use the `UPDATE` statement
- Use the `mysqladmin` command-line client program

To assign passwords using `SET PASSWORD`, connect to the server as `root` and issue a `SET PASSWORD` statement for each `root` account listed in the `mysql.user` table. Be sure to encrypt the password using the `PASSWORD()` [1263] function.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
```

```
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@ '%' = PASSWORD('newpwd');
```

The last statement is unnecessary if the `mysql.user` table has no `root` account with a host value of `%`.

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

You can also use a single statement that assigns a password to all `root` accounts by using `UPDATE` to modify the `mysql.user` table directly. This method works on any platform:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
-> WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```
shell> mysqladmin -u root password "newpwd"
shell> mysqladmin -u root -h host_name password "newpwd"
```

Those commands apply both to Windows and to Unix. The double quotation marks around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

The `mysqladmin` method of setting the `root` account passwords does not work for the `'root'@'127.0.0.1'` or `'root'@'::1'` account. Use the `SET PASSWORD` method shown earlier.

After the `root` passwords have been set, you must supply the appropriate password whenever you connect as `root` to the server. For example, to shut down the server with `mysqladmin`, use this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

## Assigning Anonymous Account Passwords

The `mysql` commands in the following instructions include a `-p` option based on the assumption that you have set the `root` account passwords using the preceding instructions and must specify that password when connecting to the server.

To assign passwords to the anonymous accounts, connect to the server as `root`, then use either `SET PASSWORD` or `UPDATE`. Be sure to encrypt the password using the `PASSWORD()` [1263] function.

To use `SET PASSWORD` on Windows, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
```

To use `SET PASSWORD` on Unix, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('newpwd');
```

To set the anonymous-user account passwords with a single `UPDATE` statement, do this (on any platform):

```

shell> mysql -u root -p
Enter password: (enter root password here)
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
-> WHERE User = '';
mysql> FLUSH PRIVILEGES;

```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

## Removing Anonymous Accounts

If you prefer to remove any anonymous accounts rather than assigning them passwords, do so as follows on Windows:

```

shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER '@localhost';

```

On Unix, remove the anonymous accounts like this:

```

shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER '@localhost';
mysql> DROP USER '@host_name';

```

## Securing Test Databases

By default, the `mysql.db` table contains rows that permit access by any user to the `test` database and other databases with names that start with `test_`. (These rows have an empty `User` column value, which for access-checking purposes matches any user name.) This means that such databases can be used even by accounts that otherwise possess no privileges. If you want to remove any-user access to test databases, do so as follows:

```

shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.db WHERE Db LIKE 'test%';
mysql> FLUSH PRIVILEGES;

```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the privilege change remains unnoticed by the server until you restart it.

With the preceding change, only users who have global database privileges or privileges granted explicitly for the `test` database can use it. However, if you do not want the database to exist at all, drop it:

```

mysql> DROP DATABASE test;

```

### Note

On Windows, you can also perform the process described in this section during installation with MySQL Installer (see [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#)). On other platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation. And MySQL Workbench is available on all platforms, and also offers the ability to manage user accounts (see [Chapter 24, MySQL Workbench](#)).

## 2.11. Upgrading or Downgrading MySQL

This section describes the steps to upgrade or downgrade a MySQL installation.

Upgrading is a common procedure, as you pick up bug fixes within the same MySQL release series or significant features between major MySQL releases. You perform this procedure first on some test systems to make sure everything works smoothly, and then on the production systems.

Downgrading is less common. Typically, you undo an upgrade because of some compatibility or performance issue that occurs on a production system, and was not uncovered during initial upgrade verification on the test systems. As with the upgrade procedure, perform and verify the downgrade procedure on some test systems first, before using it on a production system.

### 2.11.1. Upgrading MySQL

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. To upgrade from a release series previous to MySQL 5.5, upgrade to each successive release series in turn until you have reached MySQL 5.5, and then proceed with the upgrade to MySQL 5.6. For example, if you currently are running MySQL 5.1 and wish to upgrade to a newer series, upgrade to MySQL 5.5 first before upgrading to 5.6, and so forth. For information on upgrading to MySQL 5.5, see the *MySQL 5.5 Reference Manual*.

To upgrade to MySQL 5.6, use the items in the following checklist as a guide:

- Before any upgrade, back up your databases, including the `mysql` database that contains the grant tables. See [Section 7.2, “Database Backup Methods”](#).
- Read *all* the notes in [Section 2.11.1.1, “Upgrading from MySQL 5.5 to 5.6”](#). These notes enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed in that section require your attention *before* upgrading. Others require some action *after* upgrading.
- Read the [Release Notes](#) as well, which provide information about features that are new in MySQL 5.6 or differ from those found in earlier MySQL releases.
- After upgrading to a new version of MySQL, run `mysql_upgrade` (see [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#)). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

`mysql_upgrade` should not be used when the server is running with `--gtid-mode=ON` [2019], since it may make changes in nontransactional system tables in the `mysql` database, many of which are `MyISAM` and cannot be changed to use a different storage engine. See [GTID mode and mysql\\_upgrade](#).

- If you run MySQL Server on Windows, see [Section 2.3.6, “Upgrading MySQL on Windows”](#).
- If you use replication, see [Section 16.4.3, “Upgrading a Replication Setup”](#), for information on upgrading your replication setup.
- If you upgrade an installation originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.
- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

For upgrades between versions of a MySQL release series that has reached General Availability status, you can move the MySQL format files and data files between different versions on systems with the same architecture. For upgrades to a version of a MySQL release series that is in development status, that is not necessarily true. Use of development releases is at your own risk.

If you are cautious about using new versions, you can always rename your old `mysqld` before installing a newer one. For example, if you are using a version of MySQL 5.5 and want to upgrade to 5.6, rename your current server from `mysqld` to `mysqld-5.5`. If your new `mysqld` then does something unexpected, you can simply shut it down and restart with your old `mysqld`.

If problems occur, such as that the new `mysqld` server does not start or that you cannot connect without a password, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` [220] option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompile might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example from `libmysqlclient.so.15` to `libmysqlclient.so.16`).

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

It is a good idea to rebuild and reinstall the Perl `DBD: :mysql` module whenever you install a new release of MySQL. The same applies to other MySQL interfaces as well, such as PHP `mysql` extensions and the Python `MySQLdb` module.

### 2.11.1.1. Upgrading from MySQL 5.5 to 5.6

#### Note

Beginning with MySQL 5.6.6, several MySQL Server parameters have defaults that differ from previous releases. See the notes regarding these changes later in this section, particularly regarding overriding them to preserve backward compatibility if that is a concern.

#### Note

It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, protect your data by making a backup.

To upgrade to 5.6 from any previous version, MySQL recommends that you dump your tables with `mysqldump` before upgrading and reload the dump file after upgrading. Use the `--all-databases` [292] option to include all databases in the dump. If your databases include stored programs, use the `--routines` [293] and `--events` [293] options as well.

In general, do the following when upgrading from MySQL 5.5 to 5.6:

- Read *all* the items in these sections to see whether any of them might affect your applications:
  - [Section 2.11.1, “Upgrading MySQL”](#), has general update information.
  - The items in the change lists provided later in this section enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed there require your attention *before* upgrading. Others should be dealt with *after* upgrading.

- The MySQL 5.6 [Release Notes](#) describe significant new features you can use in 5.6 or that differ from those found in earlier MySQL releases. Some of these changes may result in incompatibilities.

Note particularly any changes that are marked **Known issue** or **Incompatible change**. These incompatibilities with earlier versions of MySQL may require your attention *before you upgrade*. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the incompatibility description. Sometimes this involves dumping and reloading tables, or use of a statement such as `CHECK TABLE` or `REPAIR TABLE`.

For dump and reload instructions, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#). Any procedure that involves `REPAIR TABLE` with the `USE_FRM` option *must* be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

- Before upgrading to a new version of MySQL, [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are upgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to upgrade the affected tables using the instructions in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).
- After upgrading to a new version of MySQL, run `mysql_upgrade` (see [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#)). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

- If you run MySQL Server on Windows, see [Section 2.3.6, “Upgrading MySQL on Windows”](#).
- If you use replication, see [Section 16.4.3, “Upgrading a Replication Setup”](#), for information on upgrading your replication setup.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

Read *all* the items in the following sections to see whether any of them might affect your applications:

### Configuration Changes

- Beginning with MySQL 5.6.6, several MySQL Server parameters have defaults that differ from previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for the database administrator to change settings manually. These changes are subject to possible revision in future releases as we gain feedback.

In some cases, a parameter has a different static default value. In other cases, the server autosizes a parameter at startup using a formula based on other related parameters or server host configuration, rather than using a static value. For example, the setting for `back_log` [465] now is its previous default of 50, adjusted up by an amount proportional to the value of

`max_connections` [503]. The idea behind autosizing is that when the server has information available to make a decision about a parameter setting likely to be better than a fixed default, it will.

The following table summarizes changes to defaults. Any of these can be overridden by specifying an explicit value at server startup.

Parameter	Old Default	New Default
<code>back_log</code> [465]	50	Autosized using <code>max_connections</code> [503]
<code>binlog_checksum</code> [2009]	NONE	CRC32
<code>--binlog-row-event-max-size</code> [2001]	1024	8192
<code>flush_time</code> [482]	1800 (on Windows)	0
<code>innodb_autoextend_increment</code> [1784]	64	64
<code>innodb_buffer_pool_instances</code> [1706]	1	8 (platform dependent)
<code>innodb_checksum_algorithm</code> [1710]	INNODB	CRC32
<code>innodb_concurrency_tickets</code> [1715]	500	5000
<code>innodb_file_per_table</code> [1718]	0	1
<code>innodb_old_blocks_time</code> [1738]	0	1000
<code>innodb_open_files</code> [1739]	300	Autosized using <code>innodb_file_per_table</code> [1718], <code>table_open_cache</code> [551]
<code>innodb_stats_on_metadata</code> [1747]	ON	OFF
<code>join_buffer_size</code> [490]	128KB	256KB
<code>max_allowed_packet</code> [502]	1MB	4MB
<code>max_connect_errors</code> [502]	10	100
<code>sync_master_info</code> [1997]	0	10000
<code>sync_relay_log</code> [1998]	0	10000
<code>sync_relay_log_info</code> [1999]	0	10000

With regard to compatibility with previous releases, the most important changes are:

- `innodb_file_per_table` [1718] is enabled (previously disabled).
- `innodb_checksum_algorithm` [1710] is CRC32 (previously INNODB).
- `binlog_checksum` [2009] is CRC32 (previously NONE).

Therefore, if you are upgrading an existing MySQL installation, have not already changed the values of these parameters from their previous defaults, and backward compatibility is a concern, you may want to explicitly set these parameters to their previous defaults. For example, put these lines in the server option file:

```
[mysqld]
innodb_file_per_table=0
innodb_checksum_algorithm=INNODB
binlog_checksum=NONE
```

Those settings preserve compatibility as follows:

- With the new default of `innodb_file_per_table` [1718] enabled, `ALTER TABLE` operations following an upgrade will move InnoDB tables that are in the system tablespace to individual `.ibd` files. Using `innodb_file_per_table=0` [1718] will prevent this from happening.

- Setting `innodb_checksum_algorithm=INNODB` [1710] permits binary downgrades after upgrading to this release. With a setting of `CRC32`, InnoDB would use checksumming that older MySQL versions cannot use.
- With `binlog_checksum=NONE` [2009], the server can be used as a replication master without causing failure of older slaves that do not understand binary log checksums.

## Server Changes

- **Incompatible change:** As of MySQL 5.6, the full-text stopword file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`. If any table was created with `FULLTEXT` indexes while the server character set was `ucs2`, `utf16`, `utf16le`, or `utf32`, repair it using this statement:

```
REPAIR TABLE tbl_name QUICK;
```

- **Incompatible change:** MySQL 5.6.11 and later supports `CREATE TABLE ... [SUB]PARTITION BY ALGORITHM=n [LINEAR] KEY (...)`, which can be used to create a table whose `KEY` partitioning is compatible with a MySQL 5.1 server ( $n=1$ ). (Bug #14521864, Bug #66462) This syntax is not accepted by MySQL 5.6.10 and earlier, although it is supported in MySQL 5.5 beginning with MySQL 5.5.31. `mysqldump` in MySQL 5.5.31 and later MySQL 5.5 releases includes the `ALGORITHM` option when dumping tables using this option, but surrounds it with conditional comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50531 ALGORITHM = 1 */ /*!50100 ( )
PARTITIONS 3 */
```

When importing a dump containing such `CREATE TABLE` statements into a MySQL 5.6.10 or earlier MySQL 5.6 server, the versioned comment is not ignored, which causes a syntax error. Therefore, prior to importing such a dump file, you must either change the comments so that the MySQL 5.6 server ignores them (by removing the string `!50531` or replacing it with `!50611`, wherever it occurs), or remove them.

This is not an issue with dump files made using MySQL 5.6.11 or later, where the `ALGORITHM` option is written using `/*!50611 ... */`.

## SQL Changes

- Some keywords may be reserved in MySQL 5.6 that were not reserved in MySQL 5.5. See [Section 9.3, “Reserved Words”](#).
- The `YEAR(2)` data type has certain issues that you should consider before choosing to use it. As of MySQL 5.6.6, `YEAR(2)` is deprecated. `YEAR(2)` columns in existing tables are treated as before, but `YEAR(2)` in new or altered tables are converted to `YEAR(4)`. For more information, see [Section 11.3.4, “YEAR\(2\) Limitations and Migrating to YEAR\(4\)”](#).
- As of MySQL 5.6.6, it is explicitly disallowed to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). This was not previously supported, or documented as permitted, but is flagged as an incompatible change in case existing code inadvertently used this construct. It remains permissible to assign `DEFAULT` to system variables, as before, but assigning `DEFAULT` to parameters or local variables now results in a syntax error.

After an upgrade to MySQL 5.6.6 or later, existing stored programs that use this construct produce a syntax error when invoked. If a `mysqldump` file from 5.6.5 or earlier is loaded into 5.6.6 or later, the load operation fails and affected stored program definitions must be changed.

- In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types:

- `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are assigned the `NOT NULL` attribute. (Columns of other data types, if not explicitly declared as `NOT NULL`, permit `NULL` values.) Setting such a column to `NULL` sets it to the current timestamp.
- The first `TIMESTAMP` column in a table, if not declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` clause, is automatically assigned the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.
- `TIMESTAMP` columns following the first one, if not declared with the `NULL` attribute or an explicit `DEFAULT` clause, are automatically assigned `DEFAULT '0000-00-00 00:00:00'` (the “zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

Those nonstandard behaviors remain the default for `TIMESTAMP` but as of MySQL 5.6.6 are deprecated and this warning appears at startup:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see
documentation for more details).
```

As indicated by the warning, to turn off the nonstandard behaviors, enable the new `explicit_defaults_for_timestamp` [481] system variable at server startup. With this variable enabled, the server handles `TIMESTAMP` as follows instead:

- `TIMESTAMP` columns not explicitly declared as `NOT NULL` permit `NULL` values. Setting such a column to `NULL` sets it to `NULL`, not the current timestamp.
- No `TIMESTAMP` column is assigned the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes automatically. Those attributes must be explicitly specified.
- `TIMESTAMP` columns declared as `NOT NULL` and without an explicit `DEFAULT` clause are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is assigned the implicit default of `'0000-00-00 00:00:00'` and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.

To upgrade servers used for replication, upgrade the slaves first, then the master. Replication between the master and its slaves should work provided that all use the same value of `explicit_defaults_for_timestamp` [481]:

1. Bring down the slaves, upgrade them, configure them with the desired value of `explicit_defaults_for_timestamp` [481], and bring them back up.

The slaves will recognize from the format of the binary logs received from the master that the master is older (predates the introduction of `explicit_defaults_for_timestamp` [481]) and that operations on `TIMESTAMP` columns coming from the master use the old `TIMESTAMP` behavior.

2. Bring down the master, upgrade it, and configure it with the same `explicit_defaults_for_timestamp` [481] value used on the slaves, and bring it back up.

## 2.11.2. Downgrading MySQL

This section describes what to do to downgrade to an older MySQL version, in the unlikely case that the previous version worked better than the new one.

It is always a good idea to make a backup beforehand, in case a downgrade fails and leaves the instance in an unusable state.

To downgrade between General Availability (GA) status versions within the same release series, typically you just install the new binaries on top of the old ones and do not make any changes to the databases.

Downgrades between milestone releases (or from a GA release to a milestone release) within the same release series are not supported and you may encounter issues.

The following items form a checklist of things to do whenever you perform a downgrade:

- Read the upgrading section for the release series from which you are downgrading to be sure that it does not have any features you really need. See [Section 2.11.1, “Upgrading MySQL”](#).
- If there is a downgrading section for that version, read that as well.
- To see which new features were added between the version to which you are downgrading and your current version, see the [Release Notes](#).
- Check [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are downgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to downgrade the affected tables using the instructions in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

In most cases, you can move the MySQL format files and data files between different GA versions on the same architecture as long as you stay within versions for the same release series of MySQL.

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use `mysqldump` to dump your tables before downgrading. After downgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables. For examples, see [Section 2.11.5, “Copying MySQL Databases to Another Machine”](#).

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.
4. Stop the newer MySQL server and restart the older one.
5. Reload the dump file into the older server. Your tables should be accessible.

If system tables in the `mysql` database changed, downgrading might introduce some loss of functionality or require some adjustments. Here are some examples:

- Trigger creation requires the `TRIGGER` privilege as of MySQL 5.1. In MySQL 5.0, there is no `TRIGGER` privilege and `SUPER` is required instead. If you downgrade from MySQL 5.1 to 5.0, you will need to give the `SUPER` privilege to those accounts that had the `TRIGGER` privilege in 5.1.
- Triggers were added in MySQL 5.0, so if you downgrade from 5.0 to 4.1, you cannot use triggers at all.
- The `mysql.proc.comment` column definition changed between MySQL 5.1 and 5.5. After a downgrade from 5.5 to 5.1, this table is seen as corrupt and in need of repair. To workaround this problem, execute `mysql_upgrade` from the version of MySQL to which you downgraded.

### 2.11.2.1. Downgrading to MySQL 5.5

When downgrading to MySQL 5.5 from MySQL 5.6, keep in mind the following issues relating to features found in MySQL 5.6, but not in MySQL 5.5:

## System Tables

- The `mysql.user` table in MySQL 5.6 has a `password_expired` column. The `mysql.user` table in MySQL 5.5 does not. This means that an account with an expired password in MySQL 5.6 will work normally in MySQL 5.5.

## InnoDB

- InnoDB search indexes (with a type of `FULLTEXT`), introduced in MySQL 5.6.4, are not compatible with earlier versions of MySQL, including earlier releases in the 5.6 series. Drop such indexes before performing a downgrade.
- InnoDB small page sizes specified by the `innodb_page_size [1740]` configuration option, introduced in MySQL 5.6.4, are not compatible with earlier versions of MySQL, including earlier releases in the 5.6 series. Dump all InnoDB tables in instances that use a smaller InnoDB page size, drop the tables, and re-create and reload them after the downgrade.

## Replication

- As of MySQL 5.6, the `relay-log.info` file contains a line count and a replication delay value, so the file format differs from that in older versions. See [Section 16.2.2.2, “Slave Status Logs”](#). If you downgrade a slave server to a version older than MySQL 5.6, the older server will not read the file correctly. To address this, modify the file in a text editor to delete the initial line containing the number of lines.
- Beginning with MySQL 5.6.6, the MySQL Server employs Version 2 binary log events when writing the binary log. Binary logs written using Version 2 log events cannot be read by earlier versions of MySQL Server. To generate a binary log that is written using Version 1 log events readable by older servers, start the MySQL 5.6.6 or later server using `--log-bin-use-v1-row-events=1 [2003]`, which forces the server to employ Version 1 events when writing the binary log.

### 2.11.3. Checking Whether Tables or Indexes Must Be Rebuilt

A binary upgrade or downgrade is one that installs one version of MySQL “in place” over an existing version, without dumping and reloading tables:

1. Stop the server for the existing version if it is running.
2. Install a different version of MySQL. This is an upgrade if the new version is higher than the original version, a downgrade if the version is lower.
3. Start the server for the new version.

In many cases, the tables from the previous version of MySQL can be used without problem by the new version. However, sometimes changes occur that require tables or table indexes to be rebuilt, as described in this section. If you have tables that are affected by any of the issues described here, rebuild the tables or indexes as necessary using the instructions given in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

## Table Incompatibilities

After a binary upgrade to MySQL 5.1 from a MySQL 5.0 installation that contains `ARCHIVE` tables, accessing those tables causes the server to crash, even if you have run `mysql_upgrade` or `CHECK TABLE ... FOR UPGRADE`. To work around this problem, use `mysqldump` to dump all `ARCHIVE` tables before upgrading, and reload them into MySQL 5.1 after upgrading. The same problem occurs for binary downgrades from MySQL 5.1 to 5.0.

The upgrade problem is fixed in MySQL 5.6.4: The server can open `ARCHIVE` tables created in MySQL 5.0. However, it remains the recommended upgrade procedure to dump 5.0 `ARCHIVE` tables before upgrading and reload them after upgrading.

## Index Incompatibilities

In MySQL 5.6.3, the length limit for index prefix keys is increased from 767 bytes to 3072 bytes, for InnoDB tables using `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`. See [Section 14.2.7, “Limits on InnoDB Tables”](#) for details. This change is also backported to MySQL 5.5.14. If you downgrade from one of these releases or higher, to an earlier release with a lower length limit, the index prefix keys could be truncated at 767 bytes or the downgrade could fail. This issue could only occur if the configuration option `innodb_large_prefix [1728]` was enabled on the server being downgraded.

If you perform a binary upgrade without dumping and reloading tables, you cannot upgrade directly from MySQL 4.1 to 5.1 or higher. This occurs due to an incompatible change in the `MyISAM` table index format in MySQL 5.0. Upgrade from MySQL 4.1 to 5.0 and repair all `MyISAM` tables. Then upgrade from MySQL 5.0 to 5.1 and check and repair your tables.

Modifications to the handling of character sets or collations might change the character sort order, which causes the ordering of entries in any index that uses an affected character set or collation to be incorrect. Such changes result in several possible problems:

- Comparison results that differ from previous results
- Inability to find some index values due to misordered index entries
- Misordered `ORDER BY` results
- Tables that `CHECK TABLE` reports as being in need of repair

The solution to these problems is to rebuild any indexes that use an affected character set or collation, either by dropping and re-creating the indexes, or by dumping and reloading the entire table. In some cases, it is possible to alter affected columns to use a different collation. For information about rebuilding indexes, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

To check whether a table has indexes that must be rebuilt, consult the following list. It indicates which versions of MySQL introduced character set or collation changes that require indexes to be rebuilt. Each entry indicates the version in which the change occurred and the character sets or collations that the change affects. If the change is associated with a particular bug report, the bug number is given.

The list applies both for binary upgrades and downgrades. For example, Bug #27877 was fixed in MySQL 5.1.24 and 5.4.0, so it applies to upgrades from versions older than 5.1.24 to 5.1.24 or newer, and to downgrades from 5.1.24 or newer to versions older than 5.1.24.

In many cases, you can use `CHECK TABLE ... FOR UPGRADE` to identify tables for which index rebuilding is required. It will report this message:

```
Table upgrade required.
Please do "REPAIR TABLE `tbl_name`" or dump/reload to fix it!
```

In these cases, you can also use `mysqlcheck --check-upgrade` or `mysql_upgrade`, which execute `CHECK TABLE`. However, the use of `CHECK TABLE` applies only after upgrades, not downgrades. Also, `CHECK TABLE` is not applicable to all storage engines. For details about which storage engines `CHECK TABLE` supports, see [Section 13.7.2.2, “CHECK TABLE Syntax”](#).

These changes cause index rebuilding to be necessary:

- MySQL 5.1.24, 5.4.0 (Bug #27877)

Affects indexes that use the `utf8_general_ci` or `ucs2_general_ci` collation for columns that contain 'ß' LATIN SMALL LETTER SHARP S (German). The bug fix corrected an error in the original collations but introduced an incompatibility such that 'ß' compares equal to characters with which it previously compared different.

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.30, 5.4.0 (see Bug #40053).

A workaround for this issue is implemented as of MySQL 5.1.62, 5.5.21, and 5.6.5. The workaround involves altering affected columns to use the `utf8_general_mysql500_ci` and `ucs2_general_mysql500_ci` collations, which preserve the original pre-5.1.24 ordering of `utf8_general_ci` and `ucs2_general_ci`.

- MySQL 5.0.48, 5.1.23 (Bug #27562)

Affects indexes that use the `ascii_general_ci` collation for columns that contain any of these characters: ``` GRAVE ACCENT, `[` LEFT SQUARE BRACKET, `\` REVERSE SOLIDUS, `]` RIGHT SQUARE BRACKET, `~` TILDE

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29, 5.4.0 (see Bug #39585).

- MySQL 5.0.48, 5.1.21 (Bug #29461)

Affects indexes for columns that use any of these character sets: `eurjpm`, `eurkr`, `gb2312`, `latin7`, `macce`, `ujis`

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29, 5.4.0 (see Bug #39585).

## 2.11.4. Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild a table, following changes to MySQL such as how data types or character sets are handled. For example, an error in a collation might have been corrected, requiring a table rebuild to update the indexes for character columns that use the collation. (For examples, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).) You might also need to repair or upgrade a table, as indicated by a table check operation such as that performed by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include dumping and reloading it, or using `ALTER TABLE` or `REPAIR TABLE`.

### Note

If you are rebuilding tables because a different version of MySQL will not handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before* upgrading or downgrading using your original version of MySQL. Then reload the tables *after* upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

To rebuild a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```
shell> mysqldump db_name t1 > dump.sql
shell> mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
shell> mysqldump db_name > dump.sql
shell> mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the `--all-databases` [292] option:

```
shell> mysqldump --all-databases > dump.sql
shell> mysql < dump.sql
```

To rebuild a table with `ALTER TABLE`, use a “null” alteration; that is, an `ALTER TABLE` statement that “changes” the table to use the storage engine that it already has. For example, if `t1` is a `MyISAM` table, use this statement:

```
mysql> ALTER TABLE t1 ENGINE = MyISAM;
```

If you are not sure which storage engine to specify in the `ALTER TABLE` statement, use `SHOW CREATE TABLE` to display the table definition.

If you must rebuild a table because a table checking operation indicates that the table is corrupt or needs an upgrade, you can use `REPAIR TABLE` if that statement supports the table's storage engine. For example, to repair a `MyISAM` table, use this statement:

```
mysql> REPAIR TABLE t1;
```

For storage engines such as `InnoDB` that `REPAIR TABLE` does not support, use `mysqldump` to create a dump file and `mysql` to reload the file, as described earlier.

For specifics about which storage engines `REPAIR TABLE` supports, see [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

`mysqlcheck --repair` provides command-line access to the `REPAIR TABLE` statement. This can be a more convenient means of repairing tables because you can use the `--databases` [276] or `--all-databases` [276] option to repair all tables in specific databases or all databases, respectively:

```
shell> mysqlcheck --repair --databases db_name ...
shell> mysqlcheck --repair --all-databases
```

For incompatibilities introduced in MySQL 5.1.24 by the fix for Bug #27877 that corrected the `utf8_general_ci` and `ucs2_general_ci` collations, a workaround is implemented as of MySQL 5.1.62, 5.5.21, and 5.6.5. Upgrade to one of those versions, then convert each affected table using one of the following methods. In each case, the workaround altering affected columns to use the `utf8_general_mysql500_ci` and `ucs2_general_mysql500_ci` collations, which preserve the original pre-5.1.24 ordering of `utf8_general_ci` and `ucs2_general_ci`.

- To convert an affected table after a binary upgrade that leaves the table files in place, alter the table to use the new collation. Suppose that the table `t1` contains one or more problematic `utf8` columns. To convert the table at the table level, use a statement like this:

```
ALTER TABLE t1
CONVERT TO CHARACTER SET utf8 COLLATE utf8_general_mysql500_ci;
```

To apply the change on a column-specific basis, use a statement like this (be sure to repeat the column definition as originally specified except for the `COLLATE` clause):

```
ALTER TABLE t1
MODIFY c1 CHAR(N) CHARACTER SET utf8 COLLATE utf8_general_mysql500_ci;
```

- To upgrade the table using a dump and reload procedure, dump the table using `mysqldump`, modify the `CREATE TABLE` statement in the dump file to use the new collation, and reload the table.

After making the appropriate changes, `CHECK TABLE` should report no error.

## 2.11.5. Copying MySQL Databases to Another Machine

You can copy the `.frm`, `.MYI`, and `.MYD` files for `MyISAM` tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See [Section 14.3, “The `MyISAM` Storage Engine”](#).

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Use `mysqldump --help` to see what options are available.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
shell> mysqladmin -h 'other_hostname' create db_name
shell> mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
shell> mysqladmin create db_name
shell> mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
shell> mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
shell> mysqladmin create db_name
shell> gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, `DUMPDIR` represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
shell> mkdir DUMPDIR
shell> mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine and load the files into MySQL there:

```
shell> mysqladmin create db_name           # create database
shell> cat DUMPDIR/*.sql | mysql db_name   # create tables in database
shell> mysqlimport db_name DUMPDIR/*.txt  # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

## 2.12. Environment Variables

This section lists all the environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables.

In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See [Section 4.2.3.3, “Using Option Files”](#).

Variable	Description
CXX	The name of your C++ compiler (for running <code>CMake</code> ).
CC	The name of your C compiler (for running <code>CMake</code> ).
CFLAGS	Flags for your C compiler (for running <code>CMake</code> ).
CXXFLAGS	Flags for your C++ compiler (for running <code>CMake</code> ).
DBI_USER	The default user name for Perl DBI.
DBI_TRACE	Trace options for Perl DBI.
HOME	The default path for the <code>mysql</code> history file is <code>\$HOME/.mysql_history</code> .
LD_RUN_PATH	Used to specify the location of <code>libmysqlclient.so</code> .
LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN	Enable <code>mysql_clear_password</code> authentication plugin; see <a href="#">Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”</a> .
LIBMYSQL_PLUGIN_DIR	Directory in which to look for client plugins.
LIBMYSQL_PLUGINS	Client plugins to preload.
MYSQL_DEBUG	Debug trace options when debugging.
MYSQL_GROUP_SUFFIX	Option group suffix value (like specifying <code>--defaults-group-suffix [219]</code> ).
MYSQL_HISTFILE	The path to the <code>mysql</code> history file. If this variable is set, its value overrides the default for <code>\$HOME/.mysql_history</code> .
MYSQL_HISTIGNORE	Patterns specifying statements not to log to <code>\$HOME/.mysql_history</code> .
MYSQL_HOME	The path to the directory in which the server-specific <code>my.cnf</code> file resides.
MYSQL_HOST	The default host name used by the <code>mysql</code> command-line client.
MYSQL_PS1	The command prompt to use in the <code>mysql</code> command-line client.
MYSQL_PWD	The default password when connecting to <code>mysqld</code> . Note that using this is insecure. See <a href="#">Section 6.1.2.1, “End-User Guidelines for Password Security”</a> .
MYSQL_TCP_PORT	The default TCP/IP port number.
MYSQL_TEST_LOGIN_FILE	The name of the <code>.mylogin.cnf</code> login file.
MYSQL_UNIX_PORT	The default Unix socket file name; used for connections to <code>localhost</code> .
PATH	Used by the shell to find MySQL programs.
TMPDIR	The directory where temporary files are created.
TZ	This should be set to your local time zone. See <a href="#">Section C.5.4.6, “Time Zone Problems”</a> .
UMASK	The user-file creation mode when creating files. See note following table.
UMASK_DIR	The user-directory creation mode when creating directories. See note following table.
USER	The default user name on Windows when connecting to <code>mysqld</code> .

For information about the `mysql` history file, see [Section 4.5.1.3, “mysql Logging”](#).

`MYSQL_TEST_LOGIN_FILE` is the path name of the login file (the file created by `mysql_config_editor`). If not set, the default value is `%APPDATA%\MySQL\mylogin.cnf` directory on Windows and `$HOME/.mylogin.cnf` on non-Windows systems. See [Section 4.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses `( $UMASK | 0600 )` as the mode for file creation, so that newly created files have a mode in the range from `0600` to `0666` (all values octal).

- If `UMASK_DIR` is set, `mysqld` uses `( $\$UMASK\_DIR \mid 0700$ )` as the base mode for directory creation, which then is AND-ed with `~( $\sim\$UMASK \& 0666$ )`, so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero.

## 2.13. Perl Installation Notes

The Perl `DBI` module provides a generic interface for database access. You can write a `DBI` script that works with many different database engines without change. To use `DBI`, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the `DBD:mysql` module.

Perl, and the `DBD:mysql` module for `DBI` must be installed if you want to run the MySQL benchmark scripts; see [Section 8.12.2, “The MySQL Benchmark Suite”](#).

### Note

Perl support is not included with MySQL distributions. You can obtain the necessary modules from <http://search.cpan.org> for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

The `DBI/DBD` interface requires Perl 5.6.0, and 5.6.1 or later is preferred. `DBI` *does not work* if you have an older version of Perl. You should use `DBD:mysql` 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 5.6.

### 2.13.1. Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at <http://search.cpan.org>.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD:mysql
```

The `DBD:mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and `ODBC` on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD:mysql` to ignore the failed tests.

`DBI` requires the `Data:Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a `DBI` distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

```
shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

```
shell> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
shell> perl Makefile.PL
shell> make
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD:mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD:mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: <http://servers.digitaldaze.com/extensions/perl/modules.html#modules>

Look under the heading “Installing New Modules that Require Locally Installed Modules.”

## 2.13.2. Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from <http://www.activestate.com/Products/ActivePerl/> and install it.
2. Open a console window.
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
C:\> set HTTP_proxy=my.proxy.com:3128
```

4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

5. If you have not previously done so, install `DBI`:

```
ppm> install DBI
```

6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or newer.

If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn", $user, $password) ||
die "Got error $DBI::errstr when connecting to $dsn\n";
```

## 2.13.3. Problems Using the Perl `DBI/DBD` Interface

If Perl reports that it cannot find the `./mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).
- Modify the `-L` options used to compile `DBD:mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD:mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'  
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

---

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` [248] option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as [Chapter 5, MySQL Server Administration](#).)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

### 3.1. Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you will also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
```

```
Enter password: *****
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `*****` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: *****
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 5.6.12-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter commands.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of [Chapter 2, Installing and Upgrading MySQL](#) that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see [Section C.5.2, "Common Errors When Using MySQL Programs"](#).

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control+D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

## 3.2. Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering commands, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple command that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-----+-----+
```

```
| VERSION() | CURRENT_DATE |
+-----+-----+
| 5.6.1-m4-log | 2010-08-06 |
+-----+-----+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A command normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a command, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another command.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.
- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the "rows in set" line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-----+-----+
| SIN(PI()/4) | (4+1)*5 |
+-----+-----+
| 0.70710678118655 | 25 |
+-----+-----+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+-----+
| VERSION() |
+-----+
| 5.6.1-m4-log |
+-----+
1 row in set (0.00 sec)
+-----+
| NOW() |
+-----+
| 2010-08-06 12:17:13 |
+-----+
1 row in set (0.00 sec)
```

A command need not be given all on a single line, so lengthy commands that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
-> USER()
-> ,
-> CURRENT_DATE;
+-----+-----+
| USER()      | CURRENT_DATE |
+-----+-----+
| jon@localhost | 2010-08-06   |
+-----+-----+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a command that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
-> USER()
-> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new command.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

Prompt	Meaning
<code>mysql&gt;</code>	Ready for new command.
<code>-&gt;</code>	Waiting for next line of multiple-line command.
<code>'&gt;</code>	Waiting for next line, waiting for completion of a string that began with a single quote (“'”).
<code>"&gt;</code>	Waiting for next line, waiting for completion of a string that began with a double quote (“”).
<code>`&gt;</code>	Waiting for next line, waiting for completion of an identifier that began with a backtick (“`”).
<code>/*&gt;</code>	Waiting for next line, waiting for completion of a comment that began with <code>/*</code> .

Multiple-line statements commonly occur by accident when you intend to issue a command on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()
->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
-> ;
+-----+-----+
| USER()      |
+-----+-----+
| jon@localhost |
+-----+-----+
```

The `'>` and `">` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either “'” or “”” characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `">` prompt, it means that you have entered a line containing a string that begins with a “'” or “”” quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
'>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the command. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
'> '\c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new command.

The ``>` prompt is similar to the `'>` and `">` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `">`, and ``>` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current command.

### 3.3. Creating and Using a Database

Once you know how to enter commands, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It is available in both compressed `tar` file and Zip formats at <http://dev.mysql.com/doc/>.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| mysql    |
| test     |
| tmp      |
```

```
+-----+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See [Section 13.7.5.15, “SHOW DATABASES Syntax”](#).

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a command like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

### 3.3.1. Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

#### Note

If you get an error such as `ERROR 1044 (42000): Access denied for user 'monty'@'localhost' to database 'menagerie' when attempting to create a database`, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see [Section 6.2, “The MySQL Access Privilege System”](#).

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this command:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: *****
```

**Important**

`menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, not as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

**Note**

You can see at any time which database is currently selected using `SELECT DATABASE() [1268]`.

### 3.3.2. Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
-> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be `20`. You can normally pick any length from `1` to `65535`, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+-----+
| Tables in menagerie |
+-----+
| pet                |
+-----+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| name  | varchar(20) | YES |     | NULL    |       |
| owner | varchar(20) | YES |     | NULL    |       |
| species | varchar(20) | YES |     | NULL    |       |
| sex   | char(1)   | YES |     | NULL    |       |
| birth | date      | YES |     | NULL    |       |
| death | date      | YES |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see [Chapter 11, Data Types](#).

### 3.3.3. Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in `'YYYY-MM-DD'` format; this may be different from what you are used to.)

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	
Claws	Gwen	cat	m	1994-03-17	
Buffy	Harold	dog	f	1989-05-13	
Fang	Benny	dog	m	1990-08-27	
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	
Whistler	Gwen	bird		1997-12-09	
Slim	Benny	snake	m	1996-04-29	

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler      Gwen      bird      \N      1997-12-09      \N
```

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
-> LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See [Section 6.1.6, “Security Issues with `LOAD DATA LOCAL`”](#), for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
-> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

### 3.3.4. Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

*what\_to\_select* indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” *which\_table* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *conditions\_to\_satisfy* specifies one or more conditions that rows must satisfy to qualify for retrieval.

#### 3.3.4.1. Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL
Fang	Benny	dog	m	1990-08-27	NULL
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL
Puffball	Diane	hamster	f	1999-03-30	NULL

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser

doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The `UPDATE` changes only the record in question and does not require you to reload the table.

### 3.3.4.2. Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+-----+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Bowser | Diane | dog      | m   | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+-----+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+-----+-----+-----+-----+-----+-----+
| name      | owner | species | sex | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Chirpy    | Gwen  | bird    | f   | 1998-09-11 | NULL       |
| Puffball  | Diane | hamster | f   | 1999-03-30 | NULL       |
+-----+-----+-----+-----+-----+-----+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-----+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Buffy | Harold | dog      | f   | 1989-05-13 | NULL       |
+-----+-----+-----+-----+-----+-----+
```

The preceding query uses the `AND` [1171] logical operator. There is also an `OR` [1172] operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
+-----+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth      | death      |
+-----+-----+-----+-----+-----+-----+
```

Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL

**AND** [1171] and **OR** [1172] may be intermixed, although **AND** [1171] has higher precedence than **OR** [1172]. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
-> OR (species = 'dog' AND sex = 'f');
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

### 3.3.4.3. Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the `name` and `birth` columns:

```
mysql> SELECT name, birth FROM pet;
```

name	birth
Fluffy	1993-02-04
Claws	1994-03-17
Buffy	1989-05-13
Fang	1990-08-27
Bowser	1989-08-31
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Puffball	1999-03-30

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
```

owner
Harold
Gwen
Harold
Benny
Diane
Gwen
Gwen
Benny
Diane

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword **DISTINCT**:

```
mysql> SELECT DISTINCT owner FROM pet;
```

owner
Benny
Diane
Gwen
Harold

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
-> WHERE species = 'dog' OR species = 'cat';
```

name	species	birth
Fluffy	cat	1993-02-04
Claws	cat	1994-03-17
Buffy	dog	1989-05-13
Fang	dog	1990-08-27
Bowser	dog	1989-08-31

### 3.3.4.4. Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
```

name	birth
Buffy	1989-05-13
Bowser	1989-08-31
Fang	1990-08-27
Fluffy	1993-02-04
Claws	1994-03-17
Slim	1996-04-29
Whistler	1997-12-09
Chirpy	1998-09-11
Puffball	1999-03-30

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY [1244]` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
```

name	birth
Puffball	1999-03-30
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Claws	1994-03-17
Fluffy	1993-02-04
Fang	1990-08-27
Bowser	1989-08-31
Buffy	1989-05-13

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
-> ORDER BY species, birth DESC;
```

name	species	birth
Chirpy	bird	1998-09-11
Whistler	bird	1997-12-09
Claws	cat	1994-03-17
Fluffy	cat	1993-02-04
Fang	dog	1990-08-27
Bowser	dog	1989-08-31
Buffy	dog	1989-05-13
Puffball	hamster	1999-03-30
Slim	snake	1996-04-29

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

### 3.3.4.5. Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the `TIMESTAMPDIFF()` [1224] function. Its arguments are the unit in which you want the result expressed, and the two date for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An *alias* (`age`) is used to make the final output column label more meaningful.

```
mysql> SELECT name, birth, CURDATE(),
->   TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
->   FROM pet;
```

name	birth	CURDATE()	age
Fluffy	1993-02-04	2003-08-19	10
Claws	1994-03-17	2003-08-19	9
Buffy	1989-05-13	2003-08-19	14
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Chirpy	1998-09-11	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Puffball	1999-03-30	2003-08-19	4

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
->   TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
->   FROM pet ORDER BY name;
```

name	birth	CURDATE()	age
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14
Chirpy	1998-09-11	2003-08-19	4
Claws	1994-03-17	2003-08-19	9
Fang	1990-08-27	2003-08-19	12
Fluffy	1993-02-04	2003-08-19	10
Puffball	1999-03-30	2003-08-19	4
Slim	1996-04-29	2003-08-19	7
Whistler	1997-12-09	2003-08-19	5

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
->   TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
->   FROM pet ORDER BY age;
```

name	birth	CURDATE()	age
Chirpy	1998-09-11	2003-08-19	4
Puffball	1999-03-30	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Claws	1994-03-17	2003-08-19	9
Fluffy	1993-02-04	2003-08-19	10
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```
mysql> SELECT name, birth, death,
-> TIMESTAMPDIFF(YEAR,birth,death) AS age
-> FROM pet WHERE death IS NOT NULL ORDER BY age;
```

name	birth	death	age
Bowser	1989-08-31	1995-07-29	5

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See [Section 3.3.4.6, “Working with NULL Values”](#).

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()` [1229], `MONTH()` [1220], and `DAYOFMONTH()` [1217]. `MONTH()` [1220] is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)` [1220]:

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

name	birth	MONTH(birth)
Fluffy	1993-02-04	2
Claws	1994-03-17	3
Buffy	1989-05-13	5
Fang	1990-08-27	8
Bowser	1989-08-31	8
Chirpy	1998-09-11	9
Whistler	1997-12-09	12
Slim	1996-04-29	4
Puffball	1999-03-30	3

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is `4` and you can look for animals born in May (month `5`) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
```

name	birth
Buffy	1989-05-13

There is a small complication if the current month is December. You cannot merely add one to the month number (`12`) and look for animals born in month `13`, because there is no such month. Instead, you look for animals born in January (month `1`).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` [1213] enables you to add a time interval to

a given date. If you add a month to the value of `CURDATE()` [1212], then extract the month part with `MONTH()` [1220], the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
  -> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to 0 if it is currently 12:

```
mysql> SELECT name, birth FROM pet
  -> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` [1220] returns a number between 1 and 12. And `MOD(something,12)` [1205] returns a number between 0 and 11. So the addition has to be after the `MOD()` [1205], otherwise we would go from November (11) to January (1).

### 3.3.4.6. Working with `NULL` Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing unknown value” and it is treated somewhat differently from other values.

To test for `NULL`, use the `IS NULL` [1168] and `IS NOT NULL` [1168] operators, as shown here:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----+-----+
| 1 IS NULL | 1 IS NOT NULL |
+-----+-----+
|          0 |                1 |
+-----+-----+
```

You cannot use arithmetic comparison operators such as `=` [1166], `<` [1167], or `<>` [1167] to test for `NULL`. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+-----+-----+-----+-----+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+-----+-----+-----+-----+
|        NULL |        NULL |        NULL |        NULL |
+-----+-----+-----+-----+
```

Because the result of any arithmetic comparison with `NULL` is also `NULL`, you cannot obtain any meaningful results from such comparisons.

In MySQL, 0 or `NULL` means false and anything else means true. The default truth value from a boolean operation is 1.

This special treatment of `NULL` is why, in the previous section, it was necessary to determine which animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means “not having a value.” You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----+-----+-----+-----+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----+-----+-----+-----+
|          0 |                1 |          0 |                1 |
+-----+-----+-----+-----+
```

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are in fact `NOT NULL`. See [Section C.5.5.3, “Problems with NULL Values”](#).

### 3.3.4.7. Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching enables you to use “`_`” to match any single character and “`%`” to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. You do not use `=` or `<>` when you use SQL patterns; use the `LIKE [1190]` or `NOT LIKE [1192]` comparison operators instead.

To find names beginning with “`b`”:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29

To find names ending with “`fy`”:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a “`w`”:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

To find names containing exactly five characters, use five instances of the “`_`” pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the `REGEXP [1193]` and `NOT REGEXP [1193]` operators (or `RLIKE [1193]` and `NOT RLIKE [1193]`, which are synonyms).

The following list describes some characteristics of extended regular expressions:

- “`.`” matches any single character.
- A character class “[`...`]” matches any character within the brackets. For example, “[`abc`]” matches “`a`”, “`b`”, or “`c`”. To name a range of characters, use a dash. “[`a-z`]” matches any letter, whereas “[`0-9`]” matches any digit.

- “`*`” matches zero or more instances of the thing preceding it. For example, “`x*`” matches any number of “`x`” characters, “`[0-9]*`” matches any number of digits, and “`.*`” matches any number of anything.
- A [REGEXP \[1193\]](#) pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a [LIKE \[1190\]](#) pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use “`^`” at the beginning or “`$`” at the end of the pattern.

To demonstrate how extended regular expressions work, the [LIKE \[1190\]](#) queries shown previously are rewritten here to use [REGEXP \[1193\]](#).

To find names beginning with “`b`”, use “`^`” to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29

If you really want to force a [REGEXP \[1193\]](#) comparison to be case sensitive, use the [BINARY \[1244\]](#) keyword to make one of the strings a binary string. This query matches only lowercase “`b`” at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with “`fy`”, use “`$`” to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a “`w`”, use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use “`^`” and “`$`” to match the beginning and end of the name, and five instances of “`.`” in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

You could also write the previous query using the `{n}` (“repeat-*n*-times”) operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

Section 12.5.2, “Regular Expressions”, provides more information about the syntax for regular expressions.

### 3.3.4.8. Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the `pet` table?” because there is one record per pet. `COUNT(*)` [1283] counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
```

COUNT(*)
9

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` [1283] if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
```

owner	COUNT(*)
Benny	2
Diane	2
Gwen	3
Harold	2

The preceding query uses `GROUP BY` to group all records for each `owner`. The use of `COUNT()` [1283] in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
```

species	COUNT(*)
bird	2
cat	2
dog	3
hamster	1
snake	1

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
```

sex	COUNT(*)
NULL	1
f	4
m	4

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	NULL	1
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1

You need not retrieve an entire table when you use `COUNT()` [1283]. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE species = 'dog' OR species = 'cat'
-> GROUP BY species, sex;
```

species	sex	COUNT(*)
cat	f	1
cat	m	1
dog	f	1
dog	m	2

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE sex IS NOT NULL
-> GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1

If you name columns to select in addition to the `COUNT()` [1283] value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` [606] SQL mode is enabled, an error occurs:

```
mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT()...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

- If `ONLY_FULL_GROUP_BY` [606] is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is indeterminate. The server is free to select the value from any row:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
```

```

+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Harold |      8 |
+-----+-----+
1 row in set (0.00 sec)

```

See also [Section 12.17.3, “MySQL Extensions to GROUP BY”](#).

### 3.3.4.9. Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```

mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
-> type VARCHAR(15), remark VARCHAR(255));

```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

name	date	type	remark
Fluffy	1995-05-15	litter	4 kittens, 3 female, 1 male
Buffy	1993-06-23	litter	5 puppies, 2 female, 3 male
Buffy	1994-06-19	litter	3 puppies, 3 female
Chirpy	1999-03-21	vet	needed beak straightened
Slim	1997-08-03	vet	broken rib
Bowser	1991-10-12	kennel	
Fang	1991-10-12	kennel	
Fang	1998-08-28	birthday	Gave him a new chew toy
Claws	1998-03-17	birthday	Gave him a new flea collar
Whistler	1998-12-09	birthday	First birthday

Load the records like this:

```

mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;

```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```

mysql> SELECT pet.name,
-> (YEAR(date)-YEAR(birth)) - (RIGHT(date,5)<RIGHT(birth,5)) AS age,

```

```

-> remark
-> FROM pet INNER JOIN event
->   ON pet.name = event.name
-> WHERE event.type = 'litter';
+-----+-----+-----+
| name  | age  | remark                                     |
+-----+-----+-----+
| Fluffy | 2    | 4 kittens, 3 female, 1 male             |
| Buffy  | 4    | 5 puppies, 2 female, 3 male             |
| Buffy  | 5    | 3 puppies, 3 female                       |
+-----+-----+-----+

```

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of males and females of like species:

```

mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
-> FROM pet AS p1 INNER JOIN pet AS p2
->   ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
+-----+-----+-----+-----+-----+
| name  | sex  | name  | sex  | species |
+-----+-----+-----+-----+-----+
| Fluffy | f    | Claws | m    | cat     |
| Buffy  | f    | Fang  | m    | dog     |
| Buffy  | f    | Bowser | m    | dog     |
+-----+-----+-----+-----+-----+

```

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

### 3.4. Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` [1268] function:

```

mysql> SELECT DATABASE();
+-----+
| DATABASE() |
+-----+
| menagerie  |
+-----+

```

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this command:

```
mysql> SHOW TABLES;
+-----+
| Tables_in_menagerie |
+-----+
| event                |
| pet                  |
+-----+
```

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See [Section 13.7.5.38, “SHOW TABLES Syntax”](#), for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| name  | varchar(20)   | YES  |     | NULL    |       |
| owner | varchar(20)   | YES  |     | NULL    |       |
| species | varchar(20)  | YES  |     | NULL    |       |
| sex   | char(1)       | YES  |     | NULL    |       |
| birth | date          | YES  |     | NULL    |       |
| death | date          | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

`Field` indicates the column name, `Type` is the data type for the column, `NULL` indicates whether the column can contain `NULL` values, `Key` indicates whether the column is indexed, and `Default` specifies the column's default value. `Extra` displays special information about columns: If a column was created with the `AUTO_INCREMENT` option, the value will be `auto_increment` rather than empty.

`DESC` is a short form of `DESCRIBE`. See [Section 13.8.1, “DESCRIBE Syntax”](#), for more information.

You can obtain the `CREATE TABLE` statement necessary to create an existing table using the `SHOW CREATE TABLE` statement. See [Section 13.7.5.12, “SHOW CREATE TABLE Syntax”](#).

If you have indexes on a table, `SHOW INDEX FROM tbl_name` produces information about them. See [Section 13.7.5.23, “SHOW INDEX Syntax”](#), for more about this statement.

## 3.5. Using `mysql` in Batch Mode

In the previous sections, you used `mysql` interactively to enter queries and view the results. You can also run `mysql` in batch mode. To do this, put the commands you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: *****
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` [250] command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line commands or multiple-statement sequences of commands. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
shell> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
shell> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the commands.
- Some situations do not allow for interactive use, for example, when you run a query from a `cron` job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+-----+
| species |
+-----+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+-----+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the commands that are executed, use `mysql -vvv`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

See [Section 4.5.1.5, "Executing SQL Statements from a Text File"](#), for more information.

## 3.6. Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database named `test`).

You can create and populate the example table with these statements:

```
CREATE TABLE shop (
  article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
  dealer CHAR(20) DEFAULT '' NOT NULL,
  price DOUBLE(16,2) DEFAULT '0.00' NOT NULL,
  PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
  (1, 'A', 3.45), (1, 'B', 3.99), (2, 'A', 10.99), (3, 'B', 1.45),
  (3, 'C', 1.69), (3, 'D', 1.25), (4, 'D', 19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop;
```

article	dealer	price
0001	A	3.45
0001	B	3.99
0002	A	10.99
0003	B	1.45
0003	C	1.69
0003	D	1.25
0004	D	19.95

### 3.6.1. The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;
```

article
4

### 3.6.2. The Row Holding the Maximum of a Certain Column

*Task: Find the number, dealer, and price of the most expensive article.*

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM shop
WHERE price=(SELECT MAX(price) FROM shop);
```

article	dealer	price
0004	D	19.95

Other solutions are to use a `LEFT JOIN` or to sort all rows descending by price and get only the first row using the MySQL-specific `LIMIT` clause:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;
```

```
SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

**Note**

If there were several most expensive articles, each with a price of 19.95, the `LIMIT` solution would show only one of them.

### 3.6.3. Maximum of Column per Group

*Task: Find the highest price per article.*

```
SELECT article, MAX(price) AS price
FROM shop
GROUP BY article;
```

```
+-----+-----+
| article | price |
+-----+-----+
|    0001 |   3.99 |
|    0002 |  10.99 |
|    0003 |   1.69 |
|    0004 |  19.95 |
+-----+-----+
```

### 3.6.4. The Rows Holding the Group-wise Maximum of a Certain Column

*Task: For each article, find the dealer or dealers with the most expensive price.*

This problem can be solved with a subquery like this one:

```
SELECT article, dealer, price
FROM shop s1
WHERE price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article);
```

```
+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
|    0001 | B      |   3.99 |
|    0002 | A      |  10.99 |
|    0003 | C      |   1.69 |
|    0004 | D      |  19.95 |
+-----+-----+-----+
```

The preceding example uses a correlated subquery, which can be inefficient (see [Section 13.2.10.7, "Correlated Subqueries"](#)). Other possibilities for solving the problem are to use an uncorrelated subquery in the `FROM` clause or a `LEFT JOIN`.

Uncorrelated subquery:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (
  SELECT article, MAX(price) AS price
  FROM shop
  GROUP BY article) AS s2
ON s1.article = s2.article AND s1.price = s2.price;
```

`LEFT JOIN`:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL;
```

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and the `s2` rows values will be `NULL`. See [Section 13.2.9.2, “JOIN Syntax”](#).

### 3.6.5. Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See [Section 9.4, “User-Defined Variables”](#).)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0003   | D     | 1.25  |
| 0004   | D     | 19.95 |
+-----+-----+-----+
```

#### Note

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See [Section 13.5, “SQL Syntax for Prepared Statements”](#), for more information.

### 3.6.6. Using Foreign Keys

In MySQL, `InnoDB` tables support checking of foreign key constraints. See [Section 14.2, “The InnoDB Storage Engine”](#), and [Section 1.8.5.4, “Foreign Key Differences”](#).

A foreign key constraint is not required merely to join two tables. For storage engines other than `InnoDB`, it is possible when defining a column to use a `REFERENCES tbl_name(col_name)` clause, which has no actual effect, and *serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table*. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of `CHECK` to make sure that `col_name` actually exists in `tbl_name` (or even that `tbl_name` itself exists).
- MySQL does not perform any sort of action on `tbl_name` such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON DELETE` or `ON UPDATE` behavior whatsoever. (Although you can write an `ON DELETE` or `ON UPDATE` clause as part of the `REFERENCES` clause, it is also ignored.)
- This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
  name CHAR(60) NOT NULL,
  PRIMARY KEY (id)
);

CREATE TABLE shirt (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
  style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
  color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
  owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
  PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');
```

```

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+-----+-----+
| id | name                |
+-----+-----+
|  1 | Antonio Paz         |
|  2 | Lilliana Angelovska |
+-----+-----+

SELECT * FROM shirt;
+-----+-----+-----+-----+
| id | style | color | owner |
+-----+-----+-----+-----+
|  1 | polo  | blue  | 1     |
|  2 | dress | white | 1     |
|  3 | t-shirt | blue  | 1     |
|  4 | dress | orange | 2     |
|  5 | polo  | red   | 2     |
|  6 | dress | blue  | 2     |
|  7 | t-shirt | white | 2     |
+-----+-----+-----+-----+

SELECT s.* FROM person p INNER JOIN shirt s
ON s.owner = p.id
WHERE p.name LIKE 'Lilliana%'
AND s.color <> 'white';

+-----+-----+-----+-----+
| id | style | color | owner |
+-----+-----+-----+-----+
|  4 | dress | orange | 2     |
|  5 | polo  | red   | 2     |
|  6 | dress | blue  | 2     |
+-----+-----+-----+-----+

```

When used in this fashion, the [REFERENCES](#) clause is not displayed in the output of `SHOW CREATE TABLE` or `DESCRIBE`:

```

SHOW CREATE TABLE shirt\G
***** 1. row *****
Table: shirt
Create Table: CREATE TABLE `shirt` (
  `id` smallint(5) unsigned NOT NULL auto_increment,
  `style` enum('t-shirt','polo','dress') NOT NULL,
  `color` enum('red','blue','orange','white','black') NOT NULL,
  `owner` smallint(5) unsigned NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1

```

The use of [REFERENCES](#) in this way as a comment or “reminder” in a column definition works with [MyISAM](#) tables.

### 3.6.7. Searching on Two Keys

An `OR` [1172] using a single key is well optimized, as is the handling of `AND` [1171].

The one tricky case is that of searching on two different keys combined with `OR` [1172]:

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR field2_index = '1'
```

This case is optimized. See [Section 8.13.2, “Index Merge Optimization”](#).

You can also solve the problem efficiently by using a `UNION` that combines the output of two separate `SELECT` statements. See [Section 13.2.9.4, “UNION Syntax”](#).

Each `SELECT` searches only one key and can be optimized:

```
SELECT field1_index, field2_index
FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
FROM test_table WHERE field2_index = '1';
```

### 3.6.8. Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
                 day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
                    (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
GROUP BY year,month;
```

Which returns:

```
+-----+-----+-----+
| year | month | days |
+-----+-----+-----+
| 2000 |    01 |    3 |
| 2000 |    02 |    2 |
+-----+-----+-----+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

### 3.6.9. Using `AUTO_INCREMENT`

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
  PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
  ('dog'),('cat'),('penguin'),
  ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```
+-----+-----+
| id | name |
+-----+-----+
| 1 | dog |
| 2 | cat |
| 3 | penguin |
| 4 | lax |
| 5 | whale |
| 6 | ostrich |
+-----+-----+
```

No value was specified for the `AUTO_INCREMENT` column, so MySQL assigned sequence numbers automatically. You can also explicitly assign `NULL` or 0 to the column to generate sequence numbers.

You can retrieve the most recent `AUTO_INCREMENT` value with the `LAST_INSERT_ID()` [1269] SQL function or the `mysql_insert_id()` C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the `AUTO_INCREMENT` column that is large enough to hold the maximum sequence value you will need. When the column reaches the upper limit of the data type, the next attempt to generate a sequence number fails. Use the `UNSIGNED` attribute if possible to allow a greater range. For example, if you use `TINYINT`, the maximum permissible sequence number is 127. For `TINYINT UNSIGNED`, the maximum is 255. See Section 11.2.1, “Integer Types (Exact Value) - `INTEGER`, `INT`, `SMALLINT`, `TINYINT`, `MEDIUMINT`, `BIGINT`” for the ranges of all the integer types.

#### Note

For a multiple-row insert, `LAST_INSERT_ID()` [1269] and `mysql_insert_id()` actually return the `AUTO_INCREMENT` key from the *first* of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL generates sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

To start with an `AUTO_INCREMENT` value other than 1, set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

## InnoDB Notes

For `InnoDB` tables, be careful if you modify the column containing the auto-increment value in the middle of a sequence of `INSERT` statements. For example, if you use an `UPDATE` statement to put a new, larger value in the auto-increment column, a subsequent `INSERT` could encounter a “Duplicate entry” error. The test whether an auto-increment value is already present occurs if you do a `DELETE` followed by more `INSERT` statements, or when you `COMMIT` the transaction, but not after an `UPDATE` statement.

## MyISAM Notes

For `MyISAM` tables, you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix` [1284]. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
  grp ENUM('fish','mammal','bird') NOT NULL,
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
```

```

PRIMARY KEY (grp,id)
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
  ('mammal','dog'),('mammal','cat'),
  ('bird','penguin'),('fish','lax'),('mammal','whale'),
  ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;

```

Which returns:

```

+-----+-----+-----+
| grp   | id  | name  |
+-----+-----+-----+
| fish  | 1   | lax   |
| mammal| 1   | dog   |
| mammal| 2   | cat   |
| mammal| 3   | whale |
| bird  | 1   | penguin|
| bird  | 2   | ostrich|
+-----+-----+-----+

```

In this case (when the [AUTO\\_INCREMENT](#) column is part of a multiple-column index), [AUTO\\_INCREMENT](#) values are reused if you delete the row with the biggest [AUTO\\_INCREMENT](#) value in any group. This happens even for [MyISAM](#) tables, for which [AUTO\\_INCREMENT](#) values normally are not reused.

## Further Reading

More information about [AUTO\\_INCREMENT](#) is available here:

- How to assign the [AUTO\\_INCREMENT](#) attribute to a column: [Section 13.1.14](#), “[CREATE TABLE Syntax](#)”, and [Section 13.1.6](#), “[ALTER TABLE Syntax](#)”.

- Server-system variables related to [AUTO\\_INCREMENT](#) ([auto\\_increment\\_increment \[1965\]](#) and [auto\\_increment\\_offset \[1968\]](#)) that can be used for replication: [Section 5.1.4](#), “[Server System Variables](#)”.

## 3.7. Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```

LogFormat \
  "%h" "%Y%m%d%H%M%S"t,%>s,"%b",\ "%{Content-Type}o", \
  \"%U\", \"%{Referer}i\", \"%{User-Agent}i\"

```

To load a log file in that format into MySQL, you can use a statement something like this:

```

LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\

```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

4.8.3. <code>resolveip</code> — Resolve Host name to IP Address or Vice Versa .....	377

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

## 4.1. Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one. Each program's description indicates its invocation syntax and the options that it supports.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see [Chapter 2, \*Installing and Upgrading MySQL\*](#), for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See [Section 4.2, "Using MySQL Programs"](#), for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See [Section 4.3.1, "mysqld — The MySQL Server"](#).

- `mysqld_safe`

A server startup script. `mysqld_safe` attempts to start `mysqld`. See [Section 4.3.2, "mysqld\\_safe — MySQL Server Startup Script"](#).

- `mysql.server`

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See [Section 4.3.3, "mysql.server — MySQL Server Startup Script"](#).

- `mysqld_multi`

A server startup script that can start or stop multiple servers installed on the system. See [Section 4.3.4, "mysqld\\_multi — Manage Multiple MySQL Servers"](#).

Several programs perform setup operations during MySQL installation or upgrading:

- `comp_err`

This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See [Section 4.4.1, "comp\\_err — Compile MySQL Error Message File"](#).

- `mysql_install_db`

This script creates the MySQL database, initializes the grant tables with default privileges, and sets up the [InnoDB system tablespace](#). It is usually executed only once, when first installing MySQL on a system. See [Section 4.4.3, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#), [Section 2.10.1, “Unix Postinstallation Procedures”](#), and [Section 4.4.3, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#).

- `mysql_plugin`

This program configures MySQL server plugins. See [Section 4.4.4, “mysql\\_plugin — Configure MySQL Server Plugins”](#).

- `mysql_secure_installation`

This program enables you to improve the security of your MySQL installation. SQL. See [Section 4.4.5, “mysql\\_secure\\_installation — Improve MySQL Installation Security”](#).

- `mysql_tzinfo_to_sql`

This program loads the time zone tables in the `mysql` database using the contents of the host system `zoneinfo` database (the set of files describing time zones). SQL. See [Section 4.4.6, “mysql\\_tzinfo\\_to\\_sql — Load the Time Zone Tables”](#).

- `mysql_upgrade`

This program is used after a MySQL upgrade operation. It checks tables for incompatibilities and repairs them if necessary, and updates the grant tables with any changes that have been made in newer versions of MySQL. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

MySQL client programs that connect to the MySQL server:

- `mysql`

The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

- `mysqladmin`

A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

- `mysqlcheck`

A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#).

- `mysqldump`

A client that dumps a MySQL database into a file as SQL, text, or XML. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

- `mysqlimport`

A client that imports text files into their respective tables using `LOAD DATA INFILE`. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

- `mysqlshow`

A client that displays information about databases, tables, columns, and indexes. See [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

- `mysqlslap`

A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See [Section 4.5.7, “mysqlslap — Load Emulation Client”](#).

MySQL administrative and utility programs:

- `innochecksum`

An offline InnoDB offline file checksum utility. See [Section 4.6.1, “innochecksum — Offline InnoDB File Checksum Utility”](#).

- `myisam_ftdump`

A utility that displays information about full-text indexes in MyISAM tables. See [Section 4.6.2, “myisam\\_ftdump — Display Full-Text Index information”](#).

- `myisamchk`

A utility to describe, check, optimize, and repair MyISAM tables. See [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

- `myisamlog`

A utility that processes the contents of a MyISAM log file. See [Section 4.6.4, “myisamlog — Display MyISAM Log File Contents”](#).

- `myisampack`

A utility that compresses MyISAM tables to produce smaller read-only tables. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

- `mysql_config_editor`

A utility that enables you to store authentication credentials in a secure, encrypted login file named `.mylogin.cnf`. See [Section 4.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).

- `mysqlaccess`

A script that checks the access privileges for a host name, user name, and database combination. See [Section 4.6.7, “mysqlaccess — Client for Checking Access Privileges”](#).

- `mysqlbinlog`

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

- `mysqldumpslow`

A utility to read and summarize the contents of a slow query log. See [Section 4.6.9, “mysqldumpslow — Summarize Slow Query Log Files”](#).

- `mysqlhotcopy`

A utility that quickly makes backups of MyISAM tables while the server is running. See [Section 4.6.10, “mysqlhotcopy — A Database Backup Program”](#).

- `mysql_convert_table_format`

A utility that converts tables in a database to use a given storage engine. See [Section 4.6.11, “mysql\\_convert\\_table\\_format — Convert Tables to Use a Given Storage Engine”](#).

- `mysql_find_rows`

A utility that reads files containing SQL statements (such as update logs) and extracts statements that match a given regular expression. See [Section 4.6.12, “mysql\\_find\\_rows — Extract SQL Statements from Files”](#).

- `mysql_fix_extensions`

A utility that converts the extensions for `MyISAM` table files to lowercase. This can be useful after transferring the files from a system with case-insensitive file names to a system with case-sensitive file names. See [Section 4.6.13, “mysql\\_fix\\_extensions — Normalize Table File Name Extensions”](#).

- `mysql_setpermission`

A utility for interactively setting permissions in the MySQL grant tables. See [Section 4.6.14, “mysql\\_setpermission — Interactively Set Permissions in Grant Tables”](#).

- `mysql_waitpid`

A utility that kills the process with a given process ID. See [Section 4.6.15, “mysql\\_waitpid — Kill Process and Wait for Its Termination”](#).

- `mysql_zap`

A utility that kills processes that match a pattern. See [Section 4.6.16, “mysql\\_zap — Kill Processes That Match a Pattern”](#).

MySQL program-development utilities:

- `msql2mysql`

A shell script that converts `mSQL` programs to MySQL. It doesn't handle every case, but it gives a good start when converting. See [Section 4.7.1, “msql2mysql — Convert mSQL Programs for Use with MySQL”](#).

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs. See [Section 4.7.2, “mysql\\_config — Display Options for Compiling Clients”](#).

- `my_print_defaults`

A utility that shows which options are present in option groups of option files. See [Section 4.7.3, “my\\_print\\_defaults — Display Options from Option Files”](#).

- `resolve_stack_dump`

A utility program that resolves a numeric stack trace dump to symbols. See [Section 4.7.4, “resolve\\_stack\\_dump — Resolve Numeric Stack Trace Dump to Symbols”](#).

Miscellaneous utilities:

- `perror`

A utility that displays the meaning of system or MySQL error codes. See [Section 4.8.1, “perror — Explain Error Codes”](#).

- `replace`

A utility program that performs string replacement in the input text. See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

- `resolveip`

A utility program that resolves a host name to an IP address or vice versa. See [Section 4.8.3, “resolveip — Resolve Host name to IP Address or Vice Versa”](#).

Oracle Corporation also provides the [MySQL Workbench](#) GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL. Additional GUI tools include [MySQL Notifier for Microsoft Windows](#) and [MySQL for Excel](#).

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

Environment Variable	Meaning
<code>MYSQL_UNIX_PORT</code>	The default Unix socket file; used for connections to <code>localhost</code>
<code>MYSQL_TCP_PORT</code>	The default port number; used for TCP/IP connections
<code>MYSQL_PWD</code>	The default password
<code>MYSQL_DEBUG</code>	Debug trace options when debugging
<code>TMPDIR</code>	The directory where temporary tables and files are created

For a full list of environment variables used by MySQL programs, see [Section 2.12, “Environment Variables”](#).

Use of `MYSQL_PWD` is insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

## 4.2. Using MySQL Programs

### 4.2.1. Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. “`shell>`” represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh`, `ksh`, or `bash`, `%` for `csch` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (“-”, “--”) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in [Section 4.2.3, “Specifying Program Options”](#).

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nonoption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host [211]` (or `-h`), `--user [212]` (or `-u`), and `--password [211]` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options;

they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port [211]` (or `-P`) to specify a TCP/IP port number and `--socket [211]` (or `-S`) to specify a Unix socket file on Unix (or named pipe name on Windows). For more information on options that specify connection options, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in [Section 4.2.4, “Setting Environment Variables”](#).) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

## 4.2.2. Connecting to the MySQL Server

For a client program to be able to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override them as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any connection parameters explicitly:

```
shell> mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent if neither `-p` nor `--password [211]` is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. If there is no such option, `mysql` does not select a default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line:

```
shell> mysql --host=localhost --user=myname --password=mypass mydb
shell> mysql -h localhost -u myname -pmypass mydb
```

For password options, the password value is optional:

- If you use a `-p` or `--password [211]` option and specify the password value, there must be *no space* between `-p` or `--password= [211]` and the password following it.
- If you use a `-p` or `--password [211]` option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Other users on your system may be able to see a password specified on the command line by executing a command such as `ps auxw`. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

As just mentioned, including the password value on the command line can be a security risk. To avoid this problem, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --host=localhost --user=myname --password mydb
shell> mysql -h localhost -u myname -p mydb
```

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file. This occurs even if a `--port [211]` or `-P` option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use `--host [211]` or `-h` to specify a host name value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=TCP [211]` option. For example:

```
shell> mysql --host=127.0.0.1
shell> mysql --protocol=TCP
```

The `--protocol [211]` option enables you to establish a particular type of connection even when the other options would normally default to some other protocol.

If the server is configured to accept IPv6 connections, client can connect over IPv6 using `--host>:::1 [211]`. See [Section 5.1.9, "IPv6 Support"](#).

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the `--pipe [211]` or `--protocol=PIPE [211]` option, or by specifying `.` (period) as the host name. If named-pipe connections are not enabled, an error occurs. Use the `--socket [211]` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers always use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
shell> mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port [211]` or `-P` option:

```
shell> mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix will use a socket file by default. You will need to force a TCP/IP connection as already described or any option that specifies a port number will be ignored.

For this command, the program uses a socket file on Unix and the `--port [211]` option is ignored:

```
shell> mysql --port=13306 --host=localhost
```

To cause the port number to be used, invoke the program in either of these ways:

```
shell> mysql --port=13306 --host=127.0.0.1
shell> mysql --port=13306 --protocol=TCP
```

The following list summarizes the options that can be used to control how client programs connect to the server:

- `--host=host_name [211], -h host_name`

The host where the server is running. The default value is `localhost`.

- `--password[=pass_val] [211], -p[pass_val]`

The password of the MySQL account. As described earlier, the password value is optional, but if given, there must be *no space* between `-p` or `--password=` [211] and the password following it. The default is to send no password.

- `--pipe [211], -W`

On Windows, connect to the server using a named pipe. The server must be started with the `--enable-named-pipe` [421] option to enable named-pipe connections.

- `--port=port_num [211], -P port_num`

The port number to use for the connection, for connections made using TCP/IP. The default port number is 3306.

- `--protocol={TCP|SOCKET|PIPE|MEMORY} [211]`

This option explicitly specifies a protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

```
shell> mysql --host=localhost
```

To force a TCP/IP connection to be used instead, specify a `--protocol` [211] option:

```
shell> mysql --host=localhost --protocol=TCP
```

The following table shows the permissible `--protocol` [211] option values and indicates the platforms on which each value may be used. The values are not case sensitive.

<code>--protocol</code> [211] Value	Connection Protocol	Permissible Operating Systems
TCP	TCP/IP connection to local or remote server	All
SOCKET	Unix socket file connection to local server	Unix only
PIPE	Named-pipe connection to local or remote server	Windows only
MEMORY	Shared-memory connection to local server	Windows only

- `--shared-memory-base-name=name [211]`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` [439] option to enable shared-memory connections.

- `--socket=file_name [211], -S file_name`

On Unix, the name of the Unix socket file to use, for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

On Windows, the name of the named pipe to use, for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case sensitive.

The server must be started with the `--enable-named-pipe` [421] option to enable named-pipe connections.

- `--ssl*`

Options that begin with `--ssl` [810] are used for establishing a secure connection to the server using SSL, if the server is configured with SSL support. For details, see [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name` [212], `-u user_name`

The user name of the MySQL account you want to use. The default user name is `ODBC` on Windows or your Unix login name on Unix.

It is possible to specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=your_pass
```

[Section 4.2.3.3, “Using Option Files”](#), discusses option files further.

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL user name can be specified using `USER` (this is for Windows only). The password can be specified using `MYSQL_PWD`, although this is insecure; see [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). For a list of variables, see [Section 2.12, “Environment Variables”](#).

### 4.2.3. Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables (see [Section 4.2.4, “Setting Environment Variables”](#)). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but [Section 5.6.3, “Running Multiple MySQL Instances on Unix”](#), discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
shell> mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
shell> mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by reading option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

An option can be specified by writing it in full or as any unambiguous prefix. For example, the `--compress` [284] option can be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous:

```
shell> mysqldump --comp
mysqldump: ambiguous option '--comp' (compatible, compress)
```

Be aware that the use of option prefixes can cause problems in the event that new options are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

### 4.2.3.1. Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` [211] indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an “=” sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` [211] or as `--password` [211]. In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
shell> mysql -ptest
shell> mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (“-”) and underscore (“\_”) may be used interchangeably. For example, `--skip-grant-tables` [439] and `--skip_grant_tables` [439] are equivalent. (However, the leading dashes cannot be given as underscores.)
- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024<sup>2</sup> or 1024<sup>3</sup>. For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
mysql> mysqladmin --count=1K --sleep=10 ping
```

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` [250] (or `-e`) option can be used with `mysql` to pass SQL statements to the server.

When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

```
mysql> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
Enter password: *****
+-----+-----+
| User | Host |
+-----+-----+
| root | gigan |
| root | gigan |
| jon  | localhost |
| root | localhost |
+-----+-----+
shell>
```

Note that the long form (`--execute [250]`) is followed by an equals sign (=).

If you wish to use quoted values within a statement, you will either need to escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

Multiple SQL statements may be passed in the option value on the command line, separated by semicolons:

```
shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: *****
+-----+
| VERSION() |
+-----+
| 5.1.5-alpha-log |
+-----+
+-----+
| NOW() |
+-----+
| 2006-01-05 21:19:04 |
+-----+
```

### 4.2.3.2. Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names [249]` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
--column-names=1
```

As of MySQL 5.6.2, the values `ON`, `TRUE`, `OFF`, and `FALSE` are also recognized for boolean options (not case sensitive).

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

`mysqld` enables a limit to be placed on how large client programs can set dynamic system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-query_cache_size=4M` prevents any client from making the query cache size larger than 4MB.

### 4.2.3.3. Using Option Files

Most MySQL programs can read startup options from option files (also sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program. For the MySQL server, MySQL provides a number of [preconfigured option files](#).

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` [447] and `--help` [413].) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

The `.mylogin.cnf` file that contains login path options is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#). A “login path” is an option group that permits only a limited set of options: `host`, `user`, and `password`. Client programs specify which login path to read from `.mylogin.cnf` using the `--login-path` [219] option.

On Windows, MySQL programs read startup options from the following files, in the specified order (top items are used first).

File Name	Purpose
<code>%WINDIR%\my.ini</code> , <code>%WINDIR%\my.cnf</code>	Global options
<code>C:\my.ini</code> , <code>C:\my.cnf</code>	Global options
<code>INSTALLDIR\my.ini</code> , <code>INSTALLDIR\my.cnf</code>	Global options
<code>defaults-extra-file</code>	The file specified with <code>--defaults-extra-file=path</code> [219], if any
<code>%APPDATA%\MySQL</code> <code>\.mylogin.cnf</code>	Login path options

`%WINDIR%` represents the location of your Windows directory. This is commonly `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

`INSTALLDIR` represents the MySQL installation directory. This is typically `C:\PROGRAMDIR\MySQL\MySQL 5.6 Server` where `PROGRAMDIR` represents the programs directory (usually `Program Files` on English-language versions of Windows), when MySQL 5.6 has been installed using the

installation and configuration wizards. See [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).

`%APPDATA%` represents the value of the Windows application data directory. You can determine its exact location from the value of the `APPDATA` environment variable using the following command:

```
C:\> echo %APPDATA%
```

On Unix, Linux and Mac OS X, MySQL programs read startup options from the following files, in the specified order (top items are used first).

File Name	Purpose
<code>/etc/my.cnf</code>	Global options
<code>/etc/mysql/my.cnf</code>	Global options
<code>SYSCONFDIR/my.cnf</code>	Global options
<code>\$MYSQL_HOME/my.cnf</code>	Server-specific options
<code>defaults-extra-file</code>	The file specified with <code>--defaults-extra-file=path</code> [219], if any
<code>~/.my.cnf</code>	User-specific options
<code>~/.mylogin.cnf</code>	Login path options

`~` represents the current user's home directory (the value of `$HOME`).

`SYSCONFDIR` represents the directory specified with the `SYSCONFDIR` [133] option to `CMake` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` attempts to set `MYSQL_HOME` as follows:

- Let `BASEDIR` and `DATADIR` represent the path names of the MySQL base directory and data directory, respectively.
- If there is a `my.cnf` file in `DATADIR` but not in `BASEDIR`, `mysqld_safe` sets `MYSQL_HOME` to `DATADIR`.
- Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` file in `DATADIR`, `mysqld_safe` sets `MYSQL_HOME` to `BASEDIR`.

In MySQL 5.6, use of `DATADIR` as the location for `my.cnf` is deprecated.

Typically, `DATADIR` is `/usr/local/mysql/data` for a binary installation or `/usr/local/var` for a source installation. Note that this is the data directory location that was specified at configuration time, not the one specified with the `--datadir` [418] option when `mysqld` starts. Use of `--datadir` [418] at runtime has no effect on where the server looks for option files, because it looks for them before processing any options.

MySQL looks for option files in the order just described and reads any that exist. If an option file that you want to use does not exist, create it with a plain text editor.

If multiple instances of a given option are found, the last instance takes precedence. There is one exception: For `mysqld`, the *first* instance of the `--user` [446] option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

**Note**

On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option.

The syntax for specifying options in an option file is similar to command-line syntax (see [Section 4.2.3.1, “Using Options on the Command Line”](#)). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- `#comment, ;comment`

Comment lines start with “#” or “;”. A “#” comment can start in the middle of a line as well.

- `[group]`

`group` is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case sensitive.

- `opt_name`

This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the “=” character, something that is not true on the command line. You can optionally enclose the value within single quotation marks or double quotation marks, which is useful if the value contains a “#” comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences “\b”, “\t”, “\n”, “\r”, “\\”, and “\s” in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. The escaping rules in option files are:

- If a backslash is followed by a valid escape sequence character, the sequence is converted to the character represented by the sequence. For example, “\s” is converted to a space.
- If a backslash is not followed by a valid escape sequence character, it remains unchanged. For example, “\S” is retained as is.

The preceding rules mean that a literal backslash can be given as “\\”, or as “\” if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if “x” is not a value escape sequence character, “\x” becomes “x” rather than “\x”. See [Section 9.1.1, “String Literals”](#).

The escaping rules for option file values are especially pertinent for Windows path names, which use “\” as a path name separator. A separator in a Windows path name must be written as “\\” if it is followed by an escape sequence character. It can be written as “\” or “\” if it is not. Alternatively, “/” may be used in Windows path names and will be treated as “\”. Suppose that you want to specify a base directory of `C:\Program Files\MySQL\MySQL Server 5.6` in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 5.6"
basedir="C:\\Program Files\\MySQL\\MySQL Server 5.6"
basedir="C:/Program Files/MySQL/MySQL Server 5.6"
basedir=C:\\Program\sFiles\\MySQL\\MySQL\sServer\s5.6
```

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs (but *not* by `mysqld`). This enables you to specify options that apply to all clients. For example, `[client]` is the perfect group to use to specify the password that you use to connect to the server. (But make sure that the option file is readable and writable only by yourself, so that other people cannot find out your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

The preceding option file uses `var_name=value` syntax for the lines that set the `key_buffer_size` [492] and `max_allowed_packet` [502] variables.

Here is a typical user option file:

```
[client]
# The following password will be sent to all standard MySQL clients
password="my_password"

[mysql]
no-auto-rehash
connect_timeout=2

[mysqlhotcopy]
interactive_timeout
```

If you want to create option groups that should be read by `mysqld` servers from a specific MySQL release series only, you can do this by using groups with names of `[mysqld-5.5]`, `[mysqld-5.6]`, and so forth. The following group indicates that the `--new` option should be used only by MySQL servers with 5.6.x version numbers:

```
[mysqld-5.6]
new
```

It is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

There is no guarantee about the order in which the option files in the directory will be read.

**Note**

Currently, any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

#### 4.2.3.4. Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. They affect option-file handling, so they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- `--print-defaults` [220] may be used immediately after `--defaults-file` [219] or `--defaults-extra-file` [219].
- On Windows, if the server is started with the `--defaults-file` [219] and `--install` [424] options, `--install` [424] must be first. See Section 2.3.4.8, “Starting MySQL as a Windows Service”.

When specifying file names, you should avoid the use of the “~” shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=file_name` [219]

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, the program exits with an error. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name` [219]

Use only the given option file. If the file does not exist or is otherwise inaccessible, the program exits with an error. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-group-suffix=str` [219]

If this option is given, the program reads not only its usual option groups, but also groups with the usual names and a suffix of `str`. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` [219] option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--login-path=name` [219]

Read options from the named login path in the `.mylogin.cnf` login file. A “login path” is an option group that permits only a limited set of options: `host`, `user`, and `password`. Think of a

login path as a set of values that indicate the server host and the credentials for authenticating with the server. To create the login file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--no-defaults` [\[220\]](#)

Do not read any option files. If a program does not start because it is reading unknown options from an option file, `--no-defaults` [\[220\]](#) can be used to prevent the program from reading them.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` [\[220\]](#) is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).)

- `--print-defaults` [\[220\]](#)

Print the program name and all options that it gets from option files.

### 4.2.3.5. Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See [Section 13.7.4, “SET Syntax”](#), and [Section 5.1.5, “Using System Variables”](#).

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of  $1024$ ,  $1024^2$  or  $1024^3$ . (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M

[mysqld]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

#### 4.2.3.6. Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=) sign, like this:

```
shell> mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equals sign is not required, and so the following is also valid:

```
shell> mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named “tonfisk” using an account with the user name “jon”.

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```
shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.6.12 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| jon@%          |
+-----+
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
shell> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument
```

In this case, `mysql` was unable to find a value following the `--user` [212] option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```
shell> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

Because `mysql` assumes that any string following `--host` [211] on the command line is a host name, `--host` [211] `--user` [212] is interpreted as `--host=--user` [211], and the client attempts to connect to a MySQL server running on a host named “--user”.

Options having default values always require an equals sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` [427] option has the default value

`host_name.err`, where `host_name` is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “tonfisk”, and consider the following invocation of `mysqld_safe`:

```
shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

After shutting down the server, restart it as follows:

```
shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

The result is the same, since `--log-error` [227] is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```
shell> mysqld_safe --log-error my-errors &
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended

[1]+  Done                  ./mysqld_safe --log-error my-errors
```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
shell> tail /usr/local/mysql/var/tonfisk.err
080111 22:53:32 InnoDB: Started; log sequence number 0 46409
/usr/local/mysql/libexec/mysqld: Too many arguments (first extra is 'my-errors').
Use --verbose --help to get a list of available options
080111 22:53:32 [ERROR] Aborting

080111 22:53:32 InnoDB: Starting shutdown...
080111 22:53:34 InnoDB: Shutdown completed; log sequence number 0 46409
080111 22:53:34 [Note] /usr/local/mysql/libexec/mysqld: Shutdown complete

080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```

Because the `--log-error` [227] option supplies a default value, you must use an equals sign to assign a different value to it, as shown here:

```
shell> mysqld_safe --log-error=my-errors &
[1] 31437
shell> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]

host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host [250] --user [254]` or `--host=--user [250]`, with the result shown here:

```
shell> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equals sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]
user jon
```

Trying to start `mysql` in this case causes a different error:

```
shell> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equals sign:

```
[mysql]
user=jon
```

Now the login attempt succeeds:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 5.6.12 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@localhost |
+-----+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equals sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 5.6.12 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@tonfisk |
+-----+
1 row in set (0.00 sec)
```

In MySQL 5.6, specifying an option requiring a value without a value in an option file causes the server to abort with an error. Suppose that `my.cnf` contains the following:

```
[mysqld]
log_error
relay_log
relay_log_index
```

This causes the server to fail on startup, as shown here:

```
shell> mysqld_safe &
```

```
090514 09:48:39 mysqld_safe Logging to '/home/jon/bin/mysql-5.5/var/tonfisk.err'.
090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql-5.5/var
090514 09:48:39 mysqld_safe mysqld from pid file /home/jon/bin/mysql-5.5/var/tonfisk.pid ended
```

The `--log-error` [427] option does not require an argument; however, the `--relay-log` [1974] option requires one, as shown in the error log (which in the absence of a specified value, defaults to `datadir/hostname.err`):

```
shell> tail -n 3 ../var/tonfisk.err

090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql-5.5/var
090514 9:48:39 [ERROR] /home/jon/bin/mysql-5.5/libexec/mysqld: option '--relay-log' requires an argument
090514 9:48:39 [ERROR] Aborting
```

This is a change from previous behavior, where the server would have interpreted the last two lines in the example `my.cnf` file as `--relay-log=relay_log_index` and created a relay log file using “`relay_log_index`” as the basename. (Bug #25192)

## 4.2.4. Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. [Section 2.12, “Environment Variables”](#), lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `ksh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

## 4.3. MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

### 4.3.1. `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see [Section 5.1, “The MySQL Server”](#). For information about installing MySQL and setting up the initial configuration, see [Chapter 2, \*Installing and Upgrading MySQL\*](#).

### 4.3.2. `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. A description of error logging is given later in this section.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld [228]` or `--mysqld-version [228]` option to `mysqld_safe`. You can also use `--ledir [227]` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See [Section 5.1.3, “Server Command Options”](#).

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See [Section 4.2.3.3, “Using Option Files”](#).

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` will find and use the `--log-error` [227] option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, although you should rename such sections to `[mysqld_safe]` in MySQL 5.6 installations.

`mysqld_safe` supports the following options. It also reads option files and supports the options for processing them described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.1. `mysqld_safe` Options**

Format	Option File	Description
<code>--basedir=path</code> [227]	<code>basedir</code> [227]	The path to the MySQL installation directory
<code>--core-file-size=size</code> [227]	<code>core-file-size</code> [227]	The size of the core file that <code>mysqld</code> should be able to create
<code>--datadir=path</code> [227]	<code>datadir</code> [227]	The path to the data directory
<code>--defaults-extra-file=path</code> [227]	<code>defaults-extra-file</code> [227]	The name of an option file to be read in addition to the usual option files
<code>--defaults-file=file_name</code> [227]	<code>defaults-file</code> [227]	The name of an option file to be read instead of the usual option files
<code>--help</code> [227]		Display a help message and exit
<code>--ledir=path</code> [227]	<code>ledir</code> [227]	Use this option to indicate the path name to the directory where the server is located
<code>--log-error=file_name</code> [227]	<code>log-error</code> [227]	Write the error log to the given file
<code>--malloc-lib=[lib-name]</code> [227]	<code>malloc-lib</code> [227]	Alternative malloc library to use for <code>mysqld</code>
<code>--mysqld=prog_name</code> [228]	<code>mysqld</code> [228]	The name of the server program (in the <code>ledir</code> directory) that you want to start
<code>--mysqld-version=suffix</code> [228]	<code>mysqld-version</code> [228]	This option is similar to the <code>--mysqld</code> option, but you specify only the suffix for the server program name
<code>--nice=priority</code> [228]	<code>nice</code> [228]	Use the <code>nice</code> program to set the server's scheduling priority to the given value
<code>--no-defaults</code> [228]	<code>no-defaults</code> [228]	Do not read any option files
<code>--open-files-limit=count</code> [228]	<code>open-files-limit</code> [228]	The number of files that <code>mysqld</code> should be able to open
<code>--pid-file=file_name</code> [228]	<code>pid-file=file_name</code> [228]	The path name of the process ID file
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located
<code>--port=number</code> [228]	<code>port</code> [228]	The port number that the server should use when listening for TCP/IP connections
<code>--skip-kill-mysqld</code> [229]	<code>skip-kill-mysqld</code> [229]	Do not try to kill stray <code>mysqld</code> processes
<code>--skip-syslog</code> [229]	<code>skip-syslog</code> [229]	Do not write error messages to syslog; use error log file

Format	Option File	Description
<code>--socket=path [229]</code>	<code>socket [229]</code>	The Unix socket file that the server should use when listening for local connections
<code>--syslog [229]</code>	<code>syslog [229]</code>	Tag suffix for messages written to syslog
<code>--timezone=timezone [229]</code>	<code>timezone [229]</code>	Set the TZ time zone environment variable to the given option value
<code>--user={user_name user_id} [229]</code>	<code>user [229]</code>	Run the mysqld server as the user having the name <code>user_name</code> or the numeric user ID <code>user_id</code>

- `--help [227]`  
Display a help message and exit.
- `--basedir=path [227]`  
The path to the MySQL installation directory.
- `--core-file-size=size [227]`  
The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.
- `--datadir=path [227]`  
The path to the data directory.
- `--defaults-extra-file=path [227]`  
The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. If the file does not exist or is otherwise inaccessible, the server will exit with an error.
- `--defaults-file=file_name [227]`  
The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.
- `--ledir=path [227]`  
If `mysqld_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.
- `--log-error=file_name [227]`  
Write the error log to the given file. See [Section 5.2.2, “The Error Log”](#).
- `--malloc-lib=[lib_name] [227]`  
The name of the library to use for memory allocation instead of the system `malloc()` library. Any library can be used by specifying its path name, but there is a shortcut form to enable use of the `tcmalloc` library that is shipped with binary MySQL distributions for Linux in MySQL 5.6.  
The `--malloc-lib [227]` option works by modifying the `LD_PRELOAD` environment value to affect dynamic linking to enable the loader to find the memory-allocation library when `mysqld` runs:
  - If the option is not given, or is given without a value (`--malloc-lib= [227]`), `LD_PRELOAD` is not modified and no attempt is made to use `tcmalloc`.
  - If the option is given as `--malloc-lib=tcmalloc [227]`, `mysqld_safe` looks for a `tcmalloc` library in `/usr/lib` and then in the MySQL `pkglibdir` location (for example, `/usr/local/`

`mysql/lib` or whatever is appropriate). If `tmalloc` is found, its path name is added to the beginning of the `LD_PRELOAD` value for `mysqld`. If `tcmalloc` is not found, `mysqld_safe` aborts with an error.

- If the option is given as `--malloc-lib=/path/to/some/library` [227], that full path is added to the beginning of the `LD_PRELOAD` value. If the full path points to a nonexistent or unreadable file, `mysqld_safe` aborts with an error.
- For cases where `mysqld_safe` adds a path name to `LD_PRELOAD`, it adds the path to the beginning of any existing value the variable already has.

Linux users can use the `libtcmalloc_minimal.so` included in binary packages by adding these lines to the `my.cnf` file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

Those lines also suffice for users on any platform who have installed a `tcmalloc` package in `/usr/lib`. To use a specific `tcmalloc` library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

- `--mysqld=prog_name` [228]

The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` [227] option to indicate the path name to the directory where the server is located.

- `--mysqld-version=suffix` [228]

This option is similar to the `--mysqld` [228] option, but you specify only the suffix for the server program name. The basename is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug` [228], `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` [228] is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

- `--nice=priority` [228]

Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults` [228]

Do not read any option files. This must be the first option on the command line if it is used.

- `--open-files-limit=count` [228]

The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as `root` for this to work properly!

- `--pid-file=file_name` [228]

The path name of the process ID file.

- `--plugin-dir=path` [228]

The path name of the plugin directory.

- `--port=port_num` [228]

The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--skip-kill-mysqld` [229]

Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=path` [229]

The Unix socket file that the server should use when listening for local connections.

- `--syslog` [229], `--skip-syslog` [229]

`--syslog` [229] causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file.

When `syslog` is used, the `daemon.err` syslog priority/facility is used for all log messages.

- `--syslog-tag=tag` [229]

For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with a tag of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the tag, use `--syslog-tag=tag` [229], which modifies the tags to be `mysqld_safe-tag` and `mysqld-tag`.

- `--timezone=timezone` [229]

Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}` [229]

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` [227] or `--defaults-extra-file` [227] option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See [Section 2.1.5, “Installation Layouts”](#).) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).
- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, you can specify the `--ledir` [227] and `--datadir` [227] options to indicate the directories in which the server and databases are located on your system.

In MySQL 5.6.5 and later, `mysqld_safe` tries to use the `sleep` and `date` system utilities to determine how many times it has attempted to start this second, and—if these are present and this is greater than 5 times—is forced to wait 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

There are several `mysqld_safe` options for controlling the destination of these messages:

- `--syslog` [229]: Write error messages to `syslog` on systems that support the `logger` program.
- `--skip-syslog` [229]: Do not write error messages to `syslog`. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` [227] option is given.
- `--log-error=file_name` [227]: Write error messages to the named error file.

If none of these options is given, the default is `--skip-syslog` [229].

If `--syslog` [229] and `--log-error` [227] are both given, a warning is issued and `--log-error` [227] takes precedence.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and `stdout`. Errors go to the logging destination and `stderr`.

Normally, you should not edit the `mysqld_safe` script. Instead, configure `mysqld_safe` by using command-line options or options in the `[mysqld_safe]` section of a `my.cnf` option file. In rare cases, it might be necessary to edit `mysqld_safe` to get it to start the server properly. However, if you do this, your modified version of `mysqld_safe` might be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.

### 4.3.3. mysql.server — MySQL Server Startup Script

MySQL distributions on Unix include a script named `mysql.server`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the Mac OS X Startup Item for MySQL.

`mysql.server` can be found in the `support-files` directory under your MySQL installation directory or in a MySQL source distribution.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), the `mysql.server` script will be installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See Section 2.5.1, “Installing MySQL from RPM Packages on Linux”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. Instructions are provided in Section 2.10.1.2, “Starting and Stopping MySQL Automatically”.

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, although you should rename such sections to `[mysql.server]` when using MySQL 5.6.

`mysql.server` supports the following options.

- `--basedir=path` [231]

The path to the MySQL installation directory.

- `--datadir=path` [231]

The path to the MySQL data directory.

- `--pid-file=file_name` [231]

The path name of the file in which the server should write its process ID.

- `--service-startup-timeout=file_name` [231]

How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

- `--use-mysqld_safe` [231]

Use `mysqld_safe` to start the server. This is the default.

- `--user=user_name` [231]

The login user name to use for running `mysqld`.

#### 4.3.4. `mysqld_multi` — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--config-file` option). `N` can be any positive integer. This number is referred to in the following discussion as the option group number, or *GNR*. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysqld]` group used for starting `mysqld`. (See, for example, [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

To invoke `mysqld_multi`, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|reload|report} [GNR[,GNR] ...]
```

`start`, `stop`, `reload` (stop and restart), and `report` indicate which operation to perform. (`reload` is available as of MySQL 5.6.3.) You can perform the designated operation for a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named `[mysqld17]` is 17. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

`mysqld_multi` searches for option files as follows:

- With `--no-defaults` [232], no option files are read.
- With `--defaults-file=file_name` [232], only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=file_name` [232] option, if one is given. (If the option is given multiple times, the last value is used.)

Option files read are searched for `[mysqld_multi]` and `[mysqldN]` option groups. The `[mysqld_multi]` group can be used for options to `mysqld_multi` itself. `[mysqldN]` groups can be used for options passed to specific `mysqld` instances.

The `[mysqld]` or `[mysqld_safe]` groups can be used for common options read by all instances of `mysqld` or `mysqld_safe`. You can specify a `--defaults-file=file_name` [219] option to use a different configuration file for that instance, in which case the `[mysqld]` or `[mysqld_safe]` groups from that file will be used for that instance.

`mysqld_multi` supports the following options.

- `--help` [232]

Display a help message and exit.

- `--example` [232]

Display a sample option file.

- `--log=file_name` [232]

Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name` [232]

The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name` [232]

The `mysqld` binary to be used. Note that you can specify `mysqld_safe` as the value for this option also. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the path name of the directory where the server is located. (See the descriptions for these options in [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).)  
Example:

```
[mysqld38]
mysqld = mysqld-debug
ledir  = /opt/local/mysql/libexec
```

- `--no-log` [232]

Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

- `--password=password` [233]

The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent` [233]

Silent mode; disable warnings.

- `--tcp-ip` [233]

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name` [233]

The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose` [233]

Be more verbose.

- `--version` [233]

Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important:** Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

#### Important

Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` [756] privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> GRANT SHUTDOWN ON *.*
-> TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
```

See [Section 6.2, “The MySQL Access Privilege System”](#). You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` [414] to cause different servers to listen to different interfaces.)
- The `--pid-file` [228] option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe` [228]). Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault. Please note that the `mysqld_safe` script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running `mysqld_multi`. If you have problems starting, please see the `mysqld_safe` script. Check especially the lines:

```
-----
MY_PWD=`pwd`
# Check if we are starting this relative (for the binary release)
if test -d $MY_PWD/data/mysql -a \
  -f ./share/mysql/english/errmsg.sys -a \
  -x ./bin/mysqld
-----
```

The test performed by these lines should be successful, or you might encounter problems. See [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).

- You might want to use the `--user` [446] option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix superuser (`root`). Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth [`mysqldN`] groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This file should probably be in your home dir (~/.my.cnf)
# or /etc/my.cnf
# Version 2.1 by Jani Tolonen

[mysqld_multi]
mysqld      = /usr/local/bin/mysqld_safe
mysqladmin  = /usr/local/bin/mysqladmin
user        = multi_admin
password    = multipass

[mysqld2]
socket      = /tmp/mysql.sock2
port        = 3307
pid-file    = /usr/local/mysql/var2/hostname.pid2
datadir     = /usr/local/mysql/var2
language    = /usr/local/share/mysql/english
user        = john

[mysqld3]
socket      = /tmp/mysql.sock3
port        = 3308
pid-file    = /usr/local/mysql/var3/hostname.pid3
datadir     = /usr/local/mysql/var3
language    = /usr/local/share/mysql/swedish
user        = monty

[mysqld4]
socket      = /tmp/mysql.sock4
port        = 3309
pid-file    = /usr/local/mysql/var4/hostname.pid4
datadir     = /usr/local/mysql/var4
language    = /usr/local/share/mysql/estonia
```

```

user      = tonu

[mysqld6]
socket    = /tmp/mysql.sock6
port      = 3311
pid-file  = /usr/local/mysql/var6/hostname.pid6
datadir   = /usr/local/mysql/var6
language  = /usr/local/share/mysql/japanese
user      = jani

```

See [Section 4.2.3.3, “Using Option Files”](#).

## 4.4. MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

### 4.4.1. `comp_err` — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the plaintext file located at `sql/share/errmsg.txt` in MySQL source distributions.

`comp_err` also generates `mysqld_error.h`, `mysqld_ename.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the [MySQL Internals Manual](#).

Invoke `comp_err` like this:

```
shell> comp_err [options]
```

`comp_err` supports the following options.

- `--help [235], -?`

Display a help message and exit.

- `--charset=path [235], -C path`

The character set directory. The default is `../sql/share/charsets`.

- `--debug=debug_options [235], -# debug_options`

Write a debugging log. A typical `debug_options` string is `'d:t:O,file_name'`. The default is `'d:t:O,/tmp/comp_err.trace'`.

- `--debug-info [235], -T`

Print some debugging information when the program exits.

- `--header_file=file_name [235], -H file_name`

The name of the error header file. The default is `mysqld_error.h`.

- `--in_file=file_name [235], -F file_name`

The name of the input file. The default is `../sql/share/errmsg.txt`.

- `--name_file=file_name [235], -N file_name`

The name of the error name file. The default is `mysqld_ename.h`.

- `--out_dir=path [235], -D path`

The name of the output base directory. The default is `../sql/share/`.

- `--out_file=file_name` [236], `-O file_name`

The name of the output file. The default is `errmsg.sys`.

- `--statefile=file_name` [236], `-S file_name`

The name for the SQLSTATE header file. The default is `sql_state.h`.

- `--version` [236], `-V`

Display version information and exit.

## 4.4.2. mysqlbug — Generate Bug Report

This program is obsolete.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

## 4.4.3. mysql\_install\_db — Initialize MySQL Data Directory

`mysql_install_db` initializes the MySQL data directory and creates the system tables that it contains, if they do not exist. It also initializes the [system tablespace](#) and related data structures needed to manage [InnoDB](#) tables. As of MySQL 5.6.8, `mysql_install_db` is a Perl script and can be used on any system with Perl installed. Before 5.6.8, it is a shell script and is available only on Unix platforms.

As of MySQL 5.6.8, on Unix platforms, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. You can find the template in or under the base installation directory. When started using `mysqld_safe`, the server uses `my.cnf` file by default. If `my.cnf` already exists, `mysql_install_db` assumes it to be in use and writes a new file named `my-new.cnf` instead.

With one exception, the settings in the default option file are commented and have no effect. The exception is that the file changes the `sql_mode` [545] system variable from its default of `NO_ENGINE_SUBSTITUTION` [605] to also include `STRICT_TRANS_TABLES` [607]. This setting produces a server configuration that results in errors rather than warnings for bad data in operations that modify transactional tables. See [Section 5.1.7, “Server SQL Modes”](#).

To invoke `mysql_install_db`, use the following syntax:

```
shell> mysql_install_db [options]
```

Because the MySQL server, `mysqld`, needs to access the data directory when it runs later, you should either run `mysql_install_db` from the same system account that will be used for running `mysqld` or run it as `root` and use the `--user` [238] option to indicate the user name that `mysqld` will run as. It might be necessary to specify other options such as `--basedir` [237] or `--datadir` [237] if `mysql_install_db` does not use the correct locations for the installation directory or data directory. For example:

```
shell> scripts/mysql_install_db --user=mysql \
      --basedir=/opt/mysql/mysql \
      --datadir=/opt/mysql/mysql/data
```

`mysql_install_db` needs to invoke `mysqld` with the `--bootstrap` [416] and `--skip-grant-tables` [439] options.

**Note**

If you have set a custom `TMPDIR` environment variable when performing the installation, and the specified directory is not accessible, `mysql_install_db` may fail. If so, unset `TMPDIR` or set `TMPDIR` to point to the system temporary directory (usually `/tmp`).

After `mysql_install_db` sets up the InnoDB system tablespace, changes to some of tablespace characteristics require setting up a whole new instance. This includes the file name of the first file in the system tablespace and the number of undo logs. If you do not want to use the default values, make sure that the settings for the `innodb_data_file_path` [1714] and `innodb_log_file_size` [1732] configuration options are in place in the MySQL configuration file before running `mysql_install_db`.

`mysql_install_db` supports the following options, which can be specified on the command line or in the `[mysql_install_db]` group of an option file. (Options that are common to `mysqld` can also be specified in the `[mysqld]` group.) Other options are passed to `mysqld`. For information about option files, see Section 4.2.3.3, “Using Option Files”. `mysql_install_db` also supports the options for processing option files described at Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”.

- `--basedir=path` [237]

The path to the MySQL installation directory.

- `--datadir=path` [237], `--ldata=path` [237]

The path to the MySQL data directory. Beginning with MySQL 5.6.8, `mysql_install_db` is more strict about the option value. Only the last component of the path name is created if it does not exist; the parent directory must already exist or an error occurs.

- `--force` [237]

Cause `mysql_install_db` to run even if DNS does not work. Grant table entries that normally use host names will use IP addresses.

- `--random-passwords` [237]

On Unix platforms, this option provides for more secure MySQL installation. Invoking `mysql_install_db` with `--random-passwords` [237] causes it to perform the following actions in addition to its normal operation:

- Create a random password, assign it to the initial MySQL `root` accounts, and set the “password expired” flag for those accounts.
- Write the initial password file to the `.mysql_secret` file in the directory named by the `HOME` environment variable. Depending on operating system, using a command such as `sudo` may cause the value of `HOME` to refer to the home directory of the `root` system user.

If `.mysql_secret` already exists, the new password information is appended to it. Each password entry includes a timestamp so that in the event of multiple install operations it is possible to determine the password associated with each one.

`.mysql_secret` is created with mode 600 to be accessible only to the system user for whom it is created.

- Remove the anonymous-user MySQL accounts.

As a result of these actions, it is necessary after installation to start the server, connect as `root` using the password written to the `.mysql_secret` file, and to assign a new `root` password. Until

this is done, `root` cannot do anything else. This must be done for each `root` account you intend to use. To change the password, you can use the `SET PASSWORD` statement (for example, with the `mysql` client). You can also use `mysqladmin` or `mysql_secure_installation`.

New RPM install operations (not upgrades) invoke `mysql_install_db` with the `--random-passwords` option. (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

As of MySQL 5.6.9, new Solaris PKG install operations (not upgrades) invoke `mysql_install_db` with the `--random-passwords` option.

For install operations using a binary `.tar.gz` distribution or a source distribution, you can invoke `mysql_install_db` with the `--random-passwords` option manually to make your MySQL installation more secure. This is recommended, particularly for sites with sensitive data.

This option was added in MySQL 5.6.8.

- `--rpm` [238]

For internal use. This option is used during the MySQL installation process for install operations performed using RPM packages.

- `--skip-name-resolve` [238]

Use IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

- `--srcdir=path` [238]

For internal use. This option specifies the directory under which `mysql_install_db` looks for support files such as the error message file and the file for populating the help tables.

- `--user=user_name` [238]

The system (login) user name to use for running `mysqld`. Files and directories created by `mysqld` will be owned by this user. You must be `root` to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates will be owned by you.

- `--verbose` [238]

Verbose mode. Print more information about what the program does.

- `--windows` [238]

For internal use. This option is used for creating Windows distributions.

#### 4.4.4. `mysql_plugin` — Configure MySQL Server Plugins

The `mysql_plugin` utility enables MySQL administrators to manage which plugins a MySQL server loads. It provides an alternative to manually specifying the `--plugin-load` [435] option at server startup or using the `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements at runtime. `mysql_plugin` is available as of MySQL 5.6.3.

Depending on whether `mysql_plugin` is invoked to enable or disable plugins, it inserts or deletes rows in the `mysql.plugin` table that serves as a plugin registry. (To perform this operation, `mysql_plugin` invokes the MySQL server in bootstrap mode. This means that the server must not already be running.) For normal server startups, the server loads and enables plugins listed in `mysql.plugin` automatically. For additional control over plugin activation, use `--plugin_name` options named for specific plugins, as described in [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

Each invocation of `mysql_plugin` reads a configuration file to determine how to configure the plugins contained in a single plugin library object file. To invoke `mysql_plugin`, use this syntax:

```
mysql_plugin [options] plugin {ENABLE|DISABLE}
```

*plugin* is the name of the plugin to configure. `ENABLE` or `DISABLE` (not case sensitive) specify whether to enable or disable components of the plugin library named in the configuration file. The order of the *plugin* and `ENABLE` or `DISABLE` arguments does not matter.

For example, to configure components of a plugin library file named `myplugins.so` on Linux or `myplugins.dll` on Windows, specify a *plugin* value of `myplugins`. Suppose that this plugin library contains three plugins, `plugin1`, `plugin2`, and `plugin3`, all of which should be configured under `mysql_plugin` control. By convention, configuration files have a suffix of `.ini` and the same basename as the plugin library, so the default configuration file name for this plugin library is `myplugins.ini`. The configuration file contents look like this:

```
myplugins
plugin1
plugin2
plugin3
```

The first line in the `myplugins.ini` file is the name of the library object file, without any extension such as `.so` or `.dll`. The remaining lines are the names of the components to be enabled or disabled. Each value in the file should be on a separate line. Lines on which the first character is `'#'` are taken as comments and ignored.

To enable the plugins listed in the configuration file, invoke `mysql_plugin` this way:

```
shell> mysql_plugin myplugins ENABLE
```

To disable the plugins, use `DISABLE` rather than `ENABLE`.

An error occurs if `mysql_plugin` cannot find the configuration file or plugin library file, or if `mysql_plugin` cannot start the MySQL server.

`mysql_plugin` supports the following options, which can be specified on the command line or in the `[mysqld]` group of any option file. For options specified in a `[mysqld]` group, `mysql_plugin` recognizes the `--basedir` [240], `--datadir` [240], and `--plugin-dir` [240] options and ignores others. For information about option files, see [Section 4.2.3.3, “Using Option Files”](#).

**Table 4.2. `mysql_plugin` Options**

Format	Option File	Description
<code>--basedir=path</code> [240]	<code>basedir=path</code> [240]	The server base directory
<code>--datadir=path</code> [240]	<code>datadir=path</code> [240]	The server data directory
<code>--help</code> [240]		Display help message and exit
<code>--my-print-defaults=path</code> [240]	<code>my-print-defaults=path</code> [240]	The path to <code>my_print_defaults</code>
<code>--mysqld=path</code> [240]	<code>mysqld=path</code> [240]	The path to the server
<code>--no-defaults</code> [240]	<code>no-defaults</code> [240]	Do not read configuration file
<code>--plugin-dir=path</code> [240]	<code>plugin-dir=path</code> [240]	The directory where plugins are located
<code>--plugin-ini=file_name</code> [240]	<code>plugin-ini=file_name</code> [240]	The plugin configuration file
<code>--print-defaults</code> [240]	<code>print-defaults</code> [240]	Show configuration file defaults
<code>--verbose</code> [240]		Verbose mode

Format	Option File	Description
<code>--version [240]</code>		Display version information and exit

- `--help [240], -?`  
Display a help message and exit.
- `--basedir=path [240], -b path`  
The server base directory.
- `--datadir=path [240], -d path`  
The server data directory.
- `--my-print-defaults=path [240], -b path`  
The path to the `my_print_defaults` program.
- `--mysqld=path [240], -b path`  
The path to the `mysqld` server.
- `--no-defaults [240], -p`  
Do not read values from the configuration file. This option enables an administrator to skip reading defaults from the configuration file.  
  
With `mysql_plugin`, this option need not be given first on the command line, unlike most other MySQL programs that support `--no-defaults [240]`.
- `--plugin-dir=path [240], -p path`  
The server plugin directory.
- `--plugin-ini=file_name [240], -i file_name`  
The `mysql_plugin` configuration file. Relative path names are interpreted relative to the current directory. If this option is not given, the default is `plugin.ini` in the plugin directory, where `plugin` is the `plugin` argument on the command line.
- `--print-defaults [240], -P`  
Display the default values from the configuration file. This option causes `mysql_plugin` to print the defaults for `--basedir [240]`, `--datadir [240]`, and `--plugin-dir [240]` if they are found in the configuration file. If no value for a variable is found, nothing is shown.  
  
With `mysql_plugin`, this option need not be given first on the command line, unlike most other MySQL programs that support `--print-defaults [240]`.
- `--verbose [240], -v`  
Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.
- `--version [240], -V`  
Display version information and exit.

#### 4.4.5. mysql\_secure\_installation — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.
- You can remove `root` accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

Invoke `mysql_secure_installation` without arguments:

```
shell> mysql_secure_installation
```

The script will prompt you to determine which actions to perform.

`mysql_secure_installation` is not available on Windows.

#### 4.4.6. `mysql_tzinfo_to_sql` — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a `zoneinfo` database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a `zoneinfo` database, you can use the downloadable package described in [Section 10.6, “MySQL Server Time Zone Support”](#).

`mysql_tzinfo_to_sql` can be invoked several ways:

```
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

#### 4.4.7. `mysql_upgrade` — Check and Upgrade MySQL Tables

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL Server. `mysql_upgrade` also upgrades the system tables so that you can take advantage of new privileges or capabilities that might have been added.

`mysql_upgrade` should be executed each time you upgrade MySQL.

If `mysql_upgrade` finds that a table has a possible incompatibility, it performs a table check and, if problems are found, attempts a table repair. If the table cannot be repaired, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies.

#### Note

On Windows Server 2008, Vista, and newer, you must run `mysql_upgrade` with administrator privileges. You can do this by running a Command Prompt as Administrator and running the command. Failure to do so may result in the upgrade failing to execute correctly.

#### Caution

You should always back up your current MySQL installation *before* performing an upgrade. See [Section 7.2, “Database Backup Methods”](#).

Some upgrade incompatibilities may require special handling before you upgrade your MySQL installation and run `mysql_upgrade`. See [Section 2.11.1, “Upgrading MySQL”](#), for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

To use `mysql_upgrade`, make sure that the server is running, and then invoke it like this:

```
shell> mysql_upgrade [options]
```

After running `mysql_upgrade`, stop the server and restart it so that any changes made to the system tables take effect.

`mysql_upgrade` executes the following commands to check and repair tables and to upgrade the system tables:

```
mysqlcheck --all-databases --check-upgrade --auto-repair
mysql < fix_priv_tables
mysqlcheck --all-databases --check-upgrade --fix-db-names --fix-table-names
```

Notes about the preceding commands:

- Because `mysql_upgrade` invokes `mysqlcheck` with the `--all-databases` [276] option, it processes all tables in all databases, which might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables.
- For details about what checks the `--check-upgrade` [276] option entails, see the description of the `FOR UPGRADE` option of the `CHECK TABLE` statement (see [Section 13.7.2.2, “CHECK TABLE Syntax”](#)).
- `fix_priv_tables` represents a script generated internally by `mysql_upgrade` that contains SQL statements to upgrade the tables in the `mysql` database.

All checked and repaired tables are marked with the current MySQL version number. This ensures that next time you run `mysql_upgrade` with the same version of the server, it can tell whether there is any need to check or repair the table again.

`mysql_upgrade` also saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the `--force` [243] option.

If you install MySQL from RPM packages on Linux, you must install the server and client RPMs. `mysql_upgrade` is included in the server RPM but requires the client RPM because the latter includes `mysqlcheck`. (See [Section 2.5.1, “Installing MySQL from RPM Packages on Linux”](#).)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

`mysql_upgrade` supports the following options, which can be specified on the command line or in the `[mysql_upgrade]` and `[client]` groups of an option file. Other options are passed to `mysqlcheck`. For example, it might be necessary to specify the `--password[=password]` [\[277\]](#) option. `mysql_upgrade` also supports the options for processing option files described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

- `--help` [\[243\]](#)  
Display a short help message and exit.
- `--basedir=path` [\[243\]](#)  
The path to the MySQL installation directory. This option is accepted for backward compatibility but ignored.
- `--datadir=path` [\[243\]](#)  
The path to the data directory. This option is accepted for backward compatibility but ignored.
- `--debug-check` [\[243\]](#)  
Print some debugging information when the program exits.
- `--debug-info` [\[243\]](#), `-T`  
Print debugging information and memory and CPU usage statistics when the program exits.
- `--default-auth=plugin` [\[243\]](#)  
The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).  
This option was added in MySQL 5.6.2.
- `--force` [\[243\]](#)  
Ignore the `mysql_upgrade_info` file and force execution of `mysqlcheck` even if `mysql_upgrade` has already been executed for the current version of MySQL.
- `--plugin-dir=path` [\[243\]](#)  
The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` [\[243\]](#) option is used to specify an authentication plugin but `mysql_upgrade` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).  
This option was added in MySQL 5.6.2.
- `--tmpdir=path` [\[243\]](#), `-t path`  
The path name of the directory to use for creating temporary files.
- `--upgrade-system-tables` [\[243\]](#), `-s`  
Upgrade only the system tables, do not upgrade data.
- `--user=user_name` [\[243\]](#), `-u user_name`  
The MySQL user name to use when connecting to the server. The default user name is `root`.
- `--verbose` [\[243\]](#)  
Verbose mode. Print more information about what the program does.

- `--version-check` [244], `-k`

Check the version of the server to which `mysql_upgrade` is connecting to verify that it is the same as the version for which `mysql_upgrade` was built. If not, `mysql_upgrade` exits. This option is enabled by default; to disable the check, use `--skip-version-check`. This option was added in MySQL 5.6.12.

- `--write-binlog` [244]

Cause binary logging to be enabled while `mysql_upgrade` runs. In MySQL 5.6.6 and earlier, this was the default behavior. (To disable binary logging during the upgrade, it was necessary to use the inverse of this option, by starting the program with `--skip-write-binlog`.) Beginning with MySQL 5.6.7, binary logging by `mysql_upgrade` is disabled by default (Bug #14221043), and you must invoke the program explicitly with `--write-binlog` if you want its actions to be written to the binary log. (Also beginning with MySQL 5.6.7, the `--skip-write-binlog` option effectively does nothing.)

Running `mysql_upgrade` is not recommended with a MySQL Server that is running with global transaction identifiers enabled (Bug #13833710). This is because enabling GTIDs means that any updates which `mysql_upgrade` might need to perform on system tables using a nontransactional storage engine such as `MyISAM` to fail. See [Section 16.1.3.4, “Restrictions on Replication with GTIDs”](#), for more information.

## 4.5. MySQL Client Programs

This section describes client programs that connect to the MySQL server.

### 4.5.1. `mysql` — The MySQL Command-Line Tool

`mysql` is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` [252] option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with “;”, `\g`, or `\G` and press Enter.

Typing **Control+C** causes `mysql` to attempt to kill the current statement. If this cannot be done, or **Control+C** is typed again before the statement is killed, `mysql` exits.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

On Unix, the `mysql` client logs statements executed interactively to a history file. See [Section 4.5.1.3, “mysql Logging”](#).

#### 4.5.1.1. `mysql` Options

mysql supports the following options, which can be specified on the command line or in the [mysql] and [client] groups of an option file. mysql also supports the options for processing option files described at Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”.

**Table 4.3. mysql Options**

Format	Option File	Description	Introduced
--auto-rehash [248]	auto-rehash [248]	Enable automatic rehashing	
--auto-vertical-output [248]	auto-vertical-output [248]	Enable automatic vertical result set display	
--batch [248]	batch [248]	Don't use history file	
--binary-mode [248]	binary-mode [248]	Disable \r\n - to - \n translation and treatment of \0 as end-of-query	
--bind-address=ip_address [248]	bind-address [248]	Use the specified network interface to connect to the MySQL Server	
--character-sets-dir=path [248]	character-sets-dir [248]	Set the default character set	
--column-names [249]	column-names [249]	Write column names in results	
--column-type-info [249]	column-type-info [249]	Display result set metadata	
--comments [249]	comments [249]	Whether to retain or strip comments in statements sent to the server	
--compress [249]	compress [249]	Compress all information sent between the client and the server	
--connect-expired-password [249]		Indicate to server that client can handle expired-password sandbox mode.	5.6.12
--connect_timeout=value [255]	connect_timeout [255]	Set the number of seconds before connection timeout	
--database=dbname [249]	database [249]	The database to use	
--debug[=debug_options] [249]	debug [249]	Write a debugging log	
--debug-check [249]	debug-check [249]	Print debugging information when the program exits	
--debug-info [249]	debug-info [249]	Print debugging information, memory and CPU statistics when the program exits	
--default-auth=plugin [249]	default-auth=plugin [249]	The authentication plugin to use	
--default-character-set=charset_name [249]	default-character-set [249]	Use charset_name as the default character set	
--delimiter=str [249]	delimiter [249]	Set the statement delimiter	
--enable-cleartext-plugin [250]	enable-cleartext-plugin [250]	Enable cleartext authentication plugin	5.6.7
--execute=statement [250]	execute [250]	Execute the statement and quit	
--force [250]	force [250]	Continue even if an SQL error occurs	

Format	Option File	Description	Introduced
<code>--help</code> [248]		Display help message and exit	
<code>--histignore=pattern_list</code> [250]	<code>histignore</code> [250] <code>list</code> [250]	Patterns specifying which statements to ignore for logging	5.6.8
<code>--host=host_name</code> [250]	<code>host</code> [250]	Connect to the MySQL server on the given host	
<code>--html</code> [250]	<code>html</code> [250]	Produce HTML output	
<code>--ignore-spaces</code> [250]	<code>ignore-spaces</code> [250]	Ignore spaces after function names	
<code>--init-command=str</code> [250]	<code>init-command</code> [250]	SQL statement to execute after connecting	
<code>--line-numbers</code> [250]	<code>line-numbers</code> [250]	Write line numbers for errors	
<code>--local-infile[={0 1}]</code> [250]	<code>local-infile</code> [250]	Enable or disable for LOCAL capability for LOAD DATA INFILE	
<code>--login-path=name</code> [219]		Read login path options from <code>.mylogin.cnf</code>	5.6.6
<code>--max_allowed_packet=value</code> [255]	<code>max_allowed_packet</code> [255]	The maximum packet length to send to or receive from the server	
<code>--max_join_size=value</code> [255]	<code>max_join_size</code> [255]	The automatic limit for rows in a join when using <code>--safe-updates</code>	
<code>--named-commands</code> [250]	<code>named-commands</code> [250]	Enable named mysql commands	
<code>--net_buffer_length=value</code>	<code>net_buffer_length</code>	The buffer size for TCP/IP and socket communication	
<code>--no-auto-rehash</code> [251]		Disable automatic rehashing	
<code>--no-beep</code> [251]	<code>no-beep</code> [251]	Do not beep when errors occur	
<code>--one-database</code> [251]	<code>one-database</code> [251]	Ignore statements except those for the default database named on the command line	
<code>--pager[=command]</code> [251]	<code>pager</code> [251]	Use the given command for paging query output	
<code>--password[=password]</code> [251]	<code>password</code> [251]	The password to use when connecting to the server	
<code>--plugin-dir=path</code> [252]	<code>plugin-dir=path</code> [252]	The directory where plugins are located	
<code>--port=port_num</code> [252]	<code>port</code> [252]	The TCP/IP port number to use for the connection	
<code>--prompt=format_str</code> [252]	<code>prompt</code> [252]	Set the prompt to the specified format	
<code>--protocol=type</code> [252]	<code>protocol</code> [252]	The connection protocol to use	
<code>--quick</code> [252]	<code>quick</code> [252]	Do not cache each query result	
<code>--raw</code> [252]	<code>raw</code> [252]	Write column values without escape conversion	
<code>--reconnect</code> [252]	<code>reconnect</code> [252]	If the connection to the server is lost, automatically try to reconnect	
<code>--safe-updates</code> [252]	<code>safe-updates</code> [252]	Allow only UPDATE and DELETE statements that specify key values	

Format	Option File	Description	Introduced
<code>--secure-auth</code> [253]	<code>secure-auth</code> [253]	Do not send passwords to the server in old (pre-4.1.1) format	
<code>--select_limit=value</code>	<code>select_limit</code> [255]	The automatic limit for SELECT statements when using <code>--safe-updates</code>	
<code>--server-public-key-path=file_name</code> [253]	<code>server-public-key-path=file_name</code> [253]	Display help message and exit	5.6.6
<code>--show-warnings</code> [253]	<code>show-warnings</code> [253]	Show warnings after each statement if there are any	
<code>--sigint-ignore</code> [253]	<code>sigint-ignore</code> [253]	Ignore SIGINT signals (typically the result of typing Control+C)	
<code>--silent</code> [253]	<code>silent</code> [253]	Silent mode	
<code>--skip-auto-rehash</code> [248]	<code>skip-auto-rehash</code> [248]	Disable automatic rehashing	
<code>--skip-column-names</code> [253]	<code>skip-column-names</code> [253]	Do not write column names in results	
<code>--skip-line-numbers</code> [253]	<code>skip-line-numbers</code> [253]	Skip line numbers for errors	
<code>--skip-named-commands</code> [250]	<code>skip-named-commands</code> [250]	Disable named mysql commands	
<code>--skip-pager</code> [251]	<code>skip-pager</code> [251]	Disable paging	
<code>--skip-reconnect</code> [252]	<code>skip-reconnect</code> [252]	Disable reconnecting	
<code>--socket=path</code> [253]	<code>socket</code> [253]	For connections to localhost	
<code>--ssl-ca=file_name</code> [253]	<code>ssl-ca</code> [253]	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=dir_name</code> [253]	<code>ssl-capath</code> [253]	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=file_name</code> [253]	<code>ssl-cert</code> [253]	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=cipher_list</code> [253]	<code>ssl-cipher</code> [253]	A list of allowable ciphers to use for SSL encryption	
<code>--ssl-crl=file_name</code> [253]	<code>ssl-crl</code> [253]	The path to a file that contains certificate revocation lists	5.6.3
<code>--ssl-crlpath=dir_name</code> [253]	<code>ssl-crlpath</code> [253]	The path to a directory that contains certificate revocation list files	5.6.3
<code>--ssl-key=file_name</code> [253]	<code>ssl-key</code> [253]	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert</code> [253]	<code>ssl-verify-server-cert</code> [253]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--table</code> [254]	<code>table</code> [254]	Display output in tabular format	
<code>--tee=file_name</code> [254]	<code>tee</code> [254]	Append a copy of output to the given file	

Format	Option File	Description	Introduced
<code>--unbuffered</code> [254]	<code>unbuffered</code> [254]	Flush the buffer after each query	
<code>--user=user_name</code> [254]	<code>user</code> [254]	MySQL user name to use when connecting to server	
<code>--verbose</code> [254]		Verbose mode	
<code>--version</code> [254]		Display version information and exit	
<code>--vertical</code> [254]	<code>vertical</code> [254]	Print query output rows vertically (one line per column value)	
<code>--wait</code> [254]	<code>wait</code> [254]	If the connection cannot be established, wait and retry instead of aborting	
<code>--xml</code> [254]	<code>xml</code> [254]	Produce XML output	

- `--help` [248], `-?`

Display a help message and exit.

- `--auto-rehash` [248]

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` [248] to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command if you want to use name completion.

To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

- `--auto-vertical-output` [248]

Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.)

- `--batch` [248], `-B`

Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` [252] option.

- `--binary-mode` [248]

This option helps when processing `mysqlbinlog` output that may contain `BLOB` values. By default, `mysql` translates `\r\n` in statement strings to `\n` and interprets `\0` as the statement terminator. `--binary-mode` [248] disables both features. It also disables all `mysql` commands except `charset` and `delimiter` in non-interactive mode (for input piped to `mysql` or loaded using the `source` command).

This option was added in MySQL 5.6.3.

- `--bind-address=ip_address` [248]

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=path` [248]

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--column-names` [249]

Write column names in results.

- `--column-type-info` [249], `-m`

Display result set metadata.

- `--comments` [249], `-c`

Whether to preserve comments in statements sent to the server. The default is `--skip-comments` (discard comments), enable with `--comments` (preserve comments).

- `--compress` [249], `-C`

Compress all information sent between the client and the server if both support compression.

- `--connect-expired-password` [249]

Indicate to the server that the client can handle sandbox mode if the account used to connect has an expired password. This can be useful for noninteractive invocations of `mysql` because normally the server disconnects noninteractive clients that attempt to connect using an account with an expired password. (See [Section 6.3.6, “Password Expiration and Sandbox Mode”](#).) This option was added in MySQL 5.6.12.

- `--database=db_name` [249], `-D db_name`

The database to use. This is useful primarily in an option file.

- `--debug[=debug_options]` [249], `-# [debug_options]`

Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysql.trace'`.

- `--debug-check` [249]

Print some debugging information when the program exits.

- `--debug-info` [249], `-T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin` [249]

The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--default-character-set=charset_name` [249]

Use `charset_name` as the default character set for the client and connection.

A common issue that can occur when the operating system uses `utf8` or another multi-byte character set is that output from the `mysql` client is formatted incorrectly, due to the fact that the MySQL client uses the `latin1` character set by default. You can usually fix such issues by using this option to force the client to use the system character set instead.

See [Section 10.5, “Character Set Configuration”](#), for more information.

- `--delimiter=str` [249]

Set the statement delimiter. The default is the semicolon character (`;`).

- `--disable-named-commands` [250]

Disable named commands. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semicolon (“;”). `mysql` starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See [Section 4.5.1.2, “mysql Commands”](#).

- `--enable-cleartext-plugin` [250]

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.6.7.

- `--execute=statement` [250], `-e statement`

Execute the statement and quit. The default output format is like that produced with `--batch` [248]. See [Section 4.2.3.1, “Using Options on the Command Line”](#), for some examples. With this option, `mysql` does not use the history file.

- `--force` [250], `-f`

Continue even if an SQL error occurs.

- `--histignore` [250]

A colon-separated list of one or more patterns specifying statements to ignore for logging purposes. These patterns are added to the default pattern list (“`*IDENTIFIED*:*PASSWORD*`”). The value specified for this option affects logging of statements written to the history file. For more information, see [Section 4.5.1.3, “mysql Logging”](#). This option was added in MySQL 5.6.8.

- `--host=host_name` [250], `-h host_name`

Connect to the MySQL server on the given host.

- `--html` [250], `-H`

Produce HTML output.

- `--ignore-spaces` [250], `-i`

Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` [604] SQL mode (see [Section 5.1.7, “Server SQL Modes”](#)).

- `--init-command=str` [250]

SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs.

- `--line-numbers` [250]

Write line numbers for errors. Disable this with `--skip-line-numbers` [253].

- `--local-infile[={0|1}]` [250]

Enable or disable `LOCAL` capability for `LOAD DATA INFILE`. With no value, the option enables `LOCAL`. The option may be given as `--local-infile=0` [250] or `--local-infile=1` [250] to explicitly disable or enable `LOCAL`. Enabling `LOCAL` has no effect if the server does not also support it.

- `--named-commands` [250], `-G`

Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` [250] to disable named commands. See [Section 4.5.1.2, “mysql Commands”](#).

- `--no-auto-rehash` [248], `-A`

This has the same effect as `--skip-auto-rehash`. See the description for `--auto-rehash` [248].

- `--no-beep` [251], `-b`

Do not beep when errors occur.

- `--one-database` [251], `-o`

Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on `USE` statements.

Initially, `mysql` executes statements in the input because specifying a database `db_name` on the command line is equivalent to inserting `USE db_name` at the beginning of the input. Then, for each `USE` statement encountered, `mysql` accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that `mysql` is invoked to process this set of statements:

```
DELETE FROM db2.t2;
USE db2;
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

- The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.
- The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.
- The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.
- `--pager[=command]` [251]

Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat` [`> filename`], and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager` [251]. Section 4.5.1.2, “`mysql` Commands”, discusses output paging further.

- `--password[=password]` [251], `-p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` [251] or `-p` option on the command line, `mysql` prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “`End-User Guidelines for Password Security`”. You can use an option file to avoid giving the password on the command line.

- `--pipe` [251], `-W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path` [252]

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` [249] option is used to specify an authentication plugin but `mysql` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--port=port_num` [252], `-P port_num`

The TCP/IP port number to use for the connection.

- `--prompt=format_str` [252]

Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in [Section 4.5.1.2, “mysql Commands”](#).

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [252]

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick` [252], `-q`

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw` [252], `-r`

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` [248] or `--silent` [253] option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` [252] option disables this character escaping.

The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+-----+
| CHAR(92) |
+-----+
| \       |
+-----+

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\
```

- `--reconnect` [252]

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect` [252].

- `--safe-updates` [252], `--i-am-a-dummy` [252], `-U`

Permit only those `UPDATE` and `DELETE` statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using `--safe-`

`updates` [252] on the command line. See [Section 4.5.1.6, “mysql Tips”](#), for more information about this option.

- `--secure-auth` [253]

Do not send passwords to the server in old (pre-4.1.1) format. This prevents connections except for servers that use the newer password format. As of MySQL 5.6.7, this option is enabled by default; use `--skip-secure-auth` [253] to disable it.

- `--server-public-key-path=file_name` [253]

The path name to a file containing the server RSA public key. The file must be in PEM format. The public key is used for RSA encryption of the client password for connections to the server made using accounts that authenticate with the `sha256_password` plugin. This option is ignored for client accounts that do not authenticate with that plugin. It is also ignored if password encryption is not needed, as is the case when the client connects to the server using an SSL connection.

The server sends the public key to the client as needed, so it is not necessary to use this option for RSA password encryption to occur. It is more efficient to do so because then the server need not send the key.

For additional discussion regarding use of the `sha256_password` plugin, including how to get the RSA public key, see [Section 6.3.7.2, “The SHA-256 Authentication Plugin”](#).

This option is available only if MySQL was built using OpenSSL. It was added in MySQL 5.6.6 under the name `--server-public-key` and renamed in 5.6.7 to `--server-public-key-path`.

- `--show-warnings` [253]

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- `--sigint-ignore` [253]

Ignore `SIGINT` signals (typically the result of typing **Control+C**).

- `--silent` [253], `-s`

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` [252] option.

- `--skip-column-names` [253], `-N`

Do not write column names in results.

- `--skip-line-numbers` [253], `-L`

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=path` [253], `-S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` [810] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--table [254]`, `-t`

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=file_name [254]`

Append a copy of output to the given file. This option works only in interactive mode. [Section 4.5.1.2, “mysql Commands”](#), discusses tee files further.

- `--unbuffered [254]`, `-n`

Flush the buffer after each query.

- `--user=user_name [254]`, `-u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose [254]`, `-v`

Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version [254]`, `-V`

Display version information and exit.

- `--vertical [254]`, `-E`

Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait [254]`, `-w`

If the connection cannot be established, wait and retry instead of aborting.

- `--xml [254]`, `-X`

Produce XML output.

```
<field name="column_name">NULL</field>
```

The output when `--xml [254]` is used with `mysql` matches that of `mysqldump --xml [291]`. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#) for details.

The XML output also uses an XML namespace, as shown here:

```
shell> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%'"
<?xml version="1.0"?>

<resultset statement="SHOW VARIABLES LIKE 'version%'" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
<row>
<field name="Variable_name">version</field>
<field name="Value">5.0.40-debug</field>
</row>

<row>
<field name="Variable_name">version_comment</field>
<field name="Value">Source distribution</field>
</row>

<row>
<field name="Variable_name">version_compile_machine</field>
<field name="Value">i686</field>
</row>
```

```
<row>
<field name="Variable_name">version_compile_os</field>
<field name="Value">suse-linux-gnu</field>
</row>
</resultset>
```

(See Bug #25946.)

You can also set the following variables by using `--var_name=value`.

- `connect_timeout`

The number of seconds before connection timeout. (Default value is 0.)

- `max_allowed_packet`

The maximum packet length to send to or receive from the server. (Default value is 16MB.)

- `max_join_size` [505]

The automatic limit for rows in a join when using `--safe-updates` [252]. (Default value is 1,000,000.)

- `net_buffer_length` [515]

The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `select_limit`

The automatic limit for `SELECT` statements when using `--safe-updates` [252]. (Default value is 1,000.)

#### 4.5.1.2. `mysql` Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help

List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?          (? ) Synonym for `help`.
clear      (\c) Clear command.
connect    (\r) Reconnect to the server. Optional arguments are db and host.
delimiter (\d) Set statement delimiter.
edit       (\e) Edit command with $EDITOR.
ego        (\G) Send command to mysql server, display result vertically.
exit       (\q) Exit mysql. Same as quit.
go         (\g) Send command to mysql server.
help       (\h) Display this help.
nopager    (\n) Disable pager, print to stdout.
notee     (\t) Don't write into outfile.
pager      (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print      (\p) Print current command.
prompt     (\R) Change your mysql prompt.
quit       (\q) Quit mysql.
rehash     (\#) Rebuild completion hash.
source     (\.) Execute an SQL script file. Takes a file name as an argument.
status     (\s) Get status information from the server.
system     (\!) Execute a system shell command.
tee        (\T) Set outfile [to_outfile]. Append everything into given
         outfile.
use        (\u) Use another database. Takes database name as argument.
charset    (\C) Switch to another charset. Might be needed for processing
         binlog with multi-byte charsets.
warnings   (\W) Show warnings after every statement.
```

```
nowarning (\w) Don't show warnings after every statement.
```

```
For server side help, type 'help contents'
```

If `mysql` is invoked with the `--binary-mode` [248] option, all `mysql` commands are disabled except `charset` and `delimiter` in non-interactive mode (for input piped to `mysql` or loaded using the `source` command).

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multi-line `/* ... */` comments is not supported.

- `help [arg], \h [arg], \? [arg], ? [arg]`

Display a help message listing the available `mysql` commands.

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see [Section 4.5.1.4, “mysql Server-Side Help”](#).

- `charset charset_name, \C charset_name`

Change the default character set and issue a `SET NAMES` statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

- `clear, \c`

Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name host_name]], \r [db_name host_name]]`

Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- `delimiter str, \d str`

Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (“;”).

The delimiter string can be specified as an unquoted or quoted argument on the `delimiter` command line. Quoting can be done with either single quote (‘), double quote (“), or backtick (`) characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash (“\”) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

`mysql` interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as `X`, you will be unable to use the word `INDEX` in statements. `mysql` interprets this as `INDE` followed by the delimiter `X`.

When the delimiter recognized by `mysql` is set to something other than the default of “;”, instances of that character are sent to the server without interpretation. However, the server itself still interprets “;” as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see [Section 21.8.16, “C API Support for Multiple Statement Execution”](#)), and for parsing the body of stored procedures and functions, triggers, and events (see [Section 18.1, “Defining Stored Programs”](#)).

- `edit, \e`

Edit the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine which editor to use. The default editor is `vi` if neither variable is set.

The `edit` command works only in Unix.

- `ego, \G`

Send the current statement to the server to be executed and display the result using vertical format.

- `exit, \q`

Exit `mysql`.

- `go, \g`

Send the current statement to the server to be executed.

- `nopager, \n`

Disable output paging. See the description for `pager`.

The `nopager` command works only in Unix.

- `notee, \t`

Disable output copying to the tee file. See the description for `tee`.

- `nowarning, \w`

Enable display of warnings after each statement.

- `pager [command], \P [command]`

Enable output paging. By using the `--pager [251]` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Pager functionality works only in interactive mode.

Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- `print, \p`

Print the current input statement without executing it.

- `prompt [str], \R [str]`

Reconfigure the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- `quit, \q`

Exit `mysql`.

- `rehash, \#`

Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` [248] option.)

- `source file_name, \. file_name`

Read the named file and executes the statements contained therein. On Windows, you can specify path name separators as `/` or `\\`.

- `status, \s`

Provide status information about the connection and the server you are using. If you are running in `--safe-updates` [252] mode, `status` also prints the values for the `mysql` variables that affect your queries.

- `system command, \! command`

Execute the given command using your default command interpreter.

The `system` command works only in Unix.

- `tee [file_name], \T [file_name]`

By using the `--tee` [254] option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

- `use db_name, \u db_name`

Use `db_name` as the default database.

- `warnings, \W`

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -S
```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
shell> man less
```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -S -F -X
```

- You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \  
      | tee /dr2/tmp/res2.txt | less -n -i -S
```

In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

Option	Description
<code>\c</code>	A counter that increments for each statement you issue
<code>\D</code>	The full current date
<code>\d</code>	The default database
<code>\h</code>	The server host
<code>\l</code>	The current delimiter
<code>\m</code>	Minutes of the current time
<code>\n</code>	A newline character
<code>\O</code>	The current month in three-letter format (Jan, Feb, ...)
<code>\o</code>	The current month in numeric format
<code>\P</code>	am/pm
<code>\p</code>	The current TCP/IP port or socket file
<code>\R</code>	The current time, in 24-hour military time (0–23)
<code>\r</code>	The current time, standard 12-hour time (1–12)
<code>\S</code>	Semicolon
<code>\s</code>	Seconds of the current time
<code>\t</code>	A tab character
<code>\U</code>	Your full <code>user_name@host_name</code> account name
<code>\u</code>	Your user name
<code>\v</code>	The server version
<code>\w</code>	The current day of the week in three-letter format (Mon, Tue, ...)
<code>\Y</code>	The current year, four digits
<code>\y</code>	The current year, two digits
<code>\_</code>	A space
<code>\</code>	A space (a space follows the backslash)
<code>\'</code>	Single quote
<code>\"</code>	Double quote
<code>\\</code>	A literal “\” backslash character
<code>\x</code>	<code>x</code> , for any “ <code>x</code> ” not listed above

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
shell> export MYSQL_PS1="(\\u@\\h) [\\d]> "
```

- *Use a command-line option.* You can set the `--prompt` [252] option on the command line to `mysql`. For example:

```
shell> mysql --prompt="(\\u@\\h) [\\d]> "  
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]  
prompt=(\\u@\\h) [\\d]>\\_
```

In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in [Section 4.2.3.3, “Using Option Files”](#).) The overlap may cause you problems if you use single backslashes. For example, `\\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS>` format:

```
[mysql]  
prompt="\\r:\\m:\\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\\R`) command. For example:

```
mysql> prompt (\\u@\\h) [\\d]>\\_  
PROMPT set to '(\\u@\\h) [\\d]>\\_'  
(user@host) [database]>  
(user@host) [database]> prompt  
Returning to default PROMPT of mysql>  
mysql>
```

### 4.5.1.3. mysql Logging

On Unix, the `mysql` client logs statements executed interactively to a history file. By default, this file is named `.mysql_history` in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

#### How Logging Occurs

Statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the `--batch` [248] or `--execute` [250] option.
- Statements are ignored and not logged if they match any pattern in the “ignore” list. This list is described later.
- `mysql` logs each nonignored, nonempty statement line individually.
- If a nonignored statement spans multiple lines (not including the terminating delimiter), `mysql` concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```
mysql> SELECT
-> 'Today is'
-> ,
-> CONCAT()
-> ;
```

In this case, `mysql` logs the “SELECT”, “Today is”, “,”, “CONCAT()”, and “;” lines as it reads them. It also logs the complete statement, after mapping `SELECT\n'Today is'\n,\nCURDATE()` to `SELECT 'Today is' , CURDATE()`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT
'Today is'
,
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

As of MySQL 5.6.8, `mysql` ignores for logging purposes statements that match any pattern in the “ignore” list. By default, the pattern list is “`*IDENTIFIED*:*PASSWORD*`”, to ignore statements that refer to passwords. Pattern matching is not case sensitive. Within patterns, two characters are special:

- `?` matches any single character.
- `*` matches any sequence of zero or more characters.

To specify additional patterns, use the `--histignore [250]` option or set the `MYSQL_HISTIGNORE` environment variable. (If both are specified, the option value takes precedence.) The value should be a colon-separated list of one or more patterns, which are appended to the default pattern list.

Patterns specified on the command line might need to be quoted or escaped to prevent your command interpreter from treating them specially. For example, to suppress logging for `UPDATE` and `DELETE` statements in addition to statements that refer to passwords, invoke `mysql` like this:

```
shell> mysql --histignore="*UPDATE*:*DELETE*"
```

## Controlling the History File

The `.mysql_history` file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

If you do not want to maintain a history file, first remove `.mysql_history` if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the `MYSQL_HISTFILE` environment variable to `/dev/null`. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`; this need be done only once:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

### 4.5.1.4. mysql Server-Side Help

```
mysql> help search_string
```

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.10, “Server-Side Help”](#)).

If there is no match for the search string, the search fails:

```
mysql> help me

Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the
following categories:
  Account Management
  Administration
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Language Structure
  Plugins
  Storage Engines
  Stored Routines
  Table Maintenance
  Transactions
  Triggers
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
  SHOW
  SHOW BINARY LOGS
  SHOW ENGINE
  SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as
part of the procedure described in [purge-binary-logs], that shows how
to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| binlog.000015    | 724935   |
| binlog.000016    | 733481   |
+-----+-----+
```

The search string can contain the the wildcard characters “%” and “\_”. These have the same meaning as for pattern-matching operations performed with the [LIKE \[1190\]](#) operator. For example, `HELP rep%` returns a list of topics that begin with `rep`:

```
mysql> HELP rep%
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
  REPAIR TABLE
  REPEAT FUNCTION
  REPEAT LOOP
  REPLACE
  REPLACE FUNCTION
```

#### 4.5.1.5. Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke `mysql` with the `--verbose` [254] option, which causes each statement to be displayed before the result that it produces.

`mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8` [249].

For more information about batch mode, see [Section 3.5, “Using `mysql` in Batch Mode”](#).

#### 4.5.1.6. `mysql` Tips

This section describes some techniques that can help you use `mysql` more effectively.

##### 4.5.1.6.1. Input-Line Editing

`mysql` supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the **left-arrow** and **right-arrow** keys move horizontally within the current input line, and the **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines. **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press **Enter**.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build `mysql` (for example, the `libedit` or `readline` library).

Documentation for the `libedit` and `readline` libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: `.editrc` for `libedit` and `.inputrc` for `readline`.

For example, in `libedit`, **Control+W** deletes everything before the current cursor position and **Control+U** deletes the entire line. In `readline`, **Control+W** deletes the word before the cursor and **Control+U** deletes everything before the current cursor position. If `mysql` was built using `libedit`, a user who prefers the `readline` behavior for these two keys can put the following lines in the `.editrc` file (creating the file if necessary):

```
bind "^W" ed-delete-prev-word
```

```
bind "^U" vi-kill-line-prev
```

To see the current set of key bindings, temporarily put a line that says only `bind` at the end of `.editrc`. `mysql` will show the bindings when it starts.

#### 4.5.1.6.2. Unicode Support on Windows

Windows provides APIs based on UTF-16LE for reading from and writing to the console. As of MySQL 5.6.2, the `mysql` client for Windows is able to use these APIs. As of 5.6.3, the Windows installer creates an item in the MySQL menu named `MySQL command line client - Unicode`. This item invokes the `mysql` client with properties set to communicate through the console to the MySQL server using Unicode.

To take advantage of this support manually, run `mysql` within a console that uses a compatible Unicode font and set the default character set to a Unicode character set that is supported for communication with the server:

1. Open a console window.
2. Go to the console window properties, select the font tab, and choose Lucida Console or some other compatible Unicode font. This is necessary because console windows start by default using a DOS raster font that is inadequate for Unicode.
3. Execute `mysql.exe` with the `--default-character-set=utf8` [249] (or `utf8mb4`) option. This option is necessary because `utf16le` is not supported as a connection character set.

With those changes, `mysql` will use the Windows APIs to communicate with the console using UTF-16LE, and communicate with the server using UTF-8. (The menu item mentioned previously sets the font and character set as just described.)

To avoid those steps each time you run `mysql`, you can create a shortcut that invokes `mysql.exe`. The shortcut should set the console font to Lucida Console or some other compatible Unicode font, and pass the `--default-character-set=utf8` [249] (or `utf8mb4`) option to `mysql.exe`.

Alternatively, create a shortcut that only sets the console font, and set the character set in the `[mysql]` group of your `my.ini` file:

```
[mysql]
default-character-set=utf8
```

#### 4.5.1.6.3. Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
***** 1. row *****
  msg_nro: 3068
    date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
   reply: monty@no.spam.com
 mail_to: "Thimble Smith" <tim@no.spam.com>
    sbj: UTF-8
    txt: >>>> "Thimble" == Thimble Smith writes:

Thimble> Hi. I think this is a good idea. Is anyone familiar
Thimble> with UTF-8 or Unicode? Otherwise, I'll put this on my
Thimble> TODO list and see what happens.

Yes, please do that.

Regards,
Monty
```

```
file: inbox-jani-1
hash: 190402944
1 row in set (0.09 sec)
```

#### 4.5.1.6.4. Using the `--safe-updates` [252] Option

For beginners, a useful startup option is `--safe-updates` [252] (or `--i-am-a-dummy` [252], which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM tbl_name` statement but forgotten the `WHERE` clause. Normally, such a statement deletes all rows from the table. With `--safe-updates` [252], you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` [252] option, `mysql` issues the following statement when it connects to the MySQL server:

```
SET sql_safe_updates=1, sql_select_limit=1000, max_join_size=1000000;
```

See [Section 5.1.4, “Server System Variables”](#).

The `SET` statement has the following effects:

- You are not permitted to execute an `UPDATE` or `DELETE` statement unless you specify a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;

UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large `SELECT` results to 1,000 rows unless the statement includes a `LIMIT` clause.
- The server aborts multiple-table `SELECT` statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select_limit` and `--max_join_size` options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

#### 4.5.1.6.5. Disabling `mysql` Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id: 1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+-----+
| a     |
+-----+
| NULL |
+-----+
1 row in set (0.05 sec)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` [252] option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see [Section 21.8.15, “Controlling Automatic Reconnection Behavior”](#).

## 4.5.2. `mysqladmin` — Client for Administering a MySQL Server

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- `create db_name`  
Create a new database named `db_name`.
- `debug`  
Tell the server to write debug information to the error log. Format and content of this information is subject to change.  
  
This includes information about the Event Scheduler. See [Section 18.4.5, “Event Scheduler Status”](#).
- `drop db_name`  
Delete the database named `db_name` and all its tables.
- `extended-status`  
Display the server status variables and their values.
- `flush-hosts`  
Flush all information in the host cache.
- `flush-logs`  
Flush all logs.
- `flush-privileges`  
Reload the grant tables (same as `reload`).
- `flush-status`  
Clear status variables.
- `flush-tables`  
Flush all tables.
- `flush-threads`  
Flush the thread cache.
- `kill id,id,...`  
Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

- `old-password new-password`

This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See [Section 6.1.2.4, “Password Hashing in MySQL”](#).)

- `password new-password`

Set a new password. This changes the password to `new-password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you will need to specify the new password.

If the `new-password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
shell> mysqladmin password "my new password"
```

In MySQL 5.6, the new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

#### Caution

Do not use this command used if the server was started with the `--skip-grant-tables` [439] option. No password change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- `ping`

Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- `processlist`

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` [272] option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See [Section 13.7.5.30, “SHOW PROCESSLIST Syntax”](#).)

- `reload`

Reload the grant tables.

- `refresh`

Flush all tables and close and open log files.

- `shutdown`

Stop the server.

- `start-slave`

Start replication on a slave server.

- `status`  
Display a short server status message.
- `stop-slave`  
Stop replication on a slave server.
- `variables`  
Display the server system variables and their values.
- `version`  
Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+-----+-----+-----+-----+-----+-----+-----+
| Id | User | Host | db | Command | Time | State | Info |
+-----+-----+-----+-----+-----+-----+-----+
| 51 | monty | localhost | | Query | 0 | | show processlist |
+-----+-----+-----+-----+-----+-----+-----+
Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- `Uptime [602]`  
The number of seconds the MySQL server has been running.
- `Threads`  
The number of active threads (clients).
- `Questions [596]`  
The number of questions (queries) from clients since the server was started.
- `Slow queries`  
The number of queries that have taken more than `long_query_time [500]` seconds. See [Section 5.2.5, “The Slow Query Log”](#).
- `Opens`  
The number of tables the server has opened.
- `Flush tables`  
The number of `flush-*`, `refresh`, and `reload` commands the server has executed.
- `Open tables`  
The number of tables that currently are open.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. `mysqladmin` also supports the options for

processing option files described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.4. mysqladmin Options**

Format	Option File	Description	Introduced
<code>--bind-address=ip_address</code> [270]	<code>bind-address</code> [270]	Use the specified network interface to connect to the MySQL Server	
<code>--compress</code> [270]	<code>compress</code> [270]	Compress all information sent between the client and the server	
<code>--connect_timeout=seconds</code> [272]	<code>connect_timeout</code> [272]	The number of seconds before connection timeout	
<code>--count=#</code> [270]	<code>count</code> [270]	The number of iterations to make for repeated command execution	
<code>--debug[=debug_options]</code> [271]	<code>debug</code> [271]	Write a debugging log	
<code>--debug-check</code> [271]	<code>debug-check</code> [271]	Print debugging information when the program exits	
<code>--debug-info</code> [271]	<code>debug-info</code> [271]	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code> [271]	<code>default-auth=plugin</code> [271]	The authentication plugin to use	
<code>--default-character-set=charset_name</code>	<code>default-character-set</code> [271]	Use <code>charset_name</code> as the default character set	
<code>--enable-cleartext-plugin</code> [271]	<code>enable-cleartext-plugin</code> [271]	Enable cleartext authentication plugin	5.6.7
<code>--force</code> [271]	<code>force</code> [271]	Continue even if an SQL error occurs	
<code>--help</code> [270]		Display help message and exit	
<code>--host=host_name</code> [271]	<code>host</code> [271]	Connect to the MySQL server on the given host	
<code>--login-path=name</code> [219]		Read login path options from <code>.mylogin.cnf</code>	5.6.6
<code>--no-beep</code> [271]	<code>no-beep</code> [271]	Do not beep when errors occur	
<code>--password[=password]</code> [271]	<code>password</code> [271]	The password to use when connecting to the server	
<code>--pipe</code> [271]		On Windows, connect to server using a named pipe	
<code>--plugin-dir=path</code> [271]	<code>plugin-dir=path</code> [271]	The directory where plugins are located	
<code>--port=port_num</code> [271]	<code>port</code> [271]	The TCP/IP port number to use for the connection	
<code>--protocol=type</code> [272]	<code>protocol</code> [272]	The connection protocol to use	
<code>--relative</code> [272]	<code>relative</code> [272]	Show the difference between the current and previous values when used with the <code>--sleep</code> option	
<code>--shutdown_timeout=seconds</code> [272]	<code>shutdown_timeout</code> [272]	The maximum number of seconds to wait for server shutdown	
<code>--silent</code> [272]	<code>silent</code> [272]	Silent mode	

Format	Option File	Description	Introduced
-- sleep=delay [272]	sleep [272]	Execute commands repeatedly, sleeping for delay seconds in between	
-- socket=path [272]	socket [272]	For connections to localhost	
--ssl- ca=file_name [272]	ssl-ca [272]	The path to a file that contains a list of trusted SSL CAs	
--ssl- capath=dir_name [272]	ssl-capath [272]	The path to a directory that contains trusted SSL CA certificates in PEM format	
--ssl- cert=file_name [272]	ssl-cert [272]	The name of the SSL certificate file to use for establishing a secure connection	
--ssl- cipher=cipher_list [272]	ssl-cipher [272]	A list of allowable ciphers to use for SSL encryption	
--ssl- crl=file_name [272]	ssl-crl [272]	The path to a file that contains certificate revocation lists	5.6.3
--ssl- crlpath=dir_name [272]	ssl-crlpath [272]	The path to a directory that contains certificate revocation list files	5.6.3
--ssl- key=file_name [272]	ssl-key [272]	The name of the SSL key file to use for establishing a secure connection	
--ssl-verify-server- cert [272]	ssl-verify-server- cert [272]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
-- user=user_name, [272]	user [272]	MySQL user name to use when connecting to server	
--verbose [272]		Verbose mode	
--version [272]		Display version information and exit	
--vertical [272]	vertical [272]	Print query output rows vertically (one line per column value)	
--wait [272]	wait [272]	If the connection cannot be established, wait and retry instead of aborting	

- `--help [270]`, `-?`

Display a help message and exit.

- `--bind-address=ip_address [248]`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=path [270]`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--compress [270]`, `-C`

Compress all information sent between the client and the server if both support compression.

- `--count=N [270]`, `-c N`

The number of iterations to make for repeated command execution if the `--sleep [272]` option is given.

- `--debug[=debug_options] [271], -# [debug_options]`

Write a debugging log. A typical *debug\_options* string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqladmin.trace'`.

- `--debug-check [271]`

Print some debugging information when the program exits.

- `--debug-info [271]`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin [271]`

The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--default-character-set=charset_name [271]`

Use *charset\_name* as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--enable-cleartext-plugin [271]`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.6.7.

- `--force [271], -f`

Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

- `--host=host_name [271], -h host_name`

Connect to the MySQL server on the given host.

- `--no-beep [271], -b`

Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

- `--password[=password] [271], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password [271]` or `-p` option on the command line, `mysqladmin` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe [271], -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path [271]`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth [271]` option is used to specify an authentication plugin but `mysqladmin` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--port=port_num [271], -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [272]

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--relative` [272], `-r`

Show the difference between the current and previous values when used with the `--sleep` [272] option. This option works only with the `extended-status` command.

- `--silent` [272], `-s`

Exit silently if a connection to the server cannot be established.

- `--sleep=delay` [272], `-i delay`

Execute commands repeatedly, sleeping for *delay* seconds in between. The `--count` [270] option determines the number of iterations. If `--count` [270] is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=path` [272], `-S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` [810] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name` [272], `-u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose` [272], `-v`

Verbose mode. Print more information about what the program does.

- `--version` [272], `-V`

Display version information and exit.

- `--vertical` [272], `-E`

Print output vertically. This is similar to `--relative` [272], but prints output vertically.

- `--wait[=count]` [272], `-w[count]`

If the connection cannot be established, wait and retry instead of aborting. If a *count* value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value`.

- `connect_timeout`

The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `shutdown_timeout`

The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

### 4.5.3. mysqlcheck — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#), for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` [276] or `--all-databases` [276] option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for `mysql_upgrade` because that program invokes `mysqlcheck` to check all tables and repair them if necessary.)

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in [Section 13.7.2, “Table Maintenance Statements”](#).

The `MyISAM` storage engine supports all four maintenance operations, so `mysqlcheck` can be used to perform any of them on `MyISAM` tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a `MEMORY` table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
test.t
note      : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies. This will be the case, for example, for `InnoDB` tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

### Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```
shell> mysqlcheck [options] db_name [tbl_name ...]
shell> mysqlcheck [options] --databases db_name ...
shell> mysqlcheck [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` [276] or `--all-databases` [276] option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check` [276]) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The names shown in the following table can be used to change `mysqlcheck` default behavior.

Command	Meaning
<code>mysqlrepair</code>	The default option is <code>--repair</code> [278]
<code>mysqlanalyze</code>	The default option is <code>--analyze</code> [276]
<code>mysqloptimize</code>	The default option is <code>--optimize</code> [277]

mysqlcheck supports the following options, which can be specified on the command line or in the [mysqlcheck] and [client] groups of an option file. mysqlcheck also supports the options for processing option files described at Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”.

**Table 4.5. mysqlcheck Options**

Format	Option File	Description	Introduced
--all-databases [276]	all-databases [276]	Check all tables in all databases	
--all-in-1 [276]	all-in-1 [276]	Execute a single statement for each database that names all the tables from that database	
--analyze [276]	analyze [276]	Analyze the tables	
--auto-repair [276]	auto-repair [276]	If a checked table is corrupted, automatically fix it	
--bind-address=ip_address [276]	bind-address [276]	Use the specified network interface to connect to the MySQL Server	
--character-sets-dir=path [276]	character-sets-dir [276]	The directory where character sets are installed	
--check [276]	check [276]	Check the tables for errors	
--check-only-changed [276]	check-only-changed [276]	Check only tables that have changed since the last check	
--check-upgrade [276]	check-upgrade [276]	Invoke CHECK TABLE with the FOR UPGRADE option	
--compress [276]	compress [276]	Compress all information sent between the client and the server	
--databases [276]	databases [276]	Process all tables in the named databases	
--debug [277]	debug [277]	Write a debugging log	
--debug-check [277]	debug-check [277]	Print debugging information when the program exits	
--debug-info [277]	debug-info [277]	Print debugging information, memory and CPU statistics when the program exits	
--default-auth=plugin [277]	default-auth=plugin [277]	The authentication plugin to use	5.6.2
--default-character-set=charset_name [277]	default-character-set [277]	Use charset_name as the default character set	
--extended [277]	extended [277]	Check and repair tables	
--fast [277]	fast [277]	Check only tables that have not been closed properly	
--fix-db-names [277]	fix-db-names [277]	Convert database names to 5.1 format	
--fix-table-names [277]	fix-table-names [277]	Convert table names to 5.1 format	
--force [277]	force [277]	Continue even if an SQL error occurs	
--help [276]		Display help message and exit	
--host=host_name [277]	host [277]	Connect to the MySQL server on the given host	

Format	Option File	Description	Introduced
<a href="#">--login-path=name</a> [219]		Read login path options from .mylogin.cnf	5.6.6
<a href="#">--medium-check</a> [277]	<a href="#">medium-check</a> [277]	Do a check that is faster than an --extended operation	
<a href="#">--optimize</a> [277]	<a href="#">optimize</a> [277]	Optimize the tables	
<a href="#">--password[=password]</a> [277]	<a href="#">password</a> [277]	The password to use when connecting to the server	
<a href="#">--pipe</a> [278]		On Windows, connect to server using a named pipe	
<a href="#">--plugin-dir=path</a> [278]	<a href="#">plugin-dir=path</a> [278]	The directory where plugins are located	5.6.2
<a href="#">--port=port_num</a> [278]	<a href="#">port</a> [278]	The TCP/IP port number to use for the connection	
<a href="#">--protocol=type</a> [278]	<a href="#">protocol</a> [278]	The connection protocol to use	
<a href="#">--quick</a> [278]	<a href="#">quick</a> [278]	The fastest method of checking	
<a href="#">--repair</a> [278]	<a href="#">repair</a> [278]	Perform a repair that can fix almost anything except unique keys that are not unique	
<a href="#">--silent</a> [278]	<a href="#">silent</a> [278]	Silent mode	
<a href="#">--skip-database=db_name</a> [278]	<a href="#">skip-database</a> [278]	Omit this database from performed operations	5.6.11
<a href="#">--socket=path</a> [278]	<a href="#">socket</a> [278]	For connections to localhost	
<a href="#">--ssl-ca=file_name</a> [278]	<a href="#">ssl-ca</a> [278]	The path to a file that contains a list of trusted SSL CAs	
<a href="#">--ssl-capath=dir_name</a> [278]	<a href="#">ssl-capath</a> [278]	The path to a directory that contains trusted SSL CA certificates in PEM format	
<a href="#">--ssl-cert=file_name</a> [278]	<a href="#">ssl-cert</a> [278]	The name of the SSL certificate file to use for establishing a secure connection	
<a href="#">--ssl-cipher=cipher_list</a> [278]	<a href="#">ssl-cipher</a> [278]	A list of allowable ciphers to use for SSL encryption	
<a href="#">--ssl-crl=file_name</a> [278]	<a href="#">ssl-crl</a> [278]	The path to a file that contains certificate revocation lists	5.6.3
<a href="#">--ssl-crlpath=dir_name</a> [278]	<a href="#">ssl-crlpath</a> [278]	The path to a directory that contains certificate revocation list files	5.6.3
<a href="#">--ssl-key=file_name</a> [278]	<a href="#">ssl-key</a> [278]	The name of the SSL key file to use for establishing a secure connection	
<a href="#">--ssl-verify-server-cert</a> [278]	<a href="#">ssl-verify-server-cert</a> [278]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<a href="#">--tables</a> [278]	<a href="#">tables</a> [278]	Overrides the --databases or -B option	
<a href="#">--use-frm</a> [279]	<a href="#">use-frm</a> [279]	For repair operations on MyISAM tables	
<a href="#">--user=user_name,</a> [279]	<a href="#">user</a> [279]	MySQL user name to use when connecting to server	
<a href="#">--verbose</a> [279]		Verbose mode	
<a href="#">--version</a> [279]		Display version information and exit	

Format	Option File	Description	Introduced
<code>--write-binlog</code> [279]	<code>write-binlog</code> [279]	Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. <code>--skip-write-binlog</code> adds NO_WRITE_TO_BINLOG to these statements.	

- `--help` [276], `-?`

Display a help message and exit.

- `--all-databases` [276], `-A`

Check all tables in all databases. This is the same as using the `--databases` [276] option and naming all the databases on the command line.

- `--all-in-1` [276], `-1`

Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze` [276], `-a`

Analyze the tables.

- `--auto-repair` [276]

If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=path` [276]

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--check` [276], `-c`

Check the tables for errors. This is the default operation.

- `--check-only-changed` [276], `-C`

Check only tables that have changed since the last check or that have not been closed properly.

- `--check-upgrade` [276], `-g`

Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server. This option automatically enables the `--fix-db-names` [277] and `--fix-table-names` [277] options.

- `--compress` [276]

Compress all information sent between the client and the server if both support compression.

- `--databases` [276], `-B`

Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names.

- `--debug[=debug_options] [277], -# [debug_options]`

Write a debugging log. A typical *debug\_options* string is '*d:t:o,file\_name*'. The default is '*d:t:o*'.

- `--debug-check [277]`

Print some debugging information when the program exits.

- `--debug-info [277]`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name [277]`

Use *charset\_name* as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--extended [277], -e`

If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--default-auth=plugin [277]`

The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--fast [277], -F`

Check only tables that have not been closed properly.

- `--fix-db-names [277]`

Convert database names to 5.1 format. Only database names that contain special characters are affected.

- `--fix-table-names [277]`

Convert table names to 5.1 format. Only table names that contain special characters are affected. This option also applies to views.

- `--force [277], -f`

Continue even if an SQL error occurs.

- `--host=host_name [277], -h host_name`

Connect to the MySQL server on the given host.

- `--medium-check [277], -m`

Do a check that is faster than an `--extended [277]` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--optimize [277], -o`

Optimize the tables.

- `--password[=password] [277], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password [277]` or `-p` option on the command line, `mysqlcheck` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe [278], -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path [278]`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth [277]` option is used to specify an authentication plugin but `mysqlcheck` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num [278], -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY} [278]`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick [278], -q`

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair [278], -r`

Perform a repair that can fix almost anything except unique keys that are not unique.

- `--silent [278], -s`

Silent mode. Print only error messages.

- `--skip-database=db_name [278]`

Do not include the named database (case sensitive) in the operations performed by `mysqlcheck`. This option was added in MySQL 5.6.11.

- `--socket=path [278], -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--tables [278]`

Override the `--databases` [276] or `-B` option. All name arguments following the option are regarded as table names.

- `--use-frn` [279]

For repair operations on `MyISAM` tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name` [279], `-u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose` [279], `-v`

Verbose mode. Print information about the various stages of program operation.

- `--version` [279], `-V`

Display version information and exit.

- `--write-binlog` [279]

This option is enabled by default, so that `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` [279] to cause `NO_WRITE_TO_BINLOG` to be added to the statements so that they are not logged. Use the `--skip-write-binlog` [279] when these statements should not be sent to replication slaves or run when using the binary logs for recovery from backup.

#### 4.5.4. `mysqldump` — A Database Backup Program

The `mysqldump` client is a utility that performs **logical backups**, producing a set of SQL statements that can be run to reproduce the original schema objects, table data, or both. It dumps one or more MySQL database for backup or transfer to another SQL server. The `mysqldump` command can also generate output in CSV, other delimited text, or XML format.

`mysqldump` requires at least the `SELECT` [755] privilege for dumped tables, `SHOW VIEW` [756] for dumped views, `TRIGGER` [756] for dumped triggers, and `LOCK TABLES` [755] if the `--single-transaction` [295] option is not used. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the same privileges needed to create each of the dumped objects by issuing `CREATE` statements manually.

### Performance and Scalability Considerations

`mysqldump` advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations of an existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a **physical** backup is more appropriate, to copy the data files in their original format that can be restored quickly:

- If your tables are primarily `InnoDB` tables, or if you have a mix of `InnoDB` and `MyISAM` tables, consider using the `mysqlbackup` command of the MySQL Enterprise Backup product. (Available as part of the Enterprise subscription.) It provides the best performance for `InnoDB` backups with minimal disruption; it can also back up tables from `MyISAM` and other storage engines; and it provides a number of convenient options to accommodate different backup scenarios. See [MySQL Enterprise Backup User's Guide \(Version 3.8.1\)](#).

- If your tables are primarily MyISAM tables, consider using the `mysqlhotcopy` instead, for better performance than `mysqldump` of backup and restore operations. See [Section 4.6.10](#), “`mysqlhotcopy` — A Database Backup Program”.

`mysqldump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` [294] option (or `--opt` [294], which enables `--quick` [294]). The `--opt` [294] option (and hence `--quick` [294]) is enabled by default, so to enable memory buffering, use `--skip-quick` [294].

If you are using a recent version of `mysqldump` to generate a dump to be reloaded into a very old MySQL server, use the `--skip-opt` [294] option instead of the `--opt` [294] or `--extended-insert` [294] option.

For additional information about `mysqldump`, see [Section 7.4](#), “Using `mysqldump` for Backups”.

## Syntax

There are three general ways to invoke `mysqldump`, to dump progressively more data:

```
shell> mysqldump [options] db_name [tbl_name ...]
shell> mysqldump [options] --databases db_name ...
shell> mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following `db_name`, or use the `--databases` [292] or `--all-databases` [292] option.

To see a list of the options your version of `mysqldump` supports, issue the command `mysqldump --help`.

## Option Syntax - Alphabetical Summary

`mysqldump` supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` groups of an option file. `mysqldump` also supports the options for processing option files described at [Section 4.2.3.4](#), “Command-Line Options that Affect Option-File Handling”.

**Table 4.6.** `mysqldump` Options

Format	Option File	Description	Introduced
<code>--add-drop-database</code> [286]	<code>add-drop-database</code> [286]	Add a DROP DATABASE statement before each CREATE DATABASE statement	
<code>--add-drop-table</code> [286]	<code>add-drop-table</code> [286]	Add a DROP TABLE statement before each CREATE TABLE statement	
<code>--add-drop-trigger</code> [286]	<code>add-drop-trigger</code> [286]	Add a DROP TRIGGER statement before each CREATE TRIGGER statement	
<code>--add-locks</code> [294]	<code>add-locks</code> [294]	Surround each table dump with LOCK TABLES and UNLOCK TABLES statements	
<code>--all-databases</code> [292]	<code>all-databases</code> [292]	Dump all tables in all databases	
<code>--allow-keywords</code> [286]	<code>allow-keywords</code> [286]	Allow creation of column names that are keywords	
<code>--apply-slave-statements</code> [288]	<code>apply-slave-statements</code> [288]	Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output	
<code>--bind-address=ip_address</code> [284]	<code>bind-address</code> [284]	Use the specified network interface to connect to the MySQL Server	
<code>--comments</code> [286]	<code>comments</code> [286]	Add comments to the dump file	

Format	Option File	Description	Introduced
<code>--compact</code> [290]	<code>compact</code> [290]	Produce more compact output	
<code>--compatible=name[,name,...]</code> [290]	<code>compatible</code> [290] <code>name,...</code> [290]	Produce output that is more compatible with other database systems or with older MySQL servers	
<code>--complete-insert</code> [290]	<code>complete-insert</code> [290]	Use complete INSERT statements that include column names	
<code>--create-options</code> [290]	<code>create-options</code> [290]	Include all MySQL-specific table options in CREATE TABLE statements	
<code>--databases</code> [292]	<code>databases</code> [292]	Dump several databases	
<code>--debug[=debug_options]</code> [286]	<code>debug</code> [286]	Write a debugging log	
<code>--debug-check</code> [287]	<code>debug-check</code> [287]	Print debugging information when the program exits	
<code>--debug-info</code> [287]	<code>debug-info</code> [287]	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code> [284]	<code>default-auth=plugin</code> [284]	The authentication plugin to use	
<code>--default-character-set=charset_name</code> [288]	<code>default-character-set</code> [288] <code>charset_name</code> [288]	Use <code>charset_name</code> as the default character set	
<code>--delayed-insert</code> [294]	<code>delayed-insert</code> [294]	Write INSERT DELAYED statements rather than INSERT statements	
<code>--delete-master-logs</code> [288]	<code>delete-master-logs</code> [288]	On a master replication server, delete the binary logs after performing the dump operation	
<code>--disable-keys</code> [294]	<code>disable-keys</code> [294]	For each table, surround the INSERT statements with statements to disable and enable keys	
<code>--dump-date</code> [287]	<code>dump-date</code> [287]	Include dump date as "Dump completed on" comment if <code>--comments</code> is given	
<code>--dump-slave[=value]</code> [288]	<code>dump-slave</code> [288]	Include CHANGE MASTER statement that lists binary log coordinates of slave's master	
<code>--events</code> [293]	<code>events</code> [293]	Dump events from the dumped databases	
<code>--extended-insert</code> [294]	<code>extended-insert</code> [294]	Use multiple-row INSERT syntax that include several VALUES lists	
<code>--fields-enclosed-by=string</code> [290]	<code>fields-enclosed-by</code> [290]	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--fields-escaped-by</code> [290]	<code>fields-escaped-by</code> [290]	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--fields-optionally-enclosed-by=string</code> [290]	<code>fields-optionally-enclosed-by</code> [290]	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--fields-terminated-by=string</code> [290]	<code>fields-terminated-by</code> [290]	This option is used with the <code>--tab</code> option and has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--flush-logs</code> [294]	<code>flush-logs</code> [294]	Flush the MySQL server log files before starting the dump	

Format	Option File	Description	Introduced
<a href="#">--flush-privileges [295]</a>	<a href="#">flush-privileges [295]</a>	Emit a FLUSH PRIVILEGES statement after dumping the mysql database	
<a href="#">--help [287]</a>		Display help message and exit	
<a href="#">--hex-blob [290]</a>	<a href="#">hex-blob [290]</a>	Dump binary columns using hexadecimal notation (for example, 'abc' becomes 0x616263)	
<a href="#">--host [284]</a>	<a href="#">host [284]</a>	Host to connect to (IP address or hostname)	
<a href="#">--ignore-table=db_name.tbl [293]</a>	<a href="#">ignore-table [293]</a>	Do not dump the given table	
<a href="#">--include-master-host-port [288]</a>	<a href="#">include-master-host-port [288]</a>	Include MASTER_HOST/MASTER_PORT options in CHANGE MASTER statement produced with --dump-slave	
<a href="#">--insert-ignore [294]</a>	<a href="#">insert-ignore [294]</a>	Write INSERT IGNORE statements rather than INSERT statements	
<a href="#">--lines-terminated-by=string [290]</a>	<a href="#">lines-terminated-by [290]</a>	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE	
<a href="#">--lock-all-tables [295]</a>	<a href="#">lock-all-tables [295]</a>	Lock all tables across all databases	
<a href="#">--lock-tables [295]</a>	<a href="#">lock-tables [295]</a>	Lock all tables before dumping them	
<a href="#">--log-error=file_name [287]</a>	<a href="#">log-error [287]</a>	Append warnings and errors to the named file	
<a href="#">--login-path=name [219]</a>		Read login path options from .mylogin.cnf	5.6.6
<a href="#">--master-data[=value] [288]</a>	<a href="#">master-data [288]</a>	Write the binary log file name and position to the output	
<a href="#">--max_allowed_packet=value</a>	<a href="#">max_allowed_packet [285]</a>	The maximum packet length to send to or receive from the server	
<a href="#">--net_buffer_length=value [285]</a>	<a href="#">net_buffer_length [285]</a>	The buffer size for TCP/IP and socket communication	
<a href="#">--no-autocommit [295]</a>	<a href="#">no-autocommit [295]</a>	Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements	
<a href="#">--no-create-db [286]</a>	<a href="#">no-create-db [286]</a>	This option suppresses the CREATE DATABASE statements	
<a href="#">--no-create-info [286]</a>	<a href="#">no-create-info [286]</a>	Do not write CREATE TABLE statements that re-create each dumped table	
<a href="#">--no-data [293]</a>	<a href="#">no-data [293]</a>	Do not dump table contents	
<a href="#">--no-set-names [288]</a>	<a href="#">no-set-names [288]</a>	Same as --skip-set-charset	
<a href="#">--no-tablespaces [286]</a>	<a href="#">no-tablespaces [286]</a>	Do not write any CREATE LOGFILE GROUP or CREATE TABLESPACE statements in output	
<a href="#">--opt [294]</a>	<a href="#">opt [294]</a>	Shorthand for --add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset.	
<a href="#">--order-by-primary [295]</a>	<a href="#">order-by-primary [295]</a>	Dump each table's rows sorted by its primary key, or by its first unique index	

Format	Option File	Description	Introduced
--password[=password] [285]	password [285]	The password to use when connecting to the server	
--pipe [285]		On Windows, connect to server using a named pipe	
--plugin-dir=path [285]	plugin-dir=path [285]	The directory where plugins are located	
--port=port_num [285]	port [285]	The TCP/IP port number to use for the connection	
--quick [294]	quick [294]	Retrieve rows for a table from the server a row at a time	
--quote-names [291]	quote-names [291]	Quote identifiers within backtick characters	
--replace [286]	replace [286]	Write REPLACE statements rather than INSERT statements	
--result-file=file [291]	result-file [291]	Direct output to a given file	
--routines [293]	routines [293]	Dump stored routines (procedures and functions) from the dumped databases	
--set-charset [288]	set-charset [288]	Add SET NAMES default_character_set to output	
--set-gtid-purged=value [289]	set-gtid-purged [289]	Whether to add SET @@GLOBAL.GTID_PURGED to output	5.6.9
--single-transaction [295]	single-transaction [295]	This option issues a BEGIN SQL statement before dumping data from the server	
--skip-add-drop-table [286]	skip-add-drop-table [286]	Do not add a DROP TABLE statement before each CREATE TABLE statement	
--skip-add-locks [294]	skip-add-locks [294]	Do not add locks	
--skip-comments [287]	skip-comments [287]	Do not add comments to the dump file	
--skip-compact [290]	skip-compact [290]	Do not produce more compact output	
--skip-disable-keys [294]	skip-disable-keys [294]	Do not disable keys	
--skip-extended-insert [294]	skip-extended-insert [294]	Turn off extended-insert	
--skip-opt [294]	skip-opt [294]	Turn off the options set by --opt	
--skip-quick [294]	skip-quick [294]	Do not retrieve rows for a table from the server a row at a time	
--skip-quote-names [291]	skip-quote-names [291]	Do not quote identifiers	
--skip-set-charset [288]	skip-set-charset [288]	Suppress the SET NAMES statement	
--skip-triggers [293]	skip-triggers [293]	Do not dump triggers	
--skip-tz-utc [291]	skip-tz-utc [291]	Turn off tz-utc	

Format	Option File	Description	Introduced
<code>--ssl-ca=file_name</code> [285]	<code>ssl-ca</code> [285]	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=dir_name</code> [285]	<code>ssl-capath</code> [285]	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=file_name</code> [285]	<code>ssl-cert</code> [285]	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=cipher_list</code> [285]	<code>ssl-cipher</code> [285]	A list of allowable ciphers to use for SSL encryption	
<code>--ssl-crl=file_name</code> [285]	<code>ssl-crl</code> [285]	The path to a file that contains certificate revocation lists	5.6.3
<code>--ssl-crlpath=dir_name</code> [285]	<code>ssl-crlpath</code> [285]	The path to a directory that contains certificate revocation list files	5.6.3
<code>--ssl-key=file_name</code> [285]	<code>ssl-key</code> [285]	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert</code> [285]	<code>ssl-verify-server-cert</code> [285]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--tab=path</code> [291]	<code>tab</code> [291]	Produce tab-separated data files	
<code>--tables</code> [293]	<code>tables</code> [293]	Override the <code>--databases</code> or <code>-B</code> option	
<code>--triggers</code> [293]	<code>triggers</code> [293]	Dump triggers for each dumped table	
<code>--tz-utc</code> [291]	<code>tz-utc</code> [291]	Add <code>SET TIME_ZONE='+00:00'</code> to the dump file	
<code>--user=user_name</code> [285]	<code>user</code> [285]	MySQL user name to use when connecting to server	
<code>--verbose</code> [287]		Verbose mode	
<code>--version</code> [287]		Display version information and exit	
<code>--where='where_condition'</code> [293]	<code>where</code> [293]	Dump only rows selected by the given WHERE condition	
<code>--xml</code> [291]	<code>xml</code> [291]	Produce XML output	

## Connection Options

The `mysqldump` command logs into a MySQL server to extract information. The following options specify how to connect to the MySQL server, either on the same machine or a remote system.

- `--bind-address=ip_address` [248]

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--host=host_name, -h host_name`

Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, `mysqldump` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` [284] option is used to specify an authentication plugin but `mysqldump` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` [810] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

You can also set the following variables by using `--var_name=value` syntax:

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The maximum is 1GB.

- `net_buffer_length`

The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` [294] or `--opt` [294] option), `mysqldump` creates rows up to `net_buffer_length` [515] length. If you increase this variable, ensure that the `net_buffer_length` [515] variable in the MySQL server is at least this large.

## DDL Options

Usage scenarios for `mysqldump` include setting up an entire new MySQL instance (including database tables), and replacing data inside an existing instance with existing databases and tables. The following

options let you specify which things to tear down and set up when restoring a dump, by encoding various DDL statements within the dump file.

- `--add-drop-database`

Add a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` [292] or `--databases` [292] option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- `--add-drop-table`

Add a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-trigger`

Add a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

- `--all-tablespaces, -Y`

Adds to a table dump all SQL statements needed to create any tablespaces used by an `NDB` table. This information is not otherwise included in the output from `mysqldump`. This option is currently relevant only to MySQL Cluster tables.

- `--no-create-db, -n`

This option suppresses the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` [292] or `--all-databases` [292] option is given.

- `--no-create-info, -t`

Do not write `CREATE TABLE` statements that re-create each dumped table.

#### Note

This option does *not* not exclude statements creating log file groups or tablespaces from `mysqldump` output; however, you can use the `--no-tablespaces` [286] option for this purpose.

- `--no-tablespaces, -y`

This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of `mysqldump`.

- `--replace`

Write `REPLACE` statements rather than `INSERT` statements.

## Debug Options

The following options print debugging information, encode debugging information in the dump file, or let the dump operation proceed regardless of potential problems.

- `--allow-keywords`

Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--comments, -i`

Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments` [287].

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical *debug\_options* string is `'d:t:o,file_name'`. The default value is `'d:t:o,/tmp/mysqldump.trace'`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--dump-date`

If the `--comments` [286] option is given, `mysqldump` produces a comment at the end of the dump of the following form:

```
-- Dump completed on DATE
```

However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` [287] and `--skip-dump-date` [287] control whether the date is added to the comment. The default is `--dump-date` [287] (include the date in the comment). `--skip-dump-date` [287] suppresses date printing.

- `--force, -f`

Continue even if an SQL error occurs during a table dump.

One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

- `--log-error=file_name`

Log warnings and errors by appending them to the named file. The default is to do no logging.

- `--skip-comments`

See the description for the `--comments` [286] option.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

## Help Options

The following options display information about the `mysqldump` command itself.

- `--help, -?`

Display a help message and exit.

- `--version, -V`

Display version information and exit.

## Internationalization Options

The following options change how the `mysqldump` command represents character data with national language settings.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#). If no character set is specified, `mysqldump` uses `utf8`, and earlier versions use `latin1`.

- `--no-set-names, -N`

Turns off the `--set-charset` [\[288\]](#) setting, the same as specifying `--skip-set-charset`.

- `--set-charset`

Add `SET NAMES default_character_set` to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset` [\[288\]](#).

## Replication Options

The `mysqldump` command is frequently used to create an empty instance, or an instance including data, on a slave server in a replication configuration. The following options apply to dumping and restoring data on replication master and slave servers.

- `--apply-slave-statements`

For a slave dump produced with the `--dump-slave` [\[288\]](#) option, add a `STOP SLAVE` statement before the `CHANGE MASTER TO` statement and a `START SLAVE` statement at the end of the output.

- `--delete-master-logs`

On a master replication server, delete the binary logs by sending a `PURGE BINARY LOGS` statement to the server after performing the dump operation. This option automatically enables `--master-data` [\[288\]](#).

- `--dump-slave[=value]`

This option is similar to `--master-data` [\[288\]](#) except that it is used to dump a replication slave server to produce a dump file that can be used to set up another server as a slave that has the same master as the dumped server. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped slave's master (rather than the coordinates of the dumped server, as is done by the `--master-data` [\[288\]](#) option). These are the master server coordinates from which the slave should start replicating.

The option value is handled the same way as for `--master-data` [\[288\]](#) and has the same effect as `--master-data` in terms of enabling or disabling other options and in how locking is handled.

This option causes `mysqldump` to stop the slave SQL thread before the dump and restart it again after.

In conjunction with `--dump-slave`, the `--apply-slave-statements` [\[288\]](#) and `--include-master-host-port` [\[288\]](#) options can also be used.

- `--include-master-host-port`

For the `CHANGE MASTER TO` statement in a slave dump produced with the `--dump-slave` [\[288\]](#) option, add `MASTER_PORT` and `MASTER_HOST` options for the host name and TCP/IP port number of the slave's master.

- `--master-data[=value]`

Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a `CHANGE MASTER`

`TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the master server coordinates from which the slave should start replicating after you load the dump file into the slave.

If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

This option requires the `RELOAD [755]` privilege and the binary log must be enabled.

The `--master-data` option automatically turns off `--lock-tables [295]`. It also turns on `--lock-all-tables [295]`, unless `--single-transaction [295]` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction [295]`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a slave by dumping an existing slave of the master. To do this, use the following procedure on the existing slave:

1. Stop the slave's SQL thread and get its current status:

```
mysql> STOP SLAVE SQL_THREAD;
mysql> SHOW SLAVE STATUS;
```

2. From the output of the `SHOW SLAVE STATUS` statement, the binary log coordinates of the master server from which the new slave should start replicating are the values of the `Relay_Master_Log_File` and `Exec_Master_Log_Pos` fields. Denote those values as `file_name` and `file_pos`.

3. Dump the slave server:

```
shell> mysqldump --master-data=2 --all-databases > dumpfile
```

Using `--master-data=2` works only if binary logging has been enabled on the slave. Otherwise, `mysqldump` fails with the error `Binlogging on server not active`. In this case you must handle any locking issues in another manner, using one or more of `--add-locks [294]`, `--lock-tables [295]`, `--lock-all-tables [295]`, or `--single-transaction [295]`, as required by your application and environment.

4. Restart the slave:

```
mysql> START SLAVE;
```

5. On the new slave, load the dump file:

```
shell> mysql < dumpfile
```

6. On the new slave, set the replication coordinates to those of the master server obtained earlier:

```
mysql> CHANGE MASTER TO
-> MASTER_LOG_FILE = 'file_name', MASTER_LOG_POS = file_pos;
```

The `CHANGE MASTER TO` statement might also need other parameters, such as `MASTER_HOST` to point the slave to the correct master server host. Add any such parameters as necessary.

Prior to MySQL 5.6.4, this option was required for dumping the replication log tables (see [Section 16.2.2, “Replication Relay and Status Logs”](#)).

- `--set-gtid-purged=value`

This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a `SET @@global.gtid_purged` statement to the output.

The following table shows the permitted option values. The default value is `AUTO`.

Value	Meaning
<code>OFF</code>	Add no <code>SET</code> statement to the output.
<code>ON</code>	Add a <code>SET</code> statement to the output. An error occurs if GTIDs are not enabled on the server.
<code>AUTO</code>	Add a <code>SET</code> statement to the output if GTIDs are enabled on the server.

This option was added in MySQL 5.6.9.

## Format Options

The following options specify how to represent the entire dump file or certain kinds of data in the dump file. They also control whether certain optional information is written to the dump file.

- `--compact`

Produce more compact output. This option enables the `--skip-add-drop-table` [286], `--skip-add-locks` [294], `--skip-comments` [287], `--skip-disable-keys` [294], and `--skip-set-charset` [288] options.

- `--compatible=name`

Produce output that is more compatible with other database systems or with older MySQL servers. The value of *name* can be `ansi`, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, or `no_field_options`. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

*This option requires a server version of 4.1.0 or higher. With older servers, it does nothing.*

- `--complete-insert, -c`

Use complete `INSERT` statements that include column names.

- `--create-options`

Include all MySQL-specific table options in the `CREATE TABLE` statements.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options are used with the `--tab` [291] option and have the same meaning as the corresponding `FIELDS` clauses for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, the `BLOB` types, and `BIT`.

- `--lines-terminated-by=...`

This option is used with the `--tab` [291] option and has the same meaning as the corresponding `LINES` clause for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--quote-names, -Q`

Quote identifiers (such as database, table, and column names) within “`” characters. If the [ANSI\\_QUOTES \[603\]](#) SQL mode is enabled, identifiers are quoted within “” characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible [290]` that may enable `--quote-names [291]`.

- `--result-file=file_name, -r file_name`

Direct output to a given file. This option should be used on Windows to prevent newline “\n” characters from being converted to “\r\n” carriage return/newline sequences. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

- `--tab=path, -T path`

Produce tab-separated text-format data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and the server writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

#### Note

This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. You must have the [FILE \[754\]](#) privilege, and the server must have permission to write files in the directory that you specify.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by [290]` options.

Column values are converted to the character set specified by the `--default-character-set [288]` option.

- `--tz-utc`

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE= '+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

- `--xml, -X`

Write dump output as well-formed XML.

**NULL, 'NULL', and Empty Values:** For a column named `column_name`, the `NULL` value, an empty string, and the string value `'NULL'` are distinguished from one another in the output generated by this option as follows.

Value:	XML Representation:
<code>NULL</code> ( <i>unknown value</i> )	<code>&lt;field name="column_name" xsi:nil="true" /&gt;</code>
<code>' '</code> ( <i>empty string</i> )	<code>&lt;field name="column_name"&gt;&lt;/field&gt;</code>
<code>'NULL'</code> ( <i>string value</i> )	<code>&lt;field name="column_name"&gt;NULL&lt;/field&gt;</code>

The output from the `mysql` client when run using the `--xml` [254] option also follows the preceding rules. (See [Section 4.5.1.1](#), “`mysql` Options”.)

XML output from `mysqldump` includes the XML namespace, as shown here:

```
shell> mysqldump --xml -u root world City
<?xml version="1.0"?>
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">

```

Prior to MySQL 5.6.5, this option prevented the `--routines` [293] option from working correctly—that is, no stored routines, triggers, or events could be dumped in XML format. (Bug #11760384, Bug #52792)

## Filtering Options

The following options control which kinds of schema objects are written to the dump file: by category, such as triggers or events; by name, for example, choosing which databases and tables to dump; or even filtering rows from the table data using a `WHERE` clause.

- `--all-databases, -A`

Dump all tables in all databases. This is the same as using the `--databases` [292] option and naming all the databases on the command line.

Prior to MySQL 5.6.4, the `slave_master_info` and `slave_relay_log_info` tables (see [Section 16.2.2](#), “`Replication Relay and Status Logs`”) were not included by this option.

- `--databases, -B`

Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name

arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

- `--events, -E`

Include Event Scheduler events for the dumped databases in the output.

- `--ignore-table=db_name.tbl_name`

Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- `--no-data, -d`

Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- `--routines, -R`

Include stored routines (procedures and functions) for the dumped databases in the output. Use of this option requires the `SELECT [755]` privilege for the `mysql.proc` table. The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to re-create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps. This means that when the routines are reloaded, they will be created with the timestamps equal to the reload time.

If you require routines to be re-created with their original timestamp attributes, do not use `--routines`. Instead, dump and reload the contents of the `mysql.proc` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

Prior to MySQL 5.6.5, this option had no effect when used together with the `--xml [291]` option. (Bug #11760384, Bug #52792)

- `--tables`

Override the `--databases [292]` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

- `--where='where_condition', -w 'where_condition'`

Dump only rows selected by the given `WHERE` condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

Examples:

```
--where="user='jimf'"
-w"userid>1"
-w"userid<1"
```

## Performance Options

The following options are the most relevant for the performance particularly of the restore operations. For large data sets, restore operation (processing the `INSERT` statements in the dump file) is the most time-consuming part. When it is urgent to restore data quickly, plan and test the performance of this stage in advance. For restore times measured in hours, you might prefer an alternative backup and restore solution, such as [MySQL Enterprise Backup](#) for `InnoDB`-only and mixed-use databases, or [mysqlhotcopy](#) for `MyISAM`-only databases.

Performance is also affected by the [transactional options](#), primarily for the dump operation.

- `--delayed-insert`

For those nontransactional tables that support the `INSERT DELAYED` syntax, use that statement rather than regular `INSERT` statements.

As of MySQL 5.6.6, `DELAYED` inserts are deprecated, so this option will be removed in a future release.

- `--disable-keys, -K`

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of `MyISAM` tables.

- `--extended-insert, -e`

Use multiple-row `INSERT` syntax that include several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--insert-ignore`

Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--opt`

This option, enabled by default, is shorthand for the combination of `--add-drop-table` [286] `--add-locks` [294] `--create-options` [290] `--disable-keys` [294] `--extended-insert` [294] `--lock-tables` [295] `--quick` [294] `--set-charset` [288]. It gives a fast dump operation and produces a dump file that can be reloaded into a MySQL server quickly.

Because the `--opt` option is enabled by default, you only specify its converse, the `--skip-opt` [294] to turn off several default settings. See the discussion of [mysqldump option groups](#) for information about selectively enabling or disabling a subset of the options affected by `--opt`.

- `--quick, -q`

This option is useful for dumping large tables. It forces `mysqldump` to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- `--skip-opt`

See the description for the `--opt` [294] option.

## Transactional Options

The following options trade off the performance of the dump operation, against the reliability and consistency of the exported data.

- `--add-locks`

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See [Section 8.2.2.1, “Speed of INSERT Statements”](#).

- `--flush-logs, -F`

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` [755] privilege. If you use this option in combination with the `--all-databases` [292] option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables` [295],

`--master-data` [288], or `--single-transaction` [295]: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables` [295], `--master-data` [288], or `--single-transaction` [295].

- `--flush-privileges`

Send a `FLUSH PRIVILEGES` statement to the server after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

- `--lock-all-tables, -x`

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` [295] and `--lock-tables` [295].

- `--lock-tables, -l`

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` [295] is a much better option than `--lock-tables` because it does not need to lock the tables at all.

Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

Some options, such as `--opt` [294], automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

- `--no-autocommit`

Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- `--order-by-primary`

Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a `MyISAM` table to be loaded into an `InnoDB` table, but makes the dump operation take considerably longer.

- `--single-transaction`

This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

The `--single-transaction` option and the `--lock-tables` [295] option are mutually exclusive because `LOCK TABLES` causes any pending transactions to be committed implicitly.

To dump large tables, combine the `--single-transaction` option with the `--quick` [294].

## Option Groups

- The `--opt` [294] option turns on several settings that work together to perform a fast dump operation. All of these settings are on by default, because `--opt` is on by default. Thus you rarely if

ever specify `--opt`. Instead, you can turn these settings off as a group by specifying `--skip-opt`, the optionally re-enable certain settings by specifying the associated options later on the command line.

- The `--compact` [290] option turns off several settings that control whether optional statements and comments appear in the output. Again, you can follow this option with other options that re-enable certain settings, or turn all the settings on by using the `--skip-compact` form.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys` [294] `--lock-tables` [295] `--skip-opt` [294] would not have the intended effect; it is the same as `--skip-opt` [294] by itself.

## Examples

To make a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

To load the dump file back into the server:

```
shell> mysql db_name < backup-file.sql
```

Another way to reload the dump file:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

`mysqldump` is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

You can dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` [292] option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, `mysqldump` provides a way of making an online backup:

```
shell> mysqldump --all-databases --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see [Section 5.2.4, “The Binary Log”](#)) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2
> all_databases.sql
```

The `--master-data` [288] and `--single-transaction` [295] options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

For more information on making backups, see [Section 7.2, “Database Backup Methods”](#), and [Section 7.3, “Example Backup and Recovery Strategy”](#).

- To select the effect of `--opt [294]` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt [294] --skip-extended-insert [294] --skip-quick [294]`. (Actually, `--skip-extended-insert [294] --skip-quick [294]` is sufficient because `--opt [294]` is on by default.)
- To reverse `--opt [294]` for all features except index disabling and table locking, use `--skip-opt [294] --disable-keys [294] --lock-tables [295]`.

## Restrictions

`mysqldump` does not dump the `INFORMATION_SCHEMA` database by default. To dump `INFORMATION_SCHEMA`, name it explicitly on the command line and also use the `--skip-lock-tables [295]` option.

`mysqldump` never dumps the `performance_schema` database.

Before MySQL 5.6.6, `mysqldump` does not dump the `general_log` or `slow_query_log` tables for dumps of the `mysql` database. As of 5.6.6, the dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

It is not recommended to restore from a dump made using `mysqldump` to a MySQL Server that has GTIDs enabled. See [Section 16.1.3.4, “Restrictions on Replication with GTIDs”](#).

If you encounter problems backing up views due to insufficient privileges, see [Section E.5, “Restrictions on Views”](#) for a workaround.

## 4.5.5. mysqlimport — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE SQL` statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE` syntax. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. `mysqlimport` also supports the options for processing option files described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.7. `mysqlimport` Options**

Format	Option File	Description	Introduced
<code>--bind-address=ip_address [299]</code>	<code>bind-address [299]</code>	Use the specified network interface to connect to the MySQL Server	
<code>--columns=column_list [299]</code>	<code>columns [299]</code>	This option takes a comma-separated list of column names as its value	
<code>--compress [299]</code>	<code>compress [299]</code>	Compress all information sent between the client and the server	
<code>--debug[=debug_options] [300]</code>	<code>debug [300]</code>	Write a debugging log	

Format	Option File	Description	Introduced
--debug-check [300]	debug-check [300]	Print debugging information when the program exits	
--debug-info [300]	debug-info [300]	Print debugging information, memory and CPU statistics when the program exits	
--default-auth=plugin [300]	default-auth=plugin [300]	The authentication plugin to use	5.6.2
--default-character-set=charset_name [300]	default-character-set [300]	Use charset_name as the default character set	
--delete [300]	delete [300]	Empty the table before importing the text file	
--fields-enclosed-by=string [300]	fields-enclosed-by [300]	This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
--fields-escaped-by [300]	fields-escaped-by [300]	This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
--fields-optionally-enclosed-by=string [300]	fields-optionally-enclosed-by [300]	This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
--fields-terminated-by=string [300]	fields-terminated-by [300]	-- This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
--force [300]	force [300]	Continue even if an SQL error occurs	
--help [299]		Display help message and exit	
--host=host_name [300]	host [300]	Connect to the MySQL server on the given host	
--ignore [300]	ignore [300]	See the description for the --replace option	
--ignore-lines=# [300]	ignore-lines [300]	Ignore the first N lines of the data file	
--lines-terminated-by=string [300]	lines-terminated-by [300]	This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
--local [300]	local [300]	Read input files locally from the client host	
--lock-tables [300]	lock-tables [300]	Lock all tables for writing before processing any text files	
--login-path=name [219]		Read login path options from .mylogin.cnf	5.6.6
--low-priority [301]	low-priority [301]	Use LOW_PRIORITY when loading the table.	
--password[=password] [301]	password [301]	The password to use when connecting to the server	
--pipe [301]		On Windows, connect to server using a named pipe	
--plugin-dir=path [301]	plugin-dir=path [301]	The directory where plugins are located	5.6.2
--port=port_num [301]	port [301]	The TCP/IP port number to use for the connection	
--protocol=type [301]	protocol [301]	The connection protocol to use	

Format	Option File	Description	Introduced
<code>--replace</code> [301]	<code>replace</code> [301]	The <code>--replace</code> and <code>--ignore</code> options control handling of input rows that duplicate existing rows on unique key values	
<code>--silent</code> [301]	<code>silent</code> [301]	Produce output only when errors occur	
<code>--socket=</code> <i>path</i> [301]	<code>socket</code> [301]	For connections to localhost	
<code>--ssl-ca=</code> <i>file_name</i> [301]	<code>ssl-ca</code> [301]	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=</code> <i>dir_name</i> [301]	<code>ssl-capath</code> [301]	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=</code> <i>file_name</i> [301]	<code>ssl-cert</code> [301]	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=</code> <i>cipher_list</i> [301]	<code>ssl-cipher</code> [301]	A list of allowable ciphers to use for SSL encryption	
<code>--ssl-crl=</code> <i>file_name</i> [301]	<code>ssl-crl</code> [301]	The path to a file that contains certificate revocation lists	5.6.3
<code>--ssl-crlpath=</code> <i>dir_name</i> [301]	<code>ssl-crlpath</code> [301]	The path to a directory that contains certificate revocation list files	5.6.3
<code>--ssl-key=</code> <i>file_name</i> [301]	<code>ssl-key</code> [301]	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert</code> [301]	<code>ssl-verify-server-cert</code> [301]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--use-threads=</code> <i>#</i> [302]	<code>use-threads</code> [302]	The number of threads for parallel file-loading	
<code>--user=</code> <i>user_name</i> , [302]	<code>user</code> [302]	MySQL user name to use when connecting to server	
<code>--verbose</code> [302]		Verbose mode	
<code>--version</code> [302]		Display version information and exit	

- `--help` [299], `-?`

Display a help message and exit.

- `--bind-address=`*ip\_address* [248]

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=`*path* [299]

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--columns=`*column\_list* [299], `-c` *column\_list*

This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress` [299], `-C`

Compress all information sent between the client and the server if both support compression.

- `--debug[=debug_options] [300], -# [debug_options]`

Write a debugging log. A typical *debug\_options* string is '*d:t:o,file\_name*'. The default is '*d:t:o*'.

- `--debug-check [300]`

Print some debugging information when the program exits.

- `--debug-info [300]`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name [300]`

Use *charset\_name* as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--default-auth=plugin [300]`

The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--delete [300], -D`

Empty the table before importing the text file.

- `--fields-terminated-by=... [300], --fields-enclosed-by=... [300], --fields-optionally-enclosed-by=... [300], --fields-escaped-by=... [300]`

These options have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--force [300], -f`

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force [300]`, `mysqlimport` exits if a table does not exist.

- `--host=host_name [300], -h host_name`

Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore [300], -i`

See the description for the `--replace [301]` option.

- `--ignore-lines=N [300]`

Ignore the first *N* lines of the data file.

- `--lines-terminated-by=... [300]`

This option has the same meaning as the corresponding clause for `LOAD DATA INFILE`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n" [300]`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--local [300], -L`

Read input files locally from the client host.

- `--lock-tables [295], -l`

Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--low-priority` [301]

Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `--password[=password]` [301], `-p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` [301] or `-p` option on the command line, `mysqlimport` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe` [301], `-W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path` [301]

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` [300] option is used to specify an authentication plugin but `mysqlimport` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num` [301], `-P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [301]

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--replace` [301], `-r`

The `--replace` [301] and `--ignore` [300] options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace` [301], new rows replace existing rows that have the same unique key value. If you specify `--ignore` [300], input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--silent` [301], `-s`

Silent mode. Produce output only when errors occur.

- `--socket=path` [301], `-S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` [810] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name` [302], `-u user_name`

The MySQL user name to use when connecting to the server.

- `--use-threads=N` [302]

Load files in parallel using *N* threads.

- `--verbose` [302], `-v`

Verbose mode. Print more information about what the program does.

- `--version` [302], `-V`

Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE impptest(id INT, n VARCHAR(30))' test
shell> ed
a
100      Max Sydow
101      Count Dracula
.
w impptest.txt
32
q
shell> od -c impptest.txt

## 4.5.6. mysqlshow — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See [Section 13.7.5, “SHOW Syntax”](#). The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (“\*”, “?”, “%”, or “\_”), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. “\*” and “?” characters are converted into SQL “%” and “\_” wildcard characters. This might cause some confusion when you try to display the columns for a table with a “\_” in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra “%” last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the `[mysqlshow]` and `[client]` groups of an option file. `mysqlshow` also supports the options for processing option files described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.8. `mysqlshow` Options**

Format	Option File	Description	Introduced
<code>--bind-address=ip_address</code> [304]	<code>bind-address</code> [304]	Use the specified network interface to connect to the MySQL Server	
<code>--compress</code> [304]	<code>compress</code> [304]	Compress all information sent between the client and the server	
<code>--count</code> [304]	<code>count</code> [304]	Show the number of rows per table	
<code>--debug[=debug_options]</code> [304]	<code>debug</code> [304]	Write a debugging log	
<code>--debug-check</code> [304]	<code>debug-check</code> [304]	Print debugging information when the program exits	
<code>--debug-info</code> [304]	<code>debug-info</code> [304]	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code> [305]	<code>default-auth=plugin</code> [305]	The authentication plugin to use	5.6.2
<code>--default-character-set=charset_name</code> [305]	<code>default-character-set</code> [305]	Use <code>charset_name</code> as the default character set	
<code>--help</code> [304]		Display help message and exit	
<code>--host=host_name</code> [305]	<code>host</code> [305]	Connect to the MySQL server on the given host	
<code>--keys</code> [305]	<code>keys</code> [305]	Show table indexes	
<code>--login-path=name</code> [219]		Read login path options from <code>.mylogin.cnf</code>	5.6.6
<code>--password[=password]</code> [305]	<code>password</code> [305]	The password to use when connecting to the server	
<code>--pipe</code> [305]		On Windows, connect to server using a named pipe	
<code>--plugin-dir=path</code> [305]	<code>plugin-dir=path</code> [305]	The directory where plugins are located	5.6.2
<code>--port=port_num</code> [305]	<code>port</code> [305]	The TCP/IP port number to use for the connection	
<code>--protocol=type</code> [305]	<code>protocol</code> [305]	The connection protocol to use	
<code>--show-table-type</code> [305]		Show a column indicating the table type	
<code>--socket=path</code> [305]	<code>socket</code> [305]	For connections to localhost	

Format	Option File	Description	Introduced
<code>--ssl-ca=file_name [306]</code>	<code>ssl-ca [306]</code>	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=dir_name [306]</code>	<code>ssl-capath [306]</code>	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=file_name [306]</code>	<code>ssl-cert [306]</code>	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=cipher_list [306]</code>	<code>ssl-cipher [306]</code>	A list of allowable ciphers to use for SSL encryption	
<code>--ssl-crl=file_name [306]</code>	<code>ssl-crl [306]</code>	The path to a file that contains certificate revocation lists	5.6.3
<code>--ssl-crlpath=dir_name [306]</code>	<code>ssl-crlpath [306]</code>	The path to a directory that contains certificate revocation list files	5.6.3
<code>--ssl-key=file_name [306]</code>	<code>ssl-key [306]</code>	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert [306]</code>	<code>ssl-verify-server-cert [306]</code>	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--status [306]</code>	<code>status [306]</code>	Display extra information about each table	
<code>--user=user_name, [306]</code>	<code>user [306]</code>	MySQL user name to use when connecting to server	
<code>--verbose [306]</code>		Verbose mode	
<code>--version [306]</code>		Display version information and exit	

- `--help [304], -?`

Display a help message and exit.

- `--bind-address=ip_address [248]`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=path [304]`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--compress [304], -C`

Compress all information sent between the client and the server if both support compression.

- `--count [304]`

Show the number of rows per table. This can be slow for non-MyISAM tables.

- `--debug[=debug_options] [304], -# [debug_options]`

Write a debugging log. A typical *debug\_options* string is `'d:t:o,file_name'`. The default is `'d:t:o'`.

- `--debug-check [304]`

Print some debugging information when the program exits.

- `--debug-info [304]`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name` [305]

Use *charset\_name* as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--default-auth=plugin` [305]

The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--host=host_name` [305], `-h host_name`

Connect to the MySQL server on the given host.

- `--keys` [305], `-k`

Show table indexes.

- `--password[=password]` [305], `-p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` [305] or `-p` option on the command line, `mysqlshow` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe` [305], `-W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path` [305]

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` [305] option is used to specify an authentication plugin but `mysqlshow` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num` [305], `-P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [305]

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--show-table-type` [305], `-t`

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

- `--socket=path` [305], `-S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` [810] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--status` [306], `-i`

Display extra information about each table.

- `--user=user_name` [306], `-u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose` [306], `-v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version` [306], `-V`

Display version information and exit.

## 4.5.7. mysqlslap — Load Emulation Client

`mysqlslap` is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke `mysqlslap` like this:

```
shell> mysqlslap [options]
```

Some options such as `--create` [310] or `--query` [312] enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` [311] option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";"
--create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)"
--query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqlslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20
--number-int-cols=2 --number-char-cols=3
--auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by `;` and multiple insert

statements delimited by ';'. The `--query` file will have multiple queries delimited by ';'. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5
--iterations=5 --query=query.sql --create=create.sql
--delimiter=";"
```

`mysqlslap` supports the following options, which can be specified on the command line or in the `[mysqlslap]` and `[client]` groups of an option file. `mysqlslap` also supports the options for processing option files described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.9. `mysqlslap` Options**

Format	Option File	Description	Introduced
<code>--auto-generate-sql</code> [309]	<code>auto-generate-sql</code> [309]	Generate SQL statements automatically when they are not supplied in files or using command options	
<code>--auto-generate-sql-add-autoincrement</code> [309]	<code>auto-generate-sql-add-autoincrement</code> [309]	Add AUTO_INCREMENT column to automatically generated tables	
<code>--auto-generate-sql-execute-number=#</code> [309]	<code>auto-generate-sql-execute-number</code> [309]	Specify how many queries to generate automatically	
<code>--auto-generate-sql-guid-primary</code> [309]	<code>auto-generate-sql-guid-primary</code> [309]	Add a GUID-based primary key to automatically generated tables	
<code>--auto-generate-sql-load-type=type</code> [309]	<code>auto-generate-sql-load-type</code> [309]	Specify how many queries to generate automatically	
<code>--auto-generate-sql-secondary-indexes=#</code> [310]	<code>auto-generate-sql-secondary-indexes</code> [310]	Specify how many secondary indexes to add to automatically generated tables	
<code>--auto-generate-sql-unique-query-number=#</code> [310]	<code>auto-generate-sql-unique-query-number</code> [310]	How many different queries to generate for automatic tests.	
<code>--auto-generate-sql-unique-write-number=#</code> [310]	<code>auto-generate-sql-unique-write-number</code> [310]	How many different queries to generate for <code>--auto-generate-sql-write-number</code>	
<code>--auto-generate-sql-write-number=#</code> [310]	<code>auto-generate-sql-write-number</code> [310]	How many row inserts to perform on each thread	
<code>--commit=#</code> [310]	<code>commit</code> [310]	How many statements to execute before committing.	
<code>--compress</code> [310]	<code>compress</code> [310]	Compress all information sent between the client and the server	
<code>--concurrency=#</code> [310]	<code>concurrency</code> [310]	The number of clients to simulate when issuing the SELECT statement	
<code>--create=value</code> [310]	<code>create</code> [310]	The file or string containing the statement to use for creating the table	
<code>--create-schema=value</code> [310]	<code>create-schema</code> [310]	The schema in which to run the tests	
<code>--csv=[file]</code> [310]	<code>csv</code> [310]	Generate output in comma-separated values format	

Format	Option File	Description	Introduced
-- debug[=debug_options] [310]	debug [310]	Write a debugging log	
--debug-check [310]	debug-check [310]	Print debugging information when the program exits	
--debug-info [311]	debug-info [311]	Print debugging information, memory and CPU statistics when the program exits	
--default-auth=plugin [311]	default-auth=plugin [311]	The authentication plugin to use	5.6.2
-- delimiter=str [311]	delimiter [311]	The delimiter to use in SQL statements	
-- detach=# [311]	detach [311]	Detach (close and reopen) each connection after each N statements	
--enable-cleartext-plugin [311]	enable-cleartext-plugin [311]	Enable cleartext authentication plugin	5.6.7
-- engine=engine_name [311]	engine [311]	The storage engine to use for creating the table	
--help [309]		Display help message and exit	
-- host=host_name [311]	host [311]	Connect to the MySQL server on the given host	
-- iterations=# [311]	iterations [311]	The number of times to run the tests	
--login-path=name [219]		Read login path options from .mylogin.cnf	5.6.6
--no-drop [311]	no-drop [311]	Do not drop any schema created during the test run	5.6.3
--number-char-cols=# [311]	number-char-cols [311]	The number of VARCHAR columns to use if --auto-generate-sql is specified	
--number-int-cols=# [311]	number-int-cols [311]	The number of INT columns to use if --auto-generate-sql is specified	
--number-of-queries=# [311]	number-of-queries [311]	Limit each client to approximately this number of queries	
--only-print [311]	only-print [311]	Do not connect to databases. mysqlslap only prints what it would have done	
-- password[=password] [311]	password [311]	The password to use when connecting to the server	
--pipe [312]		On Windows, connect to server using a named pipe	
--plugin-dir=path [312]	plugin-dir=path [312]	The directory where plugins are located	5.6.2
-- port=port_num [312]	port [312]	The TCP/IP port number to use for the connection	
--post-query=value [312]	post-query [312]	The file or string containing the statement to execute after the tests have completed	
--post-system=str [312]	post-system [312]	The string to execute using system() after the tests have completed	
--pre-query=value [312]	pre-query [312]	The file or string containing the statement to execute before running the tests	

Format	Option File	Description	Introduced
<code>--pre-system=str</code> [312]	<code>pre-system</code> [312]	The string to execute using <code>system()</code> before running the tests	
<code>--protocol=type</code> [312]	<code>protocol</code> [312]	The connection protocol to use	
<code>--query=value</code> [312]	<code>query</code> [312]	The file or string containing the SELECT statement to use for retrieving data	
<code>--silent</code> [312]	<code>silent</code> [312]	Silent mode	
<code>--socket=path</code> [313]	<code>socket</code> [313]	For connections to localhost	
<code>--ssl-ca=file_name</code> [313]	<code>ssl-ca</code> [313]	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=dir_name</code> [313]	<code>ssl-capath</code> [313]	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=file_name</code> [313]	<code>ssl-cert</code> [313]	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=cipher_list</code> [313]	<code>ssl-cipher</code> [313]	A list of allowable ciphers to use for SSL encryption	
<code>--ssl-crl=file_name</code> [313]	<code>ssl-crl</code> [313]	The path to a file that contains certificate revocation lists	5.6.3
<code>--ssl-crlpath=dir_name</code> [313]	<code>ssl-crlpath</code> [313]	The path to a directory that contains certificate revocation list files	5.6.3
<code>--ssl-key=file_name</code> [313]	<code>ssl-key</code> [313]	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert</code> [313]	<code>ssl-verify-server-cert</code> [313]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--user=user_name,</code> [313]	<code>user</code> [313]	MySQL user name to use when connecting to server	
<code>--verbose</code> [313]		Verbose mode	
<code>--version</code> [313]		Display version information and exit	

- `--help` [309], `-?`

Display a help message and exit.

- `--auto-generate-sql` [309], `-a`

Generate SQL statements automatically when they are not supplied in files or using command options.

- `--auto-generate-sql-add-autoincrement` [309]

Add an `AUTO_INCREMENT` column to automatically generated tables.

- `--auto-generate-sql-execute-number=N` [309]

Specify how many queries to generate automatically.

- `--auto-generate-sql-guid-primary` [309]

Add a GUID-based primary key to automatically generated tables.

- `--auto-generate-sql-load-type=type` [309]

Specify the test load type. The permissible values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is `mixed`.

- `--auto-generate-sql-secondary-indexes=N` [310]

Specify how many secondary indexes to add to automatically generated tables. By default, none are added.

- `--auto-generate-sql-unique-query-number=N` [310]

How many different queries to generate for automatic tests. For example, if you run a `key` test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- `--auto-generate-sql-unique-write-number=N` [310]

How many different queries to generate for `--auto-generate-sql-write-number` [310]. The default is 10.

- `--auto-generate-sql-write-number=N` [310]

How many row inserts to perform on each thread. The default is 100.

- `--commit=N` [310]

How many statements to execute before committing. The default is 0 (no commits are done).

- `--compress` [310], `-C`

Compress all information sent between the client and the server if both support compression.

- `--concurrency=N` [310], `-c N`

The number of clients to simulate when issuing the `SELECT` statement.

- `--create=value` [310]

The file or string containing the statement to use for creating the table.

- `--create-schema=value` [310]

The schema in which to run the tests.

#### Note

If the `--auto-generate-sql` [309] option is also given, `mysqlslap` drops the schema at the end of the test run. To avoid this, use the `--no-drop` [311] option as well.

- `--csv[=file_name]` [310]

Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- `--debug[=debug_options]` [310], `-# [debug_options]`

Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqlslap.trace'`.

- `--debug-check` [310]

Print some debugging information when the program exits.

- `--debug-info [311], -T`  
Print debugging information and memory and CPU usage statistics when the program exits.
- `--default-auth=plugin [311]`  
The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).  
This option was added in MySQL 5.6.2.
- `--delimiter=str [311], -F str`  
The delimiter to use in SQL statements supplied in files or using command options.
- `--detach=N [311]`  
Detach (close and reopen) each connection after each *N* statements. The default is 0 (connections are not detached).
- `--enable-cleartext-plugin [311]`  
Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.6.7.
- `--engine=engine_name [311], -e engine_name`  
The storage engine to use for creating tables.
- `--host=host_name [311], -h host_name`  
Connect to the MySQL server on the given host.
- `--iterations=N [311], -i N`  
The number of times to run the tests.
- `--no-drop [311]`  
Prevent `mysqlslap` from dropping any schema it creates during the test run. This option was added in MySQL 5.6.3.
- `--number-char-cols=N [311], -x N`  
The number of `VARCHAR` columns to use if `--auto-generate-sql [309]` is specified.
- `--number-int-cols=N [311], -y N`  
The number of `INT` columns to use if `--auto-generate-sql [309]` is specified.
- `--number-of-queries=N [311]`  
Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke `mysqlslap` as follows, the `;` delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.  

```
shell> mysqlslap --delimiter=";" --number-of-queries=10
--query="use test;insert into t values(null)"
```
- `--only-print [311]`  
Do not connect to databases. `mysqlslap` only prints what it would have done.
- `--password[=password] [311], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` [311] or `-p` option on the command line, `mysqlslap` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe` [312], `-W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path` [312]

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` [311] option is used to specify an authentication plugin but `mysqlslap` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num` [312], `-P port_num`

The TCP/IP port number to use for the connection.

- `--post-query=value` [312]

The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- `--shared-memory-base-name=name` [312]

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. This option applies only if the server supports shared-memory connections.

- `--post-system=str` [312]

The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes.

- `--pre-query=value` [312]

The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

- `--pre-system=str` [312]

The string to execute using `system()` before running the tests. This execution is not counted for timing purposes.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [312]

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--query=value` [312], `-q value`

The file or string containing the `SELECT` statement to use for retrieving data.

- `--silent` [312], `-s`

Silent mode. No output.

- `--socket=path` [313], `-S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` [810] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name` [313], `-u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose` [313], `-v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version` [313], `-V`

Display version information and exit.

## 4.6. MySQL Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

### 4.6.1. `innochecksum` — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for `InnoDB` files. This tool reads an `InnoDB` tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches will cause `InnoDB` to deliberately shut down a running server, it can be preferable to use this tool rather than waiting for a server in production usage to encounter the damaged pages.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace.

If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
shell> innochecksum [options] file_name
```

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- `-c`

Print a count of the number of pages in the file.

- `-d`

Debug mode; prints checksums for each page.

- `-e num`

End at this page number.

- `-p num`  
Check only this page number.
- `-s num`  
Start at this page number.
- `-v`  
Verbose mode; print a progress indicator every five seconds.

## 4.6.2. myisam\_ftdump — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable` that has the following definition:

```
CREATE TABLE mytexttable
(
  id   INT NOT NULL,
  txt  TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
) ENGINE=MyISAM;
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this:

```
shell> myisam_ftdump -c mytexttable 1 | sort -r
```

`myisam_ftdump` supports the following options:

- `--help [314]`, `-h -?`  
Display a help message and exit.
- `--count [314]`, `-c`  
Calculate per-word statistics (counts and global weights).

- `--dump` [315], `-d`  
Dump the index, including data offsets and word weights.
- `--length` [315], `-l`  
Report the length distribution.
- `--stats` [315], `-s`  
Report global index statistics. This is the default operation if no other operation is specified.
- `--verbose` [315], `-v`  
Verbose mode. Print more output about what the program does.

### 4.6.3. myisamchk — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), and [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

The use of `myisamchk` with partitioned tables is not supported.

#### Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the MyISAM tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all MyISAM tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all MyISAM tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state \
  --key_buffer_size=64M --myisam_sort_buffer_size=64M \
  --read_buffer_size=1M --write_buffer_size=1M \
  /path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with `myisamchk`, see [Section 4.6.3.6, “myisamchk Memory Usage”](#).

For additional information about using `myisamchk`, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

### Important

*You must ensure that no other program is using the tables while you are running `myisamchk`.* The most effective means of doing so is to shut down the MySQL server while running `myisamchk`, or to lock all tables that `myisamchk` is being used on.

Otherwise, when you run `myisamchk`, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the `mysqld` server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more MyISAM tables.

If `mysqld` is running, you must force it to flush any table modifications that are still buffered in memory by using `FLUSH TABLES`. You should then ensure that no one is using the tables while you are running `myisamchk`.

However, the easiest way to avoid this problem is to use `CHECK TABLE` instead of `myisamchk` to check tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#).

`myisamchk` supports the following options, which can be specified on the command line or in the `[myisamchk]` group of an option file. `myisamchk` also supports the options for processing option files described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.10. `myisamchk` Options**

Format	Option File	Description	Introduced	Deprecated
<code>--analyze [323]</code>	<code>analyze [323]</code>	Analyze the distribution of key values		
<code>--backup [321]</code>	<code>backup [321]</code>	Make a backup of the .MYD file as file_name-time.BAK		
<code>--block-search=offset [323]</code>	<code>block-search [323]</code>	Find the record that a block at the given offset belongs to		
<code>--check [320]</code>	<code>check [320]</code>	Check the table for errors		
<code>--check-only-changed [321]</code>	<code>check-only-changed [321]</code>	Check only tables that have changed since the last check		

Format	Option File	Description	Introduced	Deprecated
<a href="#">--correct-checksum [321]</a>	<a href="#">correct-checksum [321]</a>	Correct the checksum information for the table		
<a href="#">--data-file-length=len [322]</a>	<a href="#">data-file-length [322]</a>	Maximum length of the data file (when re-creating data file when it is full)		
<a href="#">--debug[=debug_options] [319]</a>	<a href="#">debug [319]</a>	Write a debugging log		
<a href="#">decode_bits=#</a>	<a href="#">decode_bits</a>	<a href="#">Decode_bits</a>		
<a href="#">--description [323]</a>	<a href="#">description [323]</a>	Print some descriptive information about the table		
<a href="#">--extend-check [321]</a>	<a href="#">extend-check [321]</a>	Do very thorough table check or repair that tries to recover every possible row from the data file		
<a href="#">--fast [321]</a>	<a href="#">fast [321]</a>	Check only tables that haven't been closed properly		
<a href="#">--force [321]</a>	<a href="#">force [321]</a>	Do a repair operation automatically if myisamchk finds any errors in the table		
<a href="#">--force</a>	<a href="#">force-recover</a>	Overwrite old temporary files. For use with the -r or -o option		
<a href="#">ft_max_word_len=#</a>	<a href="#">ft_max_word_len=#</a>	Maximum word length for FULLTEXT indexes		
<a href="#">ft_min_word_len=#</a>	<a href="#">ft_min_word_len=#</a>	Minimum word length for FULLTEXT indexes		
<a href="#">ft_stopword_file=filename</a>	<a href="#">ft_stopword_file=filename</a>	Use stopwords from this file instead of built-in list		
<a href="#">--HELP [319]</a>		Display help message and exit		
<a href="#">--help [318]</a>		Display help message and exit		
<a href="#">--information [321]</a>	<a href="#">information [321]</a>	Print informational statistics about the table that is checked		
<a href="#">key_buffer_size=#</a>	<a href="#">key_buffer_size=#</a>	The size of the buffer used for index blocks for MyISAM tables		
<a href="#">--keys-used=val [322]</a>	<a href="#">keys-used [322]</a>	A bit-value that indicates which indexes to update		
<a href="#">--max-record-length=len [322]</a>	<a href="#">max-record-length [322]</a>	Skip rows larger than the given length if myisamchk cannot allocate memory to hold them		
<a href="#">--medium-check [321]</a>	<a href="#">medium-check [321]</a>	Do a check that is faster than an --extend-check operation		
<a href="#">myisam_block_size=#</a>	<a href="#">myisam_block_size=#</a>	Block size to be used for MyISAM index pages		
<a href="#">myisam_sort_buffer_size=#</a>	<a href="#">myisam_sort_buffer_size=#</a>	The size of the buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE	5.6.9	
<a href="#">--parallel-recover [322]</a>	<a href="#">parallel-recover [322]</a>	Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta)		
<a href="#">--quick [322]</a>	<a href="#">quick [322]</a>	Achieve a faster repair by not modifying the data file.		

Format	Option File	Description	Introduced	Deprecated
read_buffer_size=#	read_buffer_size	Each thread that does a sequential scan allocates a buffer of this size for each table it scans		
--read-only [321]	read-only [321]	Don't mark the table as checked		
--recover [322]	recover [322]	Do a repair that can fix almost any problem except unique keys that aren't unique		
--safe-recover [322]	safe-recover [322]	Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found		
--set-auto-increment[=value] [323]	set-auto-increment [323]	Force AUTO_INCREMENT numbering for new records to start at the given value		
--set-collation=name [323]	set-collation [323]	Specify the collation to use for sorting table indexes		
--silent [319]	silent [319]	Silent mode		
sort_buffer_size=#	sort_buffer_size	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE		5.6.9
--sort-index [323]	sort-index [323]	Sort the index tree blocks in high-low order		
sort_key_blocks=#	sort_key_blocks	sort_key_blocks		
--sort-records=# [324]	sort-records [324]	Sort records according to a particular index		
--sort-recover [323]	sort-recover [323]	Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large		
stats_method=value	stats_method	Specifies how MyISAM index statistics collection code should treat NULLs		
--tmpdir=path [323]	tmpdir [323]	Path of the directory to be used for storing temporary files		
--unpack [323]	unpack [323]	Unpack a table that was packed with myisampack		
--update-state [321]	update-state [321]	Store information in the .MYI file to indicate when the table was checked and whether the table crashed		
--verbose [319]		Verbose mode		
--version [319]		Display version information and exit		
write_buffer_size=#	write_buffer_size	Write buffer size		

#### 4.6.3.1. myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help [318]`, `-?`

Display a help message and exit. Options are grouped by type of operation.

- `--HELP` [319], `-H`

Display a help message and exit. Options are presented in a single list.

- `--debug=debug_options` [319], `-# debug_options`

Write a debugging log. A typical *debug\_options* string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/myisamchk.trace'`.

- `--silent` [319], `-s`

Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose` [319], `-v`

Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version` [319], `-V`

Display version information and exit.

- `--wait` [319], `-w`

Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

Variable	Default Value
<code>decode_bits</code>	9
<code>ft_max_word_len</code>	version-dependent
<code>ft_min_word_len</code>	4
<code>ft_stopword_file</code>	built-in list
<code>key_buffer_size</code>	523264
<code>myisam_block_size</code>	1024
<code>myisam_sort_key_blocks</code>	16
<code>read_buffer_size</code>	262136
<code>sort_buffer_size</code>	2097144
<code>sort_key_blocks</code>	16
<code>stats_method</code>	nulls_unequal
<code>write_buffer_size</code>	262136

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover` [322]. As of MySQL 5.6.9, `myisam_sort_buffer_size` is available as an alternative name to `sort_buffer_size`. `myisam_sort_buffer_size` is preferable to `sort_buffer_size` because its name corresponds to the `myisam_sort_buffer_size` [513] server system variable that has a similar meaning. `sort_buffer_size` should be considered deprecated.

`key_buffer_size` is used when you are checking the table with `--extend-check` [321] or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover` [322].
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` [323] option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `myisam_sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` [323] option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in Section 5.1.4, “Server System Variables”, and Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes on `MyISAM` tables. `ft_stopword_file` names the stopwords file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopwords file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

### 4.6.3.2. myisamchk Check Options

`myisamchk` supports the following options for table checking operations:

- `--check` [320], `-c`

Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed` [321], `-C`

Check only tables that have changed since the last check.

- `--extend-check` [321], `-e`

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

If you are using `--extend-check` [321] and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

See also the description of this option under table repair options.

For a description of the output format, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--fast` [321], `-F`

Check only tables that haven't been closed properly.

- `--force` [321], `-f`

Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` [322] or `-r` option.

- `--information` [321], `-i`

Print informational statistics about the table that is checked.

- `--medium-check` [321], `-m`

Do a check that is faster than an `--extend-check` [321] operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only` [321], `-T`

Do not mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that does not use locking, such as `mysqld` when run with external locking disabled.

- `--update-state` [321], `-U`

Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` [321] option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

### 4.6.3.3. myisamchk Repair Options

`myisamchk` supports the following options for table repair operations (operations performed when an option such as `--recover` [322] or `--safe-recover` [322] is given):

- `--backup` [321], `-B`

Make a backup of the `.MYD` file as `file_name-time.BAK`

- `--character-sets-dir=path` [321]

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--correct-checksum` [321]

Correct the checksum information for the table.

- `--data-file-length=len` [322], `-D len`

The maximum length of the data file (when re-creating data file when it is “full”).

- `--extend-check` [321], `-e`

Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

See also the description of this option under table checking options.

For a description of the output format, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--force` [321], `-f`

Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val` [322], `-k val`

For `myisamchk`, the option value is a bit-value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--no-symlinks` [322], `-l`

Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=len` [322]

Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover` [322], `-p`

Use the same technique as `-r` and `-n`, but create all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick` [322], `-q`

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover` [322], `-r`

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with MyISAM tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` [322] only if `myisamchk` reports that the table cannot be recovered using `--recover` [322]. (In the unlikely case that `--recover` [322] fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `myisam_sort_buffer_size`.

- `--safe-recover` [322], `-o`

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover` [322], but can handle a couple of very unlikely cases that `--recover` [322] cannot. This recovery method

also uses much less disk space than `--recover` [322]. Normally, you should repair first using `--recover` [322], and then with `--safe-recover` [322] only if `--recover` [322] fails.

If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-character-set=name` [323]

Change the character set used by the table indexes. This option was replaced by `--set-collation` [323] in MySQL 5.0.3.

- `--set-collation=name` [323]

Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover` [323], `-n`

Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=path` [323], `-t path`

The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` [323] can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (“:”) on Unix and the semicolon (“;”) on Windows.

- `--unpack` [323], `-u`

Unpack a table that was packed with `myisampack`.

#### 4.6.3.4. Other `myisamchk` Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze` [323], `-a`

Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- `--block-search=offset` [323], `-b offset`

Find the record that a block at the given offset belongs to.

- `--description` [323], `-d`

Print some descriptive information about the table. Specifying the `--verbose` [319] option once or twice produces additional information. See [Section 4.6.3.5, “Obtaining Table Information with `myisamchk`”](#).

- `--set-auto-increment[=value]` [323], `-A[value]`

Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If `value` is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index` [323], `-S`

Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N [324], -R N`

Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

#### 4.6.3.5. Obtaining Table Information with `myisamchk`

To obtain a description of a `MyISAM` table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- `myisamchk -d tbl_name`

Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -dv tbl_name`

Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- `myisamchk -eis tbl_name`

Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

This is like `-eis`, but tells you what is being done.

The `tbl_name` argument can be either the name of a `MyISAM` table or the name of its index file, as described in [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). Multiple `tbl_name` arguments can be given.

Suppose that a table named `person` has the following structure. (The `MAX_ROWS` table option is included so that in the example output from `myisamchk` shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
  id          INT NOT NULL AUTO_INCREMENT,
  last_name   VARCHAR(20) NOT NULL,
  first_name  VARCHAR(20) NOT NULL,
  birth       DATE,
  death       DATE,
  PRIMARY KEY (id),
  INDEX (last_name, first_name),
  INDEX (birth)
) MAX_ROWS = 1000000;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw---- 1 mysql mysql 9347072 Aug 19 11:47 person.MYD
-rw-rw---- 1 mysql mysql 6066176 Aug 19 11:47 person.MYI
```

Example of `myisamchk -dvv` output:

```

MyISAM file:      person
Record format:    Packed
Character set:    latin1_swedish_ci (8)
File-version:     1
Creation time:    2009-08-19 16:47:41
Recover time:    2009-08-19 16:47:56
Status:           checked,analyzed,optimized keys
Auto increment key: 1 Last value: 306688
Data records:     306688 Deleted blocks: 0
Datafile parts:   306688 Deleted data: 0
Datafile pointer (bytes): 4 Keyfile pointer (bytes): 3
Datafile length: 9347072 Keyfile length: 6066176
Max datafile length: 4294967294 Max keyfile length: 17179868159
Recordlength:    54

```

## table description:

Key	Start	Len	Index	Type	Rec/key	Root	Blocksize
1	2	4	unique	long	1	99328	1024
2	6	20	multip.	varchar prefix	512	3563520	1024
	27	20		varchar	512		
3	48	3	multip.	uint24 NULL	306688	6065152	1024

Field	Start	Length	Nullpos	Nullbit	Type
1	1	1			
2	2	4			no zeros
3	6	21			varchar
4	27	21			varchar
5	48	3	1	1	no zeros
6	51	3	1	2	no zeros

Explanations for the types of information `myisamchk` produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- `MyISAM file`

Name of the `MyISAM` (index) file.

- `Record format`

The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`. (`Packed` corresponds to what `SHOW TABLE STATUS` reports as `Dynamic`.)

- `Character set`

The table default character set.

- `File-version`

Version of `MyISAM` format. Currently always 1.

- `Creation time`

When the data file was created.

- `Recover time`

When the index/data file was last reconstructed.

- `Status`

Table status flags. Possible values are `crashed`, `open`, `changed`, `analyzed`, `optimized keys`, and `sorted index pages`.

- `Auto increment key, Last value`

The key number associated the table's `AUTO_INCREMENT` column, and the most recently generated value for this column. These fields do not appear if there is no such column.

- `Data records`

The number of rows in the table.

- `Deleted blocks`

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Datafile parts`

For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as `Data records`.

- `Deleted data`

How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Datafile pointer`

The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

How long the table data file can become, in bytes.

- `Max keyfile length`

How long the table index file can become, in bytes.

- `Recordlength`

How much space each row takes, in bytes.

The `table description` part of the output includes a list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- `Key`

This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two `table description` lines for the second index. This indicates that it is a multiple-part index with two parts.

- `Start`

Where in the row this portion of the index starts.

- `Len`

How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can

index a prefix of a string column. The total length of a multiple-part key is the sum of the `Len` values for all key parts.

- `Index`

Whether a key value can exist multiple times in the index. Possible values are `unique` or `multip.` (multiple).

- `Type`

What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- `Root`

Address of the root index block.

- `Blocksize`

The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- `Rec/key`

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- `Field`

The column number.

- `Start`

The byte position of the column within table rows.

- `Length`

The length of the column in bytes.

- `Nullpos, Nullbit`

For columns that can be `NULL`, `MyISAM` stores `NULL` values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The `Nullpos` and `Nullbit` values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is `NULL`.

The position and number of bytes used to store `NULL` flags is shown in the line for field 1. This is why there are six `Field` lines for the `person` table even though it has only five columns.

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an `ENUM`.

- `zerofill(N)`

The most significant `N` bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

The `Huff tree` and `Bits` fields are displayed if the table has been compressed with `myisampack`. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#), for an example of this information.

Example of `myisamchk -eiv` output:

```
Checking MyISAM file: person
Data records: 306688 Deleted blocks: 0
- check file-size
- check record delete-chain
No recordlinks
- check key delete-chain

Blocks in 0 out 7, Messages in 0 out 0, Signals 0
```

```
Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)
```

`myisamchk -eiv` output includes the following information:

- `Data records`

The number of rows in the table.

- `Deleted blocks`

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Key`

The key number.

- `Keyblocks used`

What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

- `Packed`

MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

- `Max levels`

How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

How many rows are in the table.

- `M.recordlength`

The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

What percentage of the data file is used.

- `Empty space`

What percentage of the data file is unused.

- `Blocks/Record`

Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Recordblocks`

How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- `Deleteblocks`  
How many blocks (links) are deleted.
- `Recorddata`  
How many bytes in the data file are used.
- `Deleted data`  
How many bytes in the data file are deleted (unused).
- `Lost space`  
If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.
- `Linkdata`  
When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

#### 4.6.3.6. myisamchk Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk --myisam_sort_buffer_size=256M \
  --key_buffer_size=512M \
  --read_buffer_size=64M \
  --write_buffer_size=64M ...
```

Using `--myisam_sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=path` [323] option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick` [322]; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.
- When using `--recover` [322] or `--sort-recover` [323] (but not when using `--safe-recover` [322]), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=path` [323]). The following formula yields the amount of space required:

```
(largest_key + row_pointer_length) * number_of_rows * 2
```

You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name` (see Section 4.6.3.5, “Obtaining Table Information with `myisamchk`”). The `row_pointer_length` and `number_of_rows` values are the `Datafile pointer` and `Data records` values in the table description. To determine the `largest_key` value, check the `Key`

lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` [322] instead of `--recover` [322].

#### 4.6.4. myisamlog — Display MyISAM Log File Contents

`myisamlog` processes the contents of a MyISAM log file. To create such a file, start the server with a `--log-isam=log_file` [427] option.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?, -I`  
Display a help message and exit.
- `-c N`  
Execute only `N` commands.
- `-f N`  
Specify the maximum number of open files.
- `-i`  
Display extra information before exiting.
- `-o offset`  
Specify the starting offset.
- `-p N`  
Remove `N` components from path.
- `-r`  
Perform a recovery operation.
- `-R record_pos_file record_pos`  
Specify record position file and record position.
- `-u`  
Perform an update operation.
- `-v`  
Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.
- `-w write_file`  
Specify the write file.

- `-V`

Display version information.

#### 4.6.5. `myisampack` — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses MyISAM tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).

Invoke `myisampack` like this:

```
shell> myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, you should use `myisamchk -rq` to rebuild its indexes. [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

`myisampack` supports the following options. It also reads option files and supports the options for processing them described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

- `--help` [332], `-?`

Display a help message and exit.

- `--backup` [332], `-b`

Make a backup of each table's data file using the name `tbl_name.OLD`.

- `--character-sets-dir=path` [332]

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--debug[=debug_options]` [332], `-#` [debug\_options]

Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o'`.

- `--force` [332], `-f`

Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named `tbl_name.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the `.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that `tbl_name.TMD` exists. With `--force` [332], `myisampack` packs the table anyway.

- `--join=big_tbl_name [333], -j big_tbl_name`

Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

`big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not modified. The join operation does not create a `.frm` file for `big_tbl_name`, so after the join operation finishes, copy the `.frm` file from one of the source tables and name it `big_tbl_name.frm`.

- `--silent [333], -s`

Silent mode. Write output only when errors occur.

- `--test [333], -t`

Do not actually pack the table, just test packing it.

- `--tmpdir=path [333], -T path`

Use the named directory as the location where `myisampack` creates temporary files.

- `--verbose [333], -v`

Verbose mode. Write information about the progress of the packing operation and its result.

- `--version [333], -V`

Display version information and exit.

- `--wait [333], -w`

Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r-- 1 monty my          994128 Apr 17 19:00 station.MYD
-rw-rw-r-- 1 monty my          53248 Apr 17 19:00 station.MYI
-rw-rw-r-- 1 monty my           5767 Apr 17 19:00 station.frm

shell> myisamchk -dvv station

57	831	4	no zeros, zerofill(1)	2	9

myisampack displays the following kinds of information:

- `normal`

The number of columns for which no extra packing is used.

- `empty-space`

The number of columns containing values that are only spaces. These occupy one bit.

- `empty-zero`

The number of columns containing values that are only binary zeros. These occupy one bit.

- `empty-fill`

The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.

- `pre-space`

The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- `end-space`

The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- `table-lookup`

The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- `zero`

The number of columns for which all values are zero.

- `Original trees`

The initial number of Huffman trees.

- `After join`

The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the `Field` lines displayed by `myisamchk -dvv` include additional information about each column:

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an `ENUM`.

- `zerofill(N)`

The most significant *N* bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

After you run `myisampack`, you must run `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack [323]` option to `myisamchk`.

## 4.6.6. mysql\_config\_editor — MySQL Configuration Utility

The `mysql_config_editor` utility (available as of MySQL 5.6.6) enables you to store authentication credentials in an encrypted login file named `.mylogin.cnf`. The file location is the `%APPDATA%\MySQL` directory on Windows and the current user's home directory on non-Windows systems. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server.

To specify an alternate file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is used by the `mysql-test-run.pl` testing utility, but also is recognized by `mysql_config_editor` and by MySQL clients such as `mysql`, `mysqladmin`, and so forth.

`mysql_config_editor` encrypts the `.mylogin.cnf` file so it cannot be read as clear text, and its contents when decrypted by client programs are used only in memory. In this way, passwords can be stored in a file in non-clear-text format and used later without ever needing to be exposed on the command line or in an environment variable. `mysql_config_editor` provides a `print` command

that enables the user to display the file contents, but even in this case, password values are masked so as never to appear in a way that other users can see them.

The encryption used by `mysql_config_editor` prevents passwords from appearing in `.mylogin.cnf` as clear text and provides a measure of security by preventing inadvertent password exposure. For example, if you display a regular unencrypted `my.cnf` option file on the screen, any passwords it contains are visible for anyone to see. With `.mylogin.cnf`, that is not true. But the encryption used will not deter a determined attacker and you should not consider it unbreakable. A user who can gain system administration privileges on your machine to access your files could decrypt the `.mylogin.cnf` file with some effort.

The login file must be readable and writable to the current user, and inaccessible to other users. Otherwise, `mysql_config_editor` ignores it, and the file is not used by client programs, either. On Windows, this constraint does not apply; instead, the user must have access to the `%APPDATA%\MySQL` directory.

The unencrypted format of the `.mylogin.cnf` login file consists of option groups, similar to other option files. Each option group in `.mylogin.cnf` is called a “login path,” which is a group that permits only a limited set of options: `host`, `user`, and `password`. Think of a login path as a set of values that indicate the server host and the credentials for authenticating with the server. Here is an example:

```
[myloginpath]
user = myname
password = mypass
host = 127.0.0.1
```

When you invoke a client program to connect to the server, `.mylogin.cnf` is used in conjunction with other option files. Its precedence is higher than other option files, but less than options specified explicitly on the client command line. For information about the order in which option files are used, see [Section 4.2.3.3, “Using Option Files”](#).

Invoke `mysql_config_editor` like this:

```
shell> mysql_config_editor [program_options] command [command_options]
```

`program_options` consists of general `mysql_config_editor` options. `command` indicates what command to perform, and `command_options` indicates any additional options needed by the command.

The command indicates what action to perform on the `.mylogin.cnf` login file. For example, `set` writes a login path to the file, `remove` removes a login path, and `print` displays login path contents. Any options given provide information to the command, such as the login path name and the values to use in the login path.

The position of the command name within the set of program arguments is significant. For example, these command lines have the same arguments, but produce different results:

```
mysql_config_editor --help set
mysql_config_editor set --help
```

The first command line displays general `mysql_config_editor` help, and ignores the `set` command. The second command line displays help for the `set` command.

Suppose that you want to establish two login paths named `local` and `remote` for connecting to the local MySQL server and a server on the host `remote.example.com`. You want to authenticate to the local server with a user name and password of `localuser` and `localpass`, and to the remote server with a user name and password of `remoteuser` and `remotepass`. To set up the login paths in the `.mylogin.cnf` file, use the following `set` commands. Enter each command on a single line, then enter the appropriate password when prompted.

```
shell> mysql_config_editor set --login-path=local
--host=localhost --user=localuser --password
Enter password: enter password "localpass" here
shell> mysql_config_editor set --login-path=remote
```

```
--host=remote.example.com --user=remoteuser --password
Enter password: enter password "remotepass" here
```

To see what `mysql_config_editor` wrote to the `.mylogin.cnf` file, use the `print` command:

```
shell> mysql_config_editor print --all
[local]
user = localuser
password = *****
host = localhost
[remote]
user = remoteuser
password = *****
host = remote.example.com
```

The `print` command displays each login path as a set of lines beginning with a group header indicating the login path name in square brackets, followed by the option values for the login path. Password values are masked and do not appear as clear text.

As shown by the preceding examples, the `.mylogin.cnf` file can contain multiple login paths. In this way, `mysql_config_editor` makes it easy to set up multiple “personalities” for connecting to different MySQL servers. Any of these can be selected by name later using the `--login-path` option when you invoke a client program. For example, to connect to the local server, use this command:

```
shell> mysql --login-path=local
```

To connect to the remote server, use this command:

```
shell> mysql --login-path=remote
```

When you use the `set` command with `mysql_config_editor` to create a login path, you need not specify all three possible option values (host name, user name, and password). Only those values given are written to the path. Any missing values required later can be specified when you invoke a client path to connect to the MySQL server, either in other option files or on the command line. Also, any options specified on the command line override those in option files, including the `.mylogin.cnf` file. For example, if the credentials in the `remote` login path also apply for the host `remote2.example.com`, you can connect to the server on that host like this:

```
shell> mysql --login-path=remote --host=remote2.example.com
```

The `.mylogin.cnf` file, if it exists, is read in all cases, even when the `--no-defaults` [220] option is used. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` [220] is present.

## mysql\_config\_editor Commands

This section describes the permitted `mysql_config_editor` commands, and the interpretation of options that have a command-specific meaning. In addition, `mysql_config_editor` takes other options that can be used with any command, such as `--verbose` to produce more information as `mysql_config_editor` executes. This option may be helpful in diagnosing problems if an operation does not have the effect you expect. For a list of supported options, see [mysql\\_config\\_editor Options](#).

`mysql_config_editor` supports these commands:

- `help`

Display a help message and exit.

- `print [options]`

Print the contents of `.mylogin.cnf` in unencrypted form. Passwords are displayed as `*****`.

The `print` command takes these options:

- `--all` [342]

Print all login paths.

- `--login-path=name` [342]

Print the named login path.

If no login path is specified, the default path name is `client`. If both `--all` [342] and `--login-path` [342] are given, `--all` [342] takes precedence.

- `remove [options]`

Remove a login path from the `.mylogin.cnf` file.

The `remove` command takes these options:

- `--host` [342]

Remove the host name from the login path.

- `--login-path=name` [342]

The login path to remove. If this option is not given, the default path name is `client`.

- `--password` [342]

Remove the password from the login path.

- `--port` [342]

Remove the TCP/IP port number from the login path.

- `--socket` [343]

Remove the Unix socket file name from the login path.

- `--user` [343]

Remove the user name from the login path.

The `--host`, `--user`, and `--password` options are supported for the `remove` command as of MySQL 5.6.9. The `--port` [342] and `--socket` [343] options are supported for the `remove` command as of MySQL 5.6.11

The `remove` command removes from the login path only such values as are specified with the `--host` [342], `--password` [342], `--port` [342], `--socket` [343], and `--user` [343] options. If none of them is given, `remove` removes the entire login path. For example, this command removes only the `user` value from the `client` login path rather than the entire `client` login path:

```
mysql_config_editor remove --login-path=client --user
```

- `reset`

Empty the contents of the `.mylogin.cnf` file. The file is created if it does not exist.

- `set [options]`

Write a login path to the `.mylogin.cnf` file.

The `set` command takes these options:

- `--host=host_name` [342]

The host name to write to the login path.

- `--login-path=name` [342]

The login path to create. If this option is not given, the default path name is `client`.

- `--password` [342]

Prompt for a password to write to the login path.

- `--port=port_num` [342]

The TCP/IP port number to write to the login path.

- `--socket=file_name` [343]

The Unix socket file to write to the login path.

- `--user=user_name` [343]

The user name to write to the login path.

The `--port` [342] and `--socket` [343] options are supported for the `set` command as of MySQL 5.6.11

The `set` command writes to the login path only such values as are specified with the `--host` [342], `--password` [342], `--port` [342], `--socket` [343], and `--user` [343] options. If none of those options are given, `mysql_config_editor` writes the login path as an empty group.

To specify an empty password, use the `set` command with the `--password` [342] option, then press Enter at the password prompt. The resulting login path written to `.mylogin.cnf` will include a line like this:

```
password =
```

If the login path already exists in `.mylogin.cnf`, the `set` command replaces it. To ensure that this is what the user wants, `mysql_config_editor` prints a warning and prompts for confirmation. To suppress the warning and prompt, use the `--skip-warn` [343] option.

## mysql\_config\_editor Options

`mysql_config_editor` supports the following options.

**Table 4.11. mysql\_config\_editor Options**

Format	Option File	Description	Introduced
<code>--all</code> [342]		Print all login paths	
<code>--debug[=debug_options]</code> [342]		Write a debugging log	
<code>--help</code> [342]		Display help message and exit	
<code>--host=host_name</code> [342]		Host to write to login file	
<code>--login-path=name</code> [342]		Login path name	
<code>--password</code> [342]		Solicit password to write to login file	

Format	Option File	Description	Introduced
<code>--port=port_num [342]</code>	<code>port [342]</code>	The TCP/IP port number to write to login file	5.6.11
<code>--socket=path [343]</code>	<code>socket [343]</code>	The Unix socket file name to write to login file	5.6.11
<code>--user=user_name [343]</code>		User name to write to login file	
<code>--verbose [343]</code>		Verbose mode	
<code>--version [343]</code>		Display version information and exit	
<code>--warn [343]</code>		Warn and solicit confirmation for overwriting login path	

- `--help [342], -?`  
Display a help message and exit. If preceded by a command name such as `set` or `remove`, displays information about that command.
- `--all [342]`  
For the `print` command, print all login paths in the login file.
- `--debug[=debug_options] [342], -# debug_options`  
Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysql_config_editor.trace'`.
- `--host=host_name [342], -h host_name`  
For the `set` command, the host name to write to to the login path. For the `remove` command, removes the host name from the login path.
- `--login-path=name [342], -G name`  
For the `print`, `remove`, and `set` commands, the login path to use in the `.mylogin.cnf` login file.  
  
Client programs also support the `--login-path` option, to enable users to specify which login path to use for connecting to a MySQL server. For client programs, `--login-path` must be the first option given, which is not true for `mysql_config_editor`. See [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).
- `--password [342], -p`  
For the `set` command, cause `mysql_config_editor` to prompt for a password and write the value entered by the user to the login path. After `mysql_config_editor` starts and displays the prompt, the user should type the password and press Enter. To prevent other users from seeing the password, `mysql_config_editor` does not echo it.  
  
This option does not permit a password value following the option name. That is, with `mysql_config_editor`, you never enter a password on the command line where it might be seen by other users. This differs from most other MySQL programs, which permit the password to be given on the command line as `--password=pass_val` or `-ppass_val`. (That practice is insecure and should be avoided, however.)  
  
For the `remove` command, removes the password from the login path.
- `--port=port_num [342], -P port_num`  
For the `set` command, the TCP/IP port number to write to the login path. For the `remove` command, removes the port number from the login path.

- `--socket=file_name` [343], `-S file_name`

For the `set` command, the Unix socket file name to write to the login path. For the `remove` command, removes the socket file from the login path.

- `--user=user_name` [343], `-u user_name`

For the `set` command, the user name to write to the login path. For the `remove` command, removes the user name from the login path.

- `--verbose` [343], `-v`

Verbose mode. Print more information about what the program does.

- `--version` [343], `-V`

Display version information and exit.

- `--warn` [343], `-w`

For the `set` command, warn and prompt the user for confirmation if the command attempts to overwrite an existing login path. This option is enabled by default; use `--skip-warn` [343] to disable it.

## 4.6.7. mysqlaccess — Client for Checking Access Privileges

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a host name, user name, and database combination. Note that `mysqlaccess` checks access using only the `user` and `db` tables. It does not check table, column, or routine privileges specified in the `tables_priv`, `columns_priv`, or `procs_priv` tables.

Invoke `mysqlaccess` like this:

```
shell> mysqlaccess [host_name [user_name [db_name]]] [options]
```

`mysqlaccess` supports the following options.

**Table 4.12. mysqlaccess Options**

Format	Option File	Description
<code>--brief</code> [344]	<code>brief</code> [344]	Generate reports in single-line tabular format
<code>--commit</code> [344]	<code>commit</code> [344]	Copy the new access privileges from the temporary tables to the original grant tables
<code>--copy</code> [344]	<code>copy</code> [344]	Reload the temporary grant tables from original ones
<code>--db=db_name</code> [344]	<code>db</code> [344]	Specify the database name
<code>--debug=#</code> [344]	<code>debug</code> [344]	Specify the debug level
<code>--help</code> [344]		Display help message and exit
<code>--host=host_name</code> [344]	<code>host</code> [344]	Connect to the MySQL server on the given host
<code>--howto</code> [344]	<code>howto</code> [344]	Display some examples that show how to use <code>mysqlaccess</code>
<code>--old_server</code> [344]	<code>old_server</code> [344]	Assume that the server is an old MySQL server (prior to MySQL 3.21)
<code>--password[=password]</code> [344]	<code>password</code> [344]	The password to use when connecting to the server

Format	Option File	Description
<code>--plan [345]</code>	<code>plan [345]</code>	Display suggestions and ideas for future releases
<code>--preview [345]</code>	<code>preview [345]</code>	Show the privilege differences after making changes to the temporary grant tables
<code>--relnotes [345]</code>	<code>relnotes [345]</code>	Display the release notes
<code>--rhost=host_name [345]</code>	<code>rhost [345]</code>	Connect to the MySQL server on the given host
<code>--rollback [345]</code>	<code>rollback [345]</code>	Undo the most recent changes to the temporary grant tables.
<code>--spassword[=password] [345]</code>	<code>spassword [345]</code>	The password to use when connecting to the server as the superuser
<code>--superuser=user_name [345]</code>	<code>superuser [345]</code>	Specify the user name for connecting as the superuser
<code>--table [345]</code>	<code>table [345]</code>	Generate reports in table format
<code>--user=user_name, [345]</code>	<code>user [345]</code>	MySQL user name to use when connecting to server
<code>--version [345]</code>		Display version information and exit

- `--help [344], -?`  
Display a help message and exit.
- `--brief [344], -b`  
Generate reports in single-line tabular format.
- `--commit [344]`  
Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)
- `--copy [344]`  
Reload the temporary grant tables from original ones.
- `--db=db_name [344], -d db_name`  
Specify the database name.
- `--debug=N [344]`  
Specify the debug level. *N* can be an integer from 0 to 3.
- `--host=host_name [344], -h host_name`  
The host name to use in the access privileges.
- `--howto [344]`  
Display some examples that show how to use `mysqlaccess`.
- `--old_server [344]`  
Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full `WHERE` clauses.
- `--password[=password] [344], -p[password]`

The password to use when connecting to the server. If you omit the *password* value following the `--password [344]` or `-p` option on the command line, `mysqlaccess` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

- `--plan [345]`

Display suggestions and ideas for future releases.

- `--preview [345]`

Show the privilege differences after making changes to the temporary grant tables.

- `--relnotes [345]`

Display the release notes.

- `--rhost=host_name [345], -H host_name`

Connect to the MySQL server on the given host.

- `--rollback [345]`

Undo the most recent changes to the temporary grant tables.

- `--spassword[=password] [345], -P[password]`

The password to use when connecting to the server as the superuser. If you omit the *password* value following the `--spassword [345]` or `-p` option on the command line, `mysqlaccess` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

- `--superuser=user_name [345], -U user_name`

Specify the user name for connecting as the superuser.

- `--table [345], -t`

Generate reports in table format.

- `--user=user_name [345], -u user_name`

The user name to use in the access privileges.

- `--version [345], -v`

Display version information and exit.

If your MySQL distribution is installed in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL = '/usr/local/bin/mysql'; # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a [Broken pipe](#) error will occur when you run `mysqlaccess`.

## 4.6.8. mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in [Section 5.2.4, “The Binary Log”](#), and [Section 16.2.2, “Replication Relay and Status Logs”](#).

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See [Section 16.1.2, “Replication Formats”](#), for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309 9:28:36 server id 123  end_log_pos 245
  Query thread_id=3350  exec_time=11  error_code=0
```

In the first line, the number following `at` indicates the starting position of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to slave servers. `server id` is the `server_id` [539] value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a master server. On a slave, it is the difference of the end execution time on the slave minus the beginning execution time on the master. The difference serves as an indicator of how much replication lags behind the master. `error_code` indicates the result from executing the event. Zero means that no error occurred.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to redo the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section and in [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` [352] option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host` [351], `--password` [351], `--port` [352], `--protocol` [352], `--socket` [353], and `--user` [354]; they are ignored except when you also use the `--read-from-remote-server` [352] option.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` groups of an option file. `mysqlbinlog` also supports the options for processing option files described at [Section 4.2.3.4, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.13. `mysqlbinlog` Options**

Format	Option File	Description	Introduced
<code>--base64-output=value</code> [348]	<code>base64-output</code> [348]	Print binary log entries using base-64 encoding	
<code>--bind-address=ip_address</code> [349]	<code>bind-address</code> [349]	Use the specified network interface to connect to the MySQL Server	

Format	Option File	Description	Introduced
<code>--binlog-row-event-max-size=#</code> [349]	<code>binlog-row-event-max-size</code> [349]	Binary log max event size	
<code>--character-sets-dir=path</code> [349]	<code>character-sets-dir</code> [349]	The directory where character sets are installed	
<code>--database=db_name</code> [349]	<code>database</code> [349]	List entries for just this database	
<code>--debug[=debug_options]</code> [350]	<code>debug</code> [350]	Write a debugging log	
<code>--debug-check</code> [350]	<code>debug-check</code> [350]	Print debugging information when the program exits	
<code>--debug-info</code> [350]	<code>debug-info</code> [350]	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code> [351]	<code>default-auth=plugin</code> [351]	The authentication plugin to use	5.6.2
<code>--disable-log-bin</code> [351]	<code>disable-log-bin</code> [351]	Disable binary logging	
<code>--exclude-gtids=gtid_set</code> [351]	<code>exclude-gtids</code> [351]	Do not show any of the groups in the GTID set provided	5.6.5
<code>--force-if-open</code> [351]	<code>force-if-open</code> [351]	Read binary log files even if open or not closed properly	
<code>--force-read</code> [351]	<code>force-read</code> [351]	If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning	
<code>--help</code> [348]		Display help message and exit	
<code>--hexdump</code> [351]	<code>hexdump</code> [351]	Display a hex dump of the log in comments	
<code>--host=host_name</code> [351]	<code>host</code> [351]	Connect to the MySQL server on the given host	
<code>--idempotent</code>	<code>idempotent</code>	Cause the server to use idempotent mode while processing binary log updates from this session only	
<code>--include-gtids=gtid_set</code> [351]	<code>include-gtids</code> [351]	Show only the groups in the GTID set provided	5.6.5
<code>--local-load=path</code> [351]	<code>local-load</code> [351]	Prepare local temporary files for LOAD DATA INFILE in the specified directory	
<code>--login-path=name</code> [219]		Read login path options from <code>.mylogin.cnf</code>	5.6.6
<code>--offset=#</code> [351]	<code>offset</code> [351]	Skip the first N entries in the log	
<code>--password[=password]</code> [351]	<code>password</code> [351]	The password to use when connecting to the server	
<code>--plugin-dir=path</code> [352]	<code>plugin-dir=path</code> [352]	The directory where plugins are located	5.6.2
<code>--port=port_num</code> [352]	<code>port</code> [352]	The TCP/IP port number to use for the connection	
<code>--protocol=type</code> [352]	<code>protocol</code> [352]	The connection protocol to use	
<code>--raw</code> [352]	<code>raw</code> [352]	Write events in raw (binary) format to output files	

Format	Option File	Description	Introduced
<code>--read-from-remote-master=type</code> [352]	<code>read-from-remote-master</code> [352]	Read the binary log from a MySQL master rather than reading a local log file	5.6.5
<code>--read-from-remote-server</code> [352]	<code>read-from-remote-server</code> [352]	Read binary log from MySQL server rather than local log file	
<code>--result-file=name</code> [353]	<code>result-file</code> [353]	Direct output to the given file	
<code>--server-id=id</code> [353]	<code>server-id</code> [353]	Extract only those events created by the server having the given server ID	
<code>--set-charset=charset_name</code> [353]	<code>set-charset</code> [353]	Add a SET NAMES charset_name statement to the output	
<code>--short-form</code> [353]	<code>short-form</code> [353]	Display only the statements contained in the log	
<code>--skip-gtids[=true false]</code> [353]	<code>skip-gtids</code> [353]	Do not show any GTIDs; not recommended in production	5.6.5
<code>--socket=path</code> [353]	<code>socket</code> [353]	For connections to localhost	
<code>--start-datetime=datetime</code> [353]	<code>start-datetime</code> [353]	Read binary log from first event with timestamp equal to or later than datetime argument	
<code>--start-position=#</code> [353]	<code>start-position</code> [353]	Read binary log from first event with position equal to or greater than argument	
<code>--stop-datetime=datetime</code> [353]	<code>stop-datetime</code> [353]	Stop reading binary log at first event with timestamp equal to or greater than datetime argument	
<code>--stop-never</code> [354]	<code>stop-never</code> [354]	Stay connected to server after reading last binary log file	
<code>--stop-never-slave-server-id=#</code> [354]	<code>stop-never-slave-server-id</code> [354]	Slave server ID to report when connecting to server	
<code>--stop-position=#</code> [354]	<code>stop-position</code> [354]	Stop reading binary log at first event with position equal to or greater than argument	
<code>--to-last-log</code> [354]	<code>to-last-log</code> [354]	Do not stop at the end of requested binary log from a MySQL server, but rather continue printing to end of last binary log	
<code>--user=user_name,</code> [354]	<code>user</code> [354]	MySQL user name to use when connecting to server	
<code>--verbose</code> [354]		Reconstruct row events as SQL statements	
<code>--verify-binlog-checksum</code> [354]		Verify checksums in binary log	5.6.1
<code>--version</code> [354]		Display version information and exit	

- `--help` [348], `-?`

Display a help message and exit.

- `--base64-output=value` [348]

This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these permissible values (not case sensitive):

- `AUTO` ("automatic") or `UNSPEC` ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). If no `--base64-output` [348] option is given, the effect is the same as `--base64-output=AUTO` [348].

#### Note

Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

- `NEVER` causes `BINLOG` statements not to be displayed. `mysqlbinlog` exits with an error if a row event is found that must be displayed using `BINLOG`.
- `DECODE-ROWS` specifies to `mysqlbinlog` that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the `--verbose` [354] option. Like `NEVER`, `DECODE-ROWS` suppresses display of `BINLOG` statements, but unlike `NEVER`, it does not exit with an error if a row event is found.

For examples that show the effect of `--base64-output` [348] and `--verbose` [354] on row event output, see [Section 4.6.8.2, “mysqlbinlog Row Event Display”](#).

- `--bind-address=ip_address` [248]

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--binlog-row-event-max-size=N` [349]

<b>Command-Line Format</b>	<code>--binlog-row-event-max-size=#</code>
<b>Option-File Format</b>	<code>binlog-row-event-max-size</code>
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	4294967040
<b>Range</b>	256 .. 18446744073709547520

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 4GB.

- `--character-sets-dir=path` [349]

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--database=db_name` [349], `-d db_name`

This option causes `mysqlbinlog` to output entries from the binary log (local log only) that occur while `db_name` is been selected as the default database by `USE`.

The `--database` [349] option for `mysqlbinlog` is similar to the `--binlog-do-db` [2004] option for `mysqld`, but can be used to specify only one database. If `--database` [349] is given multiple times, only the last instance is used.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--binlog-do-db` [2004] depend on whether statement-based or row-based logging is in use.

**Statement-based logging.** The `--database` [349] option works as follows:

- While `db_name` is the default database, statements are output whether they modify tables in `db_name` or a different database.
- Unless `db_name` is selected as the default database, statements are not output, even if they modify tables in `db_name`.
- There is an exception for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE`. The database being *created*, *altered*, or *dropped* is considered to be the default database when determining whether to output the statement.

Suppose that the binary log was created by executing these statements using statement-based logging:

```
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j) VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i) VALUES(102);
INSERT INTO db2.t2 (j) VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
INSERT INTO db2.t2 (j) VALUES(202);
INSERT INTO t2 (j) VALUES(203);
```

`mysqlbinlog --database=test` does not output the first two `INSERT` statements because there is no default database. It outputs the three `INSERT` statements following `USE test`, but not the three `INSERT` statements following `USE db2`.

`mysqlbinlog --database=db2` does not output the first two `INSERT` statements because there is no default database. It does not output the three `INSERT` statements following `USE test`, but does output the three `INSERT` statements following `USE db2`.

**Row-based logging.** `mysqlbinlog` outputs only entries that change tables belonging to `db_name`. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. `mysqlbinlog --database=test` outputs only those entries that modify `t1` in the test database, regardless of whether `USE` was issued or what the default database is.

If a server is running with `binlog_format` [2010] set to `MIXED` and you want it to be possible to use `mysqlbinlog` with the `--database` [349] option, you must ensure that tables that are modified are in the database selected by `USE`. (In particular, no cross-database updates should be used.)

Prior to MySQL 5.6.10, the `--database` option did not work correctly with a log written by a GTID-enabled MySQL server. (Bug #15912728)

- `--debug[=debug_options]` [350],  `-# [debug_options]`

Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqlbinlog.trace'`.

- `--debug-check` [350]

Print some debugging information when the program exits.

- `--debug-info` [350]

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin` [351]

The client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--disable-log-bin` [351], `-D`

Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` [354] option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged.

This option requires that you have the `SUPER` [756] privilege. It causes `mysqlbinlog` to include a `SET sql_log_bin = 0` statement in its output to disable binary logging of the remaining output. The `SET` statement is ineffective unless you have the `SUPER` [756] privilege.

- `--exclude-gtids=gtid_set` [351]

Do not display any of the groups listed in the `gtid_set`. Added in MySQL 5.6.5.

- `--force-if-open` [351], `-F`

Read binary log files even if they are open or were not closed properly.

- `--force-read` [351], `-f`

With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--hexdump` [351], `-H`

Display a hex dump of the log in comments, as described in [Section 4.6.8.1, “mysqlbinlog Hex Dump Format”](#). The hex output can be helpful for replication debugging.

- `--host=host_name` [351], `-h host_name`

Get the binary log from the MySQL server on the given host.

- `--include-gtids=gtid_set` [351]

Display only the groups listed in the `gtid_set`. Added in MySQL 5.6.5.

- `--local-load=path` [351], `-l path`

Prepare local temporary files for `LOAD DATA INFILE` in the specified directory.

### Important

These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program.

- `--offset=N` [351], `-o N`

Skip the first `N` entries in the log.

- `--password[=password]` [351], `-p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value

following the `--password` [351] or `-p` option on the command line, `mysqlbinlog` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--plugin-dir=path` [352]

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` [351] option is used to specify an authentication plugin but `mysqlbinlog` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num` [352], `-P port_num`

The TCP/IP port number to use for connecting to a remote server.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [352]

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--raw` [352]

By default, `mysqlbinlog` reads binary log files and writes events in text format. The `--raw` [352] option tells `mysqlbinlog` to write them in their original binary format. Its use requires that `--read-from-remote-server` [352] also be used because the files are requested from a server. `mysqlbinlog` writes one output file for each file read from the server. The `--raw` [352] option can be used to make a backup of a server's binary log. With the `--stop-never` [354] option, the backup is “live” because `mysqlbinlog` stays connected to the server. By default, output files are written in the current directory with the same names as the original log files. Output file names can be modified using the `--result-file` [353] option. For more information, see [Section 4.6.8.3, “Using `mysqlbinlog` to Back Up Binary Log Files”](#).

This option was added in MySQL 5.6.0.

- `--read-from-remote-master=type` [352]

Read binary logs from a MySQL server with the `COM_BINLOG_DUMP` or `COM_BINLOG_DUMP_GTID` commands by setting the option value to either `BINLOG-DUMP-NON-GTIDS` or `BINLOG-DUMP-GTIDS`, respectively. If `--read-from-remote-master=BINLOG-DUMP-GTIDS` [352] is combined with `--exclude-gtids` [351], transactions can be filtered out on the master, avoiding unnecessary network traffic.

See also the description for `--read-from-remote-server` [352].

This option was added in MySQL 5.6.5.

- `--read-from-remote-server` [352], `-R`

Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host` [351], `--password` [351], `--port` [352], `--protocol` [352], `--socket` [353], and `--user` [354].

This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

As of MySQL 5.6.5, this option is like `--read-from-remote-master=BINLOG-DUMP-NON-GTIDS` [352].

- `--result-file=name` [353], `-r name`

Without the `--raw` [352] option, this option indicates the file to which `mysqlbinlog` writes text output. With `--raw` [352], `mysqlbinlog` writes one binary output file for each log file transferred from the server, writing them by default in the current directory using the same names as the original log file. In this case, the `--result-file` [353] option value is treated as a prefix that modifies output file names.

- `--server-id=id` [353]

Display only those events created by the server having the given server ID.

- `--set-charset=charset_name` [353]

Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files.

- `--short-form` [353], `-s`

Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems.

- `--skip-gtids[=(true|false)]` [353]

Do not display any GTIDs. Not recommended in production. Added in MySQL 5.6.5.

- `--socket=path` [353], `-S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--start-datetime=datetime` [353]

Start reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--start-position=N` [353], `-j N`

Start reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the first log file named on the command line.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--stop-datetime=datetime` [353]

Stop reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` [353] option for information about the `datetime` value.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--stop-never` [354]

This option is used with `--read-from-remote-server` [352]. It tells `mysqlbinlog` to remain connected to the server. Otherwise `mysqlbinlog` exits when the last log file has been transferred from the server. `--stop-never` [354] implies `--to-last-log` [354], so only the first log file to transfer need be named on the command line.

`--stop-never` [354] is commonly used with `--raw` [352] to make a live binary log backup, but also can be used without `--raw` [352] to maintain a continuous text display of log events as the server generates them.

This option was added in MySQL 5.6.0.

- `--stop-never-slave-server-id=id` [354]

With `--stop-never` [354], `mysqlbinlog` reports a server ID of 65535 when it connects to the server. `--stop-never-slave-server-id` [354] explicitly specifies the server ID to report. It can be used to avoid a conflict with the ID of a slave server or another `mysqlbinlog` process. See Section 4.6.8.4, “Specifying the `mysqlbinlog` Server ID”.

This option was added in MySQL 5.6.0.

- `--stop-position=N` [354]

Stop reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the last log file named on the command line.

This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- `--to-last-log` [354], `-t`

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server` [352].

- `--user=user_name` [354], `-u user_name`

The MySQL user name to use when connecting to a remote server.

- `--verbose` [354], `-v`

Reconstruct row events and display them as commented SQL statements. If this option is given twice, the output includes comments to indicate column data types and some metadata.

For examples that show the effect of `--base64-output` [348] and `--verbose` [354] on row event output, see Section 4.6.8.2, “`mysqlbinlog` Row Event Display”.

- `--verify-binlog-checksum` [354], `-c`

Verify checksums in binary log files. This option was added in MySQL 5.6.1.

- `--version` [354], `-V`

Display version information and exit.

Prior to MySQL 5.6.11, the `mysqlbinlog` version number shown was 3.3. In MySQL 5.6.11 and later, this is 3.4. (Bug #15894381, Bug #67643)

You can also set the following variable by using `--var_name=value` syntax:

- `open_files_limit`

Specify the number of open file descriptors to reserve.

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the events contained in the binary log. This technique is used to recover from a crash when you have an old backup (see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#)). For example:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

If the statements produced by `mysqlbinlog` may contain `BLOB` values, these may cause problems when `mysql` processes them. In this case, invoke `mysql` with the `--binary-mode` [\[248\]](#) option.

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program:

```
shell> mysqlbinlog binlog.000001 > tmpfile
shell> ... edit tmpfile ...
shell> mysql -u root -p < tmpfile
```

When `mysqlbinlog` is invoked with the `--start-position` [\[353\]](#) option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` [\[353\]](#) option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* `mysql` process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

`mysqlbinlog` can produce output that reproduces a `LOAD DATA INFILE` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL INFILE` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` [\[351\]](#) option.

Because `mysqlbinlog` converts `LOAD DATA INFILE` statements to `LOAD DATA LOCAL INFILE` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the

statements must be configured with the `LOCAL` capability enabled. See [Section 6.1.6, “Security Issues with `LOAD DATA LOCAL`”](#).

### Warning

The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

#### 4.6.8.1. mysqlbinlog Hex Dump Format

The `--hexdump` [\[351\]](#) option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```
shell> mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```
/*!40019 SET @@session.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position Timestamp Type Master ID Size Master Pos Flags
# 00000004 9d fc 5c 43 0f 01 00 00 00 5e 00 00 00 62 00 00 00 00 00
# 00000017 04 00 35 2e 30 2e 31 35 2d 64 65 62 75 67 2d 6c |..5.0.15.debug.1|
# 00000027 6f 67 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |og.....|
# 00000037 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |.....|
# 00000047 00 00 00 00 9d fc 5c 43 13 38 0d 00 08 00 12 00 |.....C.8.....|
# 00000057 04 04 04 04 12 00 00 4b 00 04 1a |.....K...|
# Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
# at startup
ROLLBACK;
```

Hex dump output currently contains the elements in the following list. This format is subject to change. (For more information about binary log format, see [MySQL Internals: The Binary Log](#).)

- **Position:** The byte position within the log file.
- **Timestamp:** The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.
- **Type:** The event type code. In the example shown, '0f' indicates a `FORMAT_DESCRIPTION_EVENT`. The following table lists the possible type codes.

TypeName	Meaning
00 UNKNOWN_EVENT	This event should never be present in the log.
01 START_EVENT_V3	This indicates the start of a log file written by MySQL 4 or earlier.
02 QUERY_EVENT	The most common type of events. These contain statements executed on the master.
03 STOP_EVENT	Indicates that master has stopped.
04 ROTATE_EVENT	Written when the master switches to a new log file.
05 INTVAR_EVENT	Used for <code>AUTO_INCREMENT</code> values or when the <code>LAST_INSERT_ID()</code> <a href="#">[1269]</a> function is used in the statement.
06 LOAD_EVENT	Used for <code>LOAD DATA INFILE</code> in MySQL 3.23.

Type	Name	Meaning
07	SLAVE_EVENT	Reserved for future use.
08	CREATE_FILE_EVENT	Used for <code>LOAD DATA INFILE</code> statements. This indicates the start of execution of such a statement. A temporary file is created on the slave. Used in MySQL 4 only.
09	APPEND_BLOCK_EVENT	Contains data for use in a <code>LOAD DATA INFILE</code> statement. The data is stored in the temporary file on the slave.
0a	EXEC_LOAD_EVENT	Used for <code>LOAD DATA INFILE</code> statements. The contents of the temporary file is stored in the table on the slave. Used in MySQL 4 only.
0b	DELETE_FILE_EVENT	Rollback of a <code>LOAD DATA INFILE</code> statement. The temporary file should be deleted on the slave.
0c	NEW_LOAD_EVENT	Used for <code>LOAD DATA INFILE</code> in MySQL 4 and earlier.
0d	RAND_EVENT	Used to send information about random values if the <code>RAND() [1206]</code> function is used in the statement.
0e	USER_VAR_EVENT	Used to replicate user variables.
0f	FORMAT_DESCRIPTION_EVENT	This indicates the start of a log file written by MySQL 5 or later.
10	XID_EVENT	Event indicating commit of an XA transaction.
11	BEGIN_LOAD_QUERY_EVENT	Used for <code>LOAD DATA INFILE</code> statements in MySQL 5 and later.
12	EXECUTE_LOAD_QUERY_EVENT	Used for <code>LOAD DATA INFILE</code> statements in MySQL 5 and later.
13	TABLE_MAP_EVENT	Information about a table definition. Used in MySQL 5.1.5 and later.
14	PRE_GA_WRITE_ROWS_EVENT	Row data for a single table that should be created. Used in MySQL 5.1.5 to 5.1.17.
15	PRE_GA_UPDATE_ROWS_EVENT	Row data for a single table that needs to be updated. Used in MySQL 5.1.5 to 5.1.17.
16	PRE_GA_DELETE_ROWS_EVENT	Row data for a single table that should be deleted. Used in MySQL 5.1.5 to 5.1.17.
17	WRITE_ROWS_EVENT	Row data for a single table that should be created. Used in MySQL 5.1.18 and later.
18	UPDATE_ROWS_EVENT	Row data for a single table that needs to be updated. Used in MySQL 5.1.18 and later.
19	DELETE_ROWS_EVENT	Row data for a single table that should be deleted. Used in MySQL 5.1.18 and later.
1a	INCIDENT_EVENT	Something out of the ordinary happened. Added in MySQL 5.1.18.

- **Master ID:** The server ID of the master that created the event.
- **Size:** The size in bytes of the event.
- **Master Pos:** The position of the next event in the original master log file.
- **Flags:** 16 flags. Currently, the following flags are used. The others are reserved for future use.

Flag	Name	Meaning
01	LOG_EVENT_BINLOG_IN_USE_F	Log file correctly closed. (Used only in <code>FORMAT_DESCRIPTION_EVENT</code> .) If this flag is

Flag	Name	Meaning
		set (if the flags are, for example, '01 00') in a <code>FORMAT_DESCRIPTION_EVENT</code> , the log file has not been properly closed. Most probably this is because of a master crash (for example, due to power failure).
02		Reserved for future use.
04	<code>LOG_EVENT_THREAD_SPECIFIC</code>	Set if the event is dependent on the connection it was executed in (for example, '04 00'), for example, if the event uses temporary tables.
08	<code>LOG_EVENT_SUPPRESS_USE_F</code>	Set in some circumstances when the event is not dependent on the default database.

#### 4.6.8.2. mysqlbinlog Row Event Display

The following examples illustrate how `mysqlbinlog` displays row events that specify data modifications. These correspond to events with the `WRITE_ROWS_EVENT`, `UPDATE_ROWS_EVENT`, and `DELETE_ROWS_EVENT` type codes. The `--base64-output=DECODE-ROWS` [348] and `--verbose` [354] options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```
CREATE TABLE t
(
  id INT NOT NULL,
  name VARCHAR(20) NOT NULL,
  date DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, `mysqlbinlog` displays row events encoded as base-64 strings using `BINLOG` statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
shell> mysqlbinlog log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258  Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAANoAAAAABEAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBcBAAAAKAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAAvhcHBsZQ==
'/*!*/;
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356  Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAC4BAAAAABEAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBgBAAAANGAAAGQABAAAQABEAAAAAAAAEAA///AEAAAAAFYXBwbGx4AQAAARwZWFyIbIP
'/*!*/;
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442  Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAABAAAAABEAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBkBAAAAAGAAALoBAAAQABEAAAAAAAAEAA//4AQAAARwZWFyIbIP
'/*!*/;
```

To see the row events as comments in the form of “pseudo-SQL” statements, run `mysqlbinlog` with the `--verbose` [354] or `-v` option. The output will contain lines beginning with `###`:

```
shell> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258  Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAANoAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAAVhcHBsZQ==
'/*!*/;
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356  Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAC4BAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBgBAAAAANGAAAGQBAABEAAAAAAAAEAA///AEAAAAFYXBwbGX4AQAAAArWZWFyIbIP
'/*!*/;
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
###   @3=NULL
### SET
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442  Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAJABAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAAQABEAAAAAAAAEAA//4AQAAAArWZWFyIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
```

Specify `--verbose` [354] or `-v` twice to also display data types and some metadata for each column. The output will contain an additional comment following each column change:

```
shell> mysqlbinlog -vv log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258  Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAANoAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAAVhcHBsZQ==
'/*!*/;
### INSERT INTO test.t
### SET
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='apple' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3=NULL /* VARSTRING(20) meta=0 nullable=1 is_null=1 */
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356  Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAC4BAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBgBAAAAANGAAAGQBAABEAAAAAAAAEAA///AEAAAAFYXBwbGX4AQAAAArWZWFyIbIP
```

```

'/*!*/;
### UPDATE test.t
### WHERE
### @1=1 /* INT meta=0 nullable=0 is_null=0 */
### @2='apple' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
### @3=NULL /* VARSTRING(20) meta=0 nullable=1 is_null=1 */
### SET
### @1=1 /* INT meta=0 nullable=0 is_null=0 */
### @2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
### @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
...
# at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAJABAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAQAABEAAAAAAAAEAA//4AQAAAAARwZWFyIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
### @1=1 /* INT meta=0 nullable=0 is_null=0 */
### @2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
### @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */

```

You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `--base64-output=DECODE-ROWS` [348] option. This is similar to `--base64-output=NEVER` [348] but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` [348] and `--verbose` [354] provides a convenient way to see row events only as SQL statements:

```

shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
# at 218
#080828 15:03:08 server id 1 end_log_pos 258 Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
### @1=1
### @2='apple'
### @3=NULL
...
# at 302
#080828 15:03:08 server id 1 end_log_pos 356 Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
### @1=1
### @2='apple'
### @3=NULL
### SET
### @1=1
### @2='pear'
### @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F
### DELETE FROM test.t
### WHERE
### @1=1
### @2='pear'
### @3='2009:01:01'

```

### Note

You should not suppress `BINLOG` statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` [354] for row events are much more readable than the corresponding `BINLOG` statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by `@N`, where `N` is a column number.

- Character set information is not available in the binary log, which affects string column display:
  - There is no distinction made between corresponding binary and nonbinary string types (`BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, `BLOB` and `TEXT`). The output uses a data type of `STRING` for fixed-length strings and `VARSTRING` for variable-length strings.
  - For multi-byte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, `STRING(4)` will be used as the data type for values from either of these column types:

```
CHAR(4) CHARACTER SET latin1
CHAR(2) CHARACTER SET ucs2
```

- Due to the storage format for events of type `UPDATE_ROWS_EVENT`, `UPDATE` statements are displayed with the `WHERE` clause preceding the `SET` clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a `BINLOG` statement in the initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events), the `--base64-output=NEVER` [348] option can be used to prevent this header from being written.

#### 4.6.8.3. Using `mysqlbinlog` to Back Up Binary Log Files

By default, `mysqlbinlog` reads binary log files and displays their contents in text format. This enables you to examine events within the files more easily or re-execute them (for example, by using the output as input to `mysql`). `mysqlbinlog` can read log files directly from the local file system, or, with the `--read-from-remote-server` [352] option, it can connect to a server and request binary log contents from that server. `mysqlbinlog` writes text output to its standard output, or to the file named as the value of the `--result-file=file_name` [353] option if that option is given.

As of MySQL 5.6, `mysqlbinlog` can read binary log files and write new files containing the same content—that is, in binary format rather than text format. This capability enables you to easily back up a binary log in its original format. `mysqlbinlog` can make a static backup, backing up a set of log files and stopping when the end of the last file is reached. It can also make a continuous (“live”) backup, staying connected to the server when it reaches the end of the last log file and continuing to copy new events as they are generated. In continuous-backup operation, `mysqlbinlog` runs until the connection ends (for example, when the server exits) or `mysqlbinlog` is forcibly terminated. When the connection ends, `mysqlbinlog` does not wait and retry the connection, unlike a slave replication server. To continue a live backup after the server has been restarted, you must also restart `mysqlbinlog`.

Binary log backup requires that you invoke `mysqlbinlog` with two options at minimum:

- The `--read-from-remote-server` [352] (or `-R`) option tells `mysqlbinlog` to connect to a server and request its binary log. (This is similar to a slave replication server connecting to its master server.)
- The `--raw` [352] option tells `mysqlbinlog` to write raw (binary) output, not text output.

Along with `--read-from-remote-server` [352], it is common to specify other options: `--host` [351] indicates where the server is running, and you may also need to specify connection options such as `--user` [354] and `--password` [351].

Several other options are useful in conjunction with `--raw` [352]:

- `--stop-never` [354]: Stay connected to the server after reaching the end of the last log file and continue to read new events.

- `--stop-never-slave-server-id=id` [354]: The server ID that `mysqlbinlog` reports to the server when `--stop-never` [354] is used. The default is 65535. This can be used to avoid a conflict with the ID of a slave server or another `mysqlbinlog` process. See [Section 4.6.8.4, “Specifying the `mysqlbinlog` Server ID”](#).
- `--result-file` [353]: A prefix for output file names, as described later.

To back up a server's binary log files with `mysqlbinlog`, you must specify file names that actually exist on the server. If you do not know the names, connect to the server and use the `SHOW BINARY LOGS` statement to see the current names. Suppose that the statement produces this output:

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name      | File_size |
+-----+-----+
| binlog.000130 |      27459 |
| binlog.000131 |      13719 |
| binlog.000132 |      43268 |
+-----+-----+
```

With that information, you can use `mysqlbinlog` to back up the binary log to the current directory as follows (enter each command on a single line):

- To make a static backup of `binlog.000130` through `binlog.000132`, use either of these commands:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  binlog.000130 binlog.000131 binlog.000132

mysqlbinlog --read-from-remote-server --host=host_name --raw
  --to-last-log binlog.000130
```

The first command specifies every file name explicitly. The second names only the first file and uses `--to-last-log` [354] to read through the last. A difference between these commands is that if the server happens to open `binlog.000133` before `mysqlbinlog` reaches the end of `binlog.000132`, the first command will not read it, but the second command will.

- To make a live backup in which `mysqlbinlog` starts with `binlog.000130` to copy existing log files, then stays connected to copy new events as the server generates them:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  --stop-never binlog.000130
```

With `--stop-never` [354], it is not necessary to specify `--to-last-log` [354] to read to the last log file because that option is implied.

## Output File Naming

Without `--raw` [352], `mysqlbinlog` produces text output and the `--result-file` [353] option, if given, specifies the name of the single file to which all output is written. With `--raw` [352], `mysqlbinlog` writes one binary output file for each log file transferred from the server. By default, `mysqlbinlog` writes the files in the current directory with the same names as the original log files. To modify the output file names, use the `--result-file` [353] option. In conjunction with `--raw` [352], the `--result-file` [353] option value is treated as a prefix that modifies the output file names.

Suppose that a server currently has binary log files named `binlog.000999` and up. If you use `mysqlbinlog --raw` to back up the files, the `--result-file` [353] option produces output file names as shown in the following table. You can write the files to a specific directory by beginning the `--result-file` [353] value with the directory path. If the `--result-file` [353] value consists only of a directory name, the value must end with the pathname separator character. Output files are overwritten if they exist.

<code>--result-file</code> [353] Option	Output File Names
<code>--result-file=x</code> [353]	<code>xbinlog.000999</code> and up
<code>--result-file=/tmp/</code> [353]	<code>/tmp/binlog.000999</code> and up
<code>--result-file=/tmp/x</code> [353]	<code>/tmp/xbinlog.000999</code> and up

### Example: `mysqldump` + `mysqlbinlog` for Backup and Restore

The following example describes a simple scenario that shows how to use `mysqldump` and `mysqlbinlog` together to back up a server's data and binary log, and how to use the backup to restore the server if data loss occurs. The example assumes that the server is running on host `host_name` and its first binary log file is named `binlog.000999`. Enter each command on a single line.

Use `mysqlbinlog` to make a continuous backup of the binary log:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
--stop-never binlog.000999
```

Use `mysqldump` to create a dump file as a snapshot of the server's data. Use `--all-databases` [292], `--events` [293], and `--routines` [293] to back up all data, and `--master-data=2` [288] to include the current binary log coordinates in the dump file.

```
mysqldump --host=host_name --all-databases --events --routines --master-data=2 > dump_file
```

Execute the `mysqldump` command periodically to create newer snapshots as desired.

If data loss occurs (for example, if the server crashes), use the most recent dump file to restore the data:

```
mysql --host=host_name -u root -p < dump_file
```

Then use the binary log backup to re-execute events that were written after the coordinates listed in the dump file. Suppose that the coordinates in the file look like this:

```
-- CHANGE MASTER TO MASTER_LOG_FILE='binlog.001002', MASTER_LOG_POS=27284;
```

If the most recent backed-up log file is named `binlog.001004`, re-execute the log events like this:

```
mysqlbinlog --start-position=27284 binlog.001002 binlog.001003 binlog.001004
| mysql --host=host_name -u root -p
```

You might find it easier to copy the backup files (dump file and binary log files) to the server host to make it easier to perform the restore operation, or if MySQL does not allow remote `root` access.

#### 4.6.8.4. Specifying the `mysqlbinlog` Server ID

When invoked with the `--read-from-remote-server` option, `mysqlbinlog` connects to a MySQL server, specifies a server ID to identify itself, and requests binary log files from the server. You can use `mysqlbinlog` to request log files from a server in several ways:

- Specify an explicitly named set of files: For each file, `mysqlbinlog` connects and issues a `Binlog dump` command. The server sends the file and disconnects. There is one connection per file.
- Specify the beginning file and `--to-last-log` [354]: `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files and disconnects.
- Specify the beginning file and `--stop-never` [354] (which implies `--to-last-log` [354]): `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files, but does not disconnect after sending the last one.

With `--read-from-remote-server` [352] only, `mysqlbinlog` connects using a server ID of 0, which tells the server to disconnect after sending the last requested log file.

With `--read-from-remote-server` [352] and `--stop-never` [354], `mysqlbinlog` connects using a nonzero server ID, so the server does not disconnect after sending the last log file. The server ID is 65535 by default, but this can be changed with `--stop-never-slave-server-id` [354].

Thus, for the first two ways of requesting files, the server disconnects because `mysqlbinlog` specifies a server ID of 0. It does not disconnect if `--stop-never` [354] is given because `mysqlbinlog` specifies a nonzero server ID.

#### 4.6.9. `mysqldumpslow` — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see Section 5.2.5, “The Slow Query Log”). `mysqldumpslow` parses MySQL slow query log files and prints a summary of their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to `N` and `'S'` when displaying summary output. The `-a` and `-n` options can be used to modify value abstracting behavior.

Invoke `mysqldumpslow` like this:

```
shell> mysqldumpslow [options] [log_file ...]
```

`mysqldumpslow` supports the following options.

**Table 4.14. `mysqldumpslow` Options**

Format	Option File	Description
<code>-a</code> [364]		Do not abstract all numbers to <code>N</code> and strings to <code>S</code>
<code>-n num</code> [365]		Abstract numbers with at least the specified digits
<code>--debug</code> [364]	<code>debug</code> [364]	Write debugging information
<code>-g pattern</code> [364]		Only consider statements that match the pattern
<code>--help</code> [364]		Display help message and exit
<code>-h name</code> [365]		Host name of the server in the log file name
<code>-i name</code> [365]		Name of the server instance
<code>-l</code> [365]		Do not subtract lock time from total time
<code>-r</code> [365]		Reverse the sort order
<code>-s value</code> [365]		How to sort output
<code>-t num</code> [365]		Display only first <code>num</code> queries
<code>--verbose</code> [365]	<code>verbose</code> [365]	Verbose mode

- `--help` [364]

Display a help message and exit.

- `-a`

Do not abstract all numbers to `N` and strings to `'S'`.

- `--debug` [364], `-d`

Run in debug mode.

- `-g pattern`

Consider only queries that match the (`grep`-style) pattern.

- `-h host_name`

Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcard. The default is `*` (match all).

- `-i name`

Name of server instance (if using `mysql.server` startup script).

- `-l`

Do not subtract lock time from total time.

- `-n N`

Abstract numbers with at least `N` digits within names.

- `-r`

Reverse the sort order.

- `-s sort_type`

How to sort the output. The value of `sort_type` should be chosen from the following list:

- `t, at`: Sort by query time or average query time
- `l, al`: Sort by lock time or average lock time
- `r, ar`: Sort by rows sent or average rows sent
- `c`: Sort by count

By default, `mysqldumpslow` sorts by average query time (equivalent to `-s at`).

- `-t N`

Display only the first `N` queries in the output.

- `--verbose [365], -v`

Verbose mode. Print more information about what the program does.

Example of usage:

```
shell> mysqldumpslow

Reading mysql slow query log from /usr/local/mysql/data/mysql51-apple-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t1 select * from t1
```

#### 4.6.10. mysqlhotcopy — A Database Backup Program

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `FLUSH TABLES`, `LOCK TABLES`, and `cp` or `scp` to make a database backup. It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up `MyISAM` and `ARCHIVE` tables. It runs on Unix.

To use `mysqlhotcopy`, you must have read access to the files for the tables that you are backing up, the `SELECT` [755] privilege for those tables, the `RELOAD` [755] privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` [755] privilege (to be able to lock the tables).

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (“~”):

```
shell> mysqlhotcopy db_name./~regex/
```

`mysqlhotcopy` supports the following options, which can be specified on the command line or in the `[mysqlhotcopy]` and `[client]` groups of an option file. For information about option files, see Section 4.2.3.3, “Using Option Files”.

**Table 4.15. `mysqlhotcopy` Options**

Format	Option File	Description
<code>--addtodest</code> [367]	<code>addtodest</code> [367]	Do not rename target directory (if it exists); merely add files to it
<code>--allowold</code> [367]	<code>allowold</code> [367]	Do not abort if a target exists; rename it by adding an <code>_old</code> suffix
<code>--checkpoint=db_name.tbl_name</code> [367]	<code>checkpoint</code> [367] <code>tbl_name</code> [367]	Insert checkpoint entries
<code>--chroot=path</code> [367]	<code>chroot</code> [367]	Base directory of the chroot jail in which <code>mysqld</code> operates
<code>--debug</code> [367]	<code>debug</code> [367]	Write a debugging log
<code>--dryrun</code> [367]	<code>dryrun</code> [367]	Report actions without performing them
<code>--flushlog</code> [367]	<code>flushlog</code> [367]	Flush logs after all tables are locked
<code>--help</code> [367]		Display help message and exit
<code>--host=host_name</code> [367]	<code>host</code> [367]	Connect to the MySQL server on the given host
<code>--keepold</code> [367]	<code>keepold</code> [367]	Do not delete previous (renamed) target when done
<code>--method</code> [367]	<code>method</code> [367]	The method for copying files
<code>--noindices</code> [367]	<code>noindices</code> [367]	Do not include full index files in the backup
<code>--old_server</code> [368]	<code>old_server</code> [368]	Connect to server that does not support <code>FLUSH TABLES tbl_list WITH READ LOCK</code>
<code>--password[=password]</code> [367]	<code>password</code> [367] [367]	The password to use when connecting to the server
<code>--port=port_num</code> [368]	<code>port</code> [368]	The TCP/IP port number to use for the connection
<code>--quiet</code> [368]	<code>quiet</code> [368]	Be silent except for errors
<code>--regex</code> [368]	<code>regex</code> [368]	Copy all databases with names that match the given regular expression
<code>--resetmaster</code> [368]	<code>resetmaster</code> [368]	Reset the binary log after locking all the tables
<code>--resetslave</code> [368]	<code>resetslave</code> [368]	Reset the master.info file after locking all the tables
<code>--socket=path</code> [368]	<code>socket</code> [368]	For connections to localhost
<code>--tmpdir=path</code> [368]	<code>tmpdir</code> [368]	The temporary directory

Format	Option File	Description
<code>--user=user_name, [368]</code>	<code>user [368]</code>	MySQL user name to use when connecting to server

- `--help [367], -?`  
Display a help message and exit.
- `--addtodest [367]`  
Do not rename target directory (if it exists); merely add files to it.
- `--allowold [367]`  
Do not abort if a target exists; rename it by adding an `_old` suffix.
- `--checkpoint=db_name.tbl_name [367]`  
Insert checkpoint entries into the specified database `db_name` and table `tbl_name`.
- `--chroot=path [367]`  
Base directory of the `chroot` jail in which `mysqld` operates. The `path` value should match that of the `--chroot [417]` option given to `mysqld`.
- `--debug [367]`  
Enable debug output.
- `--dryrun [367], -n`  
Report actions without performing them.
- `--flushlog [367]`  
Flush logs after all tables are locked.
- `--host=host_name [367], -h host_name`  
The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to `localhost` using a Unix socket file.
- `--keepold [367]`  
Do not delete previous (renamed) target when done.
- `--method=command [367]`  
The method for copying files (`cp` or `scp`). The default is `cp`.
- `--noindices [367]`  
Do not include full index files for `MyISAM` tables in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with `myisamchk -rq`.
- `--password=password [367], -ppassword`  
The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.  
  
Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num [368]`, `-P port_num`

The TCP/IP port number to use when connecting to the local server.

- `--old_server [368]`

In MySQL 5.6, `mysqlhotcopy` uses `FLUSH TABLES tbl_list WITH READ LOCK` to flush and lock tables. Use the `--old_server [368]` option if the server is older than 5.5.3, which is when that statement was introduced.

- `--quiet [368]`, `-q`

Be silent except for errors.

- `--record_log_pos=db_name.tbl_name [368]`

Record master and slave status in the specified database `db_name` and table `tbl_name`.

- `--regexp=expr [368]`

Copy all databases with names that match the given regular expression.

- `--resetmaster [368]`

Reset the binary log after locking all the tables.

- `--resetslave [368]`

Reset the `master.info` file after locking all the tables.

- `--socket=path [368]`, `-S path`

The Unix socket file to use for connections to `localhost`.

- `--suffix=str [368]`

The suffix to use for names of copied databases.

- `--tmpdir=path [368]`

The temporary directory. The default is `/tmp`.

- `--user=user_name [368]`, `-u user_name`

The MySQL user name to use when connecting to the server.

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint [367]` and `--record_log_pos [368]` options:

```
shell> perldoc mysqlhotcopy
```

#### 4.6.11. `mysql_convert_table_format` — Convert Tables to Use a Given Storage Engine

`mysql_convert_table_format` converts the tables in a database to use a particular storage engine (MyISAM by default). `mysql_convert_table_format` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see [Section 2.13, “Perl Installation Notes”](#)).

Invoke `mysql_convert_table_format` like this:

```
shell> mysql_convert_table_format [options]db_name
```

The `db_name` argument indicates the database containing the tables to be converted.

`mysql_convert_table_format` supports the options described in the following list.

- `--help` [369]  
Display a help message and exit.
- `--force` [369]  
Continue even if errors occur.
- `--host=host_name` [369]  
Connect to the MySQL server on the given host.
- `--password=password` [369]  
The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.  
  
Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.
- `--port=port_num` [369]  
The TCP/IP port number to use for the connection.
- `--socket=path` [369]  
For connections to `localhost`, the Unix socket file to use.
- `--type=engine_name` [369]  
Specify the storage engine that the tables should be converted to use. The default is `MyISAM` if this option is not given.
- `--user=user_name` [369]  
The MySQL user name to use when connecting to the server.
- `--verbose` [369]  
Verbose mode. Print more information about what the program does.
- `--version` [369]  
Display version information and exit.

#### 4.6.12. `mysql_find_rows` — Extract SQL Statements from Files

`mysql_find_rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain `USE db_name` or `SET` statements. The utility expects statements to be terminated with semicolon (`;`) characters.

Invoke `mysql_find_rows` like this:

```
shell> mysql_find_rows [options] [file_name ...]
```

Each `file_name` argument should be the name of file containing SQL statements. If no file names are given, `mysql_find_rows` reads the standard input.

Examples:

```
mysql_find_rows --regexp=problem_table --rows=20 < update.log
```

```
mysql_find_rows --regexp=problem_table update-log.1 update-log.2
```

`mysql_find_rows` supports the following options:

- `--help` [370], `--Information` [370]  
Display a help message and exit.
- `--regexp=pattern` [370]  
Display queries that match the pattern.
- `--rows=N` [370]  
Quit after displaying *N* queries.
- `--skip-use-db` [370]  
Do not include `USE db_name` statements in the output.
- `--start_row=N` [370]  
Start output from this row.

### 4.6.13. `mysql_fix_extensions` — Normalize Table File Name Extensions

`mysql_fix_extensions` converts the extensions for MyISAM (or ISAM) table files to their canonical forms. It looks for files with extensions matching any lettercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke `mysql_fix_extensions` like this, where `data_dir` is the path name to the MySQL data directory.

```
shell> mysql_fix_extensions data_dir
```

### 4.6.14. `mysql_setpermission` — Interactively Set Permissions in Grant Tables

`mysql_setpermission` is a Perl script that was originally written and contributed by Luuk de Boer. It interactively sets permissions in the MySQL grant tables. `mysql_setpermission` is written in Perl and requires that the `DBI` and `DBD:mysql` Perl modules be installed (see [Section 2.13, “Perl Installation Notes”](#)).

Invoke `mysql_setpermission` like this:

```
shell> mysql_setpermission [options]
```

`options` should be either `--help` [370] to display the help message, or options that indicate how to connect to the MySQL server. The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

`mysql_setpermissions` also reads options from the `[client]` and `[perl]` groups in the `.my.cnf` file in your home directory, if the file exists.

`mysql_setpermission` supports the following options:

- `--help` [370]  
Display a help message and exit.

- `--host=host_name` [371]

Connect to the MySQL server on the given host.

- `--password=password` [371]

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num` [371]

The TCP/IP port number to use for the connection.

- `--socket=path` [371]

For connections to `localhost`, the Unix socket file to use.

- `--user=user_name` [371]

The MySQL user name to use when connecting to the server.

#### 4.6.15. `mysql_waitpid` — Kill Process and Wait for Its Termination

`mysql_waitpid` signals a process to terminate and waits for the process to exit. It uses the `kill()` system call and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_waitpid` like this:

```
shell> mysql_waitpid [options] pid wait_time
```

`mysql_waitpid` sends signal 0 to the process identified by `pid` and waits up to `wait_time` seconds for the process to terminate. `pid` and `wait_time` must be positive integers.

If process termination occurs within the wait time or the process does not exist, `mysql_waitpid` returns 0. Otherwise, it returns 1.

If the `kill()` system call cannot handle signal 0, `mysql_waitpid()` uses signal 1 instead.

`mysql_waitpid` supports the following options:

- `--help` [371], `-?`, `-I`

Display a help message and exit.

- `--verbose` [371], `-v`

Verbose mode. Display a warning if signal 0 could not be used and signal 1 is used instead.

- `--version` [371], `-V`

Display version information and exit.

#### 4.6.16. `mysql_zap` — Kill Processes That Match a Pattern

`mysql_zap` kills processes that match a pattern. It uses the `ps` command and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_zap` like this:

```
shell> mysql_zap [-signal] [-?Ift] pattern
```

A process matches if its output line from the `ps` command contains the pattern. By default, `mysql_zap` asks for confirmation for each process. Respond `y` to kill the process, or `q` to exit `mysql_zap`. For any other response, `mysql_zap` does not attempt to kill the process.

If the `-signal` option is given, it specifies the name or number of the signal to send to each process. Otherwise, `mysql_zap` tries first with `TERM` (signal 15) and then with `KILL` (signal 9).

`mysql_zap` supports the following additional options:

- `--help [372]`, `-?`, `-I`

Display a help message and exit.

- `-f`

Force mode. `mysql_zap` attempts to kill each process without confirmation.

- `-t`

Test mode. Display information about each process but do not kill it.

## 4.7. MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the `[client]` and `[mysql]` groups:

```
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

### 4.7.1. `msql2mysql` — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`mysql2mysql` uses the `replace` utility to make the function name substitutions. See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

## 4.7.2. `mysql_config` — Display Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

`mysql_config` supports the following options.

- `--cflags` [373]

C Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use `--include` [373] for more portable options that contain only include paths.

- `--cxxflags` [373]

Like `--cflags` [373], but for C++ compiler flags. This option was added in MySQL 5.6.4.

- `--include` [373]

Compiler options to find MySQL include files.

- `--libmysqld-libs` [373], `--embedded` [373]

Libraries and options required to link with the MySQL embedded server.

- `--libs` [373]

Libraries and options required to link with the MySQL client library.

- `--libs_r` [373]

Libraries and options required to link with the thread-safe MySQL client library. In MySQL 5.6, all client libraries are thread-safe, so this option need not be used. The `--libs` [373] option can be used in all cases.

- `--plugindir` [373]

The default plugin directory path name, defined when configuring MySQL.

- `--port` [373]

The default TCP/IP port number, defined when configuring MySQL.

- `--socket` [373]

The default Unix socket file, defined when configuring MySQL.

- `--version` [373]

Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
```

```

--cflags      [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
--include     [-I/usr/local/mysql/include/mysql]
--libs       [-L/usr/local/mysql/lib/mysql -lmysqlclient
             -lpthread -lm -lrt -lssl -lcrypto -ldl]
--libs_r     [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
             -lpthread -lm -lrt -lssl -lcrypto -ldl]
--socket      [/tmp/mysql.sock]
--port       [3306]
--version    [5.6.11]
--libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld
                -lpthread -lm -lrt -lssl -lcrypto -ldl -lcrypt]

```

You can use `mysql_config` within a command line using backticks to include the output that it produces for a particular option. For example, to compile and link a MySQL client program, use `mysql_config` as follows:

```

shell> gcc -c `mysql_config --cflags` progname.c
shell> gcc -o progname progname.o `mysql_config --libs`

```

### 4.7.3. my\_print\_defaults — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```

shell> my_print_defaults mysqlcheck client
--user=myusername
--password=secret
--host=localhost

```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- `--help [374], -?`

Display a help message and exit.

- `--config-file=file_name [374], --defaults-file=file_name [374], -c file_name`

Read only the given option file.

- `--debug=debug_options [374], -# debug_options`

Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/my_print_defaults.trace'`.

- `--defaults-extra-file=file_name [374], --extra-file=file_name [374], -e file_name`

Read this option file after the global option file but (on Unix) before the user option file.

- `--defaults-group-suffix=suffix [374], -g suffix`

In addition to the groups named on the command line, read groups that have the given suffix.

- `--login-path=name [374], -l name`

Read options from the named login path in the `.mylogin.cnf` login file. See [Section 4.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--no-defaults [220], -n`

Return an empty string.

- `--verbose` [375], `-v`

Verbose mode. Print more information about what the program does.

- `--version` [375], `-V`

Display version information and exit.

#### 4.7.4. `resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols

`resolve_stack_dump` resolves a numeric stack dump to symbols.

Invoke `resolve_stack_dump` like this:

```
shell> resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack track from `mysqld`. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

`resolve_stack_dump` supports the following options.

- `--help` [375], `-h`

Display a help message and exit.

- `--numeric-dump-file=file_name` [375], `-n file_name`

Read the stack trace from the given file.

- `--symbols-file=file_name` [375], `-s file_name`

Use the given symbols file.

- `--version` [375], `-V`

Display version information and exit.

## 4.8. Miscellaneous Programs

### 4.8.1. `pererror` — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the `pererror` utility.

`pererror` prints a description for a system error code or for a storage engine (table handler) error code.

Invoke `pererror` like this:

```
shell> pererror [options] errorcode ...
```

Example:

```
shell> perror 13 64
OS error code 13: Permission denied
OS error code 64: Machine is not on the network
```

To obtain the error message for a MySQL Cluster error code, invoke `perror` with the `--ndb` [376] option:

```
shell> perror --ndb errorcode
```

Note that the meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

- `--help` [376], `--info` [376], `-I`, `-?`

Display a help message and exit.

- `--ndb` [376]

Print the error message for a MySQL Cluster error code.

- `--silent` [376], `-s`

Silent mode. Print only the error message.

- `--verbose` [376], `-v`

Verbose mode. Print error code and message. This is the default behavior.

- `--version` [376], `-V`

Display version information and exit.

## 4.8.2. `replace` — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input.

Invoke `replace` in one of the following ways:

```
shell> replace from to [from to] ... -- file_name [file_name] ...
shell> replace from to [from to] ... < file_name
```

`from` represents a string to look for and `to` represents its replacement. There can be one or more pairs of strings.

Use the `--` option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, `replace` reads the standard input and writes to the standard output.

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps `a` and `b` in the given files, `file1` and `file2`:

```
shell> replace a b b a -- file1 file2 ...
```

The `replace` program is used by `mysql2mysql`. See [Section 4.7.1, “mysql2mysql — Convert mSQL Programs for Use with MySQL”](#).

`replace` supports the following options.

- `-?`, `-I`

Display a help message and exit.

- `-#debug_options`

Enable debugging.

- `-s`

Silent mode. Print less information what the program does.

- `-v`

Verbose mode. Print more information about what the program does.

- `-V`

Display version information and exit.

### 4.8.3. resolveip — Resolve Host name to IP Address or Vice Versa

The `resolveip` utility resolves host names to IP addresses and vice versa.

Invoke `resolveip` like this:

```
shell> resolveip [options] {host_name|ip-addr} ...
```

`resolveip` supports the following options.

- `--help [377]`, `--info [377]`, `-?`, `-I`

Display a help message and exit.

- `--silent [377]`, `-s`

Silent mode. Produce less output.

- `--version [377]`, `-V`

Display version information and exit.

---

5.6.4. Using Client Programs in a Multiple-Server Environment .....	711
5.7. Tracing <a href="#">mysqld</a> Using DTrace .....	711
5.7.1. <a href="#">mysqld</a> DTrace Probe Reference .....	713

This chapter provides an overview of MySQL Server, the `mysqld` command that does most of the work in a MySQL installation. It covers administration topics for `mysqld` and for the MySQL tables and indexes containing your data:

- Configuring the server through command options and system variables. Checking the runtime status through status variables.
- Understanding server activity and troubleshooting problems with the server log files.
- Managing the physical aspects of MySQL server operations: disk space, memory, I/O, and CPU utilization related to [queries](#), [DML](#), and [DDL](#).
- Managing the logical structures within a MySQL server: databases, tables, tablespaces, and indexes.
- Managing multiple servers on a single machine.

For additional information on administrative topics, see also:

- [Chapter 6, Security](#)
- [Section 14.2.1.2, “Configuring InnoDB”](#) and [Section 14.2.2, “Administering InnoDB”](#)
- [Chapter 7, Backup and Recovery](#)
- [Chapter 16, Replication](#)
- [Chapter 17, Partitioning](#)

## 5.1. The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.
- Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.
- Server status variables. These variables contain counters and statistics about runtime operation.
- How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.
- The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

### Note

Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see [Section 13.7.5.17, “SHOW ENGINES Syntax”](#).

### 5.1.1. Server Option and Variable Reference

The following table provides a list of all the command line options, server and status variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with notification of where each option/variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding server system or status variable, the variable name is noted

immediately below the corresponding option. For status variables, the scope of the variable is shown (Scope) as either global, session, or both. Please see the corresponding sections for details on setting and using the options and variables. Where appropriate, a direct link to further information on the item as available.

**Table 5.1. Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">abort-slave-event-count [1971]</a>	Yes	Yes				
<a href="#">Aborted_clients [585]</a>				Yes	Global	No

<sup>b</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

## 5.1.2. Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at runtime. For general instructions on setting parameters at startup or runtime, see [Section 5.1.3, “Server Command Options”](#), and [Section 5.1.4, “Server System Variables”](#).

### 5.1.2.1. Changes to Server Defaults

Beginning with MySQL 5.6.6, several MySQL Server parameter defaults differ from the defaults in previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for database administrators to change settings manually.

In some cases, a parameter has a different fixed default value. In other cases, the server autosizes a parameter at startup using a formula based on other related parameters or server host configuration, rather than using a fixed value. For example, the setting for [back\\_log \[465\]](#) is its previous default of 50, adjusted up by an amount proportional to the value of [max\\_connections \[503\]](#). The idea behind autosizing is that when the server has information available to make a decision about a parameter setting likely to be better than a fixed default, it will.

The following table summarizes changes to defaults. The Version column indicates when each default changed. For variables that are autosized, the main variable description provides additional detail about the sizing algorithm. See [Section 5.1.4, “Server System Variables”](#), and [Section 14.2.6, “InnoDB Startup Options and System Variables”](#). Any of these default settings can be overridden by specifying an explicit value at server startup.

**Table 5.2. Changes to Server Defaults in MySQL 5.6**

Parameter	Old Default	New Default	Version
<a href="#">back_log [465]</a>	50	Autosized using <a href="#">max_connections [503]</a>	5.6.6
<a href="#">binlog_checksum [2009]</a>	NONE	CRC32	5.6.6
<a href="#">--binlog-row-event-max-size [2001]</a>	1024	8192	5.6.6
<a href="#">flush_time [482]</a>	1800 (on Windows)	0	5.6.6
<a href="#">host_cache_size [487]</a>	128	Autosized using <a href="#">max_connections [503]</a>	5.6.8
<a href="#">innodb_autoextend_increment [1708]</a>	8	64	5.6.6
<a href="#">innodb_buffer_pool_instances [1706]</a>	1	8 (platform dependent)	5.6.6
<a href="#">innodb_concurrency_tickets [1714]</a>	500	5000	5.6.6
<a href="#">innodb_data_file_path [1714]</a>	ibdata1:10M:autoextend	ibdata1:12M:autoextend	5.6.7

Parameter	Old Default	New Default	Version
<a href="#">innodb_file_per_table [1718]</a>	0	1	5.6.6
<a href="#">innodb_log_file_size [1732]</a>	5MB	48MB	5.6.8
<a href="#">innodb_old_blocks_time [1738]</a>	0	1000	5.6.6
<a href="#">innodb_open_files [1739]</a>	300	Autosized using <a href="#">innodb_file_per_table [1718]</a> , <a href="#">table_open_cache [551]</a>	5.6.6
<a href="#">innodb_stats_on_metadata [1747]</a>	ON	OFF	5.6.6
<a href="#">join_buffer_size [490]</a>	128KB	256KB	5.6.6
<a href="#">max_allowed_packet [502]</a>	1MB	4MB	5.6.6
<a href="#">max_connect_errors [502]</a>	10	100	5.6.6
<a href="#">open_files_limit [518]</a>	0	Autosized using <a href="#">max_connections [503]</a>	5.6.8
<a href="#">performance_schema [2307]</a>	OFF	ON	5.6.6
<a href="#">performance_schema_events_waits_history_long_size [2310]</a>	10000	Autosize	5.6.6
<a href="#">performance_schema_events_waits_history_size [2310]</a>	10	Autosize	5.6.6
<a href="#">performance_schema_max_cond_instances [2311]</a>	10000	Autosize	5.6.6
<a href="#">performance_schema_max_file_instances [2312]</a>	100000	Autosize	5.6.6
<a href="#">performance_schema_max_mutex_instances [2313]</a>	1000000	Autosize	5.6.6
<a href="#">performance_schema_max_rwlock_instances [2313]</a>	1000000	Autosize	5.6.6
<a href="#">performance_schema_max_table_handles [2315]</a>	100000	Autosize	5.6.6
<a href="#">performance_schema_max_table_instances [2315]</a>	50000	Autosize	5.6.6
<a href="#">performance_schema_max_thread_instances [2316]</a>	1000	Autosize	5.6.6
<a href="#">query_cache_size [528]</a>	0	1M	5.6.8
<a href="#">query_cache_type [529]</a>	ON	OFF	5.6.8
<a href="#">secure_auth [538]</a>	OFF	ON	5.6.7
<a href="#">sql_mode [545]</a>	" (empty string)	NO_ENGINE_SUBSTITUTION	5.6.6
<a href="#">sync_master_info [1997]</a>	0	10000	5.6.6
<a href="#">sync_relay_log [1998]</a>	0	10000	5.6.6
<a href="#">sync_relay_log_info [1999]</a>	0	10000	5.6.6
<a href="#">table_definition_cache [550]</a>	400	Autosized using <a href="#">table_open_cache [551]</a>	5.6.8
<a href="#">table_open_cache [551]</a>	400	2000	5.6.8
<a href="#">thread_cache_size [552]</a>	0	Autosized using <a href="#">max_connections [503]</a>	5.6.8

In MySQL 5.6.6, the default for [innodb\\_checksum\\_algorithm \[1710\]](#) was changed from `INNODB` to `CRC32`. For compatibility reasons, the default was returned in 5.6.7 to `INNODB`.

### 5.1.2.2. Using a Sample Default Server Configuration File

As of MySQL 5.6.8, on Unix platforms, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. You can find the template in or under the base installation directory. When started using `mysqld_safe`, the server uses `my.cnf` file by default. If `my.cnf` already exists, `mysql_install_db` assumes it to be in use and writes a new file named `my-new.cnf` instead.

With one exception, the settings in the default option file are commented and have no effect. The exception is that the file changes the `sql_mode` [545] system variable from its default of `NO_ENGINE_SUBSTITUTION` [605] to also include `STRICT_TRANS_TABLES` [607]. This setting produces a server configuration that results in errors rather than warnings for bad data in operations that modify transactional tables. See [Section 5.1.7, “Server SQL Modes”](#).

The `my-default.cnf` template replaces the older sample option files formerly supplied with MySQL distributions (`my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`). As of MySQL 5.6.8, these older files are no longer distributed.

On Windows, MySQL Installer interacts with the user and creates a file named `my.ini` in the base installation directory as the default option file. If you install on Windows from a Zip archive, you can copy the `my-default.ini` template file in the base installation directory to `my.ini` and use the latter as the default option file.

#### Note

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

On any platform, after completing the installation process, you can edit the default option file at any time to modify the parameters used by the server. For example, to use a parameter setting in the file that is commented with a `#` character at the beginning of the line, remove the `#`, and modify the parameter value if necessary. To disable a setting, either add a `#` to the beginning of the line or remove it.

For additional information about option file format and syntax, see [Section 4.2.3.3, “Using Option Files”](#).

Before MySQL 5.6.8, MySQL distributions include several sample option files that can be used as a basis for tuning the MySQL server. Look for files named `my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`, which are sample files for small, medium, large, and very large systems. On Windows, the extension is `.ini` rather than `.cnf`.

For a binary distribution, look for the sample files in or under your installation directory. If you have a source distribution, look in the `support-files` directory. To use a sample file as a base configuration file, rename a copy of it and place the copy in the appropriate location. Regarding names and appropriate location, see the general information provided in [Section 4.2.3.3, “Using Option Files”](#).

### 5.1.3. Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in [Section 4.2.3, “Specifying Program Options”](#). The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See [Section 4.2.3.3, “Using Option Files”](#). That section also describes option file format and syntax.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxx_SERVER]` groups, where `xxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute `mysqld --help`. To see the full list, use `mysqld --verbose --help`.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See [Section 6.1.4, “Security-Related `mysqld` Options and Variables”](#).

- SSL-related options: See [Section 6.3.9.4, “SSL Command Options”](#).
- Binary log control options: See [Section 5.2.4, “The Binary Log”](#).
- Replication-related options: See [Section 16.1.4, “Replication and Binary Logging Options and Variables”](#).
- Options for loading plugins such as pluggable storage engines: See [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).
- Options specific to particular storage engines: See [Section 14.2.6, “InnoDB Startup Options and System Variables”](#) and [Section 14.3.1, “MyISAM Startup Options”](#).

You can also set the values of server system variables by using variable names as options, as described at the end of this section.

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `--help [413], -?`

<b>Command-Line Format</b>	<code>-?</code>
	<code>--help</code>
<b>Option-File Format</b>	<code>help</code>

Display a short help message and exit. Use both the `--verbose [447]` and `--help [413]` options to see the full message.

- `--allow-suspicious-udfs [413]`

<b>Command-Line Format</b>	<code>--allow-suspicious-udfs</code>	
<b>Option-File Format</b>	<code>allow-suspicious-udfs</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See [Section 22.3.2.6, “User-Defined Function Security Precautions”](#).

- `--ansi [413]`

<b>Command-Line Format</b>	<code>--ansi</code>
----------------------------	---------------------

	-a
<b>Option-File Format</b>	ansi

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` [442] option instead. See [Section 1.8.3, “Running MySQL in ANSI Mode”](#), and [Section 5.1.7, “Server SQL Modes”](#).

- `--basedir=path` [414], `-b path` [414]

<b>Command-Line Format</b>	<code>--basedir=path</code>	
	<code>-b</code>	
<b>Option-File Format</b>	basedir	
<b>Option Sets Variable</b>	Yes, <code>basedir</code> [466]	
<b>Variable Name</b>	basedir	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

The path to the MySQL installation directory. All paths are usually resolved relative to this directory.

- `--big-tables` [414]

<b>Version Removed</b>	5.6.1	
<b>Command-Line Format</b>	<code>--big-tables</code>	
<b>Option-File Format</b>	big-tables	
<b>Option Sets Variable</b>	Yes, <code>big_tables</code> [466]	
<b>Variable Name</b>	big-tables	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean

Enable large result sets by saving all temporary sets in files. This option prevents most “table full” errors, but also slows down queries for which in-memory tables would suffice. Since MySQL 3.23.2, the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- `--bind-address=addr` [414]

<b>Command-Line Format</b>	<code>--bind-address=addr</code>	
<b>Option-File Format</b>	bind-address=addr	
<b>Variable Name</b>	bind-address	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	string
	<b>Default</b>	0.0.0.0
	<b>Permitted Values (&gt;= 5.6.6)</b>	

<b>Type</b>	string
<b>Default</b>	*

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, use the `--bind-address=addr` [414] option at server startup, where `addr` is an IPv4 or IPv6 address or a host name. If `addr` is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is permitted (and is the default) as of MySQL 5.6.6.
- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces. This is the default before MySQL 5.6.6.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the `mysql.user` grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to `*`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

- `--binlog-format={ROW | STATEMENT | MIXED}` [415]

<b>Command-Line Format</b>	<code>--binlog-format=format</code>	
<b>Option-File Format</b>	<code>binlog-format=format</code>	
<b>Option Sets Variable</b>	Yes, <code>binlog_format</code> [2010]	
<b>Variable Name</b>	<code>binlog_format</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	STATEMENT
	<b>Valid Values</b>	ROW STATEMENT MIXED

Specify whether to use row-based, statement-based, or mixed replication. Statement-based is the default in MySQL 5.6. See [Section 16.1.2, “Replication Formats”](#).

Under some conditions, changing this variable at runtime is not possible, or causes replication to fail. See [Section 5.2.4.2, “Setting The Binary Log Format”](#), for more information.

Setting the binary logging format without enabling binary logging sets the `binlog_format` [2010] global system variable and logs a warning.

- `--bootstrap` [416]

<b>Command-Line Format</b>	<code>--bootstrap</code>
<b>Option-File Format</b>	<code>bootstrap</code>

This option is used by the `mysql_install_db` script to create the MySQL privilege tables without having to start a full MySQL server.

In MySQL 5.6.6 and later, replication and global transaction identifiers are automatically disabled whenever this option is used (Bug #1332602). See [Section 16.1.3, “Replication with Global Transaction Identifiers”](#).

- `--character-sets-dir=path` [416]

<b>Command-Line Format</b>	<code>--character-sets-dir=path</code>	
<b>Option-File Format</b>	<code>character-sets-dir=path</code>	
<b>Option Sets Variable</b>	Yes, <code>character_sets_dir</code> [469]	
<b>Variable Name</b>	<code>character-sets-dir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--character-set-client-handshake` [416]

<b>Command-Line Format</b>	<code>--character-set-client-handshake</code>	
<b>Option-File Format</b>	<code>character-set-client-handshake</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>TRUE</code>

Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake` [416]; this makes MySQL behave like MySQL 4.0.

- `--character-set-filesystem=charset_name` [416]

<b>Command-Line Format</b>	<code>--character-set-filesystem=name</code>	
<b>Option-File Format</b>	<code>character-set-filesystem</code>	
<b>Option Sets Variable</b>	Yes, <code>character_set_filesystem</code> [468]	
<b>Variable Name</b>	<code>character_set_filesystem</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	416

	<b>Permitted Values</b>	
	<b>Type</b>	string

The file system character set. This option sets the `character_set_filesystem` [468] system variable.

- `--character-set-server=charset_name` [417], `-C charset_name`

<b>Command-Line Format</b>	<code>--character-set-server</code>	
<b>Option-File Format</b>	<code>character-set-server</code>	
<b>Option Sets Variable</b>	Yes, <code>character_set_server</code> [468]	
<b>Variable Name</b>	<code>character_set_server</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string

Use `charset_name` as the default server character set. See [Section 10.5, “Character Set Configuration”](#). If you use this option to specify a nondefault character set, you should also use `--collation-server` [417] to specify the collation.

- `--chroot=path` [417], `-r path`

<b>Command-Line Format</b>	<code>--chroot=name</code>	
	<code>-r name</code>	
<b>Option-File Format</b>	<code>chroot</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Note that use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--collation-server=collation_name` [417]

<b>Command-Line Format</b>	<code>--collation-server</code>	
<b>Option-File Format</b>	<code>collation-server</code>	
<b>Option Sets Variable</b>	Yes, <code>collation_server</code> [470]	
<b>Variable Name</b>	<code>collation_server</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string

Use `collation_name` as the default server collation. See [Section 10.5, “Character Set Configuration”](#).

- `--console` [417]

<b>Command-Line Format</b>	<code>--console</code>	
<b>Option-File Format</b>	<code>console</code>	

<b>Platform Specific</b>	windows
--------------------------	---------

(Windows only.) Write error log messages to `stderr` and `stdout`. `mysqld` does not close the console window if this option is used.

Passing in both `--log-error` [427] and `--console` [417] will write to the log file, but not to the console.

- `--core-file` [418]

<b>Command-Line Format</b>	<code>--core-file</code>	
<b>Option-File Format</b>	<code>core-file</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	OFF

Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On Mac OS X, a core file named `core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` [227] option to `mysqld_safe`. See [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#). On some systems, such as Solaris, you do not get a core file if you are also using the `--user` [446] option. There might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

- `--datadir=path` [418], `-h path`

<b>Command-Line Format</b>	<code>--datadir=path</code>	
	<code>-h</code>	
<b>Option-File Format</b>	<code>datadir</code>	
<b>Option Sets Variable</b>	Yes, <code>datadir</code> [472]	
<b>Variable Name</b>	<code>datadir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

The path to the data directory.

- `--debug[=debug_options]` [418], `-# [debug_options]`

<b>Command-Line Format</b>	<code>--debug[=debug_options]</code>	
<b>Option-File Format</b>	<code>debug</code>	
<b>Variable Name</b>	<code>debug</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string

	<b>Default</b>	'd:t:o,/tmp/mysqld.trace'
--	----------------	---------------------------

If MySQL is configured with `-DWITH_DEBUG=1` [136], you can use this option to get a trace file of what `mysqld` is doing. A typical *debug\_options* string is `'d:t:o,file_name'`. The default is `'d:t:i:o,mysqld.trace'`. See [MySQL Internals: Porting to Other Systems](#).

Using `-DWITH_DEBUG=1` [136] to configure MySQL with debugging support enables you to use the `--debug="d,parser_debug"` [418] option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with `+` or `-` are added to or subtracted from the previous value. For example, `--debug=T` [418] `--debug=+P` [418] sets the value to `P:T`.

- `--debug-sync-timeout[=N]` [419]

<b>Command-Line Format</b>	<code>--debug-sync-timeout[=#]</code>
<b>Option-File Format</b>	<code>debug-sync-timeout</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` [134] option (see [Section 2.9.4, "MySQL Source-Configuration Options"](#)). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `--default-authentication-plugin=plugin_name` [419]

<b>Version Introduced</b>	5.6.6
<b>Command-Line Format</b>	<code>--default-authentication-plugin=plugin_name</code>
<b>Option-File Format</b>	<code>default-authentication-plugin=plugin_name</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>enumeration</code>
	<b>Default</b> <code>mysql_native_password</code>
	<b>Valid Values</b> <code>mysql_native_password</code> <code>sha256_password</code>

The default authentication plugin. Acceptable values are `mysql_native_password` (use MySQL native passwords) and `sha256_password` (use SHA-256 passwords). For more information about these plugins, see [Section 6.3.7.1, "The Native Authentication Plugins"](#), and [Section 6.3.7.2, "The SHA-256 Authentication Plugin"](#). This option was added in MySQL 5.6.6.

The value of this option affects these aspects of server operation:

- It determines which plugin the server assigns to new accounts for which no plugin is explicitly specified.

- It sets the `old_passwords` [517] system variable at startup to the value that is consistent with the password hashing format required by the default plugin. This in turn affects the password hashing method used by the `PASSWORD()` [1263] function.
- For an account created with either of the following statements, the server associates the account with the default authentication plugin and assigns the account the given password, hashed according to the value of `old_passwords` [517].

```
CREATE USER ... IDENTIFIED BY 'cleartext password';
GRANT ... IDENTIFIED BY 'cleartext password';
```

- For an account created with either of the following statements, the statement fails if the password hash is not encrypted using the hash format required by the default authentication plugin. Otherwise, the server associates the account with the default authentication plugin and assigns the account the given password hash.

```
CREATE USER ... IDENTIFIED BY 'encrypted password';
GRANT ... IDENTIFIED BY 'encrypted password';
```

**Note**

If you use this option to change the default authentication method to a value other than `mysql_native_password`, clients older than MySQL 5.5.6 will no longer be able to connect because they will not understand the change to the authentication protocol.

- `--default-storage-engine=type` [420]

<b>Command-Line Format</b>	<code>--default-storage-engine=name</code>	
<b>Option-File Format</b>	<code>default-storage-engine</code>	
<b>Option Sets Variable</b>	Yes, <code>default_storage_engine</code> [474]	
<b>Variable Name</b>	<code>default_storage_engine</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>InnoDB</code>

Set the default storage engine for tables. See [Chapter 14, Storage Engines](#). As of MySQL 5.6.3, this option sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` [474] system variable.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `--default-time-zone=timezone` [420]

<b>Command-Line Format</b>	<code>--default-time-zone=name</code>	
<b>Option-File Format</b>	<code>default-time-zone</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

Set the default server time zone. This option sets the global `time_zone` [557] system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` [550] system variable).

- `--delay-key-write[={OFF|ON|ALL}]` [421]

<b>Command-Line Format</b>	<code>--delay-key-write[=name]</code>
<b>Option-File Format</b>	<code>delay-key-write</code>
<b>Option Sets Variable</b>	Yes, <code>delay_key_write</code> [475]
<b>Variable Name</b>	<code>delay-key-write</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> enumeration
	<b>Default</b> ON
	<b>Valid Values</b> ON OFF ALL

Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for `MyISAM` tables. `OFF` disables delayed key writes. `ON` enables delayed key writes for those tables that were created with the `DELAY_KEY_WRITE` option. `ALL` delays key writes for all `MyISAM` tables. See [Section 8.11.2, “Tuning Server Parameters”](#), and [Section 14.3.1, “MyISAM Startup Options”](#).

**Note**

If you set this variable to `ALL`, you should not use `MyISAM` tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

- `--des-key-file=file_name` [421]

<b>Command-Line Format</b>	<code>--des-key-file=file_name</code>
<b>Option-File Format</b>	<code>des-key-file=file_name</code>

Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` [1262] and `DES_DECRYPT()` [1261] functions.

- `--enable-named-pipe` [421]

<b>Command-Line Format</b>	<code>--enable-named-pipe</code>
<b>Option-File Format</b>	<code>enable-named-pipe</code>
<b>Option Sets Variable</b>	Yes, <code>named_pipe</code> [514]
<b>Platform Specific</b>	windows

Enable support for named pipes. This option applies only on Windows.

- `--engine-condition-pushdown={ON|OFF}`

<b>Version Removed</b>	5.6.1
<b>Command-Line Format</b>	<code>--engine-condition-pushdown</code>
<b>Option-File Format</b>	<code>engine-condition-pushdown</code>
<b>Option Sets Variable</b>	Yes, <code>engine_condition_pushdown</code> [478]
<b>Variable Name</b>	<code>engine_condition_pushdown</code>

<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.5.3, by <a href="#">optimizer_switch</a>
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>ON</code>

Formerly, this option set the [engine\\_condition\\_pushdown \[478\]](#) system variable; the option and the variable were both removed in MySQL 5.6.1. For more information, see [Section 8.13.3, “Engine Condition Pushdown Optimization”](#).

- [--event-scheduler\[=value\] \[422\]](#)

<b>Command-Line Format</b>	<code>--event-scheduler[=value]</code>
<b>Option-File Format</b>	<code>event-scheduler</code>
<b>Option Sets Variable</b>	Yes, <a href="#">event_scheduler [480]</a>
<b>Variable Name</b>	<code>event_scheduler</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>enumeration</code>
	<b>Default</b> <code>OFF</code>
	<b>Valid Values</b> <code>ON</code> <code>OFF</code> <code>DISABLED</code>

Enable or disable, and start or stop, the event scheduler.

For detailed information, see [The --event-scheduler Option \[2159\]](#).

- [--exit-info\[=flags\] \[422\]](#), `-T [flags]`

<b>Command-Line Format</b>	<code>--exit-info[=flags]</code>
	<code>-T [flags]</code>
<b>Option-File Format</b>	<code>exit-info</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>

This is a bit mask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- [--external-locking \[422\]](#)

<b>Command-Line Format</b>	<code>--external-locking</code>
<b>Option-File Format</b>	<code>external-locking</code>
<b>Option Sets Variable</b>	Yes, <a href="#">skip_external_locking [540]</a>
<b>Disabled by</b>	<code>skip-external-locking</code>
	<b>Permitted Values</b>

	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Enable external locking (system locking), which is disabled by default as of MySQL 4.0. Note that if you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.10.5, “External Locking”](#).

- `--flush` [\[423\]](#)

<b>Command-Line Format</b>	<code>--flush</code>	
<b>Option-File Format</b>	<code>flush</code>	
<b>Variable Name</b>	<code>flush</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	OFF

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section C.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

- `--gdb` [\[423\]](#)

<b>Command-Line Format</b>	<code>--gdb</code>	
<b>Option-File Format</b>	<code>gdb</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See [MySQL Internals: Porting to Other Systems](#).

- `--general-log[={0|1}]` [\[423\]](#)

<b>Command-Line Format</b>	<code>--general-log</code>	
<b>Option-File Format</b>	<code>general-log</code>	
<b>Option Sets Variable</b>	Yes, <code>general_log</code> <a href="#">[485]</a>	
<b>Variable Name</b>	<code>general_log</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	OFF

Specify the initial general query log state. With no argument or an argument of 1, the `--general-log` [\[423\]](#) option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--ignore-db-dir=dir_name` [424]

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--ignore-db-dir</code>	
<b>Option-File Format</b>	<code>ignore-db-dir</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>

This option tells the server to ignore the given directory name for purposes of the `SHOW DATABASES` statement or `INFORMATION_SCHEMA` tables. For example, if a MySQL configuration locates the data directory at the root of a file system on Unix, the system might create a `lost+found` directory there that the server should ignore. Starting the server with `--ignore-db-dir=lost+found` [424] causes that name not to be listed as a database.

To specify more than one name, use this option multiple times, once for each name. Specifying the option with an empty value (that is, as `--ignore-db-dir=` [424]) resets the directory list to the empty list.

Instances of this option given at server startup are used to set the `ignore_db_dirs` [488] system variable.

This option was added in MySQL 5.6.3.

- `--init-file=file_name` [424]

<b>Command-Line Format</b>	<code>--init-file=file_name</code>	
<b>Option-File Format</b>	<code>init-file=file_name</code>	
<b>Option Sets Variable</b>	Yes, <code>init_file</code> [489]	
<b>Variable Name</b>	<code>init_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

- `--innodb-xxx`

Set an option for the InnoDB storage engine. The InnoDB options are listed in Section 14.2.6, “InnoDB Startup Options and System Variables”.

- `--install [service_name]` [424]

<b>Command-Line Format</b>	<code>--install [service_name]</code>
----------------------------	---------------------------------------

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

- `--install-manual [service_name]` [424]

<b>Command-Line Format</b>	<code>--install-manual [service_name]</code>
----------------------------	--

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

- `--language=lang_name`, `-L lang_name` [425]

<b>Version Deprecated</b>	5.6.1	
<b>Command-Line Format</b>	<code>--language=name</code>	
	<code>-L</code>	
<b>Option-File Format</b>	<code>language</code>	
<b>Option Sets Variable</b>	Yes, <code>language</code>	
<b>Variable Name</b>	<code>language</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Deprecated</b>	5.6.1	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>
	<b>Default</b>	<code>/usr/local/mysql/share/mysql/english/</code>

The language to use for error messages. `lang_name` can be given as the language name or as the full path name to the directory where the language files are installed. See [Section 10.2, “Setting the Error Message Language”](#).

In MySQL 5.6, `--lc-messages-dir` [426] and `--lc-messages` [426] should be used rather than `--language` [425], which is deprecated as of MySQL 5.6.1 and handled as an alias for `--lc-messages-dir` [426]. The `--language` [425] option will be removed in a future MySQL release.

- `--large-pages` [425]

<b>Command-Line Format</b>	<code>--large-pages</code>	
<b>Option-File Format</b>	<code>large-pages</code>	
<b>Option Sets Variable</b>	Yes, <code>large_pages</code> [494]	
<b>Variable Name</b>	<code>large_pages</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Platform Specific</b>	linux	
	<b>Permitted Values</b>	
	<b>Type</b> (linux)	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL 5.6 supports the Linux implementation of large page support (which is called HugeTLB in Linux). See [Section 8.11.4.2, “Enabling Large Page Support”](#). For Solaris support of large pages, see the description of the `--super-large-pages` [440] option.

`--large-pages` [425] is disabled by default.

- `--lc-messages=locale_name` [426]

<b>Command-Line Format</b>	<code>--lc-messages=name</code>	
<b>Option-File Format</b>	<code>lc-messages</code>	
<b>Option Sets Variable</b>	Yes, <code>lc_messages</code> [495]	
<b>Variable Name</b>	<code>lc-messages</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The locale to use for error messages. The server converts the argument to a language name and combines it with the value of the `--lc-messages-dir` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `--lc-messages-dir=path` [426]

<b>Command-Line Format</b>	<code>--lc-messages-dir=path</code>	
<b>Option-File Format</b>	<code>lc-messages-dir</code>	
<b>Option Sets Variable</b>	Yes, <code>lc_messages_dir</code> [495]	
<b>Variable Name</b>	<code>lc-messages-dir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>

The directory where error messages are located. The value is used together with the value of `--lc-messages` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `--log[=file_name]` [426], `-l [file_name]`

<b>Version Removed</b>	5.6.1	
<b>Command-Line Format</b>	<code>--log[=name]</code>	
	<code>-l</code>	
<b>Option-File Format</b>	<code>log</code>	
<b>Option Sets Variable</b>	Yes, <code>log</code> [497]	
<b>Variable Name</b>	<code>log</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.1.29, by <code>general-log</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>OFF</code>

The `--log` [426] option was removed in MySQL 5.6.1 (along with the `log` [497] system variable). Instead, use the `--general_log` [485] option to enable the general query log and the `--general_log_file=file_name` [486] option to set the general query log file name.

- `--log-error[=file_name]` [427]

<b>Command-Line Format</b>	<code>--log-error[=name]</code>	
<b>Option-File Format</b>	<code>log-error</code>	
<b>Option Sets Variable</b>	Yes, <code>log_error</code> [497]	
<b>Variable Name</b>	<code>log_error</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

Log errors and startup messages to this file. See Section 5.2.2, “The Error Log”. If you omit the file name, MySQL uses `host_name.err`. If the file name has no extension, the server adds an extension of `.err`.

- `--log-isam[=file_name]` [427]

<b>Command-Line Format</b>	<code>--log-isam[=name]</code>	
<b>Option-File Format</b>	<code>log-isam</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

Log all MyISAM changes to this file (used only when debugging MyISAM).

- `--log-output=value,...` [427]

<b>Command-Line Format</b>	<code>--log-output=name</code>	
<b>Option-File Format</b>	<code>log-output</code>	
<b>Option Sets Variable</b>	Yes, <code>log_output</code> [498]	
<b>Variable Name</b>	<code>log_output</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>set</code>
	<b>Default</b>	<code>FILE</code>
	<b>Valid Values</b>	<code>TABLE</code> <code>FILE</code> <code>NONE</code>

This option determines the destination for general query log and slow query log output. The option value can be given as one or more of the words `TABLE`, `FILE`, or `NONE`. `TABLE` selects logging to the `general_log` [485] and `slow_log` tables in the `mysql` database as a destination. `FILE` selects logging to log files as a destination. `NONE` disables logging. If `NONE` is present in the option value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select to both log output destinations.

This option selects log output destinations, but does not enable log output. To do that, use the `--general_log` [485] and `--slow_query_log` [541] options. For FILE logging, the `--general_log_file` [486] and `--slow_query_log_file` options determine the log file location. For more information, see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”.

- `--log-queries-not-using-indexes` [428]

<b>Command-Line Format</b>	<code>--log-queries-not-using-indexes</code>	
<b>Option-File Format</b>	<code>log-queries-not-using-indexes</code>	
<b>Option Sets Variable</b>	Yes, <code>log_queries_not_using_indexes</code> [498]	
<b>Variable Name</b>	<code>log_queries_not_using_indexes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See Section 5.2.5, “The Slow Query Log”. This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- `--log-raw` [428]

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--log-raw[=value]</code>	
<b>Option-File Format</b>	<code>log-raw[=value]</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

As of MySQL 5.6.3, passwords in certain statements written to the general query log, slow query log, and binary log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` [428] option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

Before MySQL 5.6.3, passwords in statements are not rewritten and the general query log should be protected. See Section 6.1.2.3, “Passwords and Logging”.

This option was added in MySQL 5.6.3.

- `--log-short-format` [428]

<b>Command-Line Format</b>	<code>--log-short-format</code>	
<b>Option-File Format</b>	<code>log-short-format</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Log less information to the binary log and slow query log, if they have been activated.

- `--log-slow-admin-statements` [429]

<b>Command-Line Format</b>	<code>--log-slow-admin-statements</code>	
<b>Option-File Format</b>	<code>log-slow-admin-statements</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Include slow administrative statements in the statements written to the slow query log. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

- `--log-slow-queries[=file_name]` [429]

<b>Version Removed</b>	5.6.1	
<b>Command-Line Format</b>	<code>--log-slow-queries[=name]</code>	
<b>Option-File Format</b>	<code>log-slow-queries</code>	
<b>Option Sets Variable</b>	Yes, <code>log_slow_queries</code> [499]	
<b>Variable Name</b>	<code>log_slow_queries</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.1.29, by <code>slow-query-log</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>

The `--log-slow-queries` [429] option was removed in MySQL 5.6.1 (along with the `log_slow_queries` [499] system variable). Instead, use the `--slow_query_log` [541] option to enable the slow query log and the `--slow_query_log_file=file_name` [541] option to set the slow query log file name.

- `--log-tc=file_name` [429]

<b>Command-Line Format</b>	<code>--log-tc=name</code>	
<b>Option-File Format</b>	<code>log-tc</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>tc.log</code>

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. Currently, this option is unused.

- `--log-tc-size=size` [429]

<b>Command-Line Format</b>	<code>--log-tc-size=#</code>	
<b>Option-File Format</b>	<code>log-tc-size</code>	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>32</code>
	<b>Type</b>	<code>numeric</code> <sup>429</sup>

	<b>Default</b>	24576
	<b>Max Value</b>	4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	24576
	<b>Max Value</b>	18446744073709547520

The size in bytes of the memory-mapped transaction coordinator log. The default size is 24KB.

- `--log-warnings[=level] [430], -W [level]`

<b>Command-Line Format</b>	<code>--log-warnings[=#]</code>	
	<code>-W [#]</code>	
<b>Option-File Format</b>	<code>log-warnings</code>	
<b>Option Sets Variable</b>	Yes, <code>log_warnings</code> [499]	
<b>Variable Name</b>	<code>log_warnings</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Disabled by</b>	<code>skip-log-warnings</code>	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	1
	<b>Range</b>	0 .. 18446744073709547520

Print out warnings such as `Aborted connection...` to the error log. Enabling this option is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). This option is enabled (1) by default, and the default `level` value if omitted is 1. To disable this option, use `--log-warnings=0` [430]. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See [Section C.5.2.11, “Communication Errors and Aborted Connections”](#).

If a slave server was started with `--log-warnings` [430] enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth. The server logs messages about statements that are unsafe for statement-based logging only if `--log-warnings` [430] is enabled.

- `--low-priority-updates` [430]

<b>Command-Line Format</b>	<code>--low-priority-updates</code>
<b>Option-File Format</b>	<code>low-priority-updates</code>
<b>Option Sets Variable</b>	Yes, <code>low_priority_updates</code> [500]
<b>Variable Name</b>	<code>low_priority_updates</code>

<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	boolean
<b>Default</b>	FALSE

Give table-modifying operations (`INSERT`, `REPLACE`, `DELETE`, `UPDATE`) lower priority than selects. This can also be done using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`). See [Section 8.10.2, “Table Locking Issues”](#).

- `--min-examined-row-limit=number` [431]

<b>Command-Line Format</b>	<code>--min-examined-row-limit=#</code>
<b>Option-File Format</b>	<code>min-examined-row-limit</code>
<b>Variable Name</b>	<code>min_examined_row_limit</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 32
	<b>Type</b> numeric
	<b>Default</b> 0
	<b>Range</b> 0 .. 4294967295
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 64
	<b>Type</b> numeric
	<b>Default</b> 0
	<b>Range</b> 0 .. 18446744073709547520

When this option is set, queries which examine fewer than `number` rows are not written to the slow query log. The default is 0.

- `--memlock` [431]

<b>Command-Line Format</b>	<code>--memlock</code>
<b>Option-File Format</b>	<code>memlock</code>
<b>Variable Name</b>	<code>locked_in_memory</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> boolean
	<b>Default</b> FALSE

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` [431] works on systems that support the `mlockall()` system call; this includes Solaris, most Linux distributions that use a 2.4 or newer kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
shell> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

**Important**

Use of this option may require you to run the server as `root`, which, for reasons of security, is normally not a good idea. See [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

On Linux and perhaps other systems, you can avoid the need to run the server as `root` by changing the `limits.conf` file. See the notes regarding the `memlock` limit in [Section 8.11.4.2, “Enabling Large Page Support”](#).

You must not try to use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` will very likely crash as soon as you try to start it.

- `--myisam-block-size=N` [432]

<b>Command-Line Format</b>	<code>--myisam-block-size=#</code>
<b>Option-File Format</b>	<code>myisam-block-size</code>
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 1024
	<b>Range</b> 1024 .. 16384

The block size to be used for `MyISAM` index pages.

- `--myisam-recover-options[=option[,option]...]` [432]

<b>Command-Line Format</b>	<code>--myisam-recover-options[=name]</code>
<b>Option-File Format</b>	<code>myisam-recover-options</code>
<b>Option Sets Variable</b>	Yes, <code>myisam_recover_options</code> [512]
	<b>Permitted Values</b>
	<b>Type</b> enumeration
	<b>Default</b> OFF
	<b>Valid Values</b> OFF DEFAULT BACKUP FORCE QUICK

Set the `MyISAM` storage engine recovery mode. The option value is any combination of the values of `OFF`, `DEFAULT`, `BACKUP`, `FORCE`, or `QUICK`. If you specify multiple values, separate them by commas. Specifying the option with no argument is the same as specifying `DEFAULT`, and specifying with an explicit value of `" "` disables recovery (same as a value of `OFF`). If recovery is enabled, each time `mysqld` opens a `MyISAM` table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

The following options affect how the repair works.

Option	Description
<code>OFF</code>	No recovery.
<code>DEFAULT</code>	Recovery without backup, forcing, or quick checking.
<code>BACKUP</code>	If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code> .
<code>FORCE</code>	Run recovery even if we would lose more than one row from the <code>.MYD</code> file.
<code>QUICK</code>	Do not check the rows in the table if there are not any delete blocks.

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP`, `FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See [Section 14.3.1, “MyISAM Startup Options”](#).

- `--old-alter-table` [\[433\]](#)

<b>Command-Line Format</b>	<code>--old-alter-table</code>	
<b>Option-File Format</b>	<code>old-alter-table</code>	
<b>Option Sets Variable</b>	Yes, <code>old_alter_table</code> <a href="#">[517]</a>	
<b>Variable Name</b>	<code>old_alter_table</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

When this option is given, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 13.1.6, “ALTER TABLE Syntax”](#).

- `--old-style-user-limits` [\[433\]](#)

<b>Command-Line Format</b>	<code>--old-style-user-limits</code>	
<b>Option-File Format</b>	<code>old-style-user-limits</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See [Section 6.3.4, “Setting Account Resource Limits”](#).

- `--one-thread` [\[434\]](#)

<b>Version Removed</b>	5.6.1
<b>Command-Line Format</b>	<code>--one-thread</code>
<b>Option-File Format</b>	<code>one-thread</code>

This option was removed in MySQL 5.6.1. Use `--thread_handling=no-threads` [\[553\]](#) instead.

- `--open-files-limit=count` [\[434\]](#)

<b>Command-Line Format</b>	<code>--open-files-limit=#</code>
<b>Option-File Format</b>	<code>open-files-limit</code>
<b>Option Sets Variable</b>	Yes, <code>open_files_limit</code> <a href="#">[518]</a>
<b>Variable Name</b>	<code>open_files_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values (&lt;= 5.6.7)</b>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	0
<b>Range</b>	0 .. 65535
	<b>Permitted Values (&gt;= 5.6.8)</b>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	-1 (autosized)
<b>Range</b>	0 .. 65535

Changes the number of file descriptors available to `mysqld`. You should try increasing the value of this option if `mysqld` gives you the error `Too many open files`. `mysqld` uses the option value to reserve descriptors with `setrlimit()`. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

`mysqld` may attempt to allocate more than the requested number of descriptors (if they are available), using the values of `max_connections` [\[503\]](#) and `table_open_cache` [\[551\]](#) to estimate whether more descriptors will be needed.

On Unix, the value cannot be set less than `ulimit -n`.

- `--partition[=value]` [\[434\]](#)

<b>Command-Line Format</b>	<code>--partition</code>
<b>Option-File Format</b>	<code>partition</code>
<b>Option Sets Variable</b>	Yes, <code>have_partitioning</code> <a href="#">[487]</a>
<b>Variable Name</b>	<code>partition</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Disabled by</b>	<code>skip-partition</code>

	<b>Permitted Values</b>	
<b>Type</b>	boolean	
<b>Default</b>	ON	

Enables or disables user-defined partitioning support in the MySQL Server.

- `--performance-schema-xxx`

Configure a Performance Schema option. For details, see [Section 20.11, “Performance Schema Command Options”](#).

- `--pid-file=path` [435]

<b>Command-Line Format</b>	<code>--pid-file=file_name</code>	
<b>Option-File Format</b>	<code>pid-file=file_name</code>	
<b>Option Sets Variable</b>	Yes, <code>pid_file</code> [524]	
<b>Variable Name</b>	<code>pid_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

The path name of the process ID file. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. This file is used by other programs such as `mysqld_safe` to determine the server's process ID.

- `--plugin-xxx` [435]

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a `--plugin` [435] prefix. Thus, the `--innodb_file_per_table` [1718] option for InnoDB can be specified as `--plugin-innodb_file_per_table` [1718].

For boolean options that can be enabled or disabled, the `--skip` prefix and other alternative formats are supported as well (see [Section 4.2.3.2, “Program Option Modifiers”](#)). For example, `--skip-plugin-innodb_file_per_table` [1718] disables `innodb_file_per_table` [1718].

The rationale for the `--plugin` prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin “sql” and implement a “mode” option, the option name might be `--sql-mode` [442], which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as `--plugin-sql-mode`. Use of the `--plugin` prefix for plugin options is recommended to avoid any question of ambiguity.

- `--plugin-load=plugin_list` [435]

<b>Command-Line Format</b>	<code>--plugin-load=plugin_list</code>	
<b>Option-File Format</b>	<code>plugin-load=plugin_list</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	string

This option tells the server to load the named plugins at startup. The option value is a semicolon-separated list of `name=plugin_library` pairs. Each `name` is the name of the plugin, and `plugin_library` is the name of the shared library that contains the plugin code. Each library file

must be located in the directory named by the `plugin_dir` [525] system variable. For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to load them at startup:

```
shell> mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value here because semicolon (`;`) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

If multiple `--plugin-load` [435] options are given, only the last one is used. Additional plugins to load may be specified using `--plugin-load-add` [436] options.

If a plugin library is named without any preceding plugin name, the server loads all plugins in the library.

Each plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` [435] is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

Under normal startup, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` [439] option, it does not consult the `mysql.plugins` table and does not load plugins listed there. `--plugin-load` [435] enables plugins to be loaded even when `--skip-grant-tables` [439] is given. `--plugin-load` [435] also enables plugins to be loaded at startup under configurations when plugins cannot be loaded at runtime.

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

- `--plugin-load-add=plugin_list` [436]

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--plugin-load-add=plugin_list</code>	
<b>Option-File Format</b>	<code>plugin-load-add=plugin_list</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

This option complements the `--plugin-load` [435] option. `--plugin-load-add` [436] adds a plugin or plugins to the set of plugins to be loaded at startup. The argument format is the same as for `--plugin-load` [435]. `--plugin-load-add` [436] can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` [435] argument. This option was added in MySQL 5.6.3.

`--plugin-load-add` [436] can be given in the absence of `--plugin-load` [435], but any instance of `--plugin-load-add` [436] that appears before `--plugin-load` [435] has no effect because `--plugin-load` [435] resets the set of plugins to load. In other words, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

- `--port=port_num [437]`, `-P port_num`

<b>Command-Line Format</b>	<code>--port=#</code>	
	<code>-P</code>	
<b>Option-File Format</b>	<code>port</code>	
<b>Option Sets Variable</b>	Yes, <code>port</code> [525]	
<b>Variable Name</b>	<code>port</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>3306</code>
	<b>Range</b>	<code>0 .. 65535</code>

The port number to use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--port-open-timeout=num [437]`

<b>Command-Line Format</b>	<code>--port-open-timeout=#</code>	
<b>Option-File Format</b>	<code>port-open-timeout</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- `--remove [service_name] [437]`

<b>Command-Line Format</b>	<code>--remove [service_name]</code>
----------------------------	--------------------------------------

(Windows only) Remove a MySQL Windows service. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

- `--safe-mode [437]`

<b>Version Removed</b>	5.6.6
<b>Command-Line Format</b>	<code>--safe-mode</code>
<b>Option-File Format</b>	<code>safe-mode</code>
<b>Deprecated</b>	5.5.26

Skip some optimization stages. This option was removed in MySQL 5.6.6.

- `--safe-user-create` [438]

<b>Command-Line Format</b>	<code>--safe-user-create</code>	
<b>Option-File Format</b>	<code>safe-user-create</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	FALSE

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` [755] privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth` [438]

<b>Command-Line Format</b>	<code>--secure-auth</code>	
<b>Option-File Format</b>	<code>secure-auth</code>	
<b>Option Sets Variable</b>	Yes, <code>secure_auth</code> [538]	
<b>Variable Name</b>	<code>secure_auth</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.4)</b>	
	<b>Type</b>	boolean
	<b>Default</b>	OFF
	<b>Permitted Values (&gt;= 5.6.5)</b>	
	<b>Type</b>	boolean
	<b>Default</b>	ON

This option causes the server to block connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format. Use it to prevent all use of passwords employing the old format (and hence insecure communication over the network). Before MySQL 5.6.5, this option is disabled by default. As of MySQL 5.6.5, it is enabled by default; to disable it, use `--skip-secure-auth` [438].

Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format. See [Section C.5.2.4](#), “Client does not support authentication protocol”.

The `mysql` client also has a `--secure-auth` [253] option, which prevents connections to a server if the server requires a password in old format for the client account.

- `--secure-file-priv=path` [438]

<b>Command-Line Format</b>	<code>--secure-file-priv=path</code>	
<b>Option-File Format</b>	<code>secure-file-priv=path</code>	
<b>Option Sets Variable</b>	Yes, <code>secure_file_priv</code> [538]	

<b>Variable Name</b>	<code>secure-file-priv</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

This option limits the effect of the `LOAD_FILE()` [1181] function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in the specified directory.

- `--shared-memory` [439]

Enable shared-memory connections by local clients. This option is available only on Windows.

- `--shared-memory-base-name=name` [439]

The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive.

- `--skip-concurrent-insert` [439]

Turn off the ability to select and insert at the same time on `MyISAM` tables. (This is to be used only if you think you have found a bug in this feature.) See [Section 8.10.3, “Concurrent Inserts”](#).

- `--skip-external-locking` [439]

Do not use external locking (system locking). This affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.10.5, “External Locking”](#).

External locking has been disabled by default since MySQL 4.0.

- `--skip-event-scheduler` [439]

<b>Command-Line Format</b>	<code>--skip-event-scheduler</code>
	<code>--disable-event-scheduler</code>
<b>Option-File Format</b>	<code>skip-event-scheduler</code>

Turns the Event Scheduler `OFF`. This is not the same as disabling the Event Scheduler, which requires setting `--event-scheduler=DISABLED` [422]; see [The `--event-scheduler` Option \[2159\]](#), for more information.

- `--skip-grant-tables` [439]

This option causes the server to start without using the privilege system at all, which gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server. This option also suppresses loading of plugins that were installed with the `INSTALL PLUGIN` statement, user-defined functions (UDFs), and scheduled events. To cause plugins to be loaded anyway, use the `--plugin-load` [435] option.

Note that `FLUSH PRIVILEGES` might be executed implicitly by other actions performed after startup. For example, `mysql_upgrade` flushes the privileges during the upgrade procedure.

- `--skip-host-cache` [439]

Disable use of the internal host cache for faster name-to-IP resolution. In this case, the server performs a DNS lookup every time a client connects. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).

Use of `--skip-host-cache` [439] is similar to setting the `host_cache_size` [487] system variable to 0, but `host_cache_size` [487] is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

If you start the server with `--skip-host-cache` [439], that does not prevent changes to the value of `host_cache_size` [487], but such changes have no effect and the cache is not re-enabled even if `host_cache_size` [487] is set larger than 0.

- `--skip-innodb` [1698]

Disable the InnoDB storage engine. In this case, because the default storage engine is InnoDB, the server will not start unless you also use `--default-storage-engine` [474] and `--default-tmp-storage-engine` [474] to set the default to some other engine for both permanent and TEMPORARY tables.

- `--skip-name-resolve` [440]

Do not resolve host names when checking client connections. Use only IP addresses. If you use this option, all `Host` column values in the grant tables must be IP addresses or `localhost`. See Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”.

- `--skip-networking` [440]

Do not listen for TCP/IP connections at all. All interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”.

- `--skip-partition` [440]

<b>Command-Line Format</b>	<code>--skip-partition</code>
	<code>--disable-partition</code>
<b>Option-File Format</b>	<code>skip-partition</code>

Disables user-defined partitioning. Partitioned tables can be seen using `SHOW TABLES` or by querying the `INFORMATION_SCHEMA.TABLES` table, but cannot be created or modified, nor can data in such tables be accessed. All partition-specific columns in the `INFORMATION_SCHEMA.PARTITIONS` table display `NULL`.

Since `DROP TABLE` removes table definition (`.frm`) files, this statement works on partitioned tables even when partitioning is disabled using the option. The statement, however, does not remove `.par` files associated with partitioned tables in such cases. For this reason, you should avoid dropping partitioned tables with partitioning disabled, or take action to remove the orphaned `.par` files manually.

- `--ssl*`

Options that begin with `--ssl` [810] specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

- `--standalone` [440]

<b>Command-Line Format</b>	<code>--standalone</code>
<b>Option-File Format</b>	<code>standalone</code>
<b>Platform Specific</b>	windows

Available on Windows only; instructs the MySQL server not to run as a service.

- `--super-large-pages` [440]

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` [440] or `--skip-super-large-pages` [440] option.

- `--symbolic-links` [441], `--skip-symbolic-links` [441]

<b>Command-Line Format</b>	<code>--symbolic-links</code>
<b>Option-File Format</b>	<code>symbolic-links</code>

Enable or disable symbolic link support. This option has different effects on Windows and Unix:

- On Windows, enabling symbolic links enables you to establish a symbolic link to a database directory by creating a `db_name.sym` file that contains the path to the real directory. See [Section 8.11.3.1.3, “Using Symbolic Links for Databases on Windows”](#).
- On Unix, enabling symbolic links means that you can link a `MyISAM` index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See [Section 8.11.3.1.2, “Using Symbolic Links for `MyISAM` Tables on Unix”](#).
- `--skip-show-database` [441]

<b>Command-Line Format</b>	<code>--skip-show-database</code>
<b>Option-File Format</b>	<code>skip-show-database</code>
<b>Option Sets Variable</b>	Yes, <code>skip_show_database</code> [540]
<b>Variable Name</b>	<code>skip_show_database</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

This option sets the `skip_show_database` [540] system variable that controls who is permitted to use the `SHOW DATABASES` statement. See [Section 5.1.4, “Server System Variables”](#).

- `--skip-stack-trace` [441]

<b>Command-Line Format</b>	<code>--skip-stack-trace</code>
<b>Option-File Format</b>	<code>skip-stack-trace</code>

Do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See [MySQL Internals: Porting to Other Systems](#).

- `--skip-thread-priority` [441]

<b>Version Removed</b>	5.6.1
<b>Command-Line Format</b>	<code>--skip-thread-priority</code>
<b>Option-File Format</b>	<code>skip-thread-priority</code>
<b>Deprecated</b>	5.1.29

Disable using thread priorities for faster response time. This option was unused and was removed in MySQL 5.6.1.

- `--slow-query-log[={0|1}]` [441]

<b>Command-Line Format</b>	<code>--slow-query-log</code>
----------------------------	-------------------------------

<b>Option-File Format</b>	<code>slow-query-log</code>
<b>Option Sets Variable</b>	Yes, <code>slow_query_log</code> [541]
<b>Variable Name</b>	<code>slow_query_log</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>OFF</code>

Specify the initial slow query log state. With no argument or an argument of 1, the `--slow-query-log` [441] option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--slow-start-timeout=timeout` [442]

<b>Version Introduced</b>	5.6.5
<b>Command-Line Format</b>	<code>--slow-start-timeout=#</code>
<b>Option-File Format</b>	<code>slow-start-timeout=#</code>
	<b>Permitted Values</b>
<b>Type</b> (windows)	<code>numeric</code>
<b>Default</b>	<code>15000</code>

This option controls the Windows service control manager's service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- `--socket=path` [442]

<b>Command-Line Format</b>	<code>--socket=name</code>
<b>Option-File Format</b>	<code>socket</code>
<b>Option Sets Variable</b>	Yes, <code>socket</code> [542]
<b>Variable Name</b>	<code>socket</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
<b>Type</b>	<code>file name</code>
<b>Default</b>	<code>/tmp/mysql.sock</code>

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=value[,value[,value...]]` [442]

<b>Command-Line Format</b>	<code>--sql-mode=name</code>
<b>Option-File Format</b>	<code>sql-mode</code> 442

<b>Option Sets Variable</b>	Yes, <a href="#">sql_mode</a> [545]
<b>Variable Name</b>	<a href="#">sql_mode</a>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&lt;= 5.6.5)</b>
<b>Type</b>	set
<b>Default</b>	''
<b>Valid Values</b>	ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_CREATE_USER NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_FIELD_OPTIONS NO_KEY_OPTIONS NO_TABLE_OPTIONS NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES
	<b>Permitted Values (&gt;= 5.6.6)</b>
<b>Type</b>	set
<b>Default</b>	NO_ENGINE_SUBSTITUTION
<b>Valid Values</b>	ALLOW_INVALID_DATES ANSI_QUOTES

	ERROR_FOR_DIVISION_BY_ZERO
	HIGH_NOT_PRECEDENCE
	IGNORE_SPACE
	NO_AUTO_CREATE_USER
	NO_AUTO_VALUE_ON_ZERO
	NO_BACKSLASH_ESCAPES
	NO_DIR_IN_CREATE
	NO_ENGINE_SUBSTITUTION
	NO_FIELD_OPTIONS
	NO_KEY_OPTIONS
	NO_TABLE_OPTIONS
	NO_UNSIGNED_SUBTRACTION
	NO_ZERO_DATE
	NO_ZERO_IN_DATE
	ONLY_FULL_GROUP_BY
	PAD_CHAR_TO_FULL_LENGTH
	PIPES_AS_CONCAT
	REAL_AS_FLOAT
	STRICT_ALL_TABLES
	STRICT_TRANS_TABLES

Set the SQL mode. Prior to MySQL 5.6.6, the default was '' (an empty string); beginning with MySQL 5.6.6, the default is `NO_ENGINE_SUBSTITUTION`. See [Section 5.1.7, “Server SQL Modes”](#).

- `--sysdate-is-now` [\[444\]](#)

<b>Command-Line Format</b>	<code>--sysdate-is-now</code>
<b>Option-File Format</b>	<code>sysdate-is-now</code>
	<b>Permitted Values</b>
<b>Type</b>	boolean
<b>Default</b>	FALSE

`SYSDATE()` [\[1223\]](#) by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()` [\[1220\]](#). This option causes `SYSDATE()` [\[1223\]](#) to be an alias for `NOW()` [\[1220\]](#). For information about the implications for binary logging and replication, see the description for `SYSDATE()` [\[1223\]](#) in [Section 12.7, “Date and Time Functions”](#) and for `SET TIMESTAMP` in [Section 5.1.4, “Server System Variables”](#).

- `--tc-heuristic-recover={COMMIT|ROLLBACK}` [\[444\]](#)

<b>Command-Line Format</b>	<code>--tc-heuristic-recover=name</code>
<b>Option-File Format</b>	<code>tc-heuristic-recover</code>
	<b>Permitted Values</b>
	<b>Type</b> enumeration
	<b>Valid Values</b> COMMIT RECOVER

The type of decision to use in the heuristic recovery process. Currently, this option is unused.

- `--temp-pool` [445]

<b>Command-Line Format</b>	<code>--temp-pool</code>
<b>Option-File Format</b>	<code>temp-pool</code>
	<b>Permitted Values</b>
	<b>Type</b> boolean
	<b>Default</b> TRUE

This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to “leak” memory, because it is being allocated to the directory entry cache rather than to the disk cache. This option is ignored except on Linux.

- `--transaction-isolation=level` [445]

<b>Command-Line Format</b>	<code>--transaction-isolation=name</code>
<b>Option-File Format</b>	<code>transaction-isolation</code>
<b>Option Sets Variable</b>	Yes, <code>tx_isolation</code> [560]
	<b>Permitted Values</b>
	<b>Type</b> enumeration
	<b>Valid Values</b> READ-UNCOMMITTED READ-COMMITTED REPEATABLE-READ SERIALIZABLE

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED` [1470], `READ-COMMITTED` [1469], `REPEATABLE-READ` [1469], or `SERIALIZABLE` [1470]. See Section 13.3.6, “`SET TRANSACTION Syntax`”.

The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `tx_isolation` [560] system variable.

- `--transaction-read-only` [445]

<b>Version Introduced</b>	5.6.5
<b>Command-Line Format</b>	<code>--transaction-read-only</code>
<b>Option-File Format</b>	<code>transaction-read-only</code>
<b>Option Sets Variable</b>	Yes, <code>tx_read_only</code> [561]

	<b>Permitted Values</b>	
<b>Type</b>	boolean	
<b>Default</b>	OFF	

Sets the default transaction access mode. By default, read-only mode is disabled, so the mode is read/write.

To set the default transaction access mode at runtime, use the `SET TRANSACTION` statement or set the `tx_read_only` [561] system variable. See Section 13.3.6, “`SET TRANSACTION Syntax`”.

This option was added in MySQL 5.6.5.

- `--tmpdir=path` [446], `-t path`

<b>Command-Line Format</b>	<code>--tmpdir=path</code>	
	<code>-t</code>	
<b>Option-File Format</b>	<code>tmpdir</code>	
<b>Option Sets Variable</b>	Yes, <code>tmpdir</code> [559]	
<b>Variable Name</b>	<code>tmpdir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (“:”) on Unix and semicolon characters (“;”) on Windows. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` [446] to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see Section C.5.4.4, “Where MySQL Stores Temporary Files”. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name|user_id}` [446], `-u {user_name|user_id}`

<b>Command-Line Format</b>	<code>--user=name</code>	
	<code>-u name</code>	
<b>Option-File Format</b>	<code>user</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	string

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See Section 6.1.1, “Security Guidelines”.

To avoid a possible security hole where a user adds a `--user=root` [446] option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` [446] option specified and produces a warning if there are multiple `--user` [446] options. Options in `/etc/my.cnf` and

`$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user [446]` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user [446]` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user [446]` option is found.

- `--verbose [447]`, `-v [447]`

Use this option with the `--help [413]` option for detailed help.

- `--version [447]`, `-V`

Display version information and exit.

You can assign a value to a server system variable by using an option of the form `--var_name=value`. For example, `--key_buffer_size=32M [492]` sets the `key_buffer_size [492]` variable to a value of 32MB.

Note that when you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

If you want to restrict the maximum value to which a variable can be set at runtime with `SET`, you can define this by using the `--maximum-var_name=value` command-line option.

You can change the values of most system variables for a running server with the `SET` statement. See [Section 13.7.4, “SET Syntax”](#).

[Section 5.1.4, “Server System Variables”](#), provides a full description for all variables, and additional information for setting them at server startup and runtime. [Section 8.11.2, “Tuning Server Parameters”](#), includes information on optimizing the server by tuning system variables.

## 5.1.4. Server System Variables

The MySQL server maintains many system variables that indicate how it is configured. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server will use based on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysqld --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement.

This section provides a description of each system variable. Variables with no version indicated are present in all MySQL 5.6 releases. For historical information concerning their implementation, please see <http://dev.mysql.com/doc/refman/5.0/en/>, and <http://dev.mysql.com/doc/refman/4.1/en/>.

The following table lists all available system variables.

**Table 5.3. System Variable Summary**

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
<code>audit_log_buffer_size [824]</code>			Yes	Global	No

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
<a href="#">audit_log_file [825]</a>			Yes	Global	No
<a href="#">audit_log_flush [825]</a>			Yes	Global	Yes
<a href="#">audit_log_policy [826]</a>			Yes	Global	Yes
<a href="#">audit_log_rotate_on_size [826]</a>			Yes	Global	Yes
<a href="#">audit_log_strategy [827]</a>			Yes	Global	No
<a href="#">auto_increment_increment [1965]</a>	Yes	Yes	Yes	Both	Yes
<a href="#">auto_increment_offset [1968]</a>	Yes	Yes	Yes	Both	Yes
<a href="#">autocommit [464]</a>	Yes	Yes	Yes	Both	Yes
<a href="#">automatic_sp_privileges [464]</a>			Yes	Global	Yes
<a href="#">back_log [465]</a>	Yes	Yes	Yes	Global	No
<a href="#">basedir [414]</a>	Yes	Yes	Yes	Global	No
<a href="#">big-tables [414]</a>	Yes	Yes			Yes
- Variable: <a href="#">big_tables</a>			Yes	Both	Yes
<a href="#">bind-address [414]</a>	Yes	Yes	Yes	Global	No
<a href="#">binlog_cache_size [2008]</a>	Yes	Yes	Yes	Global	Yes
<a href="#">binlog_checksum [2009]</a>			Yes	Global	Yes
<a href="#">binlog_direct_non_transactional_updates [2010]</a>	Yes	Yes	Yes	Both	Yes
<a href="#">binlog-format [415]</a>	Yes	Yes			Yes
- Variable: <a href="#">binlog_format</a>			Yes	Both	Yes
<a href="#">binlog_max_flush_queue_time [2011]</a>			Yes	Global	Yes
<a href="#">binlog_order_commits [2012]</a>			Yes	Global	Yes
<a href="#">binlog_row_image [2013]</a>	Yes		Yes	Both	Yes
<a href="#">binlog_rows_query_log_events [2014]</a>			Yes	Both	Yes
<a href="#">binlog_stmt_cache_size [2014]</a>	Yes	Yes	Yes	Global	Yes
<a href="#">bulk_insert_buffer_size [466]</a>	Yes	Yes	Yes	Both	Yes
<a href="#">character_set_client [467]</a>			Yes	Both	Yes
<a href="#">character_set_connection [467]</a>			Yes	Both	Yes
<a href="#">character_set_database [468]<sup>a</sup></a>			Yes	Both	Yes
<a href="#">character-set-filesystem [416]</a>	Yes	Yes			Yes
- Variable: <a href="#">character_set_filesystem</a>			Yes	Both	Yes
<a href="#">character_set_results [468]</a>			Yes	Both	Yes
<a href="#">character-set-server [417]</a>	Yes	Yes			Yes
- Variable: <a href="#">character_set_server</a>			Yes	Both	Yes
<a href="#">character_set_system [469]</a>			Yes	Global	No
<a href="#">character-sets-dir [416]</a>	Yes	Yes			No

Server System Variables

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
- Variable: character_sets_dir			Yes	Global	No
collation_connection [469]			Yes	Both	Yes
collation_database [469] <sup>b</sup>			Yes	Both	Yes
collation-server [417]	Yes	Yes			Yes
- Variable: collation_server			Yes	Both	Yes
completion_type [470]	Yes	Yes	Yes	Both	Yes
concurrent_insert [471]	Yes	Yes	Yes	Global	Yes
connect_timeout [472]	Yes	Yes	Yes	Global	Yes
core_file [472]			Yes	Global	No
daemon_memcached_enable_binlog [1698]	Yes	Yes	Yes	Global	No
daemon_memcached_engine_lib_name [1698]	Yes	Yes	Yes	Global	No
daemon_memcached_engine_lib_path [1699]	Yes	Yes	Yes	Global	No
daemon_memcached_extern [1699]	Yes	Yes	Yes	Global	No
daemon_memcached_flush_batch_size [1700]	Yes	Yes	Yes	Global	No
daemon_memcached_flush_batch_size [1700]	Yes	Yes	Yes	Global	No
datadir [418]	Yes	Yes	Yes	Global	No
date_format [472]			Yes	Global	No
datetime_format [472]			Yes	Global	No
debug [418]	Yes	Yes	Yes	Both	Yes

<sup>a</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

<sup>b</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

For additional system variable information, see these sections:

- [Section 5.1.5, “Using System Variables”](#), discusses the syntax for setting and displaying system variable values.
- [Section 5.1.5.2, “Dynamic System Variables”](#), lists the variables that can be set at runtime.
- Information on tuning system variables can be found in [Section 8.11.2, “Tuning Server Parameters”](#).
- [Section 14.2.6, “InnoDB Startup Options and System Variables”](#), lists InnoDB system variables.
- [MySQL Cluster System Variables](#), lists system variables which are specific to MySQL Cluster.
- For information on server system variables specific to replication, see [Section 16.1.4, “Replication and Binary Logging Options and Variables”](#).

**Note**

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, before MySQL 5.6.2, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` [475] works but `--delay_key_write=ON` [475] does not. As of MySQL 5.6.2, boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case sensitive). See [Section 4.2.3.2, “Program Option Modifiers”](#).

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `authentication_windows_log_level` [463]

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--authentication_windows_log_level</code>	
<b>Option-File Format</b>	<code>authentication_windows_log_level</code>	
<b>Option Sets Variable</b>	Yes, <code>authentication_windows_log_level</code> [463]	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 4</code>

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

Value	Description
0	No logging
1	Log only error messages
2	Log level 1 messages and warning messages
3	Log level 2 messages and information notes
4	Log level 3 messages and debug messages

This variable was added in MySQL 5.6.10.

- `authentication_windows_use_principal_name` [464]

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--authentication_windows_use_principal_name</code>	
<b>Option-File Format</b>	<code>authentication_windows_use_principal_name</code>	
<b>Option Sets Variable</b>	Yes, <code>authentication_windows_use_principal_name</code> [464]	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client in clear text. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which will happen primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

This variable was added in MySQL 5.6.10.

- `autocommit` [464]

<b>Command-Line Format</b>	<code>--autocommit[=#]</code>	
<b>Option-File Format</b>	<code>autocommit</code>	
<b>Option Sets Variable</b>	Yes, <code>autocommit</code> [464]	
<b>Variable Name</b>	<code>autocommit</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` [464] is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

By default, client connections begin with `autocommit` [464] set to 1. To cause clients to begin with a default of 0, set the global `autocommit` [464] value by starting the server with the `--autocommit=0` [464] option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

- `automatic_sp_privileges` [464]

<b>Variable Name</b>	<code>automatic_sp_privileges</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>TRUE</code>

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` [754] and `ALTER ROUTINE` [754] privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` [754] privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` [464] is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

See also [Section 18.2.2, “Stored Routines and MySQL Privileges”](#).

- `back_log` [465]

<b>Command-Line Format</b>	<code>--back_log=#</code>	
<b>Option-File Format</b>	<code>back_log</code>	
<b>Option Sets Variable</b>	Yes, <code>back_log</code> [465]	
<b>Variable Name</b>	<code>back_log</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>50</code>
	<b>Range</b>	<code>1 .. 65535</code>
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>-1 (autosized)</code>
	<b>Range</b>	<code>1 .. 65535</code>

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` [465] value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` [465] cannot be set higher than your operating system limit.

As of MySQL 5.6.6, the default value is based on the following formula, capped to a limit of 900:

```
50 + (max_connections / 5)
```

Before 5.6.6, the default is 50.

- [basedir \[466\]](#)

<b>Command-Line Format</b>	<code>--basedir=path</code>	
	<code>-b</code>	
<b>Option-File Format</b>	<code>basedir</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">basedir [466]</a>	
<b>Variable Name</b>	<code>basedir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The MySQL installation base directory. This variable can be set with the `--basedir [414]` option. Relative path names for other variables usually are resolved relative to the base directory.

- [big\\_tables \[466\]](#)

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required.

- [bind\\_address \[466\]](#)

<b>Command-Line Format</b>	<code>--bind-address=addr</code>	
<b>Option-File Format</b>	<code>bind-address=addr</code>	
<b>Variable Name</b>	<code>bind-address</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>0.0.0.0</code>
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>*</code>

The value of the `--bind-address [414]` option. This variable was added in MySQL 5.6.1.

- [bulk\\_insert\\_buffer\\_size \[466\]](#)

<b>Command-Line Format</b>	<code>--bulk_insert_buffer_size=#</code>
<b>Option-File Format</b>	<code>bulk_insert_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <a href="#">bulk_insert_buffer_size [466]</a>
<b>Variable Name</b>	<code>bulk_insert_buffer_size</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes

	<b>Permitted Values</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	8388608
<b>Range</b>	0 .. 4294967295
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	8388608
<b>Range</b>	0 .. 18446744073709547520

MyISAM uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

- `character_set_client` [467]

<b>Variable Name</b>	<code>character_set_client</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	string

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also [Section 10.1.4, “Connection Character Sets and Collations”](#).) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
- `mysqld` was started with the `--skip-character-set-client-handshake` [416] option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

`ucs2`, `utf16`, `utf16le`, and `utf32` cannot be used as a client character set, which means that they also do not work for `SET NAMES` or `SET CHARACTER SET`.

- `character_set_connection` [467]

<b>Variable Name</b>	<code>character_set_connection</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>

	<b>Type</b>	string
--	-------------	--------

The character set used for literals that do not have a character set introducer and for number-to-string conversion.

- [character\\_set\\_database \[468\]](#)

<b>Variable Name</b>	character_set_database	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
<b>Footnote</b>	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as [character\\_set\\_server \[468\]](#).

- [character\\_set\\_filesystem \[468\]](#)

<b>Command-Line Format</b>	--character-set-filesystem=name	
<b>Option-File Format</b>	character-set-filesystem	
<b>Option Sets Variable</b>	Yes, <a href="#">character_set_filesystem [468]</a>	
<b>Variable Name</b>	character_set_filesystem	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` [1181] function. Such file names are converted from [character\\_set\\_client \[467\]](#) to [character\\_set\\_filesystem \[468\]](#) before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multi-byte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set [character\\_set\\_filesystem \[468\]](#) to `'utf8'`.

- [character\\_set\\_results \[468\]](#)

<b>Variable Name</b>	character_set_results	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The character set used for returning query results such as result sets or error messages to the client.

- [character\\_set\\_server \[468\]](#)

<b>Command-Line Format</b>	468	--character-set-server
----------------------------	-----	------------------------

<b>Option-File Format</b>	<code>character-set-server</code>	
<b>Option Sets Variable</b>	Yes, <code>character_set_server</code> [468]	
<b>Variable Name</b>	<code>character_set_server</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The server's default character set.

- `character_set_system` [469]

<b>Variable Name</b>	<code>character_set_system</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The character set used by the server for storing identifiers. The value is always `utf8`.

- `character_sets_dir` [469]

<b>Command-Line Format</b>	<code>--character-sets-dir=path</code>	
<b>Option-File Format</b>	<code>character-sets-dir=path</code>	
<b>Option Sets Variable</b>	Yes, <code>character_sets_dir</code> [469]	
<b>Variable Name</b>	<code>character-sets-dir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	directory name

The directory where character sets are installed.

- `collation_connection` [469]

<b>Variable Name</b>	<code>collation_connection</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The collation of the connection character set.

- `collation_database` [469]

<b>Variable Name</b>	<code>collation_database</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	

<b>Footnote</b>	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server` [470].

- `collation_server` [470]

<b>Command-Line Format</b>	<code>--collation-server</code>	
<b>Option-File Format</b>	<code>collation-server</code>	
<b>Option Sets Variable</b>	Yes, <code>collation_server</code> [470]	
<b>Variable Name</b>	<code>collation_server</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The server's default collation.

- `completion_type` [470]

<b>Command-Line Format</b>	<code>--completion_type=#</code>	
<b>Option-File Format</b>	<code>completion_type</code>	
<b>Option Sets Variable</b>	Yes, <code>completion_type</code> [470]	
<b>Variable Name</b>	<code>completion_type</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	NO_CHAIN
	<b>Valid Values</b>	NO_CHAIN CHAIN RELEASE 0 1 2

The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

Value	Description
NO_CHAIN (or 0)	COMMIT and ROLLBACK are unaffected. This is the default value.

Value	Description
CHAIN (or 1)	COMMIT and ROLLBACK are equivalent to COMMIT AND CHAIN and ROLLBACK AND CHAIN, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)
RELEASE (or 2)	COMMIT and ROLLBACK are equivalent to COMMIT RELEASE and ROLLBACK RELEASE, respectively. (The server disconnects after terminating the transaction.)

completion\_type [470] affects transactions that begin with START TRANSACTION or BEGIN and end with COMMIT or ROLLBACK. It does not apply to implicit commits resulting from execution of the statements listed in Section 13.3.3, “Statements That Cause an Implicit Commit”. It also does not apply for XA COMMIT, XA ROLLBACK, or when autocommit=1 [464].

- concurrent\_insert [471]

<b>Command-Line Format</b>	--concurrent_insert[#]	
<b>Option-File Format</b>	concurrent_insert	
<b>Option Sets Variable</b>	Yes, concurrent_insert [471]	
<b>Variable Name</b>	concurrent_insert	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	AUTO
	<b>Valid Values</b>	NEVER AUTO ALWAYS 0 1 2

If AUTO (the default), MySQL permits INSERT and SELECT statements to run concurrently for MyISAM tables that have no free blocks in the middle of the data file. If you start mysqld with --skip-new [516], this variable is set to NEVER.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

Value	Description
NEVER (or 0)	Disables concurrent inserts
AUTO (or 1)	(Default) Enables concurrent insert for MyISAM tables that do not have holes
ALWAYS (or 2)	Enables concurrent inserts for all MyISAM tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.

See also Section 8.10.3, “Concurrent Inserts”.

- [connect\\_timeout \[472\]](#)

<b>Command-Line Format</b>	<code>--connect_timeout=#</code>	
<b>Option-File Format</b>	<code>connect_timeout</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">connect_timeout [472]</a>	
<b>Variable Name</b>	<code>connect_timeout</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>10</code>

The number of seconds that the `mysqld` server waits for a connect packet before responding with `Bad handshake`. The default value is 10 seconds.

Increasing the [connect\\_timeout \[472\]](#) value might help if clients frequently encounter errors of the form `Lost connection to MySQL server at 'XXX', system error: errno`.

- [core\\_file \[472\]](#)

<b>Version Introduced</b>	5.6.2	
<b>Variable Name</b>	<code>core_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Whether to write a core file if the server crashes. This variable is set by the `--core-file [418]` option. It was added in MySQL 5.6.2.

- [datadir \[472\]](#)

<b>Command-Line Format</b>	<code>--datadir=path</code>	
	<code>-h</code>	
<b>Option-File Format</b>	<code>datadir</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">datadir [472]</a>	
<b>Variable Name</b>	<code>datadir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The MySQL data directory. This variable can be set with the `--datadir [418]` option.

- [date\\_format \[472\]](#)

This variable is unused. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- [datetime\\_format \[472\]](#)

This variable is unused. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- [debug \[473\]](#)

<b>Command-Line Format</b>	<code>--debug[=debug_options]</code>	
<b>Option-File Format</b>	<code>debug</code>	
<b>Variable Name</b>	<code>debug</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>'d:t:o,/tmp/mysqld.trace'</code>

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug [418]` option given at server startup. The global and session values may be set at runtime; the [SUPER \[756\]](#) privilege is required, even for the session value.

Assigning a value that begins with `+` or `-` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| P:T     |
+-----+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+
```

- [debug\\_sync \[473\]](#)

<b>Variable Name</b>	<code>debug_sync</code>	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1 [134]` option (see [Section 2.9.4, "MySQL Source-Configuration Options"](#)). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` [473] is `OFF`. If the server is started with `--debug-sync-timeout=N` [419], where *N* is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` [473] is `ON - current signal` followed by the signal name. Also, *N* becomes the default timeout for individual synchronization points.

The session value can be read by any user and will have the same value as the global variable. The session value can be set by users that have the `SUPER` [756] privilege to control synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `default_storage_engine` [474]

<b>Command-Line Format</b>	<code>--default-storage-engine=name</code>	
<b>Option-File Format</b>	<code>default-storage-engine</code>	
<b>Option Sets Variable</b>	Yes, <code>default_storage_engine</code> [474]	
<b>Variable Name</b>	<code>default_storage_engine</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>InnoDB</code>

The default storage engine. As of MySQL 5.6.3, this variable sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` [474] system variable.

`default_storage_engine` [474] should be used in preference to `storage_engine` [549], which is deprecated.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `default_tmp_storage_engine` [474]

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--default_tmp_storage_engine=name</code>	
<b>Option-File Format</b>	<code>default_tmp_storage_engine</code>	
<b>Option Sets Variable</b>	Yes, <code>default_tmp_storage_engine</code> [474]	
<b>Variable Name</b>	<code>default_tmp_storage_engine</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>InnoDB</code>

The default storage engine for `TEMPORARY` tables (created with `CREATE TEMPORARY TABLE`). To set the storage engine for permanent tables, set the `default_storage_engine` [474] system variable.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

`default_tmp_storage_engine` [474] was added in MySQL 5.6.3.

- `default_week_format` [475]

<b>Command-Line Format</b>	<code>--default-week-format=#</code>	
<b>Option-File Format</b>	<code>default-week-format</code>	
<b>Option Sets Variable</b>	Yes, <code>default-week-format</code> [475]	
<b>Variable Name</b>	<code>default-week-format</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 7</code>

The default mode value to use for the `WEEK()` [1228] function. See Section 12.7, “Date and Time Functions”.

- `delay_key_write` [475]

<b>Command-Line Format</b>	<code>--delay-key-write[=name]</code>	
<b>Option-File Format</b>	<code>delay-key-write</code>	
<b>Option Sets Variable</b>	Yes, <code>delay-key-write</code> [475]	
<b>Variable Name</b>	<code>delay-key-write</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>ON</code>
	<b>Valid Values</b>	<code>ON</code> <code>OFF</code> <code>ALL</code>

This option applies only to `MyISAM` tables. It can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

Option	Description
<code>OFF</code>	<code>DELAY_KEY_WRITE</code> is ignored.
<code>ON</code>	MySQL honors any <code>DELAY_KEY_WRITE</code> option specified in <code>CREATE TABLE</code> statements. This is the default value.
<code>ALL</code>	All new opened tables are treated as if they were created with the <code>DELAY_KEY_WRITE</code> option enabled.

If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you

use this feature, you should add automatic checking of all `MyISAM` tables by starting the server with the `--myisam-recover-options` [432] option (for example, `--myisam-recover-options=BACKUP,FORCE` [432]). See Section 5.1.3, “Server Command Options”, and Section 14.3.1, “MyISAM Startup Options”.

### Warning

If you enable external locking with `--external-locking` [422], there is no protection against index corruption for tables that use delayed key writes.

- `delayed_insert_limit` [476]

<b>Version Deprecated</b>	5.6.7
<b>Command-Line Format</b>	<code>--delayed_insert_limit=#</code>
<b>Option-File Format</b>	<code>delayed_insert_limit</code>
<b>Option Sets Variable</b>	Yes, <code>delayed_insert_limit</code> [476]
<b>Variable Name</b>	<code>delayed_insert_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.6.7
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 32
	<b>Type</b> <code>numeric</code>
	<b>Default</b> 100
	<b>Range</b> 1 .. 4294967295
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 64
	<b>Type</b> <code>numeric</code>
	<b>Default</b> 100
	<b>Range</b> 1 .. 18446744073709547520

After inserting `delayed_insert_limit` [476] delayed rows into a nontransactional table, the `INSERT DELAYED` handler thread checks whether there are any `SELECT` statements pending. If so, it permits them to execute before continuing to insert delayed rows.

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `delayed_insert_timeout` [476]

<b>Version Deprecated</b>	5.6.7
<b>Command-Line Format</b>	<code>--delayed_insert_timeout=#</code>
<b>Option-File Format</b>	<code>delayed_insert_timeout</code>
<b>Option Sets Variable</b>	Yes, <code>delayed_insert_timeout</code> [476]
<b>Variable Name</b>	<code>delayed_insert_timeout</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.6.7

	<b>Permitted Values</b>	
<b>Type</b>	numeric	
<b>Default</b>	300	

How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `delayed_queue_size` [477]

<b>Version Deprecated</b>	5.6.7	
<b>Command-Line Format</b>	<code>--delayed_queue_size=#</code>	
<b>Option-File Format</b>	<code>delayed_queue_size</code>	
<b>Option Sets Variable</b>	Yes, <code>delayed_queue_size</code> [477]	
<b>Variable Name</b>	<code>delayed_queue_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.6.7	
	<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32	
<b>Type</b>	numeric	
<b>Default</b>	1000	
<b>Range</b>	1 .. 4294967295	
	<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64	
<b>Type</b>	numeric	
<b>Default</b>	1000	
<b>Range</b>	1 .. 18446744073709547520	

This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements for nontransactional tables. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `disconnect_on_expired_passwords` [477]

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--disconnect_on_expired_passwords=#</code>	
<b>Option-File Format</b>	<code>disconnect_on_expired_passwords</code>	
<b>Option Sets Variable</b>	Yes, <code>disconnect_on_expired_passwords</code> [477]	
<b>Variable Name</b>	<code>disconnect_on_expired_passwords</code>	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	No	

	<b>Permitted Values</b>	
<b>Type</b>	boolean	
<b>Default</b>	ON	

This variable controls how the server handles clients with expired passwords:

- If the client indicates that it can handle expires passwords, the value of `disconnect_on_expired_passwords` [477] is irrelevant. The server permits the client to connect but puts it in sandbox mode.
- If the client does not indicate that it can handle expires passwords, the server handles the client according to the value of `disconnect_on_expired_passwords` [477]:
  - If `disconnect_on_expired_passwords` [477]: is enabled, the server disconnects the client.
  - If `disconnect_on_expired_passwords` [477]: is disabled, the server permits the client to connect but puts it in sandbox mode.

For more information about the interaction of client and server settings relating to expired-password handling, see [Section 6.3.6, “Password Expiration and Sandbox Mode”](#).

This variable was added in MySQL 5.6.10.

- `div_precision_increment` [478]

<b>Command-Line Format</b>	<code>--div_precision_increment=#</code>
<b>Option-File Format</b>	<code>div_precision_increment</code>
<b>Option Sets Variable</b>	Yes, <code>div_precision_increment</code> [478]
<b>Variable Name</b>	<code>div_precision_increment</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	4
<b>Range</b>	0 .. 30

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` [1200] operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+-----+
| 1/7   |
+-----+
| 0.1429 |
+-----+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+-----+
| 1/7   |
+-----+
| 0.142857142857 |
+-----+
```

- `engine_condition_pushdown` [478]

<b>Version Removed</b>	5.6.1	
<b>Command-Line Format</b>	<code>--engine-condition-pushdown</code>	
<b>Option-File Format</b>	<code>engine-condition-pushdown</code>	
<b>Option Sets Variable</b>	Yes, <code>engine_condition_pushdown</code> [478]	
<b>Variable Name</b>	<code>engine_condition_pushdown</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.5.3, by <code>optimizer_switch</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

This variable was removed in MySQL 5.6.1. Use the `engine_condition_pushdown` flag of the `optimizer_switch` [520] variable instead. See Section 8.8.5.2, “Controlling Switchable Optimizations”.

- `end_markers_in_json` [479]

<b>Version Introduced</b>	5.6.5	
<b>Variable Name</b>	<code>end_markers_in_json</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Whether optimizer JSON output should add end markers.

- `eq_range_index_dive_limit` [479]

<b>Version Introduced</b>	5.6.5	
<b>Command-Line Format</b>	<code>--eq_range_index_dive_limit=#</code>	
<b>Option-File Format</b>	<code>eq_range_index_dive_limit</code>	
<b>Option Sets Variable</b>	Yes, <code>eq_range_index_dive_limit</code> [479]	
<b>Variable Name</b>	<code>eq_range_index_dive_limit</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>10</code>
	<b>Range</b>	<code>0 .. 4294967295</code>

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up `col_name` values:

```
col_name IN(val1, ..., valN)
```

```
col_name = val1 OR ... OR col_name = valN
```

In both cases, the expression contains  $N$  equality ranges. The optimizer can make row estimates using index dives or index statistics. If `eq_range_index_dive_limit` [479] is greater than 0, the optimizer uses existing index statistics instead of index dives if there are `eq_range_index_dive_limit` [479] or more equality ranges. Thus, to permit use of index dives for up to  $N$  equality ranges, set `eq_range_index_dive_limit` [479] to  $N + 1$ . Set `eq_range_index_dive_limit` [479] to 0 to disable use of index statistics and always use index dives regardless of  $N$ .

For more information, see [Section 8.13.1.3, “Equality Range Optimization of Many-Valued Comparisons”](#).

This variable was added in MySQL 5.6.5. Before 5.6.5, the optimizer makes row estimates using index dives in all cases.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

- `error_count` [480]

The number of errors that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.5.18, “SHOW ERRORS Syntax”](#).

- `event_scheduler` [480]

<b>Command-Line Format</b>	<code>--event-scheduler[=value]</code>	
<b>Option-File Format</b>	<code>event-scheduler</code>	
<b>Option Sets Variable</b>	Yes, <code>event_scheduler</code> [480]	
<b>Variable Name</b>	<code>event_scheduler</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	OFF
	<b>Valid Values</b>	ON OFF DISABLED

This variable indicates the status of the Event Scheduler; possible values are `ON`, `OFF`, and `DISABLED`, with the default being `OFF`. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in the [Overview section of the Events chapter \[2159\]](#).

- `expire_logs_days` [480]

<b>Command-Line Format</b>	<code>--expire_logs_days=#</code>	
<b>Option-File Format</b>	<code>expire_logs_days</code>	
<b>Option Sets Variable</b>	Yes, <code>expire_logs_days</code> [480]	
<b>Variable Name</b>	<code>expire_logs_days</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric

<b>Default</b>	0
<b>Range</b>	0 .. 99

The number of days for automatic binary log file removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in [Section 5.2, “MySQL Server Logs”](#).

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

- `explicit_defaults_for_timestamp` [481]

<b>Version Introduced</b>	5.6.6	
<b>Command-Line Format</b>	<code>--explicit_defaults_for_timestamp=#</code>	
<b>Option-File Format</b>	<code>explicit_defaults_for_timestamp</code>	
<b>Option Sets Variable</b>	Yes, <code>explicit_defaults_for_timestamp</code> [481]	
<b>Variable Name</b>	<code>explicit_defaults_for_timestamp</code>	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types:

- `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are assigned the `NOT NULL` attribute. (Columns of other data types, if not explicitly declared as `NOT NULL`, permit `NULL` values.) Setting such a column to `NULL` sets it to the current timestamp.
- The first `TIMESTAMP` column in a table, if not declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` clause, is automatically assigned the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.
- `TIMESTAMP` columns following the first one, if not declared with the `NULL` attribute or an explicit `DEFAULT` clause, are automatically assigned `DEFAULT '0000-00-00 00:00:00'` (the “zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

Those nonstandard behaviors remain the default for `TIMESTAMP` but as of MySQL 5.6.6 are deprecated and this warning appears at startup:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see
documentation for more details).
```

As indicated by the warning, to turn off the nonstandard behaviors, enable the new `explicit_defaults_for_timestamp` [481] system variable at server startup. With this variable enabled, the server handles `TIMESTAMP` as follows instead:

- `TIMESTAMP` columns not explicitly declared as `NOT NULL` permit `NULL` values. Setting such a column to `NULL` sets it to `NULL`, not the current timestamp.
- No `TIMESTAMP` column is assigned the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes automatically. Those attributes must be explicitly specified.

- `TIMESTAMP` columns declared as `NOT NULL` and without an explicit `DEFAULT` clause are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is assigned the implicit default of `'0000-00-00 00:00:00'` and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.

This variable was added in MySQL 5.6.6.

- `external_user` [482]

<b>Variable Name</b>	<code>external_user</code>	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. See [Section 6.3.8, “Proxy Users”](#).

- `flush` [482]

<b>Command-Line Format</b>	<code>--flush</code>	
<b>Option-File Format</b>	<code>flush</code>	
<b>Variable Name</b>	<code>flush</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section C.5.4.2, “What to Do If MySQL Keeps Crashing”](#). This variable is set to `ON` if you start `mysqld` with the `--flush` [423] option.

- `flush_time` [482]

<b>Command-Line Format</b>	<code>--flush_time=#</code>	
<b>Option-File Format</b>	<code>flush_time</code>	
<b>Option Sets Variable</b>	Yes, <code>flush_time</code> [482]	
<b>Variable Name</b>	<code>flush_time</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b> (windows)	<code>numeric</code>
	<b>Default</b>	<code>1800</code>

	<b>Min Value</b>	0
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b> (windows)	numeric
	<b>Default</b>	0
	<b>Min Value</b>	0

If this is set to a nonzero value, all tables are closed every `flush_time` [482] seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources. The default is 0 except that before MySQL 5.6.6, the default is 1800 on Windows.

- `foreign_key_checks` [483]

If set to 1 (the default), `foreign key` constraints for `InnoDB` tables are checked. If set to 0, they are ignored. Typically you leave this setting enabled during normal operation, to enforce `referential integrity`. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See [Section 5.4.5, “InnoDB and FOREIGN KEY Constraints”](#).

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

#### Note

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` [483] will not be verified for consistency.

- `ft_boolean_syntax` [483]

<b>Command-Line Format</b>	<code>--ft_boolean_syntax=name</code>	
<b>Option-File Format</b>	<code>ft_boolean_syntax</code>	
<b>Variable Name</b>	<code>ft_boolean_syntax</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	<code>+-&gt;&lt;()~*:""&amp;</code>

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See [Section 12.9.2, “Boolean Full-Text Searches”](#).

The default variable value is `'+-><()~*:""&|'`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.
- Either the first or second character must be a space.

- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to “:”, “&”, and “|”) are reserved for future extensions.
- `ft_max_word_len` [484]

<b>Command-Line Format</b>	<code>--ft_max_word_len=#</code>	
<b>Option-File Format</b>	<code>ft_max_word_len</code>	
<b>Option Sets Variable</b>	Yes, <code>ft_max_word_len</code> [484]	
<b>Variable Name</b>	<code>ft_max_word_len</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Min Value</b>	10

The maximum length of the word to be included in a `MyISAM FULLTEXT` index.

**Note**

`FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_min_word_len` [484]

<b>Command-Line Format</b>	<code>--ft_min_word_len=#</code>	
<b>Option-File Format</b>	<code>ft_min_word_len</code>	
<b>Option Sets Variable</b>	Yes, <code>ft_min_word_len</code> [484]	
<b>Variable Name</b>	<code>ft_min_word_len</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	4
	<b>Min Value</b>	1

The minimum length of the word to be included in a `MyISAM FULLTEXT` index.

**Note**

`FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_query_expansion_limit` [484]

<b>Command-Line Format</b>	<code>--ft_query_expansion_limit=#</code>
<b>Option-File Format</b>	<code>ft_query_expansion_limit</code>

<b>Option Sets Variable</b>	Yes, <code>ft_query_expansion_limit</code> [484]	
<b>Variable Name</b>	<code>ft_query_expansion_limit</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>20</code>
	<b>Range</b>	<code>0 .. 1000</code>

The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`.

- `ft_stopword_file` [485]

<b>Command-Line Format</b>	<code>--ft_stopword_file=file_name</code>	
<b>Option-File Format</b>	<code>ft_stopword_file=file_name</code>	
<b>Option Sets Variable</b>	Yes, <code>ft_stopword_file</code> [485]	
<b>Variable Name</b>	<code>ft_stopword_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The file from which to read the list of stopwords for full-text searches on `MyISAM` tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string ( `'` ) disables stopwords filtering. See also [Section 12.9.4, “Full-Text Stopwords”](#).

#### Note

`FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable or the contents of the stopwords file. Use `REPAIR TABLE tbl_name QUICK`.

- `general_log` [485]

<b>Command-Line Format</b>	<code>--general-log</code>	
<b>Option-File Format</b>	<code>general-log</code>	
<b>Option Sets Variable</b>	Yes, <code>general_log</code> [485]	
<b>Variable Name</b>	<code>general_log</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Whether the general query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--general_log` [485] option is given. The destination for log output is controlled by the `log_output` [498] system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- [general\\_log\\_file \[486\]](#)

<b>Command-Line Format</b>	<code>--general-log-file=file_name</code>	
<b>Option-File Format</b>	<code>general_log_file</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">general_log_file [486]</a>	
<b>Variable Name</b>	<code>general_log_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>host_name.log</code>

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general_log_file [486]` option.

- [group\\_concat\\_max\\_len \[486\]](#)

<b>Command-Line Format</b>	<code>--group_concat_max_len=#</code>	
<b>Option-File Format</b>	<code>group_concat_max_len</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">group_concat_max_len [486]</a>	
<b>Variable Name</b>	<code>group_concat_max_len</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	1024
	<b>Range</b>	4 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	1024
	<b>Range</b>	4 .. 18446744073709547520

The maximum permitted result length in bytes for the `GROUP_CONCAT()` [1283] function. The default is 1024.

- [have\\_compress \[486\]](#)

`YES` if the `zlib` compression library is available to the server, `NO` if not. If not, the `COMPRESS()` [1261] and `UNCOMPRESS()` [1265] functions cannot be used.

- [have\\_crypt \[486\]](#)

`YES` if the `crypt()` system call is available to the server, `NO` if not. If not, the `ENCRYPT()` [1262] function cannot be used.

- [have\\_csv \[486\]](#)

YES if `mysqld` supports CSV tables, NO if not.

This variable was removed in MySQL 5.6.1. Use `SHOW ENGINES` instead.

- `have_dynamic_loading` [487]

YES if `mysqld` supports dynamic loading of plugins, NO if not.

- `have_geometry` [487]

YES if the server supports spatial data types, NO if not.

- `have_innodb` [487]

YES if `mysqld` supports InnoDB tables. DISABLED if `--skip-innodb` [1698] is used.

This variable was removed in MySQL 5.6.1. Use `SHOW ENGINES` instead.

- `have_openssl` [487]

This variable is an alias for `have_ssl` [487].

- `have_partitioning` [487]

YES if `mysqld` supports partitioning.

This variable was removed in MySQL 5.6.1. Use `SHOW ENGINES` instead.

- `have_profiling` [487]

YES if statement profiling capability is present, NO if not. If present, the `profiling` system variable controls whether this capability is enabled or disabled. See [Section 13.7.5.32, "SHOW PROFILES Syntax"](#).

This variable is deprecated in MySQL 5.6.8 and will be removed in a future MySQL release.

- `have_query_cache` [487]

YES if `mysqld` supports the query cache, NO if not.

- `have_rtree_keys` [487]

YES if RTREE indexes are available, NO if not. (These are used for spatial indexes in MyISAM tables.)

- `have_ssl` [487]

YES if `mysqld` supports SSL connections, NO if not. DISABLED indicates that the server was compiled with SSL support, but was not started with the appropriate `--ssl-xxx` options. For more information, see [Section 6.3.9.2, "Configuring MySQL for SSL"](#).

- `have_symlink` [487]

YES if symbolic link support is enabled, NO if not. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options, and on Windows for support of data directory symlinks. If the server is started with the `--skip-symbolic-links` [441] option, the value is DISABLED.

- `host_cache_size` [487]

<b>Version Introduced</b>	5.6.5
<b>Command-Line Format</b>	<code>--host_cache_size=#</code>
<b>Option-File Format</b>	<code>host_cache_size</code>

<b>Option Sets Variable</b>	Yes, <a href="#">host_cache_size</a> [487]	
<b>Variable Name</b>	<a href="#">host_cache_size</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.7)</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	128
	<b>Range</b>	0 .. 65536
	<b>Permitted Values (&gt;= 5.6.8)</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	-1 (autosized)
	<b>Range</b>	0 .. 65536

The size of the internal host cache (see [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#)). Setting the size to 0 disables the host cache. Changing the cache size at runtime implicitly causes a `FLUSH HOSTS` operation to clear the host cache and truncate the `host_cache` table.

The default value is 128, plus 1 for a value of `max_connections` [503] up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` [503] value, capped to a limit of 2000. Before MySQL 5.6.8, the default is 128.

Use of `--skip-host-cache` [439] is similar to setting the `host_cache_size` [487] system variable to 0, but `host_cache_size` [487] is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

If you start the server with `--skip-host-cache` [439], that does not prevent changes to the value of `host_cache_size` [487], but such changes have no effect and the cache is not re-enabled even if `host_cache_size` [487] is set larger than 0.

This variable was added in MySQL 5.6.5.

- [hostname](#) [488]

<b>Variable Name</b>	<a href="#">hostname</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">string</a>

The server sets this variable to the server host name at startup.

- [identity](#) [488]

This variable is a synonym for the `last_insert_id` [495] variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- [ignore\\_db\\_dirs](#) [488]

<b>Version Introduced</b>	5.6.3
<b>Variable Name</b>	<a href="#">ignore_db_dirs</a>
<b>Variable Scope</b>	Global

<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	string

A comma-separated list of names that are not considered as database directories in the data directory. The value is set from any instances of `--ignore-db-dir` [424] given at server startup.

This variable was added in MySQL 5.6.3.

- [init\\_connect](#) [489]

<b>Command-Line Format</b>	<code>--init-connect=name</code>	
<b>Option-File Format</b>	<code>init_connect</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">init_connect</a> [489]	
<b>Variable Name</b>	<code>init_connect</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters. For example, each client session begins by default with autocommit mode enabled. For older servers (before MySQL 5.5.8), there is no global [autocommit](#) [464] system variable to specify that autocommit should be disabled by default, but as a workaround [init\\_connect](#) [489] can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET autocommit=0';
```

The [init\\_connect](#) [489] variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

The content of [init\\_connect](#) [489] is not executed for users that have the [SUPER](#) [756] privilege. This is done so that an erroneous value for [init\\_connect](#) [489] does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing [init\\_connect](#) [489] for users that have the [SUPER](#) [756] privilege enables them to open a connection and fix the [init\\_connect](#) [489] value.

- [init\\_file](#) [489]

<b>Command-Line Format</b>	<code>--init-file=file_name</code>	
<b>Option-File Format</b>	<code>init-file=file_name</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">init_file</a> [489]	
<b>Variable Name</b>	<code>init_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

The name of the file specified with the `--init-file` [424] option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. No statement terminator such as `;`, `\g`, or `\G` should be given at the end of each statement.

- `innodb_xxx`

InnoDB system variables are listed in [Section 14.2.6, “InnoDB Startup Options and System Variables”](#). These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that [InnoDB is the default storage engine](#).

- `insert_id` [490]

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `interactive_timeout` [490]

<b>Command-Line Format</b>	<code>--interactive_timeout=#</code>
<b>Option-File Format</b>	<code>interactive_timeout</code>
<b>Option Sets Variable</b>	Yes, <code>interactive_timeout</code> [490]
<b>Variable Name</b>	<code>interactive_timeout</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 28800
	<b>Min Value</b> 1

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout` [563].

- `join_buffer_size` [490]

<b>Command-Line Format</b>	<code>--join_buffer_size=#</code>
<b>Option-File Format</b>	<code>join_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <code>join_buffer_size</code> [490]
<b>Variable Name</b>	<code>join_buffer_size</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&gt;= 5.6.0, &lt;= 5.6.5)</b>
	<b>Platform Bit Size</b> 64
	<b>Type</b> numeric
	<b>Default</b> 131072
	<b>Range</b> 128 .. 18446744073709547520
	<b>Permitted Values (&gt;= 5.6.0, &lt;= 5.6.5)</b>

	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	131072
	<b>Range</b>	128 .. 4294967295
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	262144
	<b>Range</b>	128 .. 4294967295
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	262144
	<b>Range</b>	128 .. 18446744073709547520

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` [490] to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary. There is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

The default is 256KB as of MySQL 5.6.6, 128KB before that. The maximum permissible setting for `join_buffer_size` [490] is 4GB. Values larger than 4GB are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

For additional information about join buffering, see [Section 8.13.8, “Nested-Loop Join Algorithms”](#).

- `keep_files_on_create` [491]

<b>Command-Line Format</b>	<code>--keep_files_on_create=#</code>	
<b>Option-File Format</b>	<code>keep_files_on_create</code>	
<b>Option Sets Variable</b>	Yes, <code>keep_files_on_create</code> [491]	
<b>Variable Name</b>	<code>keep_files_on_create</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	OFF

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this

behavior, set the `keep_files_on_create` [491] variable to `ON` (1), in which case `MyISAM` will not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

- `key_buffer_size` [492]

<b>Command-Line Format</b>	<code>--key_buffer_size=#</code>
<b>Option-File Format</b>	<code>key_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <code>key_buffer_size</code> [492]
<b>Variable Name</b>	<code>key_buffer_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 32
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>8388608</code>
	<b>Range</b> <code>8 .. 4294967295</code>

Index blocks for `MyISAM` tables are buffered and are shared by all threads.

`key_buffer_size` [492] is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for `key_buffer_size` [492] is 4GB on 32-bit platforms. Values larger than 4GB are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the `MyISAM` storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to `MyISAM`.

For even more speed when writing many rows at the same time, use `LOCK TABLES`. See [Section 8.2.2.1, "Speed of INSERT Statements"](#).

You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests` [594], `Key_reads` [594], `Key_write_requests` [594], and `Key_writes` [594] status variables. (See [Section 13.7.5, "SHOW Syntax"](#).) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` [492] in conjunction with the `Key_blocks_unused` [594] status variable and the buffer block size, which is available from the `key_cache_block_size` [493] system variable:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple `MyISAM` key caches. The size limit of 4GB applies to each cache individually, not as a group. See [Section 8.9.2, “The `MyISAM` Key Cache”](#).

- `key_cache_age_threshold` [493]

<b>Command-Line Format</b>	<code>--key_cache_age_threshold=#</code>
<b>Option-File Format</b>	<code>key_cache_age_threshold</code>
<b>Option Sets Variable</b>	Yes, <code>key_cache_age_threshold</code> [493]
<b>Variable Name</b>	<code>key_cache_age_threshold</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 32
	<b>Type</b> numeric
	<b>Default</b> 300
	<b>Range</b> 100 .. 4294967295
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 64
	<b>Type</b> numeric
	<b>Default</b> 300
	<b>Range</b> 100 .. 18446744073709547520

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See [Section 8.9.2, “The `MyISAM` Key Cache”](#).

- `key_cache_block_size` [493]

<b>Command-Line Format</b>	<code>--key_cache_block_size=#</code>
<b>Option-File Format</b>	<code>key_cache_block_size</code>
<b>Option Sets Variable</b>	Yes, <code>key_cache_block_size</code> [493]
<b>Variable Name</b>	<code>key_cache_block_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>

	<b>Type</b>	numeric
	<b>Default</b>	1024
	<b>Range</b>	512 .. 16384

The size in bytes of blocks in the key cache. The default value is 1024. See [Section 8.9.2, “The MyISAM Key Cache”](#).

- [key\\_cache\\_division\\_limit \[494\]](#)

<b>Command-Line Format</b>	<code>--key_cache_division_limit=#</code>	
<b>Option-File Format</b>	<code>key_cache_division_limit</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">key_cache_division_limit [494]</a>	
<b>Variable Name</b>	<code>key_cache_division_limit</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	100
	<b>Range</b>	1 .. 100

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See [Section 8.9.2, “The MyISAM Key Cache”](#).

- [large\\_files\\_support \[494\]](#)

<b>Variable Name</b>	<code>large_files_support</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

Whether `mysqld` was compiled with options for large file support.

- [large\\_pages \[494\]](#)

<b>Command-Line Format</b>	<code>--large-pages</code>	
<b>Option-File Format</b>	<code>large-pages</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">large_pages [494]</a>	
<b>Variable Name</b>	<code>large_pages</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Platform Specific</b>	linux	
	<b>Permitted Values</b>	
	<b>Type</b> (linux)	boolean
	<b>Default</b>	FALSE

Whether large page support is enabled (via the `--large-pages [425]` option). See [Section 8.11.4.2, “Enabling Large Page Support”](#).

- [large\\_page\\_size \[494\]](#)

<b>Variable Name</b>	<code>large_page_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type (linux)</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>

If large page support is enabled, this shows the size of memory pages. Currently, large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See [Section 8.11.4.2, “Enabling Large Page Support”](#).

- `last_insert_id` [\[495\]](#)

The value to be returned from `LAST_INSERT_ID()` [\[1269\]](#). This is stored in the binary log when you use `LAST_INSERT_ID()` [\[1269\]](#) in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `lc_messages` [\[495\]](#)

<b>Command-Line Format</b>	<code>--lc-messages=name</code>	
<b>Option-File Format</b>	<code>lc-messages</code>	
<b>Option Sets Variable</b>	Yes, <code>lc_messages</code> <a href="#">[495]</a>	
<b>Variable Name</b>	<code>lc-messages</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The locale to use for error messages. The server converts the value to a language name and combines it with the value of the `lc_messages_dir` [\[495\]](#) to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `lc_messages_dir` [\[495\]](#)

<b>Command-Line Format</b>	<code>--lc-messages-dir=path</code>	
<b>Option-File Format</b>	<code>lc-messages-dir</code>	
<b>Option Sets Variable</b>	Yes, <code>lc_messages_dir</code> <a href="#">[495]</a>	
<b>Variable Name</b>	<code>lc-messages-dir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>

The directory where error messages are located. The value is used together with the value of `lc_messages` [\[495\]](#) to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `lc_time_names` [\[495\]](#)

<b>Variable Name</b>	<code>lc_time_names</code>
----------------------	----------------------------

<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	string

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()` [1215], `DAYNAME()` [1217] and `MONTHNAME()` [1220] functions. Locale names are POSIX-style values such as 'ja\_JP' or 'pt\_BR'. The default value is 'en\_US' regardless of your system's locale setting. For further information, see [Section 10.7, “MySQL Server Locale Support”](#).

- [license](#) [496]

<b>Variable Name</b>	license	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	string
	<b>Default</b>	GPL

The type of license the server has.

- [local\\_infile](#) [496]

<b>Variable Name</b>	local_infile	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean

Whether `LOCAL` is supported for `LOAD DATA INFILE` statements. If this variable is disabled, clients cannot use `LOCAL` in `LOAD DATA` statements. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

- [lock\\_wait\\_timeout](#) [496]

<b>Command-Line Format</b>	--lock_wait_timeout=#	
<b>Option-File Format</b>	lock_wait_timeout	
<b>Option Sets Variable</b>	Yes, <a href="#">lock_wait_timeout</a> [496]	
<b>Variable Name</b>	lock_wait_timeout	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	31536000
	<b>Range</b>	1 .. 31536000

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as `LOCK TABLES`, `FLUSH TABLES WITH READ LOCK`, and `HANDLER` statements.

This timeout does not apply to implicit accesses to system tables in the `mysql` database, such as grant tables modified by `GRANT` or `REVOKE` statements or table logging statements. The timeout does apply to system tables accessed directly, such as with `SELECT` or `UPDATE`.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the `lock_wait_timeout` [496] value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` [3674] is reported.

`lock_wait_timeout` [496] does not apply to delayed inserts, which always execute with a timeout of 1 year. This is done to avoid unnecessary timeouts because a session that issues a delayed insert receives no notification of delayed insert timeouts.

- `locked_in_memory` [497]

<b>Variable Name</b>	<code>locked_in_memory</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

Whether `mysqld` was locked in memory with `--memlock` [431].

- `log` [497]

This variable removed in MySQL 5.6.1. Use `general_log` [485] instead.

- `log_bin_trust_function_creators` [497]

<b>Command-Line Format</b>	<code>--log-bin-trust-function-creators</code>	
<b>Option-File Format</b>	<code>log-bin-trust-function-creators</code>	
<b>Option Sets Variable</b>	Yes, <code>log_bin_trust_function_creators</code> [497]	
<b>Variable Name</b>	<code>log_bin_trust_function_creators</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` [756] privilege in addition to the `CREATE ROUTINE` [754] or `ALTER ROUTINE` [754] privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See [Section 18.7, “Binary Logging of Stored Programs”](#).

- `log_error` [497]

<b>Command-Line Format</b>	<code>--log-error[=name]</code>
<b>Option-File Format</b>	<code>log-error</code>

<b>Option Sets Variable</b>	Yes, <code>log_error</code> [497]	
<b>Variable Name</b>	<code>log_error</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The location of the error log.

- `log_output` [498]

<b>Command-Line Format</b>	<code>--log-output=name</code>	
<b>Option-File Format</b>	<code>log-output</code>	
<b>Option Sets Variable</b>	Yes, <code>log_output</code> [498]	
<b>Variable Name</b>	<code>log_output</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>set</code>
	<b>Default</b>	<code>FILE</code>
	<b>Valid Values</b>	<code>TABLE</code> <code>FILE</code> <code>NONE</code>

The destination for general query log and slow query log output. The value can be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). The default value is `FILE`. `NONE`, if present, takes precedence over any other specifiers. If the value is `NONE` log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of `log_output` [498] is not `NONE`. For more information, see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

- `log_queries_not_using_indexes` [498]

<b>Command-Line Format</b>	<code>--log-queries-not-using-indexes</code>	
<b>Option-File Format</b>	<code>log-queries-not-using-indexes</code>	
<b>Option Sets Variable</b>	Yes, <code>log_queries_not_using_indexes</code> [498]	
<b>Variable Name</b>	<code>log_queries_not_using_indexes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Whether queries that do not use indexes are logged to the slow query log. See [Section 5.2.5, “The Slow Query Log”](#).

- `log_slow_admin_statements` [498]

<b>Version Introduced</b>	5.6.11	
<b>Variable Name</b>	<code>log_slow_admin_statements</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Log slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log. This variable was added in MySQL 5.6.11.

- [log\\_slow\\_queries \[499\]](#)

<b>Version Removed</b>	5.6.1	
<b>Command-Line Format</b>	<code>--log-slow-queries[=name]</code>	
<b>Option-File Format</b>	<code>log-slow-queries</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">log_slow_queries [499]</a>	
<b>Variable Name</b>	<code>log_slow_queries</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.1.29, by <code>slow-query-log</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>

This variable was removed in MySQL 5.6.1. Use [slow\\_query\\_log \[541\]](#) instead.

- [log\\_throttle\\_queries\\_not\\_using\\_indexes \[499\]](#)

<b>Version Introduced</b>	5.6.5	
<b>Variable Name</b>	<code>log_throttle_queries_not_using_indexes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>

If [log\\_queries\\_not\\_using\\_indexes \[498\]](#) is enabled, the [log\\_throttle\\_queries\\_not\\_using\\_indexes \[499\]](#) variable limits the number of such queries per minute that can be written to the slow query log. A value of 0 (the default) means “no limit”. For more information, see [Section 5.2.5, “The Slow Query Log”](#).

This variable was added in MySQL 5.6.5.

- [log\\_warnings \[499\]](#)

<b>Command-Line Format</b>	<code>--log-warnings[=#]</code>
	<code>-W [#]</code>
<b>Option-File Format</b>	<code>log-warnings</code>

<b>Option Sets Variable</b>	Yes, <a href="#">log_warnings</a> [499]
<b>Variable Name</b>	<code>log_warnings</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Disabled by</b>	<code>skip-log-warnings</code>
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	1
<b>Range</b>	0 .. 18446744073709547520

Whether to produce additional warning messages to the error log. It is enabled (1) by default and can be disabled by setting it to 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1. The server logs messages about statements that are unsafe for statement-based logging only if the value is greater than 0.

- [long\\_query\\_time](#) [500]

<b>Command-Line Format</b>	<code>--long_query_time=#</code>
<b>Option-File Format</b>	<code>long_query_time</code>
<b>Option Sets Variable</b>	Yes, <a href="#">long_query_time</a> [500]
<b>Variable Name</b>	<code>long_query_time</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	10
<b>Min Value</b>	0

If a query takes longer than this many seconds, the server increments the [Slow\\_queries](#) [599] status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of [long\\_query\\_time](#) [500] are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored. See [Section 5.2.5, “The Slow Query Log”](#).

- [low\\_priority\\_updates](#) [500]

<b>Command-Line Format</b>	<code>--low-priority-updates</code>
<b>Option-File Format</b>	<code>low-priority-updates</code>
<b>Option Sets Variable</b>	Yes, <a href="#">low_priority_updates</a> [500]
<b>Variable Name</b>	<code>low_priority_updates</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>

	<b>Type</b>	boolean
	<b>Default</b>	FALSE

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `lower_case_file_system` [501]

<b>Command-Line Format</b>	<code>--lower_case_file_system[=#]</code>	
<b>Option-File Format</b>	<code>lower_case_file_system</code>	
<b>Option Sets Variable</b>	Yes, <code>lower_case_file_system</code> [501]	
<b>Variable Name</b>	<code>lower_case_file_system</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case sensitive, `ON` means they are not case sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names` [501]

<b>Command-Line Format</b>	<code>--lower_case_table_names[=#]</code>	
<b>Option-File Format</b>	<code>lower_case_table_names</code>	
<b>Option Sets Variable</b>	Yes, <code>lower_case_table_names</code> [501]	
<b>Variable Name</b>	<code>lower_case_table_names</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 2

If set to 0, table names are stored as specified and comparisons are case sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional information, see [Section 9.2.2, “Identifier Case Sensitivity”](#).

You should *not* set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or Mac OS X). If you set this variable to 0 on such a system and access `MyISAM` table names using different lettercases, index corruption may result. On Windows the default value is 1. On Mac OS X, the default value is 2.

If you are using `InnoDB` tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable in MySQL 5.6 affects the behavior of replication filtering options with regard to case sensitivity. This is a change from previous versions of MySQL. (Bug #51639) See [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

In previous versions of MySQL, using different settings for `lower_case_table_names` on replication masters and slaves could cause replication to fail when the slave used a case-sensitive file system. This issue is resolved in MySQL 5.6.1. For more information, see [Section 16.4.1.32, “Replication and Variables”](#).

- `max_allowed_packet` [\[502\]](#)

<b>Command-Line Format</b>	<code>--max_allowed_packet=#</code>	
<b>Option-File Format</b>	<code>max_allowed_packet</code>	
<b>Option Sets Variable</b>	Yes, <code>max_allowed_packet</code> <a href="#">[502]</a>	
<b>Variable Name</b>	<code>max_allowed_packet</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1048576</code>
	<b>Range</b>	<code>1024 .. 1073741824</code>
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>4194304</code>
	<b>Range</b>	<code>1024 .. 1073741824</code>

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 4MB as of MySQL 5.6.6, 1MB before that.

The packet message buffer is initialized to `net_buffer_length` [\[515\]](#) bytes, but can grow up to `max_allowed_packet` [\[502\]](#) bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` [\[502\]](#) is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` [\[502\]](#) variable, you should also change the buffer size on the client side if your client program permits it. On the client side, `max_allowed_packet` [\[502\]](#) has a default of 1GB. Some programs such as `mysql` and `mysqldump` enable you to change the client-side value by setting `max_allowed_packet` [\[502\]](#) on the command line or in an option file.

The session value of this variable is read only.

- `max_connect_errors` [\[502\]](#)

<b>Command-Line Format</b>	<code>--max_connect_errors=#</code>	
<b>Option-File Format</b>	<code>max_connect_errors</code>	
<b>Option Sets Variable</b>	Yes, <code>max_connect_errors</code> <a href="#">[502]</a>	
<b>Variable Name</b>	<code>max_connect_errors</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.5)</b>	

	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	1 .. 4294967295
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	1 .. 18446744073709547520
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	100
	<b>Range</b>	1 .. 4294967295
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	100
	<b>Range</b>	1 .. 18446744073709547520

If more than this many successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. You can unblock blocked hosts by flushing the host cache. To do so, issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command. If a connection is established successfully within fewer than `max_connect_errors` [502] attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, flushing the host cache is the only way to unblock it. The default is 100 as of MySQL 5.6.6, 10 before that.

- `max_connections` [503]

<b>Command-Line Format</b>	<code>--max_connections=#</code>	
<b>Option-File Format</b>	<code>max_connections</code>	
<b>Option Sets Variable</b>	Yes, <code>max_connections</code> [503]	
<b>Variable Name</b>	<code>max_connections</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	151
	<b>Range</b>	1 .. 100000

The maximum permitted number of simultaneous client connections. By default, this is 151. See [Section C.5.2.7, “Too many connections”](#), for more information.

Increasing this value increases the number of file descriptors that `mysqld` requires. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#), for comments on file descriptor limits.

Connections refused because the `max_connections` [503] limit is reached increment the `Connection_errors_max_connections` [587] status variable.

- `max_delayed_threads` [504]

<b>Version Deprecated</b>	5.6.7	
<b>Command-Line Format</b>	<code>--max_delayed_threads=#</code>	
<b>Option-File Format</b>	<code>max_delayed_threads</code>	
<b>Option Sets Variable</b>	Yes, <code>max_delayed_threads</code> [504]	
<b>Variable Name</b>	<code>max_delayed_threads</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.6.7	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>20</code>
	<b>Range</b>	<code>0 .. 16384</code>

Do not start more than this number of threads to handle `INSERT DELAYED` statements for nontransactional tables. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute was not specified. If you set this to 0, MySQL never creates a thread to handle `DELAYED` rows; in effect, this disables `DELAYED` entirely.

For the `SESSION` value of this variable, the only valid values are 0 or the `GLOBAL` value.

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `max_error_count` [504]

<b>Command-Line Format</b>	<code>--max_error_count=#</code>	
<b>Option-File Format</b>	<code>max_error_count</code>	
<b>Option Sets Variable</b>	Yes, <code>max_error_count</code> [504]	
<b>Variable Name</b>	<code>max_error_count</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>64</code>
	<b>Range</b>	<code>0 .. 65535</code>

The maximum number of error, warning, and note messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by `GET DIAGNOSTICS`.

- `max_heap_table_size` [504]

<b>Command-Line Format</b>	<code>--max_heap_table_size=#</code>
----------------------------	--------------------------------------

<b>Option-File Format</b>	<code>max_heap_table_size</code>	
<b>Option Sets Variable</b>	Yes, <code>max_heap_table_size</code> [504]	
<b>Variable Name</b>	<code>max_heap_table_size</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	16777216
	<b>Range</b>	16384 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	16777216
	<b>Range</b>	16384 .. 1844674407370954752

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` [504] value.

This variable is also used in conjunction with `tmp_table_size` [558] to limit the size of internal in-memory tables. See Section 8.4.3.3, “How MySQL Uses Internal Temporary Tables”.

`max_heap_table_size` is not replicated. See Section 16.4.1.20, “Replication and `MEMORY` Tables”, and Section 16.4.1.32, “Replication and Variables”, for more information.

- `max_insert_delayed_threads` [505]

<b>Version Deprecated</b>	5.6.7	
<b>Variable Name</b>	<code>max_insert_delayed_threads</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.6.7	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric

This variable is a synonym for `max_delayed_threads` [504].

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `max_join_size` [505]

<b>Command-Line Format</b>	<code>--max_join_size=#</code>
<b>Option-File Format</b>	<code>max_join_size</code>
<b>Option Sets Variable</b>	Yes, <code>max_join_size</code> [505]

<b>Variable Name</b>	max_join_size	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	18446744073709551615
	<b>Range</b>	1 .. 18446744073709551615

Do not permit statements that probably need to examine more than `max_join_size` [505] rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` [505] disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` [543] to 0. If you set the `sql_big_selects` [543] value again, the `max_join_size` [505] variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

- `max_length_for_sort_data` [506]

<b>Command-Line Format</b>	--max_length_for_sort_data=#	
<b>Option-File Format</b>	max_length_for_sort_data	
<b>Option Sets Variable</b>	Yes, <code>max_length_for_sort_data</code> [506]	
<b>Variable Name</b>	max_length_for_sort_data	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	1024
	<b>Range</b>	4 .. 8388608

The cutoff on the size of index values that determines which `filesort` algorithm to use. See [Section 8.13.13, “ORDER BY Optimization”](#).

- `max_prepared_stmt_count` [506]

<b>Command-Line Format</b>	--max_prepared_stmt_count=#	
<b>Option-File Format</b>	max_prepared_stmt_count	
<b>Option Sets Variable</b>	Yes, <code>max_prepared_stmt_count</code> [506]	
<b>Variable Name</b>	max_prepared_stmt_count	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	16382
	<b>Range</b>	0 .. 1048576

This variable limits the total number of prepared statements in the server. (The sum of the number of prepared statements across all sessions.) It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements.

- [max\\_relay\\_log\\_size \[507\]](#)

<b>Command-Line Format</b>	<code>--max_relay_log_size=#</code>	
<b>Option-File Format</b>	<code>max_relay_log_size</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">max_relay_log_size [507]</a>	
<b>Variable Name</b>	<code>max_relay_log_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 1073741824</code>

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If [max\\_relay\\_log\\_size \[507\]](#) is 0, the server uses [max\\_binlog\\_size \[2016\]](#) for both the binary log and the relay log. If [max\\_relay\\_log\\_size \[507\]](#) is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set [max\\_relay\\_log\\_size \[507\]](#) to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See [Section 16.2.1, “Replication Implementation Details”](#).

- [max\\_seeks\\_for\\_key \[507\]](#)

<b>Command-Line Format</b>	<code>--max_seeks_for_key=#</code>	
<b>Option-File Format</b>	<code>max_seeks_for_key</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">max_seeks_for_key [507]</a>	
<b>Variable Name</b>	<code>max_seeks_for_key</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>32</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>4294967295</code>
	<b>Range</b>	<code>1 .. 4294967295</code>
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>64</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>18446744073709547520</code>

	<b>Range</b>	1 .. 18446744073709547520
--	--------------	---------------------------

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see [Section 13.7.5.23, “SHOW INDEX Syntax”](#)). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- [max\\_sort\\_length \[508\]](#)

<b>Command-Line Format</b>	<code>--max_sort_length=#</code>	
<b>Option-File Format</b>	<code>max_sort_length</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">max_sort_length [508]</a>	
<b>Variable Name</b>	<code>max_sort_length</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1024</code>
	<b>Range</b>	<code>4 .. 8388608</code>

The number of bytes to use when sorting data values. Only the first [max\\_sort\\_length \[508\]](#) bytes of each value are used; the rest are ignored.

As of MySQL 5.6.9, [max\\_sort\\_length \[508\]](#) is ignored for integer, decimal, floating-point, and temporal data types.

- [max\\_sp\\_recursion\\_depth \[508\]](#)

<b>Command-Line Format</b>	<code>--max_sp_recursion_depth[=#]</code>	
<b>Option-File Format</b>	<code>max_sp_recursion_depth</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">max_sp_recursion_depth [508]</a>	
<b>Variable Name</b>	<code>max_sp_recursion_depth</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Max Value</b>	<code>255</code>

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of [max\\_sp\\_recursion\\_depth \[508\]](#), it may be necessary to increase thread stack size by increasing the value of [thread\\_stack \[556\]](#) at server startup.

- [max\\_tmp\\_tables \[508\]](#)

This variable is unused. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- `max_user_connections` [509]

<b>Command-Line Format</b>	<code>--max_user_connections=#</code>	
<b>Option-File Format</b>	<code>max_user_connections</code>	
<b>Option Sets Variable</b>	Yes, <code>max_user_connections</code> [509]	
<b>Variable Name</b>	<code>max_user_connections</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 4294967295</code>

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` [509] value is set to that limit.
- Otherwise, the session `max_user_connections` [509] value is set to the global value.

Account resource limits are specified using the `GRANT` statement. See [Section 6.3.4, “Setting Account Resource Limits”](#), and [Section 13.7.1.4, “GRANT Syntax”](#).

- `max_write_lock_count` [509]

<b>Command-Line Format</b>	<code>--max_write_lock_count=#</code>	
<b>Option-File Format</b>	<code>max_write_lock_count</code>	
<b>Option Sets Variable</b>	Yes, <code>max_write_lock_count</code> [509]	
<b>Variable Name</b>	<code>max_write_lock_count</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>32</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>4294967295</code>
	<b>Range</b>	<code>1 .. 4294967295</code>
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>64</code>
	<b>Type</b>	<code>numeric</code>

	<b>Default</b>	18446744073709547520
	<b>Range</b>	1 .. 18446744073709547520

After this many write locks, permit some pending read lock requests to be processed in between.

- [metadata\\_locks\\_cache\\_size \[510\]](#)

<b>Version Introduced</b>	5.6.4	
<b>Variable Name</b>	<code>metadata_locks_cache_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	1024
	<b>Range</b>	1 .. 1048576

The size of the metadata locks cache. The server uses this cache to avoid creation and destruction of synchronization objects. This is particularly helpful on systems where such operations are expensive, such as Windows XP. This variable was added in MySQL 5.6.4.

- [metadata\\_locks\\_hash\\_instances \[510\]](#)

<b>Version Introduced</b>	5.6.8	
<b>Variable Name</b>	<code>metadata_locks_hash_instances</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	8
	<b>Range</b>	1 .. 1024

The set of metadata locks can be partitioned into separate hashes to permit connections accessing different objects to use different locking hashes and reduce contention. The [metadata\\_locks\\_hash\\_instances \[510\]](#) system variable specifies the number of hashes (default 8). This variable was added in MySQL 5.6.8.

- [min\\_examined\\_row\\_limit \[510\]](#)

<b>Command-Line Format</b>	<code>--min-examined-row-limit=#</code>	
<b>Option-File Format</b>	<code>min-examined-row-limit</code>	
<b>Variable Name</b>	<code>min_examined_row_limit</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4294967295

	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0 .. 18446744073709547520

Queries that examine fewer than this number of rows are not logged to the slow query log.

- `myisam_data_pointer_size` [511]

<b>Command-Line Format</b>	<code>--myisam_data_pointer_size=#</code>
<b>Option-File Format</b>	<code>myisam_data_pointer_size</code>
<b>Option Sets Variable</b>	Yes, <code>myisam_data_pointer_size</code> [511]
<b>Variable Name</b>	<code>myisam_data_pointer_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	6
<b>Range</b>	2 .. 7

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See [Section C.5.2.12](#), “The table is full”.

- `myisam_max_sort_file_size` [511]

<b>Command-Line Format</b>	<code>--myisam_max_sort_file_size=#</code>
<b>Option-File Format</b>	<code>myisam_max_sort_file_size</code>
<b>Option Sets Variable</b>	Yes, <code>myisam_max_sort_file_size</code> [511]
<b>Variable Name</b>	<code>myisam_max_sort_file_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	2147483648
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	9223372036854775807

The maximum size of the temporary file that MySQL is permitted to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be

larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

The default value is 2GB. If `MyISAM` index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_mmap_size` [512]

<b>Command-Line Format</b>	<code>--myisam_mmap_size=#</code>	
<b>Option-File Format</b>	<code>myisam_mmap_size</code>	
<b>Option Sets Variable</b>	Yes, <code>myisam_mmap_size</code> [512]	
<b>Variable Name</b>	<code>myisam_mmap_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	4294967295
	<b>Range</b>	7 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	18446744073709547520
	<b>Range</b>	7 .. 18446744073709547520

The maximum amount of memory to use for memory mapping compressed `MyISAM` files. If many compressed `MyISAM` tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- `myisam_recover_options` [512]

<b>Variable Name</b>	<code>myisam_recover_options</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

The value of the `--myisam-recover-options` [432] option. See [Section 5.1.3, “Server Command Options”](#).

- `myisam_repair_threads` [512]

<b>Command-Line Format</b>	<code>--myisam_repair_threads=#</code>	
<b>Option-File Format</b>	<code>myisam_repair_threads</code>	
<b>Option Sets Variable</b>	Yes, <code>myisam_repair_threads</code> [512]	
<b>Variable Name</b>	<code>myisam_repair_threads</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	

	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	1
	<b>Range</b>	1 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	1
	<b>Range</b>	1 .. 18446744073709547520

If this value is greater than 1, `MyISAM` table indexes are created in parallel (each index in its own thread) during the `Repair by sorting` process. The default value is 1.

**Note**

Multi-threaded repair is still *beta-quality* code.

- `myisam_sort_buffer_size` [513]

<b>Command-Line Format</b>	<code>--myisam_sort_buffer_size=#</code>	
<b>Option-File Format</b>	<code>myisam_sort_buffer_size</code>	
<b>Option Sets Variable</b>	Yes, <code>myisam_sort_buffer_size</code> [513]	
<b>Variable Name</b>	<code>myisam_sort_buffer_size</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	8388608
	<b>Range</b>	4 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	8388608
	<b>Range</b>	4 .. 18446744073709547520

The size of the buffer that is allocated when sorting `MyISAM` indexes during a `REPAIR TABLE` or when creating indexes with `CREATE INDEX` or `ALTER TABLE`.

The maximum permissible setting for `myisam_sort_buffer_size` [513] is 4GB. Values larger than 4GB are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

- `myisam_stats_method` [513]

<b>Command-Line Format</b>	<code>--myisam_stats_method=name</code>
<b>Option-File Format</b>	<code>myisam_stats_method</code>
<b>Option Sets Variable</b>	Yes, <code>myisam_stats_method</code> [513]
<b>Variable Name</b>	<code>myisam_stats_method</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>enumeration</code>
	<b>Valid Values</b> <code>nulls_equal</code> <code>nulls_unequal</code> <code>nulls_ignored</code>

How the server treats `NULL` values when collecting statistics about the distribution of index values for `MyISAM` tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group that has a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- `myisam_use_mmap` [514]

<b>Command-Line Format</b>	<code>--myisam_use_mmap</code>
<b>Option-File Format</b>	<code>myisam_use_mmap</code>
<b>Option Sets Variable</b>	Yes, <code>myisam_use_mmap</code> [514]
<b>Variable Name</b>	<code>myisam_use_mmap</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>OFF</code>

Use memory mapping for reading and writing `MyISAM` tables.

- `named_pipe` [514]

<b>Variable Name</b>	<code>named_pipe</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Platform Specific</b>	windows
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code> (windows)
	<b>Default</b> <code>OFF</code>

(Windows only.) Indicates whether the server supports connections over named pipes.

- [net\\_buffer\\_length \[515\]](#)

<b>Command-Line Format</b>	<code>--net_buffer_length=#</code>	
<b>Option-File Format</b>	<code>net_buffer_length</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">net_buffer_length [515]</a>	
<b>Variable Name</b>	<code>net_buffer_length</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>16384</code>
	<b>Range</b>	<code>1024 .. 1048576</code>

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by [net\\_buffer\\_length \[515\]](#) but are dynamically enlarged up to [max\\_allowed\\_packet \[502\]](#) bytes as needed. The result buffer shrinks to [net\\_buffer\\_length \[515\]](#) after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which [net\\_buffer\\_length \[515\]](#) can be set is 1MB.

The session value of this variable is read only.

- [net\\_read\\_timeout \[515\]](#)

<b>Command-Line Format</b>	<code>--net_read_timeout=#</code>	
<b>Option-File Format</b>	<code>net_read_timeout</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">net_read_timeout [515]</a>	
<b>Variable Name</b>	<code>net_read_timeout</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>30</code>
	<b>Min Value</b>	<code>1</code>

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, [net\\_read\\_timeout \[515\]](#) is the timeout value controlling when to abort. When the server is writing to the client, [net\\_write\\_timeout \[516\]](#) is the timeout value controlling when to abort. See also [slave\\_net\\_timeout \[1993\]](#).

- [net\\_retry\\_count \[515\]](#)

<b>Command-Line Format</b>	<code>--net_retry_count=#</code>
<b>Option-File Format</b>	<code>net_retry_count</code>

<b>Option Sets Variable</b>	Yes, <a href="#">net_retry_count</a> [515]
<b>Variable Name</b>	<a href="#">net_retry_count</a>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 32
	<b>Type</b> <a href="#">numeric</a>
	<b>Default</b> 10
	<b>Range</b> 1 .. 4294967295
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 64
	<b>Type</b> <a href="#">numeric</a>
	<b>Default</b> 10
	<b>Range</b> 1 .. 18446744073709547520

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- [net\\_write\\_timeout](#) [516]

<b>Command-Line Format</b>	<code>--net_write_timeout=#</code>
<b>Option-File Format</b>	<a href="#">net_write_timeout</a>
<b>Option Sets Variable</b>	Yes, <a href="#">net_write_timeout</a> [516]
<b>Variable Name</b>	<a href="#">net_write_timeout</a>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <a href="#">numeric</a>
	<b>Default</b> 60
	<b>Min Value</b> 1

The number of seconds to wait for a block to be written to a connection before aborting the write. See also [net\\_read\\_timeout](#) [515].

- [new](#) [516]

<b>Command-Line Format</b>	<code>--new</code>
	<code>-n</code>
<b>Option-File Format</b>	<a href="#">new</a>
<b>Option Sets Variable</b>	Yes, <a href="#">new</a> [516]
<b>Variable Name</b>	<a href="#">new</a>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
<b>Disabled by</b>	<a href="#">skip-new</a>

	<b>Permitted Values</b>	
<b>Type</b>	boolean	
<b>Default</b>	FALSE	

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. In MySQL 5.6, its value is always `OFF`.

- [old \[517\]](#)

<b>Command-Line Format</b>	<code>--old</code>
<b>Option-File Format</b>	<code>old</code>
<b>Variable Name</b>	<code>old</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

`old [517]` is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

Currently, when `old [517]` is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See [Section 13.2.9.3, “Index Hint Syntax”](#).) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

- [old\\_alter\\_table \[517\]](#)

<b>Command-Line Format</b>	<code>--old-alter-table</code>	
<b>Option-File Format</b>	<code>old-alter-table</code>	
<b>Option Sets Variable</b>	Yes, <code>old_alter_table [517]</code>	
<b>Variable Name</b>	<code>old_alter_table</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
<b>Type</b>	boolean	
<b>Default</b>	OFF	

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 13.1.6, “ALTER TABLE Syntax”](#).

- [old\\_passwords \[517\]](#)

<b>Variable Name</b>	<code>old_passwords</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
<b>Type</b>	boolean	
<b>Default</b>	0	
	<b>Permitted Values (&gt;= 5.6.6)</b>	

<b>Type</b>	enumeration
<b>Default</b>	0
<b>Valid Values</b>	0 1 2

This variable determines the type of password hashing performed by the `PASSWORD()` [1263] function and statements such as `CREATE USER` and `GRANT`.

The following table shows the permitted values of `old_passwords` [517], as well as the type of password hashing each value produces, and the plugins that use each hashing type. These values are permitted as of MySQL 5.6.6. Before 5.6.6, the value can be 0 (or `OFF`), or 1 (or `ON`).

Value	Password Hashing Format	Intended Use
0	MySQL 4.1 native hashing	Accounts that authenticate with the <code>mysql_native_password</code> plugin
1	Pre-4.1 (“old”) native hashing	Accounts that authenticate with the <code>mysql_old_password</code> plugin
2	SHA-256 hashing	Accounts that authenticate with the <code>sha256_password</code> plugin

If `old_passwords=1`, `PASSWORD('str')` [1263] returns the same value as `OLD_PASSWORD('str')` [1263].

For information about authentication plugins and hashing formats, see [Section 6.3.7, “Pluggable Authentication”](#), and [Section 6.1.2.4, “Password Hashing in MySQL”](#). If you set `old_passwords=2`, follow the instructions for using the `sha256_password` plugin at [Section 6.3.7.2, “The SHA-256 Authentication Plugin”](#).

- `open_files_limit` [518]

<b>Command-Line Format</b>	<code>--open-files-limit=#</code>
<b>Option-File Format</b>	<code>open-files-limit</code>
<b>Option Sets Variable</b>	Yes, <code>open_files_limit</code> [518]
<b>Variable Name</b>	<code>open_files_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values (&lt;= 5.6.7)</b>
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0 .. 65535
	<b>Permitted Values (&gt;= 5.6.8)</b>
<b>Type</b>	numeric
<b>Default</b>	-1 (autosized)
<b>Range</b>	0 .. 65535

The number of files that the operating system permits `mysqld` to open. The value of this variable at runtime is the real value permitted by the system and might be different from the value you specify at server startup. The value is 0 on systems where MySQL cannot change the number of open files.

The effective `open_files_limit` [518] value is based on the value specified at system startup (if any) and the values of `max_connections` [503] and `table_open_cache` [551], using these formulas:

```
1) 10 + max_connections + (table_open_cache * 2)
2) max_connections * 5
3) open_files_limit value specified at startup, 5000 if none
```

The server attempts to obtain the number of file descriptors using the maximum of those three values. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system will permit.

- `optimizer_join_cache_level` [519]

<b>Version Introduced</b>	5.6.1	
<b>Version Removed</b>	5.6.3	
<b>Command-Line Format</b>	<code>--optimizer_join_cache_level=#</code>	
<b>Option-File Format</b>	<code>optimizer_join_cache_level</code>	
<b>Option Sets Variable</b>	Yes, <code>optimizer_join_cache_level</code> [519]	
<b>Variable Name</b>	<code>optimizer_join_cache_level</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>4</code>
	<b>Range</b>	<code>0 .. 4</code>

Before MySQL 5.6.3, this variable is used for join buffer management. It controls how join buffers are used for join operations. As of MySQL 5.6.3, it is removed and the `optimizer_switch` [520] variable is used instead. See [Section 8.13.12, “Block Nested-Loop and Batched Key Access Joins”](#).

The following table shows the permissible `optimizer_join_cache_level` [519] values.

Option	Description
0	No join buffer is used for any join operation. This setting can be useful for assessing baseline join performance in comparison to performance with nonzero values that enable use of join buffering.
1	This is the default value. Join buffers are employed only for inner joins that are executed by the original Block Nested-Loop (BNL) join algorithm. When this algorithm is applied, rows of the inner table are accessed through a table scan, a plain index scan, or a range index scan.
2	The server employs an incremental join buffer for a join operation if its first operand is produced by a join operation that uses a join buffer itself.
3	The BNL algorithm is used for outer join operations with one inner table and for inner joins.
4	The BNL algorithm uses incremental buffers for inner tables. In this case, the BNL algorithm can be used for nested outer joins (outer joins with several inner tables). Such an operation can be executed only if incremental join buffers are used to join all inner tables but the first one.

- `optimizer_prune_level` [519]

<b>Command-Line Format</b>	<code>--optimizer_prune_level[=#]</code>
<b>Option-File Format</b>	<code>optimizer_prune_level</code>
<b>Option Sets Variable</b>	Yes, <code>optimizer_prune_level</code> [519]
<b>Variable Name</b>	<code>optimizer_prune_level</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>1</code>

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth` [520]

<b>Command-Line Format</b>	<code>--optimizer_search_depth[=#]</code>
<b>Option-File Format</b>	<code>optimizer_search_depth</code>
<b>Option Sets Variable</b>	Yes, <code>optimizer_search_depth</code> [520]
<b>Variable Name</b>	<code>optimizer_search_depth</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&gt;= 5.6)</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>62</code>
	<b>Range</b> <code>0 .. 62</code>

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- `optimizer_switch` [520]

<b>Command-Line Format</b>	<code>--optimizer_switch=value</code>
<b>Option-File Format</b>	<code>optimizer_switch</code>
	<code>optimizer_switch</code>
	<code>optimizer_switch</code>
<b>Option Sets Variable</b>	Yes, <code>optimizer_switch</code> [520]
<b>Variable Name</b>	<code>optimizer_switch</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&gt;= 5.6.1, &lt;= 5.6.2)</b>
	<b>Type</b> <code>set</code>

	<b>Valid Values</b>	<p>engine_condition_pushdown={on off}</p> <p>index_condition_pushdown={on off}</p> <p>index_merge={on off}</p> <p>index_merge_intersection={on off}</p> <p>index_merge_sort_union={on off}</p> <p>index_merge_union={on off}</p> <p>mrr={on off}</p> <p>mrr_cost_based={on off}</p>
<b>Permitted Values (&gt;= 5.6.3, &lt;= 5.6.4)</b>		
	<b>Type</b>	set
	<b>Valid Values</b>	<p>batched_key_access={on off}</p> <p>block_nested_loop={on off}</p> <p>engine_condition_pushdown={on off}</p> <p>index_condition_pushdown={on off}</p> <p>index_merge={on off}</p> <p>index_merge_intersection={on off}</p> <p>index_merge_sort_union={on off}</p> <p>index_merge_union={on off}</p> <p>mrr={on off}</p> <p>mrr_cost_based={on off}</p>
<b>Permitted Values (&gt;= 5.6.5, &lt;= 5.6.6)</b>		
	<b>Type</b>	set
	<b>Valid Values</b>	<p>batched_key_access={on off}</p> <p>block_nested_loop={on off}</p> <p>engine_condition_pushdown={on off}</p> <p>firstmatch={on off}</p> <p>index_condition_pushdown={on off}</p> <p>index_merge={on off}</p> <p>index_merge_intersection={on off}</p> <p>index_merge_sort_union={on off}</p> <p>index_merge_union={on off}</p> <p>loosescan={on off}</p> <p>materialization={on off}</p>

	<pre>mrr={on off} mrr_cost_based={on off} semijoin={on off}</pre>				
	<p><b>Permitted Values (&gt;= 5.6.7, &lt;= 5.6.8)</b></p> <table border="1"> <tr> <td><b>Type</b></td> <td>set</td> </tr> <tr> <td><b>Valid Values</b></td> <td> <pre>batched_key_access={on off} block_nested_loop={on off} engine_condition_pushdown={on off} firstmatch={on off} index_condition_pushdown={on off} index_merge={on off} index_merge_intersection={on off} index_merge_sort_union={on off} index_merge_union={on off} loosescan={on off} materialization={on off} mrr={on off} mrr_cost_based={on off} semijoin={on off} subquery_materialization_cost_based={on off}</pre> </td> </tr> </table>	<b>Type</b>	set	<b>Valid Values</b>	<pre>batched_key_access={on off} block_nested_loop={on off} engine_condition_pushdown={on off} firstmatch={on off} index_condition_pushdown={on off} index_merge={on off} index_merge_intersection={on off} index_merge_sort_union={on off} index_merge_union={on off} loosescan={on off} materialization={on off} mrr={on off} mrr_cost_based={on off} semijoin={on off} subquery_materialization_cost_based={on off}</pre>

<b>Type</b>	set				
<b>Valid Values</b>	<pre>batched_key_access={on off} block_nested_loop={on off} engine_condition_pushdown={on off} firstmatch={on off} index_condition_pushdown={on off} index_merge={on off} index_merge_intersection={on off} index_merge_sort_union={on off} index_merge_union={on off} loosescan={on off} materialization={on off}</pre>				

	<pre>mrr={on off} mrr_cost_based={on off} semijoin={on off} subquery_materialization_cost_based={on off} use_index_extensions={on off}</pre>
--	--

The `optimizer_switch` [520] system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see [Section 8.8.5.2, “Controlling Switchable Optimizations”](#).

- `optimizer_trace` [523]

<b>Version Introduced</b>	5.6.3	
<b>Variable Name</b>	<code>optimizer_trace</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

This variable controls optimizer tracing. For details, see [MySQL Internals: Tracing the Optimizer](#). This variable was added in MySQL 5.6.3.

- `optimizer_trace_features` [523]

<b>Version Introduced</b>	5.6.3	
<b>Variable Name</b>	<code>optimizer_trace_features</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

This variable enables or disables selected optimizer tracing features. For details, see [MySQL Internals: Tracing the Optimizer](#). This variable was added in MySQL 5.6.3.

- `optimizer_trace_limit` [524]

<b>Version Introduced</b>	5.6.3	
<b>Variable Name</b>	<code>optimizer_trace_limit</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>

The maximum number of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#). This variable was added in MySQL 5.6.3.

- `optimizer_trace_max_mem_size` [524]

<b>Version Introduced</b>	5.6.3	
<b>Variable Name</b>	<code>optimizer_trace_max_mem_size</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>16384</code>

The maximum cumulative size of stored optimizer traces. For details, see [MySQL Internals: Tracing the Optimizer](#). This variable was added in MySQL 5.6.3.

- `optimizer_trace_offset` [524]

<b>Version Introduced</b>	5.6.3	
<b>Variable Name</b>	<code>optimizer_trace_offset</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>-1</code>

The offset of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#). This variable was added in MySQL 5.6.3.

- `performance_schema_xxx`

Performance Schema system variables are listed in [Section 20.12, “Performance Schema System Variables”](#). These variables may be used to configure Performance Schema operation.

- `pid_file` [524]

<b>Command-Line Format</b>	<code>--pid-file=file_name</code>
<b>Option-File Format</b>	<code>pid-file=file_name</code>
<b>Option Sets Variable</b>	Yes, <code>pid_file</code> [524]
<b>Variable Name</b>	<code>pid_file</code>
<b>Variable Scope</b>	Global

<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

The path name of the process ID (PID) file. This variable can be set with the `--pid-file` [435] option.

- `plugin_dir` [525]

<b>Command-Line Format</b>	<code>--plugin_dir=path</code>	
<b>Option-File Format</b>	<code>plugin_dir</code>	
<b>Option Sets Variable</b>	Yes, <code>plugin_dir</code> [525]	
<b>Variable Name</b>	<code>plugin_dir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	directory name
	<b>Default</b>	<code>BASEDIR/lib/plugin</code>

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` [525] read only to the server or by setting `--secure-file-priv` [438] to a directory where `SELECT` writes can be made safely.

- `port` [525]

<b>Command-Line Format</b>	<code>--port=#</code>	
	<code>-P</code>	
<b>Option-File Format</b>	<code>port</code>	
<b>Option Sets Variable</b>	Yes, <code>port</code> [525]	
<b>Variable Name</b>	<code>port</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	3306
	<b>Range</b>	0 .. 65535

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` [437] option.

- `preload_buffer_size` [525]

<b>Command-Line Format</b>	<code>--preload_buffer_size=#</code>	
<b>Option-File Format</b>	<code>preload_buffer_size</code>	
<b>Option Sets Variable</b>	Yes, <code>preload_buffer_size</code> [525]	
<b>Variable Name</b>	<code>preload_buffer_size</code>	

<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	32768
	<b>Range</b>	1024 .. 1073741824

The size of the buffer that is allocated when preloading indexes.

- [profiling \[526\]](#)

If set to 0 or `OFF` (the default), statement profiling is disabled. If set to 1 or `ON`, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See [Section 13.7.5.32, “SHOW PROFILES Syntax”](#).

This variable is deprecated in MySQL 5.6.8 and will be removed in a future MySQL release.

- [profiling\\_history\\_size \[526\]](#)

The number of statements for which to maintain profiling information if [profiling \[526\]](#) is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See [Section 13.7.5.32, “SHOW PROFILES Syntax”](#).

This variable is deprecated in MySQL 5.6.8 and will be removed in a future MySQL release.

- [protocol\\_version \[526\]](#)

<b>Variable Name</b>	<code>protocol_version</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric

The version of the client/server protocol used by the MySQL server.

- [proxy\\_user \[526\]](#)

<b>Variable Name</b>	<code>proxy_user</code>	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	string

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is `NULL`. See [Section 6.3.8, “Proxy Users”](#).

- [pseudo\\_slave\\_mode \[526\]](#)

<b>Version Introduced</b>	5.6.10
<b>Variable Name</b>	<code>pseudo_slave_mode</code>
<b>Variable Scope</b>	Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>

	<b>Type</b>	numeric
--	-------------	---------

This variable is for internal server use. It was added in MySQL 5.6.10.

- [pseudo\\_thread\\_id \[527\]](#)

<b>Variable Name</b>	pseudo_thread_id	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric

This variable is for internal server use.

- [query\\_alloc\\_block\\_size \[527\]](#)

<b>Command-Line Format</b>	--query_alloc_block_size=#	
<b>Option-File Format</b>	query_alloc_block_size	
<b>Option Sets Variable</b>	Yes, <a href="#">query_alloc_block_size [527]</a>	
<b>Variable Name</b>	query_alloc_block_size	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	8192
	<b>Range</b>	1024 .. 4294967295
	<b>Block Size</b>	1024
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	8192
	<b>Range</b>	1024 .. 18446744073709547520
	<b>Block Size</b>	1024

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- [query\\_cache\\_limit \[527\]](#)

<b>Command-Line Format</b>	--query_cache_limit=#	
<b>Option-File Format</b>	query_cache_limit	
<b>Option Sets Variable</b>	Yes, <a href="#">query_cache_limit [527]</a>	
<b>Variable Name</b>	query_cache_limit	

<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	1048576
<b>Range</b>	0 .. 4294967295
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	1048576
<b>Range</b>	0 .. 18446744073709547520

Do not cache results that are larger than this number of bytes. The default value is 1MB.

- [query\\_cache\\_min\\_res\\_unit \[528\]](#)

<b>Command-Line Format</b>	--query_cache_min_res_unit=#
<b>Option-File Format</b>	query_cache_min_res_unit
<b>Option Sets Variable</b>	Yes, <a href="#">query_cache_min_res_unit [528]</a>
<b>Variable Name</b>	query_cache_min_res_unit
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	512 .. 4294967295
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	512 .. 18446744073709547520

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in [Section 8.9.3.3, "Query Cache Configuration"](#).

- [query\\_cache\\_size \[528\]](#)

<b>Command-Line Format</b>	--query_cache_size=#
<b>Option-File Format</b>	query_cache_size
<b>Option Sets Variable</b>	Yes, <a href="#">query_cache_size [528]</a>
<b>Variable Name</b>	query_cache_size

<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&lt;= 5.6.7)</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0 .. 18446744073709547520
	<b>Permitted Values (&lt;= 5.6.7)</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0 .. 4294967295
	<b>Permitted Values (&gt;= 5.6.8)</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	1048576
<b>Range</b>	0 .. 18446744073709547520
	<b>Permitted Values (&gt;= 5.6.8)</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	1048576
<b>Range</b>	0 .. 4294967295

The amount of memory allocated for caching query results. By default, the query cache is disabled. This is achieved using a default value of 1M, with a default for `query_cache_type` of 0. (Before MySQL 5.6.8, the default size is 0, with a default `query_cache_type` of 1. To reduce overhead significantly, you should also start the server with `query_cache_type=0` [529] if you will not be using the query cache.)

The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. Note that `query_cache_size` [528] bytes of memory are allocated even if `query_cache_type` [529] is set to 0. See Section 8.9.3.3, “Query Cache Configuration”, for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` [528] too small, a warning will occur, as described in Section 8.9.3.3, “Query Cache Configuration”.

- `query_cache_type` [529]

<b>Command-Line Format</b>	<code>--query_cache_type=#</code>
<b>Option-File Format</b>	<code>query_cache_type</code>
<b>Option Sets Variable</b>	Yes, <code>query_cache_type</code> [529]
<b>Variable Name</b>	<code>query_cache_type</code>
<b>Variable Scope</b>	Global, Session

<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.7)</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	1
	<b>Valid Values</b>	0 1 2
	<b>Permitted Values (&gt;= 5.6.8)</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	0
	<b>Valid Values</b>	0 1 2

Set the query cache type. Setting the `GLOBAL` value sets the type for all clients that connect thereafter. Individual clients can set the `SESSION` value to affect their own use of the query cache. Possible values are shown in the following table.

Option	Description
0 or <code>OFF</code>	Do not cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set <code>query_cache_size</code> [528] to 0.
1 or <code>ON</code>	Cache all cacheable query results except for those that begin with <code>SELECT SQL_NO_CACHE</code> .
2 or <code>DEMAND</code>	Cache results only for cacheable queries that begin with <code>SELECT SQL_CACHE</code> .

This variable defaults to `OFF` as of MySQL 5.6.8, `ON` before that.

If the server is started with `query_cache_type` set to 0, it does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

- `query_cache_wlock_invalidate` [530]

<b>Command-Line Format</b>	<code>--query_cache_wlock_invalidate</code>	
<b>Option-File Format</b>	<code>query_cache_wlock_invalidate</code>	
<b>Option Sets Variable</b>	Yes, <code>query_cache_wlock_invalidate</code> [530]	
<b>Variable Name</b>	<code>query_cache_wlock_invalidate</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	<code>FALSE</code>

Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in

the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- [query\\_prealloc\\_size \[531\]](#)

<b>Command-Line Format</b>	<code>--query_prealloc_size=#</code>	
<b>Option-File Format</b>	<code>query_prealloc_size</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">query_prealloc_size [531]</a>	
<b>Variable Name</b>	<code>query_prealloc_size</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	8192
	<b>Range</b>	8192 .. 4294967295
	<b>Block Size</b>	1024
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	8192
	<b>Range</b>	8192 .. 18446744073709547520
	<b>Block Size</b>	1024

The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger [query\\_prealloc\\_size \[531\]](#) value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- [rand\\_seed1 \[531\]](#)

The [rand\\_seed1 \[531\]](#) and [rand\\_seed2 \[531\]](#) variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the [RAND\( \) \[1206\]](#) function. For statements that invoke [RAND\( \) \[1206\]](#), the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables [rand\\_seed1 \[531\]](#) and [rand\\_seed2 \[531\]](#) so that [RAND\( \) \[1206\]](#) on the slave generates the same value as on the master.

- [rand\\_seed2 \[531\]](#)

See the description for [rand\\_seed1 \[531\]](#).

- [range\\_alloc\\_block\\_size \[531\]](#)

<b>Command-Line Format</b>	<code>--range_alloc_block_size=#</code>
----------------------------	---

<b>Option-File Format</b>	<code>range_alloc_block_size</code>
<b>Option Sets Variable</b>	Yes, <a href="#">range_alloc_block_size [531]</a>
<b>Variable Name</b>	<code>range_alloc_block_size</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	4096 .. 4294967295
<b>Block Size</b>	1024

The size of blocks that are allocated when doing range optimization.

- [read\\_buffer\\_size \[532\]](#)

<b>Command-Line Format</b>	<code>--read_buffer_size=#</code>
<b>Option-File Format</b>	<code>read_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <a href="#">read_buffer_size [532]</a>
<b>Variable Name</b>	<code>read_buffer_size</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	131072
<b>Range</b>	8200 .. 2147479552

Each thread that does a sequential scan for a `MyISAM` table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all search engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for `ORDER BY`.
- For bulk insert into partitions.
- For caching results of nested queries.

and in one other storage engine-specific way: to determine the memory block size for `MEMORY` tables.

The maximum permissible setting for [read\\_buffer\\_size \[532\]](#) is 2GB.

For more information about memory use during different operations, see [Section 8.11.4.1, “How MySQL Uses Memory”](#).

- [read\\_only \[532\]](#)

<b>Command-Line Format</b>	<code>--read-only</code>
<b>Option-File Format</b>	<code>read_only</code>
<b>Option Sets Variable</b>	Yes, <code>read_only</code> [532]
<b>Variable Name</b>	<code>read_only</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>false</code>

This variable is off by default. When it is enabled, the server permits no updates except from users that have the `SUPER` [756] privilege or (on a slave server) from updates performed by slave threads. In replication setups, it can be useful to enable `read_only` [532] on slave servers to ensure that slaves accept updates only from the master server and not from clients.

`read_only` [532] does not apply to `TEMPORARY` tables, nor does it prevent the server from inserting rows into the log tables (see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”). This variable does not prevent the use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements because its purpose is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only slaves can be performed with `mysqlcheck --all-databases --analyze`.

`read_only` [532] exists only as a `GLOBAL` variable, so changes to its value require the `SUPER` [756] privilege. Changes to `read_only` [532] on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

### Important

In MySQL 5.6, enabling `read_only` prevents the use of the `SET PASSWORD` statement by any user not having the `SUPER` [756] privilege. This is not necessarily the case for all MySQL release series. When replicating from one MySQL release series to another (for example, from a MySQL 5.0 master to a MySQL 5.1 or later slave), you should check the documentation for the versions running on both master and slave to determine whether the behavior of `read_only` in this regard is or is not the same, and, if it is different, whether this has an impact on your applications.

The following conditions apply:

- If you attempt to enable `read_only` [532] while you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction, an error occurs.
- If you attempt to enable `read_only` [532] while other clients hold explicit table locks or have pending transactions, the attempt blocks until the locks are released and the transactions end. While the attempt to enable `read_only` [532] is pending, requests by other clients for table locks or to begin transactions also block until `read_only` [532] has been set.
- `read_only` [532] can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.

In MySQL 5.6, attempts to set `read_only` [532] block for active transactions that hold metadata locks until those transactions end.

- `read_rnd_buffer_size` [533]

<b>Command-Line Format</b>	<code>--read_rnd_buffer_size=#</code>
<b>Option-File Format</b>	<code>read_rnd_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <code>read_rnd_buffer_size</code> [533]
<b>Variable Name</b>	<code>read_rnd_buffer_size</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>262144</code>
	<b>Range</b> <code>8200 .. 4294967295</code>

When reading rows from a `MyISAM` table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See [Section 8.13.13, “ORDER BY Optimization”](#). Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

The maximum permissible setting for `read_rnd_buffer_size` [533] is 2GB.

For more information about memory use during different operations, see [Section 8.11.4.1, “How MySQL Uses Memory”](#).

- `relay_log_purge` [534]

<b>Command-Line Format</b>	<code>--relay_log_purge</code>
<b>Option-File Format</b>	<code>relay_log_purge</code>
<b>Option Sets Variable</b>	Yes, <code>relay_log_purge</code> [534]
<b>Variable Name</b>	<code>relay_log_purge</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>TRUE</code>

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- `relay_log_space_limit` [534]

<b>Command-Line Format</b>	<code>--relay_log_space_limit=#</code>
<b>Option-File Format</b>	<code>relay_log_space_limit</code>
<b>Option Sets Variable</b>	Yes, <code>relay_log_space_limit</code> [534]
<b>Variable Name</b>	<code>relay_log_space_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> <code>32</code>

	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4294967295
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 18446744073709547520

The maximum amount of space to use for all relay logs.

- `report_host` [535]

<b>Command-Line Format</b>	<code>--report-host=host_name</code>	
<b>Option-File Format</b>	<code>report-host</code>	
<b>Option Sets Variable</b>	Yes, <code>report_host</code> [535]	
<b>Variable Name</b>	<code>report-host</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The value of the `--report-host` [1980] option.

- `report_password` [535]

<b>Command-Line Format</b>	<code>--report-password=name</code>	
<b>Option-File Format</b>	<code>report-password</code>	
<b>Option Sets Variable</b>	Yes, <code>report_password</code> [535]	
<b>Variable Name</b>	<code>report-password</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The value of the `--report-password` [1981] option. Not the same as the password used for the MySQL replication user account.

- `report_port` [535]

<b>Command-Line Format</b>	<code>--report-port=#</code>	
<b>Option-File Format</b>	<code>report-port</code>	
<b>Option Sets Variable</b>	Yes, <code>report_port</code> [535]	
<b>Variable Name</b>	<code>report-port</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b> ( $\geq 5.6.5$ )	

	<b>Type</b>	numeric
	<b>Default</b>	[slave_port]
	<b>Range</b>	0 .. 65535

The value of the `--report-port` [1981] option.

- `report_user` [536]

<b>Command-Line Format</b>	<code>--report-user=name</code>	
<b>Option-File Format</b>	<code>report-user</code>	
<b>Option Sets Variable</b>	Yes, <code>report_user</code> [536]	
<b>Variable Name</b>	<code>report-user</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The value of the `--report-user` [1982] option. Not the same as the name for the MySQL replication user account.

- `rpl_semi_sync_master_enabled` [536]

<b>Variable Name</b>	<code>rpl_semi_sync_master_enabled</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	OFF

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_timeout` [536]

<b>Variable Name</b>	<code>rpl_semi_sync_master_timeout</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10000

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_trace_level` [536]

<b>Variable Name</b>	<code>rpl_semi_sync_master_trace_level</code>
----------------------	---

<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	32

The semisynchronous replication debug trace level on the master. Currently, four levels are defined:

- 1 = general level (for example, time function failures)
- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_no_slave` [537]

<b>Variable Name</b>	<code>rpl_semi_sync_master_wait_no_slave</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	boolean
<b>Default</b>	ON

With semisynchronous replication, for each transaction, the master waits until timeout for acknowledgment of receipt from some semisynchronous slave. If no response occurs during this period, the master reverts to normal replication. This variable controls whether the master waits for the timeout to expire before reverting to normal replication even if the slave count drops to zero during the timeout period.

If the value is `ON` (the default), it is permissible for the slave count to drop to zero during the timeout period (for example, if slaves disconnect). The master still waits for the timeout, so as long as some slave reconnects and acknowledges the transaction within the timeout interval, semisynchronous replication continues.

If the value is `OFF`, the master reverts to normal replication if the slave count drops to zero during the timeout period.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_slave_enabled` [537]

<b>Variable Name</b>	<code>rpl_semi_sync_slave_enabled</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	boolean
<b>Default</b>	OFF

Controls whether semisynchronous replication is enabled on the slave. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- [rpl\\_semi\\_sync\\_slave\\_trace\\_level \[538\]](#)

<b>Variable Name</b>	<code>rpl_semi_sync_slave_trace_level</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>32</code>

The semisynchronous replication debug trace level on the slave. See [rpl\\_semi\\_sync\\_master\\_trace\\_level \[536\]](#) for the permissible values.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- [secure\\_auth \[538\]](#)

<b>Command-Line Format</b>	<code>--secure-auth</code>	
<b>Option-File Format</b>	<code>secure-auth</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">secure_auth [538]</a>	
<b>Variable Name</b>	<code>secure_auth</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.4)</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>
	<b>Permitted Values (&gt;= 5.6.5)</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

If this variable is enabled, the server blocks connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format.

Enable this variable to prevent all use of passwords employing the old format (and hence insecure communication over the network). Before MySQL 5.6.5, this variable is disabled by default. As of MySQL 5.6.5, it is enabled by default.

Server startup fails with an error if this variable is enabled and the privilege tables are in pre-4.1 format. See [Section C.5.2.4, “Client does not support authentication protocol”](#).

- [secure\\_file\\_priv \[538\]](#)

<b>Command-Line Format</b>	<code>--secure-file-priv=path</code>	
<b>Option-File Format</b>	<code>secure-file-priv=path</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">secure_file_priv [538]</a>	
<b>Variable Name</b>	<code>secure-file-priv</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	

	<b>Type</b>	string
--	-------------	--------

By default, this variable is empty. If set to the name of a directory, it limits the effect of the `LOAD_FILE()` [1181] function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in that directory.

- `server_id` [539]

<b>Command-Line Format</b>	<code>--server-id=#</code>	
<b>Option-File Format</b>	<code>server-id</code>	
<b>Option Sets Variable</b>	Yes, <code>server_id</code> [539]	
<b>Variable Name</b>	<code>server_id</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4294967295

The server ID, used in replication to give each master and slave a unique identity. This variable is set by the `--server-id` [1955] option. For each server participating in replication, you should pick a positive integer in the range from 1 to  $2^{32} - 1$  to act as that server's ID.

- `sha256_password_private_key_path` [539]

<b>Version Introduced</b>	5.6.6	
<b>Variable Name</b>	<code>sha256_password_private_key_path</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name
	<b>Default</b>	<code>private_key.pem</code>

The path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, including instructions for creating the RSA key files, see [Section 6.3.7.2, “The SHA-256 Authentication Plugin”](#).

This variable is available only if MySQL was built using OpenSSL. It was added in MySQL 5.6.6.

- `sha256_password_public_key_path` [539]

<b>Version Introduced</b>	5.6.6	
<b>Variable Name</b>	<code>sha256_password_public_key_path</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

	<b>Default</b>	<code>public_key.pem</code>
--	----------------	-----------------------------

The path name of the RSA public key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password`, including instructions for creating the RSA key files and how clients specify the RSA public key, see [Section 6.3.7.2, “The SHA-256 Authentication Plugin”](#).

This variable is available only if MySQL was built using OpenSSL. It was added in MySQL 5.6.6.

- [shared\\_memory \[540\]](#)

<b>Variable Name</b>	<code>shared_memory</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Platform Specific</b>	windows

(Windows only.) Whether the server permits shared-memory connections.

- [shared\\_memory\\_base\\_name \[540\]](#)

<b>Variable Name</b>	<code>shared_memory_base_name</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Platform Specific</b>	windows

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case sensitive.

- [skip\\_external\\_locking \[540\]](#)

This is `OFF` if `mysqld` uses external locking, `ON` if external locking is disabled. This affects only `MyISAM` table access.

- [skip\\_name\\_resolve \[540\]](#)

This variable is set from the value of the `--skip-name-resolve [440]` option. If it is `ON`, `mysqld` resolves host names when checking client connections. If `OFF`, `mysqld` uses only IP numbers and all `Host` column values in the grant tables must be IP addresses or `localhost`. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).

- [skip\\_networking \[540\]](#)

This is `ON` if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. This variable can be set to `ON` with the `--skip-networking [440]` option.

- [skip\\_show\\_database \[540\]](#)

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES [756]` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES [756]` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES [756]` privilege, and the statement displays all database names. If

the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` [756] or other privilege. (Note that *any* global privilege is considered a privilege for the database.)

- `slow_launch_time` [541]

<b>Command-Line Format</b>	<code>--slow_launch_time=#</code>	
<b>Option-File Format</b>	<code>slow_launch_time</code>	
<b>Option Sets Variable</b>	Yes, <code>slow_launch_time</code> [541]	
<b>Variable Name</b>	<code>slow_launch_time</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>2</code>

If creating a thread takes longer than this many seconds, the server increments the `slow_launch_threads` [598] status variable.

- `slow_query_log` [541]

<b>Command-Line Format</b>	<code>--slow-query-log</code>	
<b>Option-File Format</b>	<code>slow-query-log</code>	
<b>Option Sets Variable</b>	Yes, <code>slow_query_log</code> [541]	
<b>Variable Name</b>	<code>slow_query_log</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--slow_query_log` [541] option is given. The destination for log output is controlled by the `log_output` [498] system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` [500] variable. See Section 5.2.5, “The Slow Query Log”.

- `slow_query_log_file` [541]

<b>Command-Line Format</b>	<code>--slow-query-log-file=file_name</code>	
<b>Option-File Format</b>	<code>slow_query_log_file</code>	
<b>Option Sets Variable</b>	Yes, <code>slow_query_log_file</code> [541]	
<b>Variable Name</b>	<code>slow_query_log_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- [socket \[542\]](#)

<b>Command-Line Format</b>	<code>--socket=name</code>	
<b>Option-File Format</b>	<code>socket</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">socket [542]</a>	
<b>Variable Name</b>	<code>socket</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>/tmp/mysql.sock</code>

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case sensitive).

- [sort\\_buffer\\_size \[542\]](#)

<b>Command-Line Format</b>	<code>--sort_buffer_size=#</code>	
<b>Option-File Format</b>	<code>sort_buffer_size</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">sort_buffer_size [542]</a>	
<b>Variable Name</b>	<code>sort_buffer_size</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.3)</b>	
	<b>Platform Bit Size</b>	<code>64</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>2097144</code>
	<b>Range</b>	<code>32768 .. 18446744073709547520</code>
	<b>Permitted Values (&lt;= 5.6.3)</b>	
	<b>Platform Bit Size</b>	<code>32</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>2097144</code>
	<b>Range</b>	<code>32768 .. 4294967295</code>
	<b>Permitted Values (&gt;= 5.6.4)</b>	
	<b>Platform Bit Size</b>	<code>64</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>262144</code>

	<b>Range</b>	32768 .. 18446744073709547520
	<b>Permitted Values (&gt;= 5.6.4)</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	262144
	<b>Range</b>	32768 .. 4294967295

Each session that needs to do a sort allocates a buffer of this size. `sort_buffer_size` [542] is not specific to any storage engine and applies in a general manner for optimization. See [Section 8.13.13, “ORDER BY Optimization”](#), for example.

If you see many `Sort_merge_passes` [599] per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` [542] value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

As of MySQL 5.6.4, the optimizer tries to work out how much space is needed but can allocate more, up to the limit. Before MySQL 5.6.4, the optimizer allocates the entire buffer even if it is not all needed. In either case, setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See [Section C.5.4.4, “Where MySQL Stores Temporary Files”](#).

The maximum permissible setting for `sort_buffer_size` [542] is 4GB. Values larger than 4GB are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

- `sql_auto_is_null` [543]

<b>Variable Name</b>	<code>sql_auto_is_null</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	0

If this variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` [1269] function. For details, including the return value after a multiple-row insert, see [Section 12.14, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` [1168] comparison is used by some ODBC programs, such as Access. See [Section 21.1.7.1.1, “Obtaining Auto-Increment Values”](#). This behavior can be disabled by setting `sql_auto_is_null` [543] to 0.

The default value of `sql_auto_is_null` [543] is 0 in MySQL 5.6.

- `sql_big_selects` [543]

<b>Variable Name</b>	<code>sql_big_selects</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>1</code>

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size` [505]). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which permits all `SELECT` statements.

If you set the `max_join_size` [505] system variable to a value other than `DEFAULT`, `sql_big_selects` [543] is set to 0.

- `sql_buffer_result` [544]

<b>Variable Name</b>	<code>sql_buffer_result</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>0</code>

If set to 1, `sql_buffer_result` [544] forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- `sql_log_bin` [544]

<b>Variable Name</b>	<code>sql_log_bin</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>

This variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` [756] privilege to set this variable.

In MySQL 5.6, it is not possible to set `@@session.sql_log_bin` within a transaction or subquery. (Bug #53437)

- `sql_log_off` [544]

<b>Variable Name</b>	<code>sql_log_off</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>0</code>

This variable controls whether logging to the general query log is done. The default value is 0 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` [756] privilege to set this option. The default value is 0.

- `sql_mode` [545]

<b>Command-Line Format</b>	<code>--sql-mode=name</code>
<b>Option-File Format</b>	<code>sql-mode</code>
<b>Option Sets Variable</b>	Yes, <code>sql_mode</code> [545]
<b>Variable Name</b>	<code>sql_mode</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&lt;= 5.6.5)</b>
	<b>Type</b> <code>set</code>
	<b>Default</b> <code>''</code>
	<b>Valid Values</b> <code>ALLOW_INVALID_DATES</code> <code>ANSI_QUOTES</code> <code>ERROR_FOR_DIVISION_BY_ZERO</code> <code>HIGH_NOT_PRECEDENCE</code> <code>IGNORE_SPACE</code> <code>NO_AUTO_CREATE_USER</code> <code>NO_AUTO_VALUE_ON_ZERO</code> <code>NO_BACKSLASH_ESCAPES</code> <code>NO_DIR_IN_CREATE</code> <code>NO_ENGINE_SUBSTITUTION</code> <code>NO_FIELD_OPTIONS</code> <code>NO_KEY_OPTIONS</code> <code>NO_TABLE_OPTIONS</code> <code>NO_UNSIGNED_SUBTRACTION</code> <code>NO_ZERO_DATE</code> <code>NO_ZERO_IN_DATE</code> <code>ONLY_FULL_GROUP_BY</code> <code>PAD_CHAR_TO_FULL_LENGTH</code> <code>PIPES_AS_CONCAT</code> <code>REAL_AS_FLOAT</code> <code>STRICT_ALL_TABLES</code>

	STRICT_TRANS_TABLES
	<b>Permitted Values (&gt;= 5.6.6)</b>
<b>Type</b>	set
<b>Default</b>	NO_ENGINE_SUBSTITUTION
<b>Valid Values</b>	ALLOW_INVALID_DATES ANSI_QUOTES ERROR_FOR_DIVISION_BY_ZERO HIGH_NOT_PRECEDENCE IGNORE_SPACE NO_AUTO_CREATE_USER NO_AUTO_VALUE_ON_ZERO NO_BACKSLASH_ESCAPES NO_DIR_IN_CREATE NO_ENGINE_SUBSTITUTION NO_FIELD_OPTIONS NO_KEY_OPTIONS NO_TABLE_OPTIONS NO_UNSIGNED_SUBTRACTION NO_ZERO_DATE NO_ZERO_IN_DATE ONLY_FULL_GROUP_BY PAD_CHAR_TO_FULL_LENGTH PIPES_AS_CONCAT REAL_AS_FLOAT STRICT_ALL_TABLES STRICT_TRANS_TABLES

The current server SQL mode, which can be set dynamically. The default as of MySQL 5.6.6 is `NO_ENGINE_SUBSTITUTION`; previously it was an empty string. See [Section 5.1.7, “Server SQL Modes”](#).

- [sql\\_notes \[546\]](#)

If set to 1 (the default), warnings of `Note` level increment `warning_count` and the server records them. If set to 0, `Note` warnings do not increment `warning_count` [564] and the server does not record them. `mysqldump` includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- [sql\\_quote\\_show\\_create \[546\]](#)

If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 13.7.5.12, “SHOW CREATE TABLE Syntax”](#), and [Section 13.7.5.8, “SHOW CREATE DATABASE Syntax”](#).

- `sql_safe_updates` [\[547\]](#)

If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- `sql_select_limit` [\[547\]](#)

<b>Variable Name</b>	<code>sql_select_limit</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are  $(2^{32})-1$  or  $(2^{64})-1$ . If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit` [\[547\]](#).

- `sql_warnings` [\[547\]](#)

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- `ssl_ca` [\[547\]](#)

<b>Command-Line Format</b>	<code>--ssl-ca=name</code>	
<b>Option-File Format</b>	<code>ssl-ca</code>	
<b>Option Sets Variable</b>	Yes, <code>ssl_ca</code> <a href="#">[547]</a>	
<b>Variable Name</b>	<code>ssl-ca</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The path to a file with a list of trusted SSL CAs.

- `ssl_capath` [\[547\]](#)

<b>Command-Line Format</b>	<code>--ssl-capath=name</code>	
<b>Option-File Format</b>	<code>ssl-capath</code>	
<b>Option Sets Variable</b>	Yes, <code>ssl_capath</code> <a href="#">[547]</a>	
<b>Variable Name</b>	<code>ssl-capath</code>	
<b>Variable Scope</b>	Global	

<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	directory name

The path to a directory that contains trusted SSL CA certificates in PEM format.

- [ssl\\_cert \[548\]](#)

<b>Command-Line Format</b>	<code>--ssl-cert=name</code>	
<b>Option-File Format</b>	<code>ssl-cert</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">ssl_cert [548]</a>	
<b>Variable Name</b>	<code>ssl-cert</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

The name of the SSL certificate file to use for establishing a secure connection.

- [ssl\\_cipher \[548\]](#)

<b>Command-Line Format</b>	<code>--ssl-cipher=name</code>	
<b>Option-File Format</b>	<code>ssl-cipher</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">ssl_cipher [548]</a>	
<b>Variable Name</b>	<code>ssl-cipher</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

A list of permissible ciphers to use for SSL encryption.

- [ssl\\_crl \[548\]](#)

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--ssl-crl=name</code>	
<b>Option-File Format</b>	<code>ssl-crl</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">ssl_crl [548]</a>	
<b>Variable Name</b>	<code>ssl-crl</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	file name

The path to a file containing certificate revocation lists in PEM format. Revocation lists work for MySQL distributions compiled against OpenSSL (but not yaSSL).

This variable was added in MySQL 5.6.3.

- [ssl\\_crlpath \[548\]](#)

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--ssl-crlpath=name</code>	
<b>Option-File Format</b>	<code>ssl-crlpath</code>	
<b>Option Sets Variable</b>	Yes, <code>ssl_crlpath</code> [548]	
<b>Variable Name</b>	<code>ssl-crlpath</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>directory name</code>

The path to a directory that contains files containing certificate revocation lists in PEM format. Revocation lists work for MySQL distributions compiled against OpenSSL (but not yaSSL).

This variable was added in MySQL 5.6.3.

- `ssl_key` [549]

<b>Command-Line Format</b>	<code>--ssl-key=name</code>	
<b>Option-File Format</b>	<code>ssl-key</code>	
<b>Option Sets Variable</b>	Yes, <code>ssl_key</code> [549]	
<b>Variable Name</b>	<code>ssl-key</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The name of the SSL key file to use for establishing a secure connection.

- `storage_engine` [549]

<b>Variable Name</b>	<code>storage_engine</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>InnoDB</code>

The default storage engine (table type). To set the storage engine at server startup, use the `--default-storage-engine` [420] option. See Section 5.1.3, “Server Command Options”.

This variable is deprecated. Use `default_storage_engine` [474] instead.

- `stored_program_cache` [549]

<b>Version Introduced</b>	5.6.5	
<b>Command-Line Format</b>	<code>--stored-program-cache=#</code>	
<b>Option-File Format</b>	<code>stored_program_cache</code>	
<b>Variable Name</b>	<code>stored_program_cache</code>	
<b>Variable Scope</b>	Global	

<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	256
	<b>Range</b>	256 .. 524288

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

- [sync\\_frm \[550\]](#)

<b>Command-Line Format</b>	<code>--sync_frm</code>	
<b>Option-File Format</b>	<code>sync_frm</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">sync_frm [550]</a>	
<b>Variable Name</b>	<code>sync_frm</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	boolean
	<b>Default</b>	TRUE

If this variable is set to 1, when any nontemporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

- [system\\_time\\_zone \[550\]](#)

<b>Variable Name</b>	<code>system_time_zone</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	string

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set [system\\_time\\_zone \[550\]](#). Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone [229]` option of the `mysqld_safe` script.

The [system\\_time\\_zone \[550\]](#) variable differs from [time\\_zone \[557\]](#). Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 10.6, “MySQL Server Time Zone Support”](#).

- [table\\_definition\\_cache \[550\]](#)

<b>Command-Line Format</b>	<code>--table_definition_cache=#</code>	
<b>Option-File Format</b>	<code>table_definition_cache</code>	
<b>Option Sets Variable</b>	Yes, <code>table_definition_cache</code> [550]	
<b>Variable Name</b>	<code>table_definition_cache</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.7)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>400</code>
	<b>Range</b>	<code>400 .. 524288</code>
	<b>Permitted Values (&gt;= 5.6.8)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>-1 (autosized)</code>
	<b>Range</b>	<code>400 .. 524288</code>

The number of table definitions (from `.frm` files) that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

```
400 + (table_open_cache / 2)
```

Before MySQL 5.6.8, the default is 400.

- `table_open_cache` [551]

<b>Command-Line Format</b>	<code>--table-open-cache=#</code>	
<b>Option-File Format</b>	<code>table_open_cache</code>	
<b>Variable Name</b>	<code>table_open_cache</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.7)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>400</code>
	<b>Range</b>	<code>400 .. 524288</code>
	<b>Permitted Values (&gt;= 5.6.8)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>2000</code>
	<b>Range</b>	<code>400 .. 524288</code>

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` [595] status variable. See Section 5.1.6, “Server Status Variables”. If the value of `Opened_tables` [595] is large and you do not use `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_open_cache` [551] variable. For more information about the table cache, see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

- [table\\_open\\_cache\\_instances](#) [552]

<b>Version Introduced</b>	5.6.6	
<b>Command-Line Format</b>	<code>--table-open-cache_instances=#</code>	
<b>Option-File Format</b>	<code>table_open_cache_instances</code>	
<b>Variable Name</b>	<code>table_open_cache_instances</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>

The number of open tables cache instances (default 1). To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size `table_open_cache` [551] / `table_open_cache_instances` [552]. A session need lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that need to use the cache when many there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

This variable was added in MySQL 5.6.6.

- [thread\\_cache\\_size](#) [552]

<b>Command-Line Format</b>	<code>--thread_cache_size=#</code>	
<b>Option-File Format</b>	<code>thread_cache_size</code>	
<b>Option Sets Variable</b>	Yes, <code>thread_cache_size</code> [552]	
<b>Variable Name</b>	<code>thread_cache_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values (&lt;= 5.6.7)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 16384</code>
	<b>Permitted Values (&gt;= 5.6.8)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>-1 (autosized)</code>
	<b>Range</b>	<code>0 .. 16384</code>

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` [552] threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` [552] high enough so that most new connections use cached threads. By examining the difference between the

`Connections` [587] and `Threads_created` [601] status variables, you can see how efficient the thread cache is. For details, see [Section 5.1.6, “Server Status Variables”](#).

The default value is based on the following formula, capped to a limit of 100:

```
8 + (max_connections / 100)
```

Before MySQL 5.6.8, the default is 0.

- `thread_concurrency` [553]

<b>Version Deprecated</b>	5.6.1	
<b>Command-Line Format</b>	<code>--thread_concurrency=#</code>	
<b>Option-File Format</b>	<code>thread_concurrency</code>	
<b>Option Sets Variable</b>	Yes, <code>thread_concurrency</code> [553]	
<b>Variable Name</b>	<code>thread_concurrency</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Deprecated</b>	5.6.1	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>10</code>
	<b>Range</b>	<code>1 .. 512</code>

This variable is specific to Solaris systems, for which `mysqld` invokes the `thr_setconcurrency()` with the variable value. This function enables applications to give the threads system a hint about the desired number of threads that should be run at the same time.

This variable is deprecated as of MySQL 5.6.1 and will be removed in a future MySQL release.

- `thread_handling` [553]

<b>Command-Line Format</b>	<code>--thread_handling=name</code>	
<b>Option-File Format</b>	<code>thread_handling=name</code>	
<b>Option Sets Variable</b>	Yes, <code>thread_handling</code> [553]	
<b>Variable Name</b>	<code>thread_handling</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Valid Values</b>	<code>no-threads</code> <code>one-thread-per-connection</code> <code>dynamically-loaded</code>

The thread-handling model used by the server for connection threads. The permissible values are `no-threads` (the server uses a single thread) and `one-thread-per-connection` (the server uses one thread to handle each client connection). `no-threads` is useful for debugging under Linux; see [MySQL Internals: Porting to Other Systems](#).

If the thread pool plugin is enabled, the server sets the `thread_handling` [553] value to `dynamically-loaded`. See Section 8.11.6.1, “Thread Pool Components and Installation”.

- `thread_pool_algorithm` [554]

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--thread_pool_algorithm=#</code>	
<b>Option-File Format</b>	<code>thread_pool_algorithm=#</code>	
<b>Option Sets Variable</b>	Yes, <code>thread_pool_algorithm</code> [554]	
<b>Variable Name</b>	<code>thread_pool_algorithm</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 1</code>

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.
- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See Section 8.11.6, “The Thread Pool Plugin”

- `thread_pool_high_priority_connection` [554]

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--thread_pool_high_priority_connection=#</code>	
<b>Option-File Format</b>	<code>thread_pool_high_priority_connection=#</code>	
<b>Option Sets Variable</b>	Yes, <code>thread_pool_high_priority_connection</code> [554]	
<b>Variable Name</b>	<code>thread_pool_high_priority_connection</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0 .. 1</code>

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See Section 8.11.6, “The Thread Pool Plugin”

- `thread_pool_max_unused_threads` [555]

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--thread_pool_max_unused_threads=#</code>	
<b>Option-File Format</b>	<code>thread_pool_max_unused_threads=#</code>	
<b>Option Sets Variable</b>	Yes, <code>thread_pool_max_unused_threads</code> [555]	
<b>Variable Name</b>	<code>thread_pool_max_unused_threads</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0 .. 4096

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of  $N$  where  $N$  is greater than 0 means 1 consumer thread and  $N-1$  reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it will sleep as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- `thread_pool_prio_kickup_timer` [555]

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--thread_pool_prio_kickup_timer=#</code>	
<b>Option-File Format</b>	<code>thread_pool_prio_kickup_timer=#</code>	
<b>Option Sets Variable</b>	Yes, <code>thread_pool_prio_kickup_timer</code> [555]	
<b>Variable Name</b>	<code>thread_pool_prio_kickup_timer</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	1000
	<b>Range</b>	0 .. 4294967294

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second). The range of values is 0 to  $2^{32} - 2$ .

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- [thread\\_pool\\_size \[556\]](#)

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--thread_pool_size=#</code>	
<b>Option-File Format</b>	<code>thread_pool_size=#</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">thread_pool_size [556]</a>	
<b>Variable Name</b>	<code>thread_pool_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>16</code>
	<b>Range</b>	<code>1 .. 64</code>

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. The default value is 16, with a range from 1 to 64 of permissible values. If a value outside this range is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- [thread\\_pool\\_stall\\_limit \[556\]](#)

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--thread_pool_stall_limit=#</code>	
<b>Option-File Format</b>	<code>thread_pool_stall_limit=#</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">thread_pool_stall_limit [556]</a>	
<b>Variable Name</b>	<code>thread_pool_stall_limit</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>6</code>
	<b>Range</b>	<code>4 .. 600</code>

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so a value of 6 (the default) means 60ms. The range of values is 4 to 600 (40ms to 6s). Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- [thread\\_stack \[556\]](#)

<b>Command-Line Format</b>	<code>--thread_stack=#</code>
----------------------------	-------------------------------

<b>Option-File Format</b>	<code>thread_stack</code>
<b>Option Sets Variable</b>	Yes, <code>thread_stack</code> [556]
<b>Variable Name</b>	<code>thread_stack</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	<code>numeric</code>
<b>Default</b>	196608
<b>Range</b>	131072 .. 4294967295
<b>Block Size</b>	1024
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	<code>numeric</code>
<b>Default</b>	262144
<b>Range</b>	131072 .. 18446744073709547520
<b>Block Size</b>	1024

The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. See [Section 8.12.2, “The MySQL Benchmark Suite”](#). The default of 192KB (256KB for 64-bit systems) is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_format` [557]

This variable is unused. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- `time_zone` [557]

<b>Command-Line Format</b>	<code>--default_time_zone=string</code>
<b>Option-File Format</b>	<code>default_time_zone</code>
<b>Variable Name</b>	<code>time_zone</code>
<b>Variable Scope</b>	Global, Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	<code>string</code>

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is `'SYSTEM'` (which means, “use the value of `system_time_zone` [550]”). The value can be specified explicitly at server startup with the `--default-time-zone` [420] option. See [Section 10.6, “MySQL Server Time Zone Support”](#).

- `timed_mutexes` [557]

<b>Command-Line Format</b>	<code>--timed_mutexes</code>	
<b>Option-File Format</b>	<code>timed_mutexes</code>	
<b>Option Sets Variable</b>	Yes, <code>timed_mutexes</code> [557]	
<b>Variable Name</b>	<code>timed_mutexes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

This variable controls whether `InnoDB` mutexes are timed. If this variable is set to 0 or `OFF` (the default), mutex timing is disabled. If the variable is set to 1 or `ON`, mutex timing is enabled. With timing enabled, the `os_wait_times` value in the output from `SHOW ENGINE INNODB MUTEX` indicates the amount of time (in ms) spent in operating system waits. Otherwise, the value is 0.

- `timestamp = {timestamp_value | DEFAULT}` [558]

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp, not a MySQL timestamp.

As of MySQL 5.6.4, `timestamp` [558] is a `DOUBLE` rather than `BIGINT` because its value includes a microseconds part.

`SET timestamp` affects the value returned by `NOW()` [1220] but not by `SYSDATE()` [1223]. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()` [1223]. The server can be started with the `--sysdate-is-now` [444] option to cause `SYSDATE()` [1223] to be an alias for `NOW()` [1220], in which case `SET timestamp` affects both functions.

- `tmp_table_size` [558]

<b>Command-Line Format</b>	<code>--tmp_table_size=#</code>	
<b>Option-File Format</b>	<code>tmp_table_size</code>	
<b>Option Sets Variable</b>	Yes, <code>tmp_table_size</code> [558]	
<b>Variable Name</b>	<code>tmp_table_size</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>system dependent</code>
	<b>Range</b>	<code>1024 .. 4294967295</code>

The maximum size of internal in-memory temporary tables. (The actual limit is determined as the minimum of `tmp_table_size` [558] and `max_heap_table_size` [504].) If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk `MyISAM` table. Increase the value of `tmp_table_size` [558] (and `max_heap_table_size` [504] if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory. This variable does not apply to user-created `MEMORY` tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` [587] and `Created_tmp_tables` [588] variables.

See also [Section 8.4.3.3, “How MySQL Uses Internal Temporary Tables”](#).

- `tmpdir` [\[559\]](#)

<b>Command-Line Format</b>	<code>--tmpdir=path</code>	
	<code>-t</code>	
<b>Option-File Format</b>	<code>tmpdir</code>	
<b>Option Sets Variable</b>	Yes, <code>tmpdir</code> <a href="#">[559]</a>	
<b>Variable Name</b>	<code>tmpdir</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>file name</code>

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (“:”) on Unix and semicolon characters (“;”) on Windows.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` [\[559\]](#) to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. You can set the slave's temporary directory using the `slave_load_tmpdir` [\[1992\]](#) variable. In that case, the slave will not use the general `tmpdir` [\[559\]](#) value and you can set `tmpdir` [\[559\]](#) to a nonpermanent location.

- `transaction_alloc_block_size` [\[559\]](#)

<b>Command-Line Format</b>	<code>--transaction_alloc_block_size=#</code>	
<b>Option-File Format</b>	<code>transaction_alloc_block_size</code>	
<b>Option Sets Variable</b>	Yes, <code>transaction_alloc_block_size</code> <a href="#">[559]</a>	
<b>Variable Name</b>	<code>transaction_alloc_block_size</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	8192
	<b>Range</b>	1024 .. 4294967295
	<b>Block Size</b>	1024
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	8192

	<b>Range</b>	1024 .. 18446744073709547520
	<b>Block Size</b>	1024

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size` [560].

- `transaction_prealloc_size` [560]

<b>Command-Line Format</b>	<code>--transaction_prealloc_size=#</code>	
<b>Option-File Format</b>	<code>transaction_prealloc_size</code>	
<b>Option Sets Variable</b>	Yes, <code>transaction_prealloc_size</code> [560]	
<b>Variable Name</b>	<code>transaction_prealloc_size</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	4096
	<b>Range</b>	1024 .. 4294967295
	<b>Block Size</b>	1024
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	4096
	<b>Range</b>	1024 .. 18446744073709547520
	<b>Block Size</b>	1024

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size` [560]. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` [559] bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` [560] bytes.

By making `transaction_prealloc_size` [560] sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `tx_isolation` [560]

<b>Variable Name</b>	<code>tx_isolation</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	REPEATABLE-READ

	<b>Valid Values</b>	<a href="#">READ-UNCOMMITTED</a> <a href="#">READ-COMMITTED</a> <a href="#">REPEATABLE-READ</a> <a href="#">SERIALIZABLE</a>
--	---------------------	---

The default transaction isolation level. Defaults to [REPEATABLE-READ](#) [1469].

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See [Section 13.3.6, “SET TRANSACTION Syntax”](#). If you set `tx_isolation` [560] directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

Any unique prefix of a valid value may be used to set the value of this variable.

The default transaction isolation level can also be set at startup using the `--transaction-isolation` [445] server option.

- [tx\\_read\\_only](#) [561]

<b>Version Introduced</b>	5.6.5	
<b>Variable Name</b>	<a href="#">tx_read_only</a>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">boolean</a>
	<b>Default</b>	<a href="#">OFF</a>

The default transaction access mode. The value can be [OFF](#) (read/write, the default) or [ON](#) (read only).

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

To set the default transaction access mode at startup, use the `--transaction-read-only` [445] server option.

This variable was added in MySQL 5.6.5.

- [unique\\_checks](#) [561]

<b>Variable Name</b>	<a href="#">unique_checks</a>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">boolean</a>
	<b>Default</b>	<a href="#">1</a>

If set to 1 (the default), uniqueness checks for secondary indexes in [InnoDB](#) tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to [InnoDB](#).

Note that setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- [updatable\\_views\\_with\\_limit](#) [562]

<b>Command-Line Format</b>	<code>--updatable_views_with_limit=#</code>	
<b>Option-File Format</b>	<code>updatable_views_with_limit</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">updatable_views_with_limit</a> [562]	
<b>Variable Name</b>	<code>updatable_views_with_limit</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>1</code>

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a `LIMIT` clause. (Such updates often are generated by GUI tools.) An update is an `UPDATE` or `DELETE` statement. Primary key here means a `PRIMARY KEY`, or a `UNIQUE` index in which no column can contain `NULL`.

The variable can have two values:

- `1` or `YES`: Issue a warning only (not an error message). This is the default value.
  - `0` or `NO`: Prohibit the update.
- [validate\\_password\\_xxx](#)

The `validate_password` plugin implements a set of system variables having names of the form `validate_password_xxx`. These variables affect password testing by that plugin; see [Section 6.1.2.6.2, “Password Validation Plugin Options and Variables”](#).

- [validate\\_user\\_plugins](#) [562]

<b>Version Introduced</b>	5.6.11	
<b>Variable Name</b>	<code>validate_user_plugins</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

If this variable is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.
- The account requires the `sha256_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by this plugin.

Enabling `validate_user_plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this variable at startup to avoid the performance decrement.

This variable was added in MySQL 5.6.11.

- `version` [563]

The version number for the server. The value might also include a suffix indicating server build or configuration information. `-log` indicates that one or more of the general log, slow query log, or binary log are enabled. `-debug` indicates that the server was built with debugging support enabled.

- `version_comment` [563]

<b>Variable Name</b>	<code>version_comment</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The CMake configuration program has a `COMPILATION_COMMENT` [134] option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. See Section 2.9.4, “MySQL Source-Configuration Options”.

- `version_compile_machine` [563]

<b>Variable Name</b>	<code>version_compile_machine</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The type of the server binary.

- `version_compile_os` [563]

<b>Variable Name</b>	<code>version_compile_os</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

The type of operating system on which MySQL was built.

- `wait_timeout` [563]

<b>Command-Line Format</b>	<code>--wait_timeout=#</code>	
<b>Option-File Format</b>	<code>wait_timeout</code>	
<b>Option Sets Variable</b>	Yes, <code>wait_timeout</code> [563]	
<b>Variable Name</b>	<code>wait_timeout</code>	
<b>Variable Scope</b>	Global, Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>28800</code>

	<b>Range</b>	1 .. 31536000
	<b>Permitted Values</b>	
	<b>Type</b> (windows)	numeric
	<b>Default</b>	28800
	<b>Range</b>	1 .. 2147483

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` [563] value is initialized from the global `wait_timeout` [563] value or from the global `interactive_timeout` [490] value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout` [490].

- `warning_count` [564]

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

## 5.1.5. Using System Variables

The MySQL server maintains many system variables that indicate how it is configured. [Section 5.1.4, “Server System Variables”](#), describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

The server maintains two kinds of system variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes all global variables to their default values. These defaults can be changed by options specified on the command line or in an option file. (See [Section 4.2.3, “Specifying Program Options”](#).)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, the client's SQL mode is controlled by the session `sql_mode` [545] value, which is initialized when the client connects to the value of the global `sql_mode` [545] value.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024<sup>2</sup> or 1024<sup>3</sup>; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --query_cache_size=16M --max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

If you want to restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, you can specify this maximum by using an option of the form

`--maximum-var_name=value` at server startup. For example, to prevent the value of `query_cache_size` [528] from being increased to more than 32MB at runtime, use the option `--maximum-query_cache_size=32M`.

Many system variables are dynamic and can be changed while the server runs by using the `SET` statement. For a list, see [Section 5.1.5.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it as `var_name`, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global..`. The `SUPER` [756] privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session.`, or `@@`. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session..`
- If no modifier is present, `SET` changes the session variable.

A `SET` statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

The `@@var_name` syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the `SET GLOBAL` statement).

To prevent incorrect usage, MySQL produces an error if you use `SET GLOBAL` with a variable that can only be used with `SET SESSION` or if you do not specify `GLOBAL` (or `@@global..`) when setting a global variable.

To set a `SESSION` variable to the `GLOBAL` value or a `GLOBAL` value to the compiled-in MySQL default value, use the `DEFAULT` keyword. For example, the following two statements are identical in setting the session value of `max_join_size` [505] to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, use of `DEFAULT` results in an error.

You can refer to the values of specific global or session system variables in expressions by using one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

**Note**

Some variables displayed by `SHOW VARIABLES` may not be available using `SELECT @@var_name` syntax; an `Unknown system variable` occurs. As a workaround in such cases, you can use `SHOW VARIABLES LIKE 'var_name'`.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

**Note**

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` [475] works but `--delay_key_write=ON` [475] does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
| automatic_sp_privileges | ON |
| back_log | 50 |
| basedir | /home/mysql/ |
| binlog_cache_size | 32768 |
| bulk_insert_buffer_size | 8388608 |
| character_set_client | latin1 |
| character_set_connection | latin1 |
| character_set_database | latin1 |
| character_set_results | latin1 |
| character_set_server | latin1 |
| character_set_system | utf8 |
| character_sets_dir | /home/mysql/share/mysql/charsets/ |
| collation_connection | latin1_swedish_ci |
| collation_database | latin1_swedish_ci |
| collation_server | latin1_swedish_ci |
| ... | ... |
| innodb_additional_mem_pool_size | 1048576 |
| innodb_autoextend_increment | 8 |
| innodb_buffer_pool_size | 8388608 |
| innodb_checksums | ON |
| innodb_commit_concurrency | 0 |
| innodb_concurrency_tickets | 500 |
| innodb_data_file_path | ibdata1:10M:autoextend |
| innodb_data_home_dir | |
| ... | ... |
| version | 5.1.6-alpha-log |
| version_comment | Source distribution |
| version_compile_machine | i686 |
| version_compile_os | suse-linux |
| wait_timeout | 28800 |
+-----+-----+
```

With a [LIKE \[1190\]](#) clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a [LIKE \[1190\]](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the “%” wildcard character in a [LIKE \[1190\]](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because “\_” is a wildcard that matches any single character, you should escape it as “\\_” to match it literally. In practice, this is rarely necessary.

For [SHOW VARIABLES](#), if you specify neither [GLOBAL](#) nor [SESSION](#), MySQL returns [SESSION](#) values.

The reason for requiring the [GLOBAL](#) keyword when setting [GLOBAL](#)-only variables but not when retrieving them is to prevent problems in the future. If we were to remove a [SESSION](#) variable that has the same name as a [GLOBAL](#) variable, a client with the [SUPER \[756\]](#) privilege might accidentally change the [GLOBAL](#) variable rather than just the [SESSION](#) variable for its own connection. If we add a [SESSION](#) variable with the same name as a [GLOBAL](#) variable, a client that intends to change the [GLOBAL](#) variable might find only its own [SESSION](#) variable changed.

### 5.1.5.1. Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL 5.6 supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- [key\\_buffer\\_size \[492\]](#)
- [key\\_cache\\_block\\_size \[493\]](#)
- [key\\_cache\\_division\\_limit \[494\]](#)
- [key\\_cache\\_age\\_threshold \[493\]](#)

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in [Section 8.9.2, “The MyISAM Key Cache”](#).

To refer to a component of a structured variable instance, you can use a compound name in [instance\\_name.component\\_name](#) format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of [default](#) is always predefined. If you refer to a component of a structured variable without any instance name, the [default](#) instance is used. Thus, [default.key\\_buffer\\_size](#) and [key\\_buffer\\_size \[492\]](#) both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable

types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.

- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@global.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
  --extra_cache.key_buffer_size=128K \
  --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
  --hot_cache.key_buffer_size=2M \
  --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` [1190] pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

### 5.1.5.2. Dynamic System Variables

Many server system variables are dynamic and can be set at runtime using `SET GLOBAL` or `SET SESSION`. You can also obtain their values using `SELECT`. See [Section 5.1.5, “Using System Variables”](#).

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether `GLOBAL` or `SESSION` (or both) apply. The table also lists session options that can be set with the `SET` statement. [Section 5.1.4, “Server System Variables”](#), discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. (If you set them on the command line or in an option file, use the numeric values.) Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from `ENUM` columns, for which the first enumeration value corresponds to 1.

**Table 5.4. Dynamic Variable Summary**

Variable Name	Variable Type	Variable Scope

### 5.1.6. Server Status Variables

The server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see [Section 13.7.5.36, “SHOW STATUS Syntax”](#)). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_clients | 0 |
| Aborted_connects | 0 |
| Bytes_received | 155372598 |
| Bytes_sent | 1176560426 |
| ... | |
| Connections | 30023 |
| Created_tmp_disk_tables | 0 |
| Created_tmp_files | 3 |
| Created_tmp_tables | 2 |
| ... | |
| Threads_created | 217 |
| Threads_running | 88 |
| Uptime | 1389872 |
+-----+-----+
```

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

The following table lists all available server status variables:

**Table 5.5. Status Variable Summary**

Variable Name	Variable Type	Variable Scope
<a href="#">Aborted_clients [585]</a>	numeric	GLOBAL
<a href="#">Aborted_connects [585]</a>	numeric	GLOBAL

## Server Status Variables

Variable Name	Variable Type	Variable Scope
<a href="#">Binlog_cache_disk_use [586]</a>	numeric	GLOBAL

The status variables have the following meanings.

- [Aborted\\_clients \[585\]](#)

The number of connections that were aborted because the client died without closing the connection properly. See [Section C.5.2.11, “Communication Errors and Aborted Connections”](#).

- [Aborted\\_connects \[585\]](#)

The number of failed attempts to connect to the MySQL server. See [Section C.5.2.11, “Communication Errors and Aborted Connections”](#).

For additional connection-related information, check the `Connection_errors_xxx` [587] status variables and the `host_cache` table.

- `Binlog_cache_disk_use` [586]

The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` [2008] and used a temporary file to store statements from the transaction.

The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the `Binlog_stmt_cache_disk_use` [586] status variable.

- `Binlog_cache_use` [586]

The number of transactions that used the binary log cache.

- `Binlog_stmt_cache_disk_use` [586]

The number of nontransaction statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` [2014] and used a temporary file to store those statements.

- `Binlog_stmt_cache_use` [586]

The number of nontransactional statements that used the binary log statement cache.

- `Bytes_received` [586]

The number of bytes received from all clients.

- `Bytes_sent` [586]

The number of bytes sent to all clients.

- `Com_xxx`

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

If a query result is returned from query cache, the server increments the `Qcache_hits` [595] status variable, not `Com_select`. See [Section 8.9.3.4, “Query Cache Status and Maintenance”](#).

All of the `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

The `Com_stmt_xxx` status variables are as follows:

- `Com_stmt_prepare`
- `Com_stmt_execute`
- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

- [Compression \[587\]](#)

Whether the client connection uses compression in the client/server protocol.

- [Connection\\_errors\\_xxx \[587\]](#)

These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#)), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). These variables were added in MySQL 5.6.5.

- [Connection\\_errors\\_accept \[587\]](#)

The number of errors that occurred during calls to `accept()` on the listening port.

- [Connection\\_errors\\_internal \[587\]](#)

The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

- [Connection\\_errors\\_max\\_connections \[587\]](#)

The number of connections refused because the server `max_connections` [\[503\]](#) limit was reached.

- [Connection\\_errors\\_peer\\_addr \[587\]](#)

The number of errors that occurred while searching for connecting client IP addresses.

- [Connection\\_errors\\_select \[587\]](#)

The number of errors that occurred during calls to `select()` or `poll()` on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

- [Connection\\_errors\\_tcpwrap \[587\]](#)

The number of connections refused by the `libwrap` library.

- [Connections \[587\]](#)

The number of connection attempts (successful or not) to the MySQL server.

- [Created\\_tmp\\_disk\\_tables \[587\]](#)

The number of internal on-disk temporary tables created by the server while executing statements.

If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` [558] and `max_heap_table_size` [504] values. If `Created_tmp_disk_tables` [587] is large, you may want to increase the `tmp_table_size` [558] or `max_heap_table_size` [504] value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` [587] and `Created_tmp_tables` [588] variables.

See also [Section 8.4.3.3, “How MySQL Uses Internal Temporary Tables”](#).

- `Created_tmp_files` [588]

How many temporary files `mysqld` has created.

- `Created_tmp_tables` [588]

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` [587] and `Created_tmp_tables` [588] variables.

See also [Section 8.4.3.3, “How MySQL Uses Internal Temporary Tables”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` [588] value.

- `Delayed_errors` [588]

The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).

As of MySQL 5.6.7, this status variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `Delayed_insert_threads` [588]

The number of `INSERT DELAYED` handler threads in use for nontransactional tables.

As of MySQL 5.6.7, this status variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `Delayed_writes` [588]

The number of `INSERT DELAYED` rows written to nontransactional tables.

As of MySQL 5.6.7, this status variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `Flush_commands` [588]

The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush` [586], which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- `Handler_commit` [588]

The number of internal `COMMIT` statements.

- [Handler\\_delete \[589\]](#)

The number of times that rows have been deleted from tables.

- [Handler\\_external\\_lock \[589\]](#)

The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked. This variable was added in MySQL 5.6.2.

- [Handler\\_mrr\\_init \[589\]](#)

The number of times the server uses a storage engine's own Multi-Range Read implementation for table access. This variable was added in MySQL 5.6.1.

- [Handler\\_prepare \[589\]](#)

A counter for the prepare phase of two-phase commit operations.

- [Handler\\_read\\_first \[589\]](#)

The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed.

- [Handler\\_read\\_key \[589\]](#)

The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- [Handler\\_read\\_last \[589\]](#)

The number of requests to read the last key in an index. With `ORDER BY`, the server will issue a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server will issue a last-key request followed by several previous-key requests. This variable was added in MySQL 5.6.1.

- [Handler\\_read\\_next \[589\]](#)

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- [Handler\\_read\\_prev \[589\]](#)

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- [Handler\\_read\\_rnd \[589\]](#)

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- [Handler\\_read\\_rnd\\_next \[589\]](#)

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- [Handler\\_rollback \[590\]](#)

The number of requests for a storage engine to perform a rollback operation.

- [Handler\\_savepoint \[590\]](#)

The number of requests for a storage engine to place a savepoint.

- [Handler\\_savepoint\\_rollback \[590\]](#)

The number of requests for a storage engine to roll back to a savepoint.

- [Handler\\_update \[590\]](#)

The number of requests to update a row in a table.

- [Handler\\_write \[590\]](#)

The number of requests to insert a row in a table.

- [Innodb\\_available\\_undo\\_logs \[590\]](#)

The total number of available [InnoDB undo logs](#). Supplements the [innodb\\_undo\\_logs \[1752\]](#) system variable, which reports the number of active undo logs.

- [Innodb\\_buffer\\_pool\\_dump\\_status \[590\]](#)

The progress of an operation to record the [pages](#) held in the [InnoDB buffer pool](#), triggered by the setting of [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) or [innodb\\_buffer\\_pool\\_dump\\_now](#).

- [Innodb\\_buffer\\_pool\\_load\\_status \[590\]](#)

The progress of an operation to [warm up](#) the [InnoDB buffer pool](#) by reading in a set of [pages](#) corresponding to an earlier point in time, triggered by the setting of [innodb\\_buffer\\_pool\\_load\\_at\\_startup \[1707\]](#) or [innodb\\_buffer\\_pool\\_load\\_now \[1708\]](#). If the operation introduces too much overhead, you can cancel it by setting [innodb\\_buffer\\_pool\\_load\\_abort \[1707\]](#).

- [Innodb\\_buffer\\_pool\\_bytes\\_data \[590\]](#)

The total number of bytes in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. For more accurate memory usage calculations than with [Innodb\\_buffer\\_pool\\_pages\\_data \[590\]](#), when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- [Innodb\\_buffer\\_pool\\_pages\\_data \[590\]](#)

The number of [pages](#) in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages.

- [Innodb\\_buffer\\_pool\\_bytes\\_dirty \[590\]](#)

The total current number of bytes held in [dirty pages](#) in the [InnoDB buffer pool](#). For more accurate memory usage calculations than with [Innodb\\_buffer\\_pool\\_pages\\_dirty \[590\]](#), when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- [Innodb\\_buffer\\_pool\\_pages\\_dirty \[590\]](#)

The current number of [dirty pages](#) in the [InnoDB buffer pool](#).

- [Innodb\\_buffer\\_pool\\_pages\\_flushed \[591\]](#)

The number of requests to [flush pages](#) from the [InnoDB buffer pool](#).

- [Innodb\\_buffer\\_pool\\_pages\\_free \[591\]](#)

The number of free [pages](#) in the [InnoDB buffer pool](#).

- [Innodb\\_buffer\\_pool\\_pages\\_latched \[591\]](#)

The number of latched [pages](#) in the [InnoDB buffer pool](#). These are pages currently being read or written, or that cannot be [flushed](#) or removed for some other reason. Calculation of this variable is expensive, so it is available only when the [UNIV\\_DEBUG](#) system is defined at server build time.

- [Innodb\\_buffer\\_pool\\_pages\\_misc \[591\]](#)

The number of [pages](#) in the [InnoDB buffer pool](#) that are busy because they have been allocated for administrative overhead, such as [row locks](#) or the [adaptive hash index](#). This value can also be calculated as [Innodb\\_buffer\\_pool\\_pages\\_total \[591\]](#) – [Innodb\\_buffer\\_pool\\_pages\\_free \[591\]](#) – [Innodb\\_buffer\\_pool\\_pages\\_data \[590\]](#).

- [Innodb\\_buffer\\_pool\\_pages\\_total \[591\]](#)

The total size of the [InnoDB buffer pool](#), in [pages](#).

- [Innodb\\_buffer\\_pool\\_read\\_ahead \[591\]](#)

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread.

- [Innodb\\_buffer\\_pool\\_read\\_ahead\\_evicted \[591\]](#)

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread that were subsequently [evicted](#) without having been accessed by queries.

- [Innodb\\_buffer\\_pool\\_read\\_requests \[591\]](#)

The number of logical read requests made to the [InnoDB buffer pool](#). These requests could be serviced by returning data that was already in memory, or by reading the data from disk into memory first.

- [Innodb\\_buffer\\_pool\\_reads \[591\]](#)

The number of logical reads that [InnoDB](#) could not satisfy from the [buffer pool](#), and had to read directly from disk.

- [Innodb\\_buffer\\_pool\\_wait\\_free \[591\]](#)

Normally, writes to the [InnoDB buffer pool](#) happen in the background. When [InnoDB](#) needs to read or create a [page](#) and no clean pages are available, [InnoDB](#) flushes some [dirty pages](#) first and waits for that operation to finish. This counter counts instances of these waits. If [innodb\\_buffer\\_pool\\_size \[1708\]](#) has been set properly, this value should be small.

- [Innodb\\_buffer\\_pool\\_write\\_requests \[591\]](#)

The number of writes done to the [InnoDB buffer pool](#).

- [Innodb\\_data\\_fsyncs \[591\]](#)

The number of `fsync()` operations so far. The frequency of `fsync()` calls is influenced by the setting of the [innodb\\_flush\\_method \[1719\]](#) configuration option.

- [Innodb\\_data\\_pending\\_fsyncs \[591\]](#)
-

The current number of pending `fsync()` operations. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` [1719] configuration option.

- `Innodb_data_pending_reads` [592]

The current number of pending reads.

- `Innodb_data_pending_writes` [592]

The current number of pending writes.

- `Innodb_data_read` [592]

The amount of data read since the server was started.

- `Innodb_data_reads` [592]

The total number of data reads.

- `Innodb_data_writes` [592]

The total number of data writes.

- `Innodb_data_written` [592]

The amount of data written so far, in bytes.

- `Innodb_dblwr_pages_written` [592]

The number of `pages` that have been written to the `doublewrite` buffer. See [Section 5.3.1, “InnoDB Disk I/O”](#).

- `Innodb_dblwr_writes` [592]

The number of `doublewrite` operations that have been performed. See [Section 5.3.1, “InnoDB Disk I/O”](#).

- `Innodb_have_atomic_builtins` [592]

Indicates whether the server was built with `atomic instructions`.

- `Innodb_log_waits` [592]

The number of times that the `log buffer` was too small and a `wait` was required for it to be `flushed` before continuing.

- `Innodb_log_write_requests` [592]

The number of write requests for the `InnoDB redo log`.

- `Innodb_log_writes` [592]

The number of physical writes to the `InnoDB redo log` file.

- `Innodb_num_open_files` [592]

The number of files `InnoDB` currently holds open.

- `Innodb_os_log_fsyncs` [592]

The number of `fsync()` writes done to the `InnoDB redo log` files.

- `Innodb_os_log_pending_fsyncs` [592]

The number of pending `fsync()` operations for the `InnoDB redo log` files.

- `InnoDB_os_log_pending_writes` [593]

The number of pending writes to the `InnoDB redo log` files.

- `InnoDB_os_log_written` [593]

The number of bytes written to the `InnoDB redo log` files.

- `InnoDB_page_size` [593]

The compiled-in `InnoDB` page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- `InnoDB_pages_created` [593]

The number of pages created by operations on `InnoDB` tables.

- `InnoDB_pages_read` [593]

The number of pages read by operations on `InnoDB` tables.

- `InnoDB_pages_written` [593]

The number of pages written by operations on `InnoDB` tables.

- `InnoDB_row_lock_current_waits` [593]

The number of `row locks` currently being waited for by operations on `InnoDB` tables.

- `InnoDB_row_lock_time` [593]

The total time spent in acquiring `row locks` for `InnoDB` tables, in milliseconds.

- `InnoDB_row_lock_time_avg` [593]

The average time to acquire a `row lock` for `InnoDB` tables, in milliseconds.

- `InnoDB_row_lock_time_max` [593]

The maximum time to acquire a `row lock` for `InnoDB` tables, in milliseconds.

- `InnoDB_row_lock_waits` [593]

The number of times operations on `InnoDB` tables had to wait for a `row lock`.

- `InnoDB_rows_deleted` [593]

The number of rows deleted from `InnoDB` tables.

- `InnoDB_rows_inserted` [593]

The number of rows inserted into `InnoDB` tables.

- `InnoDB_rows_read` [593]

The number of rows read from `InnoDB` tables.

- `InnoDB_rows_updated` [593]

The number of rows updated in `InnoDB` tables.

- `InnoDB_truncated_status_writes` [593]

The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.

- [Key\\_blocks\\_not\\_flushed \[594\]](#)

The number of key blocks in the `MyISAM` key cache that have changed but have not yet been flushed to disk.

- [Key\\_blocks\\_unused \[594\]](#)

The number of unused blocks in the `MyISAM` key cache. You can use this value to determine how much of the key cache is in use; see the discussion of [key\\_buffer\\_size \[492\]](#) in [Section 5.1.4, “Server System Variables”](#).

- [Key\\_blocks\\_used \[594\]](#)

The number of used blocks in the `MyISAM` key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- [Key\\_read\\_requests \[594\]](#)

The number of requests to read a key block from the `MyISAM` key cache.

- [Key\\_reads \[594\]](#)

The number of physical reads of a key block from disk into the `MyISAM` key cache. If [Key\\_reads \[594\]](#) is large, then your [key\\_buffer\\_size \[492\]](#) value is probably too small. The cache miss rate can be calculated as  $\text{Key\_reads [594]} / \text{Key\_read\_requests [594]}$ .

- [Key\\_write\\_requests \[594\]](#)

The number of requests to write a key block to the `MyISAM` key cache.

- [Key\\_writes \[594\]](#)

The number of physical writes of a key block from the `MyISAM` key cache to disk.

- [Last\\_query\\_cost \[594\]](#)

The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. [Last\\_query\\_cost \[594\]](#) has session scope.

The [Last\\_query\\_cost \[594\]](#) value can be computed accurately only for simple “flat” queries, not complex queries such as those with subqueries or `UNION`. For the latter, the value is set to 0.

- [Last\\_query\\_partial\\_plans \[594\]](#)

The number of iterations the query optimizer made in execution plan construction for the previous query. [Last\\_query\\_cost \[594\]](#) has session scope. This variable was added in MySQL 5.6.5.

- [Max\\_used\\_connections \[594\]](#)

The maximum number of connections that have been in use simultaneously since the server started.

- [Not\\_flushed\\_delayed\\_rows \[594\]](#)

The number of rows waiting to be written to nontransactional tables in `INSERT DELAYED` queues.

As of MySQL 5.6.7, this status variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- [Open\\_files \[594\]](#)

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- [Open\\_streams \[595\]](#)

The number of streams that are open (used mainly for logging).

- [Open\\_table\\_definitions \[595\]](#)

The number of cached `.frm` files.

- [Open\\_tables \[595\]](#)

The number of tables that are open.

- [Opened\\_files \[595\]](#)

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- [Opened\\_table\\_definitions \[595\]](#)

The number of `.frm` files that have been cached.

- [Opened\\_tables \[595\]](#)

The number of tables that have been opened. If [Opened\\_tables \[595\]](#) is big, your [table\\_open\\_cache \[551\]](#) value is probably too small.

- [Performance\\_schema\\_xxx](#)

Performance Schema status variables are listed in [Section 20.13, "Performance Schema Status Variables"](#). These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- [Prepared\\_stmt\\_count \[595\]](#)

The current number of prepared statements. (The maximum number of statements is given by the [max\\_prepared\\_stmt\\_count \[506\]](#) system variable.)

- [Qcache\\_free\\_blocks \[595\]](#)

The number of free memory blocks in the query cache.

- [Qcache\\_free\\_memory \[595\]](#)

The amount of free memory for the query cache.

- [Qcache\\_hits \[595\]](#)

The number of query cache hits.

- [Qcache\\_inserts \[595\]](#)

The number of queries added to the query cache.

- [Qcache\\_lowmem\\_prunes \[595\]](#)

The number of queries that were deleted from the query cache because of low memory.

- [Qcache\\_not\\_cached \[595\]](#)

The number of noncached queries (not cacheable, or not cached due to the `query_cache_type` [529] setting).

- `Qcache_queries_in_cache` [596]

The number of queries registered in the query cache.

- `Qcache_total_blocks` [596]

The total number of blocks in the query cache.

- `Queries` [596]

The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

- `Questions` [596]

The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

- `Rpl_semi_sync_master_clients` [596]

The number of semisynchronous slaves.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_avg_wait_time` [596]

The average time in microseconds the master waited for a slave reply.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_wait_time` [596]

The total time in microseconds the master waited for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_waits` [596]

The total number of times the master waited for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_times` [596]

The number of times the master turned off semisynchronous replication.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_tx` [596]

The number of commits that were not acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_status` [596]

Whether semisynchronous replication currently is operational on the master. The value is `ON` if the plugin has been enabled and a commit acknowledgment has occurred. It is `OFF` if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [Rpl\\_semi\\_sync\\_master\\_timefunc\\_failures \[597\]](#)

The number of times the master failed when calling time functions such as `gettimeofday()`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [Rpl\\_semi\\_sync\\_master\\_tx\\_avg\\_wait\\_time \[597\]](#)

The average time in microseconds the master waited for each transaction.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [Rpl\\_semi\\_sync\\_master\\_tx\\_wait\\_time \[597\]](#)

The total time in microseconds the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [Rpl\\_semi\\_sync\\_master\\_tx\\_waits \[597\]](#)

The total number of times the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [Rpl\\_semi\\_sync\\_master\\_wait\\_pos\\_backtraverse \[597\]](#)

The total number of times the master waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [Rpl\\_semi\\_sync\\_master\\_wait\\_sessions \[597\]](#)

The number of sessions currently waiting for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [Rpl\\_semi\\_sync\\_master\\_yes\\_tx \[597\]](#)

The number of commits that were acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [Rpl\\_semi\\_sync\\_slave\\_status \[597\]](#)

Whether semisynchronous replication currently is operational on the slave. This is `ON` if the plugin has been enabled and the slave I/O thread is running, `OFF` otherwise.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- [Rsa\\_public\\_key \[597\]](#)

The RSA public key value used by the `sha256_password` authentication plugin.

The value is nonempty only if the server successfully initializes the private and public

keys in the files named by the `sha256_password_private_key_path` [539] and `sha256_password_public_key_path` [539] system variables. The value of `Rsa_public_key` [597] comes from the latter file.

For information about `sha256_password`, see [Section 6.3.7.2, “The SHA-256 Authentication Plugin”](#).

This variable is available only if MySQL was built using OpenSSL. It was added in MySQL 5.6.6.

- `Select_full_join` [598]

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join` [598]

The number of joins that used a range search on a reference table.

- `Select_range` [598]

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check` [598]

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan` [598]

The number of joins that did a full scan of the first table.

- `Slave_heartbeat_period` [598]

Shows the replication heartbeat interval (in seconds) on a replication slave.

- `Slave_last_heartbeat` [598]

Shows when the most recent heartbeat signal was received by a replication slave, as a `TIMESTAMP` value.

- `Slave_open_temp_tables` [598]

The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see [Section 16.4.1.21, “Replication and Temporary Tables”](#).

- `Slave_received_heartbeats` [598]

This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

- `Slave_retried_transactions` [598]

The total number of times since startup that the replication slave SQL thread has retried transactions.

- `Slave_running` [598]

This is `ON` if this server is a replication slave that is connected to a replication master, and both the I/O and SQL threads are running; otherwise, it is `OFF`.

- `Slow_launch_threads` [598]

The number of threads that have taken more than `slow_launch_time` [541] seconds to create.

- [Slow\\_queries \[599\]](#)

The number of queries that have taken more than [long\\_query\\_time \[500\]](#) seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see [Section 5.2.5, “The Slow Query Log”](#).

- [Sort\\_merge\\_passes \[599\]](#)

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the [sort\\_buffer\\_size \[542\]](#) system variable.

- [Sort\\_range \[599\]](#)

The number of sorts that were done using ranges.

- [Sort\\_rows \[599\]](#)

The number of sorted rows.

- [Sort\\_scan \[599\]](#)

The number of sorts that were done by scanning the table.

- [Ssl\\_accept\\_renegotiates \[599\]](#)

The number of negotiates needed to establish the connection.

- [Ssl\\_accepts \[599\]](#)

The number of accepted SSL connections.

- [Ssl\\_callback\\_cache\\_hits \[599\]](#)

The number of callback cache hits.

- [Ssl\\_cipher \[599\]](#)

The current SSL cipher (empty for non-SSL connections).

- [Ssl\\_cipher\\_list \[599\]](#)

The list of possible SSL ciphers.

- [Ssl\\_client\\_connects \[599\]](#)

The number of SSL connection attempts to an SSL-enabled master.

- [Ssl\\_connect\\_renegotiates \[599\]](#)

The number of negotiates needed to establish the connection to an SSL-enabled master.

- [Ssl\\_ctx\\_verify\\_depth \[599\]](#)

The SSL context verification depth (how many certificates in the chain are tested).

- [Ssl\\_ctx\\_verify\\_mode \[599\]](#)

The SSL context verification mode.

- [Ssl\\_default\\_timeout \[599\]](#)

The default SSL timeout.

- [Ssl\\_finished\\_accepts \[599\]](#)

The number of successful SSL connections to the server.

- [Ssl\\_finished\\_connects \[600\]](#)

The number of successful slave connections to an SSL-enabled master.

- [Ssl\\_server\\_not\\_after \[600\]](#)

The last date for which the SSL certificate is valid. This variable was added in MySQL 5.6.3.

- [Ssl\\_server\\_not\\_before \[600\]](#)

The first date for which the SSL certificate is valid. This variable was added in MySQL 5.6.3.

- [Ssl\\_session\\_cache\\_hits \[600\]](#)

The number of SSL session cache hits.

- [Ssl\\_session\\_cache\\_misses \[600\]](#)

The number of SSL session cache misses.

- [Ssl\\_session\\_cache\\_mode \[600\]](#)

The SSL session cache mode.

- [Ssl\\_session\\_cache\\_overflows \[600\]](#)

The number of SSL session cache overflows.

- [Ssl\\_session\\_cache\\_size \[600\]](#)

The SSL session cache size.

- [Ssl\\_session\\_cache\\_timeouts \[600\]](#)

The number of SSL session cache timeouts.

- [Ssl\\_sessions\\_reused \[600\]](#)

How many SSL connections were reused from the cache.

- [Ssl\\_used\\_session\\_cache\\_entries \[600\]](#)

How many SSL session cache entries were used.

- [Ssl\\_verify\\_depth \[600\]](#)

The verification depth for replication SSL connections.

- [Ssl\\_verify\\_mode \[600\]](#)

The verification mode for replication SSL connections.

- [Ssl\\_version \[600\]](#)

The SSL protocol version of the connection.

- [Table\\_locks\\_immediate \[600\]](#)

The number of times that a request for a table lock could be granted immediately.

- [Table\\_locks\\_waited \[600\]](#)

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- [Table\\_open\\_cache\\_hits](#) [601]

The number of hits for open tables cache lookups. This variable was added in MySQL 5.6.6.

- [Table\\_open\\_cache\\_misses](#) [601]

The number of misses for open tables cache lookups. This variable was added in MySQL 5.6.6.

- [Table\\_open\\_cache\\_overflows](#) [601]

The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than [table\\_open\\_cache](#) [551] / [table\\_open\\_cache\\_instances](#) [552]. This variable was added in MySQL 5.6.6.

- [Tc\\_log\\_max\\_pages\\_used](#) [601]

For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of [Tc\\_log\\_max\\_pages\\_used](#) [601] and [Tc\\_log\\_page\\_size](#) [601] is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` [429] option. Currently, this variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines capable of two-phase commit is greater than one. (InnoDB is the only applicable engine.)

- [Tc\\_log\\_page\\_size](#) [601]

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. Currently, this variable is unused for the same reasons as described for [Tc\\_log\\_max\\_pages\\_used](#) [601].

- [Tc\\_log\\_page\\_waits](#) [601]

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` [429] option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- [Threads\\_cached](#) [601]

The number of threads in the thread cache.

- [Threads\\_connected](#) [601]

The number of currently open connections.

- [Threads\\_created](#) [601]

The number of threads created to handle connections. If [Threads\\_created](#) [601] is big, you may want to increase the [thread\\_cache\\_size](#) [552] value. The cache miss rate can be calculated as [Threads\\_created](#) [601]/[Connections](#) [587].

- [Threads\\_running](#) [601]

The number of threads that are not sleeping.

- [Uptime](#) [602]

The number of seconds that the server has been up.

- [Uptime\\_since\\_flush\\_status](#) [602]

The number of seconds since the most recent `FLUSH STATUS` statement.

## 5.1.7. Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

For answers to some questions that are often asked about server SQL modes in MySQL, see [Section B.3, “MySQL 5.6 FAQ: Server SQL Mode”](#).

Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

When working with `InnoDB` tables, consider also the `innodb_strict_mode` [1749] configuration option. It enables additional error checks for `InnoDB` tables, as listed in [Section 14.2.5.7, “InnoDB Strict Mode”](#).

### Setting the SQL Mode

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="modes"` [442] option, or by using `sql-mode="modes"` [442] in `my.cnf` (Unix operating systems) or `my.ini` (Windows). `modes` is a list of different modes separated by comma (",") characters. The default SQL mode in MySQL 5.6.6 and later is `NO_ENGINE_SUBSTITUTION`; in MySQL 5.6.5 and earlier, it was empty (no modes set). To clear the mode explicitly, set it to an empty string using `--sql-mode=""` [442] on the command line, or with `sql-mode=""` [442] in `my.cnf` on Unix systems or in `my.ini` on Windows.

You can change the SQL mode at runtime by using a `SET [GLOBAL|SESSION] sql_mode='modes'` statement to set the `sql_mode` [545] system value. Setting the `GLOBAL` variable requires the `SUPER` [756] privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Any client can change its own session `sql_mode` [545] value at any time.

#### Important

**SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on master and slave can also lead to problems. For best results, you should always use the same server SQL mode on the master and on the slave.

See [Section 17.6, “Restrictions and Limitations on Partitioning”](#), for more information.

You can retrieve the current global or session `sql_mode` [545] value with the following statements:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

### Most Important SQL Modes

The most important `sql_mode` [545] values are probably these:

- [ANSI \[608\]](#)

This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special [combination modes](#) listed at the end of this section.

- [STRICT\\_TRANS\\_TABLES \[607\]](#)

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More detail is given later in this section.

- [TRADITIONAL \[609\]](#)

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special [combination modes](#) listed at the end of this section.

#### Note

The [INSERT/UPDATE](#) aborts as soon as the error is noticed. This may not be what you want if you are using a nontransactional storage engine, because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode where at least one of [STRICT\\_TRANS\\_TABLES \[607\]](#) or [STRICT\\_ALL\\_TABLES \[607\]](#) is enabled.

## Full List of SQL Modes

The following list describes all supported modes:

- [ALLOW\\_INVALID\\_DATES \[603\]](#)

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to [DATE](#) and [DATETIME](#) columns. It does not apply [TIMESTAMP](#) columns, which always require a valid date.

The server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable [ALLOW\\_INVALID\\_DATES \[603\]](#).

- [ANSI\\_QUOTES \[603\]](#)

Treat “`”` as an identifier quote character (like the “```” quote character) and not as a string quote character. You can still use “```” to quote identifiers with this mode enabled. With [ANSI\\_QUOTES \[603\]](#) enabled, you cannot use double quotation marks to quote literal strings, because it is interpreted as an identifier.

- [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO \[603\]](#)

Produce an error in strict mode (otherwise a warning) when a division by zero (or [MOD\(X, 0\) \[1205\]](#)) occurs during an [INSERT](#) or [UPDATE](#). If this mode is not enabled, MySQL instead returns [NULL](#) for divisions by zero. For [INSERT IGNORE](#) or [UPDATE IGNORE](#), MySQL generates a warning for divisions by zero, but the result of the operation is [NULL](#).

- [HIGH\\_NOT\\_PRECEDENCE \[603\]](#)

The precedence of the `NOT` [1171] operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` [603] SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 1
```

- `IGNORE_SPACE` [604]

Permit spaces between a function name and the “(” character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in [Section 9.2, “Schema Object Names”](#). For example, because there is a `COUNT()` [1283] function, the use of `count` as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The `IGNORE_SPACE` [604] SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether `IGNORE_SPACE` [604] is enabled.

For further discussion of `IGNORE_SPACE` [604], see [Section 9.2.4, “Function Name Parsing and Resolution”](#).

- `NO_AUTO_CREATE_USER` [604]

Prevent the `GRANT` statement from automatically creating new users if it would otherwise do so, unless authentication information is specified. The statement must specify a nonempty password using `IDENTIFIED BY` or an authentication plugin using `IDENTIFIED WITH`.

- `NO_AUTO_VALUE_ON_ZERO` [604]

`NO_AUTO_VALUE_ON_ZERO` [604] affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` [604] suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` [604] before reloading the dump file solves this problem. `mysqldump` now automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO` [604], to avoid this problem.

- `NO_BACKSLASH_ESCAPES` [604]

Disable the use of the backslash character (“\”) as an escape character within strings. With this mode enabled, backslash becomes an ordinary character like any other.

- `NO_DIR_IN_CREATE` [604]

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on slave replication servers.

- `NO_ENGINE_SUBSTITUTION` [605]

Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

With `NO_ENGINE_SUBSTITUTION` [605] disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

With `NO_ENGINE_SUBSTITUTION` [605] enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- `NO_FIELD_OPTIONS` [605]

Do not print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_KEY_OPTIONS` [605]

Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_TABLE_OPTIONS` [605]

Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_UNSIGNED_SUBTRACTION` [605]

By default, subtraction between integer operands produces an `UNSIGNED` result if any operand is `UNSIGNED`. When `NO_UNSIGNED_SUBTRACTION` [605] is enabled, the subtraction result is signed, *even if any operand is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21) unsigned |      |     | 0        |       |
+-----+-----+-----+-----+-----+-----+

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21)          |      |     | 0        |       |
+-----+-----+-----+-----+-----+-----+
```

Note that this means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See [Section 12.10, “Cast Functions and Operators”](#).

```
mysql> SET sql_mode = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
```

```

| CAST(0 AS UNSIGNED) - 1 |
+-----+
|          18446744073709551615 |
+-----+

mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
|                      -1 |
+-----+

```

- [NO\\_ZERO\\_DATE \[606\]](#)

In strict mode, do not permit '0000-00-00' as a valid date. You can still insert zero dates with the [IGNORE](#) option. When not in strict mode, the date is accepted but a warning is generated.

- [NO\\_ZERO\\_IN\\_DATE \[606\]](#)

In strict mode, do not accept dates where the year part is nonzero but the month or day part is 0 (for example, '0000-00-00' is legal but '2010-00-01' and '2010-01-00' are not). If used with the [IGNORE](#) option, MySQL inserts a '0000-00-00' date for any such date. When not in strict mode, the date is accepted but a warning is generated.

- [ONLY\\_FULL\\_GROUP\\_BY \[606\]](#)

Do not permit queries for which the select list or [HAVING](#) list or (as of MySQL 5.6.5) [ORDER](#) list refers to nonaggregated columns that are not named in the [GROUP BY](#) clause.

The following queries are invalid with [ONLY\\_FULL\\_GROUP\\_BY \[606\]](#) enabled. The first is invalid because [address](#) in the select list is not named in the [GROUP BY](#) clause, and the second because [max\\_age](#) in the [HAVING](#) clause is not named in the [GROUP BY](#) clause:

```

mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): 't.address' isn't in GROUP BY

```

```

mysql> SELECT name, MAX(age) AS max_age FROM t GROUP BY name
-> HAVING max_age < 30;
Empty set (0.00 sec)
ERROR 1463 (42000): Non-grouping field 'max_age' is used in HAVING clause

```

In the second example, the query could be rewritten to use [HAVING MAX\(age\)](#) instead, so that the reference is to a column named in an aggregate function. ([max\\_age](#) fails because it *is* an aggregate function.)

In addition, if a query has aggregate functions and no [GROUP BY](#) clause, it cannot have nonaggregated columns in the select list or [ORDER BY](#) list:

```

mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT(),...)
with no GROUP columns is illegal if there is no GROUP BY clause

```

For more information, see [Section 12.17.3, “MySQL Extensions to GROUP BY”](#).

- [PAD\\_CHAR\\_TO\\_FULL\\_LENGTH \[606\]](#)

By default, trailing spaces are trimmed from [CHAR](#) column values on retrieval. If [PAD\\_CHAR\\_TO\\_FULL\\_LENGTH \[606\]](#) is enabled, trimming does not occur and retrieved [CHAR](#) values are padded to their full length. This mode does not apply to [VARCHAR](#) columns, for which trailing spaces are retained on retrieval.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1   | CHAR_LENGTH(c1) |
+-----+-----+
| xy   |                2 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1   | CHAR_LENGTH(c1) |
+-----+-----+
| xy   |                10 |
+-----+-----+
1 row in set (0.00 sec)
```

- [PIPES\\_AS\\_CONCAT \[607\]](#)

Treat `||` [\[1172\]](#) as a string concatenation operator (same as `CONCAT()` [\[1178\]](#)) rather than as a synonym for `OR` [\[1172\]](#).

- [REAL\\_AS\\_FLOAT \[607\]](#)

Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- [STRICT\\_ALL\\_TABLES \[607\]](#)

Enable strict mode for all storage engines. Invalid data values are rejected. Additional detail follows.

- [STRICT\\_TRANS\\_TABLES \[607\]](#)

Enable strict mode for transactional storage engines, and when possible for nontransactional storage engines. Additional details follow.

Strict mode controls how MySQL handles input values that are invalid or missing. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.)

For transactional tables, an error occurs for invalid or missing values in a statement when either of the [STRICT\\_ALL\\_TABLES \[607\]](#) or [STRICT\\_TRANS\\_TABLES \[607\]](#) modes are enabled. The statement is aborted and rolled back.

For nontransactional tables, the behavior is the same for either mode, if the bad value occurs in the first row to be inserted or updated. The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict option is enabled:

- For [STRICT\\_ALL\\_TABLES \[607\]](#), MySQL returns an error and ignores the rest of the rows. However, in this case, the earlier rows still have been inserted or updated. This means that you might get a partial update, which might not be what you want. To avoid this, it is best to use single-row statements because these can be aborted without changing the table.

- For `STRICT_TRANS_TABLES` [607], MySQL converts an invalid value to the closest valid value for the column and insert the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in [Section 11.5, “Data Type Default Values”](#).

Strict mode disallows invalid date values such as `'2004-04-31'`. It does not disallow dates with zero month or day parts such as `'2004-04-00'` or “zero” dates. To disallow these as well, enable the `NO_ZERO_IN_DATE` [606] and `NO_ZERO_DATE` [606] SQL modes in addition to strict mode.

If you are not using strict mode (that is, neither `STRICT_TRANS_TABLES` [607] nor `STRICT_ALL_TABLES` [607] is enabled), MySQL inserts adjusted values for invalid or missing values and produces warnings. In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` [483] can be used for that. (See [Section 5.1.4, “Server System Variables”](#).)

## Combination Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

The descriptions include all mode values that are available in the most recent version of MySQL. For older versions, a combination mode does not include individual mode values that are not available except in newer versions.

- `ANSI` [608]

Equivalent to `REAL_AS_FLOAT` [607], `PIPES_AS_CONCAT` [607], `ANSI_QUOTES` [603], `IGNORE_SPACE` [604].

`ANSI` [608] mode also causes the server to return an error for queries where a set function `S` with an outer reference `S(outer_ref)` cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, `MAX(t1.b)` [1284] cannot be aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If `ANSI` [608] mode is not enabled, the server treats `S(outer_ref)` in such queries the same way that it would interpret `S(const)`.

See [Section 1.8.3, “Running MySQL in ANSI Mode”](#).

- `DB2` [608]

Equivalent to `PIPES_AS_CONCAT` [607], `ANSI_QUOTES` [603], `IGNORE_SPACE` [604], `NO_KEY_OPTIONS` [605], `NO_TABLE_OPTIONS` [605], `NO_FIELD_OPTIONS` [605].

- `MAXDB` [608]

Equivalent to `PIPES_AS_CONCAT` [607], `ANSI_QUOTES` [603], `IGNORE_SPACE` [604], `NO_KEY_OPTIONS` [605], `NO_TABLE_OPTIONS` [605], `NO_FIELD_OPTIONS` [605], `NO_AUTO_CREATE_USER` [604].

- `MSSQL` [608]

Equivalent to `PIPES_AS_CONCAT` [607], `ANSI_QUOTES` [603], `IGNORE_SPACE` [604], `NO_KEY_OPTIONS` [605], `NO_TABLE_OPTIONS` [605], `NO_FIELD_OPTIONS` [605].

- `MYSQL323` [608]

Equivalent to `NO_FIELD_OPTIONS` [605], `HIGH_NOT_PRECEDENCE` [603].

- `MYSQL40` [609]

Equivalent to `NO_FIELD_OPTIONS` [605], `HIGH_NOT_PRECEDENCE` [603].

- `ORACLE` [609]

Equivalent to `PIPES_AS_CONCAT` [607], `ANSI_QUOTES` [603], `IGNORE_SPACE` [604], `NO_KEY_OPTIONS` [605], `NO_TABLE_OPTIONS` [605], `NO_FIELD_OPTIONS` [605], `NO_AUTO_CREATE_USER` [604].

- `POSTGRESQL` [609]

Equivalent to `PIPES_AS_CONCAT` [607], `ANSI_QUOTES` [603], `IGNORE_SPACE` [604], `NO_KEY_OPTIONS` [605], `NO_TABLE_OPTIONS` [605], `NO_FIELD_OPTIONS` [605].

- `TRADITIONAL` [609]

Equivalent to `STRICT_TRANS_TABLES` [607], `STRICT_ALL_TABLES` [607], `NO_ZERO_IN_DATE` [606], `NO_ZERO_DATE` [606], `ERROR_FOR_DIVISION_BY_ZERO` [603], `NO_AUTO_CREATE_USER` [604], and `NO_ENGINE_SUBSTITUTION` [605].

## 5.1.8. Server Plugins

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The components supported by this interface include, but are not limited to, storage engines, full-text parser plugins, partitioning support, and server extensions.

### 5.1.8.1. Installing and Uninstalling Plugins

Server plugins must be loaded in to the server before they can be used. MySQL enables you to load a plugin at server startup or at runtime. It is also possible to control the activation of loaded plugins at startup, and to unload them at runtime.

- [Installing plugins](#)
- [Controlling plugin activation](#)
- [Uninstalling plugins](#)

#### Installing Plugins

Server plugins must be known to the server before they can be used. A plugin can be made known several ways, as described here. In the following descriptions, *plugin\_name* stands for a plugin name such as `innodb` or `csv`.

##### Built-in plugins:

A plugin that is built in to the server is known by the server automatically. Normally, the server enables the plugin at startup, although this can be changed with the `--plugin_name` option.

##### Plugins registered in the `mysql.plugin` table:

The `mysql.plugin` table serves as a registry of plugins. The server normally enables each plugin listed in the table at startup, although whether a given plugin is enabled can be changed with the `--plugin_name` option. If the server is started with the `--skip-grant-tables` [439] option, it does not consult this table and does not load the plugins listed there.

##### Plugins named with command-line options:

A plugin that is located in a plugin library file can be loaded at server startup with the `--plugin-load [435]` option. Normally, the server enables the plugin at startup, although this can be changed with the `--plugin_name` option.

The option value is a semicolon-separated list of `name=plugin_library` pairs. Each `name` is the name of the plugin, and `plugin_library` is the name of the shared library that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. Each library file must be located in the directory named by the `plugin_dir [525]` system variable.

This option does not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load [435]` is given again. That is, this option effects a one-time installation that persists only for one server invocation.

`--plugin-load [435]` enables plugins to be loaded even when `--skip-grant-tables [439]` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load [435]` also enables plugins to be loaded at startup under configurations when plugins cannot be loaded at runtime.

The `--plugin-load-add [436]` option complements the `--plugin-load [435]` option. `--plugin-load-add [436]` adds a plugin or plugins to the set of plugins to be loaded at startup. The argument format is the same as for `--plugin-load [435]`. `--plugin-load-add [436]` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load [435]` argument. `--plugin-load-add [436]` can be given in the absence of `--plugin-load [435]`, but any instance of `--plugin-load-add [436]` that appears before `--plugin-load [435]` has no effect because `--plugin-load [435]` resets the set of plugins to load. In other words, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

### Plugins installed with the `INSTALL PLUGIN` statement:

A plugin that is located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT [755]` privilege for the `mysql.plugin` table.

If a plugin is named both using a `--plugin-load [435]` option and in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
100310 19:15:44 [ERROR] Function 'plugin_name' already exists
100310 19:15:44 [Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

Example: The `--plugin-load [435]` option installs a plugin at server startup. To install a plugin named `myplugin` in a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load [435]` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The server lists the plugin in the `mysql.plugin` table to ensure that it is loaded on subsequent server restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, use `--plugin-load` [435] rather than `INSTALL PLUGIN`.

While a plugin is loaded, information about it is available at runtime from several sources, such as the `INFORMATION_SCHEMA.PLUGINS` table and the `SHOW PLUGINS` statement. For more information, see [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

## Controlling Plugin Activation

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load` [435] option or registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation for such a plugin using a `--plugin_name[=value]` startup option named after the plugin. In the following descriptions, `plugin_name` stands for a plugin name such as `innodb` or `csv`. As with other options, dashes and underscores are interchangeable in option names. For example, `--my_plugin=ON` and `--my-plugin=ON` are equivalent.

- `--plugin_name=OFF`

Tells the server to disable the plugin.

- `--plugin_name[=ON]`

Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`

Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`

Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

The values `OFF`, `ON`, `FORCE`, and `FORCE_PLUS_PERMANENT` are not case sensitive.

The activation state for plugins is visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, but must require that `BLACKHOLE` initialization succeeds, and `ARCHIVE` should be disabled. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is supported as a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are supported as synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but failed to initialize, aspects of server operation that require the plugin will change. For example, if the plugin

implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` [605] SQL mode has been enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` [1698] to disable `InnoDB`, other `innodb_XXX` options likely will need to be omitted from the startup command. In addition, because `InnoDB` is the default storage engine, it will not start unless you specify another available storage engine with `--default_storage_engine` [474]. As of MySQL 5.6.3, you will also need to set `--default_tmp_storage_engine` [474].

## Uninstalling Plugins

A plugin known to the server can be uninstalled to disable it at runtime with the `UNINSTALL PLUGIN` statement. The statement unloads the plugin and removes it from the `mysql.plugin` table if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` [754] privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server will not load the plugin automatically for subsequent restarts.

`UNINSTALL PLUGIN` can unload plugins regardless of whether they were loaded with `INSTALL PLUGIN` or `--plugin-load` [435].

`UNINSTALL PLUGIN` is subject to these exceptions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.
- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

### 5.1.8.2. Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```
mysql> SELECT * FROM information_schema.PLUGINS\G
***** 1. row *****
      PLUGIN_NAME: binlog
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 50158.0
      PLUGIN_LIBRARY: NULL
      PLUGIN_LIBRARY_VERSION: NULL
      PLUGIN_AUTHOR: MySQL AB
      PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: FORCE
...
***** 10. row *****
      PLUGIN_NAME: InnoDB
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 50158.0
      PLUGIN_LIBRARY: ha_innodb_plugin.so
      PLUGIN_LIBRARY_VERSION: 1.0
      PLUGIN_AUTHOR: Innobase Oy
      PLUGIN_DESCRIPTION: Supports transactions, row-level locking,
                        and foreign keys
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: ON
...
```

- The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

```
mysql> SHOW PLUGINS\G
***** 1. row *****
Name: binlog
Status: ACTIVE
Type: STORAGE ENGINE
Library: NULL
License: GPL
...
***** 10. row *****
Name: InnoDB
Status: ACTIVE
Type: STORAGE ENGINE
Library: ha_innodb_plugin.so
License: GPL
...
```

- The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

## 5.1.9. IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
shell> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See [Section 5.1.9.1, “Verifying System Support for IPv6”](#).
- The default MySQL server configuration permits only IPv4 connections, so the server must be configured for IPv6 connections. To permit IPv6 connections in addition to or instead of IPv4 connections, start the server with an appropriate `--bind-address [414]` option. See [Section 5.1.4, “Server System Variables”](#).
- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See [Section 6.2.3, “Specifying Account Names”](#). IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

```
mysql> CREATE USER 'bill'@':::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@':::1';
```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` [1276] and `INET6_NTOA()` [1277] are similar to `INET_ATON()` [1276] and `INET_NTOA()` [1276], but handle IPv6 addresses in addition to IPv4 addresses. See [Section 12.16, “Miscellaneous Functions”](#).

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

### 5.1.9.1. Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
shell> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
```

```
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- [Windows XP](#)
- [Gentoo Linux](#)
- [Ubuntu Linux](#)
- [Linux \(Generic\)](#)
- [Mac OS X](#)

### 5.1.9.2. Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, use the `--bind-address=addr` [414] option at server startup, where `addr` is an IPv4 or IPv6 address or a host name. (IPv6 addresses are not supported before MySQL 5.5.3.) If `addr` is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is permitted (and is the default) as of MySQL 5.6.6.
- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces. This is the default before MySQL 5.6.6.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `:::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the `mysql.user` grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to `:::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@':::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

### 5.1.9.3. Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `:::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `--bind-address` [414] option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = * # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to `::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#).

2. As an administrator, connect to the server and create an account for a local user who will connect from the `::1` local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see [Section 6.2.3, “Specifying Account Names”](#). In addition to the `CREATE USER` statement, you can issue `GRANT` statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:  ::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| ipv6user@::1   | ::             |
+-----+-----+
```

#### 5.1.9.4. Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

```
Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2
```

These addresses are chosen from the nonroutable address range recommended by [IANA](#) for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see [Section 5.1.9.5, “Obtaining an IPv6 Address from a Broker”](#).

1. Start the MySQL server with an appropriate `--bind-address` [414] option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = * # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to `2001:db8:0:f101::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and

rejects IPv4 connections. For more information, see [Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#).

2. On the server host (`2001:db8:0:f101::1`), create an account for a user who will connect from the client host (`2001:db8:0:f101::2`):

```
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (`2001:db8:0:f101::2`), invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection: 2001:db8:0:f101::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| remoteipv6user@2001:db8:0:f101::2 | :: |
+-----+-----+
```

### 5.1.9.5. Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The [Wikipedia IPv6 Tunnel Broker page](#) lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `--bind-address [414]` option to permit the server to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind-address = * # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to the specific IPv6 address provided by the broker, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#). In addition, if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you may be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the `gogoc` IPv6 client package on Gentoo Linux.

1. Create a account at Freenet6 by visiting this URL and signing up:

```
http://gogonet.gogo6.com
```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

```
http://gogonet.gogo6.com/page/freenet6-registration
```

3. As `root`, install `gogoc`:

```
shell> emerge gogoc
```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

```
userid=gogouser
passwd=gogopass
```

5. Start `gogoc`:

```
shell> /etc/init.d/gogoc start
```

To start `gogoc` each time your system boots, execute this command:

```
shell> rc-update add gogoc default
```

6. Use `ping6` to try to ping a host:

```
shell> ping6 ipv6.google.com
```

7. To see your IPv6 address:

```
shell> ifconfig tun
```

## 5.1.10. Server-Side Help

MySQL Server supports a `HELP` statement that returns online information from the MySQL Reference manual (see [Section 13.8.3, “HELP Syntax”](#)). The proper operation of this statement requires that the help tables in the `mysql` database be initialized with help topic information, which is done by processing the contents of the `fill_help_tables.sql` script.

If you install MySQL using a binary or source distribution on Unix, help table setup occurs when you run `mysql_install_db`. For an RPM distribution on Linux or binary distribution on Windows, help table setup occurs as part of the MySQL installation process.

If you upgrade MySQL using a binary distribution, the help tables are not upgraded automatically, but you can upgrade them manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

You can also obtain the latest `fill_help_tables.sql` at any time to upgrade your help tables. Download the proper file for your version of MySQL from <http://dev.mysql.com/doc/index-other.html>. After downloading and uncompressing the file, process it with `mysql` as described previously.

If you are working with Bazaar and a MySQL development source tree, you will need to download the `fill_help_tables.sql` file because the tree contains only a “stub” version.

## 5.1.11. Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- `SIGTERM` causes the server to shut down.
- `SIGHUP` causes the server to reload the grant tables and flush the logs (like `FLUSH PRIVILEGES` and `FLUSH LOGS`). It also writes a status report to the error log that has this format:

```
Status information:

Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:

Key caches:
default
Buffer_size:      8388600
Block_size:      1024
```

```

Division_limit:      100
Age_limit:          300
blocks used:        0
not flushed:        0
w_requests:         0
writes:             0
r_requests:         0
reads:              0

handler status:
read_key:           0
read_next:          0
read_rnd            0
read_first:         1
write:              0
delete              0
update:             0

Table status:
Opened tables:      5
Open tables:        0
Open files:         7
Open streams:       0

Alarm status:
Active alarms:      1
Max used alarms:    2
Next alarm time:    67

```

On some Mac OS X 10.3 versions, `mysqld` ignores `SIGHUP` and `SIGQUIT`.

## 5.1.12. The Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

This can occur initiated several ways. For example, a user with the `SHUTDOWN [756]` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see

[Section 13.7.6.4, “KILL Syntax”](#), in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on `MyISAM` tables.

For threads that have an open transaction, the transaction is rolled back. Note that if a thread is updating a nontransactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated because the operation can terminate before completion.

If the server is a master replication server, it treats threads associated with currently connected slaves like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a `KILL QUERY` or `KILL CONNECTION` statement. See also [Section 13.4.2.6, “STOP SLAVE Syntax”](#). Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

#### Note

In order to guarantee crash safety on the slave, you must also run the slave with `--relay-log-recovery [1975]` enabled.

See also [Section 16.2.2, “Replication Relay and Status Logs”](#)).

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. `InnoDB` flushes its buffer pool to disk (unless `innodb_fast_shutdown [1716]` is 2), writes the current LSN to the tablespace, and terminates its own internal threads. `MyISAM` flushes any pending index writes for a table.

6. The server exits.

## 5.2. MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

Log Type	Information Written to Log
Error log	Problems encountered starting, running, or stopping <code>mysqld</code>
General query log	Established client connections and statements received from clients
Binary log	Statements that change data (also used for replication)
Relay log	Data changes received from a replication master server
Slow query log	Queries that took more than <code>long_query_time [500]</code> seconds to execute

By default, no logs are enabled (except the error log on Windows). The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement; execute `mysqladmin` with a `flush-logs` or `refresh` argument; or execute `mysqldump` with a `--flush-logs [294]` or `--master-data [288]` option. See [Section 13.7.6.3, “FLUSH Syntax”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition,

the binary log is flushed when its size reaches the value of the `max_binlog_size` [2016] system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#), [Section 5.2.3, “The General Query Log”](#), and [Section 5.2.5, “The Slow Query Log”](#).

The relay log is used only on slave replication servers, to hold data changes from the master server that must also be made on the slave. For discussion of relay log contents and configuration, see [Section 16.2.2.1, “The Slave Relay Log”](#).

For information about log maintenance operations such as expiration of old log files, see [Section 5.2.6, “Server Log Maintenance”](#).

For information about keeping logs secure, see [Section 6.1.2.3, “Passwords and Logging”](#).

## 5.2.1. Selecting General Query and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` database. Either or both destinations can be selected.

Currently, logging to tables incurs significantly more server overhead than logging to files. If you enable the general log or slow query log and require highest performance, you should use file logging, not table logging.

**Log control at server startup.** The `--log-output` [427] option specifies the destination for log output. This option does not in itself enable the logs. Its syntax is `--log-output[=value,...] [427]`:

- If `--log-output` [427] is given with a value, the value should be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.
- If `--log-output` [427] is omitted, the default logging destination is `FILE`.

The `general_log` [485] system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` [485] takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` [486] variable. Similarly, the `slow_query_log` [541] variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` [541] specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log-output=TABLE,FILE [427]` to select both log destinations and `--general_log [485]` to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log-output=TABLE [427]` to select tables as the log destination and `--general_log [485]` and `--slow_query_log [541]` to enable both logs.
- To write slow query log entries only to the log file, use `--log-output=FILE [427]` to select files as the log destination and `--slow_query_log [541]` to enable the slow query log. (In this case, because the default log destination is `FILE`, you could omit the `--log-output [427]` option.)

**Log control at runtime.** The system variables associated with log tables and files enable runtime control over logging:

- The global `log_output` [498] system variable indicates the current logging destination. It can be modified at runtime to change the destination.
- The global `general_log` [485] and `slow_query_log` [541] variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The global `general_log_file` [486] and `slow_query_log_file` [541] variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.
- To disable or enable general query logging for the current connection, set the session `sql_log_off` [544] variable to `ON` or `OFF`.

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.
- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.
- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.
- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` [541] system variable.

```
SET @old_log_state = @@global.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

- `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.
- `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```
USE mysql;
DROP TABLE IF EXISTS general_log2;
CREATE TABLE general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- `CHECK TABLE` is a valid operation on a log table.
- `LOCK TABLES` cannot be used on a log table.
- `INSERT`, `DELETE`, and `UPDATE` cannot be used on a log table. These operations are permitted only internally to the server itself.
- `FLUSH TABLES WITH READ LOCK` and the state of the global `read_only` [532] system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to slave servers. (Prior to MySQL 5.6.9, this was not always enforced correctly. See Bug #14741537.)
- To flush the log tables or log files, use `FLUSH TABLES` or `FLUSH LOGS`, respectively.
- Partitioning of log tables is not permitted.
- Before MySQL 5.6.6, `mysqldump` does not dump the `general_log` or `slow_query_log` tables for dumps of the `mysql` database. As of 5.6.6, the dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

## 5.2.2. The Error Log

The error log contains information indicating when `mysqld` was started and stopped and also any critical errors that occur while the server is running. If `mysqld` notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` dies. The trace can be used to determine where `mysqld` died. See [MySQL Internals: Porting to Other Systems](#).

You can specify where `mysqld` writes the error log with the `--log-error[=file_name]` [427] option. If the option is given with no `file_name` value, `mysqld` uses the name `host_name.err` by default. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

If you do not specify `--log-error` [427], or (on Windows) if you use the `--console` [417] option, errors are written to `stderr`, the standard error output. Usually this is your terminal.

On Windows, error output is always written to the error log if `--console` [417] is not given.

In addition, on Windows, events and error messages are written to the Windows Event Log within the Application log. Entries marked as `Warning` and `Note` are written to the Event Log, but informational messages (such as information statements from individual storage engines) are not copied to the Event Log. The log entries have a source of **MySQL**. You cannot disable writing information to the Windows Event Log.

If you flush the logs using `FLUSH LOGS` or `mysqladmin flush-logs` and `mysqld` is writing the error log to a file (for example, if it was started with the `--log-error` [427] option), the server closes and reopens the log file. To rename the file, you can do so manually before flushing. Then flushing the logs reopens a new file with the original file name. For example, you can rename the file and create a new one using the following commands:

```
shell> mv host_name.err host_name.err-old
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

No error log renaming occurs when the logs are flushed if the server is not writing to a named file.

If you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for `mysqld` to write error messages to a log file or to `syslog`. `mysqld_safe` has three error-logging options, `--syslog` [229], `--skip-syslog` [229], and `--log-error` [227]. The default with no logging options or with `--skip-syslog` [229] is to use the default log file. To explicitly specify use of an error log file, specify `--log-error=file_name` [227] to `mysqld_safe`, and `mysqld_safe` will arrange for `mysqld` to write messages to a log file. To use `syslog` instead, specify the `--syslog` [229] option.

If you specify `--log-error` [427] in an option file in a `[mysqld]`, `[server]`, or `[mysqld_safe]` section, `mysqld_safe` will find and use the option.

If `mysqld_safe` is used to start `mysqld` and `mysqld` dies unexpectedly, `mysqld_safe` notices that it needs to restart `mysqld` and writes a `restarted mysqld` message to the error log.

The `--log-warnings` [430] option or `log_warnings` [499] system variable can be used to control warning logging to the error log. The default value is enabled (1). Warning logging can be disabled using a value of 0. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section C.5.2.11, “Communication Errors and Aborted Connections”.

### 5.2.3. The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order contrasts to the binary log, for which statements are written after they are executed but before any locks are released. (Also, the query log contains all statements, whereas the binary log does not contain statements that only select data.)

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log[={0|1}]` [485]. With no argument or an argument of 1, `--general_log` [485] enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name` [486]. To specify the log destination, use `--log-output` [427] (as described in Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”).

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` [485] and `general_log_file` [486] system variables. Set `general_log` [485] to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` [486] to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `--log-output` [427] option or `log_output` [498] system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). You can rename the file and create a new one by using the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
```

```
shell> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally; for example, from the command line. Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

The session `sql_log_off` [544] variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

As of MySQL 5.6.3, passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` [428] option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

Before MySQL 5.6.3, passwords in statements are not rewritten and the general query log should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

## 5.2.4. The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a master replication server provides a record of the data changes to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 16.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See [Section 5.2.3, “The General Query Log”](#).

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

Beginning with MySQL 5.6.2, the binary log is crash-safe. Only complete events or transactions are logged or read back.

As of MySQL 5.6.3, passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. Before MySQL 5.6.3, passwords in statements are not rewritten and the binary log should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see [Section 16.1.4.4, “Binary Log Options and Variables”](#).

To enable the binary log, start the server with the `--log-bin[=base_name]` [2002] option. If no *base\_name* value is given, the default name is the value of the `pid-file` option (which by default is the name of host machine) followed by `-bin`. If the basename is given, the server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. It is recommended that you specify a basename explicitly rather than using the default of the host name; see [Section C.5.8, “Known Issues in MySQL”](#), for the reason.

If you supply an extension in the log name (for example, `--log-bin=base_name.extension` [2002]), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log basename to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time it starts or flushes the logs. The server also creates a new binary log file automatically after the current log's size reaches `max_binlog_size` [2016]. A binary log file may become larger than `max_binlog_size` [2016] if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of all used binary log files. By default, this has the same basename as the binary log file, with the extension `.index`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` [2002] option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

A client that has the `SUPER` [756] privilege can disable binary logging of its own statements by using a `SET sql_log_bin=0` statement. See [Section 5.1.4, “Server System Variables”](#).

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` [2009] system variable. When reading back from the binary log, the master uses the event length by default, but can be made to use checksums if available by enabling the `master_verify_checksum` [2015] system variable. The slave I/O thread also verifies events received from the master. You can cause the slave SQL thread to use checksums if available when reading from the relay log by enabling the `slave_sql_verify_checksum` [1995] system variable.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported, row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For general descriptions of the logging formats, see [Section 5.2.4.1, “Binary Logging Formats”](#). For detailed information about the format of the binary log, see [MySQL Internals: The Binary Log](#).

The server evaluates the `--binlog-do-db` [2004] and `--binlog-ignore-db` [2005] options in the same way as it does the `--replicate-do-db` [1976] and `--replicate-ignore-db` [1977] options. For information about how this is done, see [Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

A replication slave server by default does not write to its own binary log any data modifications that are received from the replication master. To log these modifications, start the slave with the `--log-slave-updates` [1971] option in addition to the `--log-bin` [2002] option (see [Section 16.1.4.3, “Replication Slave Options and Variables”](#)). This is done when a slave is also to act as a master to other slaves in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See [Section 13.7.6.6, “RESET Syntax”](#), and [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

If you are using replication, you should not delete old binary log files on the master until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days

behind, once a day you can execute `mysqladmin flush-logs` on the master and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display replication slave relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#). For more information about the binary log and recovery operations, see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` [2008] to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` [586] status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` [586] status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` [2008] to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` [2016] system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See [Section 16.4.1, “Replication Features and Issues”](#).

Binary logging for stored programs is done as described in [Section 18.7, “Binary Logging of Stored Programs”](#).

Note that the binary log format differs in MySQL 5.6 from previous versions of MySQL, due to enhancements in replication. See [Section 16.4.2, “Replication Compatibility Between MySQL Versions”](#).

Writes to the binary log file and binary log index file are handled in the same way as writes to `MyISAM` tables. See [Section C.5.4.3, “How MySQL Handles a Full Disk”](#).

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, you can make the binary log be synchronized to disk after every *N* writes to the binary log, with the `sync_binlog` [2017] system variable. See [Section 5.1.4, “Server System Variables”](#). 1 is the safest value for `sync_binlog` [2017], but also the slowest. Even with `sync_binlog` [2017] set to 1, there is still the chance of an inconsistency between the table content and binary log content in case of a crash. For example, if you are using `InnoDB` tables and the MySQL server processes a `COMMIT` statement, it writes the whole transaction to the binary log and then commits this transaction into `InnoDB`. If the server crashes between those two operations, the transaction is rolled back by `InnoDB` at restart but still exists in the binary log. To resolve this, you should set `--innodb_support_xa` [1749] to 1. Although this option is related to the support of XA transactions in `InnoDB`, it also ensures that the binary log and `InnoDB` data files are synchronized.

For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the `InnoDB` logs to disk before committing the transaction. The `InnoDB` logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server cuts rolled back `InnoDB` transactions from the binary log. This ensures that the binary log reflects the exact data of `InnoDB` tables, and so, that the slave remains in synchrony with the master (not receiving a statement which has been rolled back).

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed `InnoDB` transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

The session values of the following system variables are written to the binary log and honored by the replication slave when parsing the binary log:

- `sql_mode` [545] (except that the `NO_DIR_IN_CREATE` [604] mode is not replicated; see [Section 16.4.1.32, “Replication and Variables”](#))
- `foreign_key_checks` [483]
- `unique_checks` [561]
- `character_set_client` [467]
- `collation_connection` [469]
- `collation_database` [469]
- `collation_server` [470]
- `sql_auto_is_null` [543]

### 5.2.4.1. Binary Logging Formats

The server uses several logging formats to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT` [415].
- In *row-based logging*, the master writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW` [415].

- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED` [415].

In MySQL 5.6, the default binary logging format is `STATEMENT`.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a master and slave which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, `Statement may not be safe to log in statement format`.

You can avoid these issues by using MySQL's row-based replication instead.

#### 5.2.4.2. Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type` [415]. The supported values for *type* are:

- `STATEMENT` causes logging to be statement based.
- `ROW` causes logging to be row based.
- `MIXED` causes logging to use mixed format.

In MySQL 5.6, the default binary logging format is `STATEMENT`.

The logging format also can be switched at runtime. To specify the format globally for all clients, set the global value of the `binlog_format` [2010] system variable:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format` [2010]:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

#### Note

Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` [2010] is set with global or session scope). This means that changing the logging format on a replication master does not cause a slave to change its logging format to match. (When using `STATEMENT` mode, the `binlog_format` [2010] system variable is not replicated; when using `MIXED` or `ROW` logging mode, it is replicated but is ignored by the slave.) Changing the binary logging format on the master while replication is ongoing, or without also changing it on the slave can thus cause unexpected results, or even cause replication to fail altogether.

To change the global or session `binlog_format` [2010] value, you must have the `SUPER` [756] privilege.

In addition to switching the logging format manually, a slave server may switch the format *automatically*. This happens when the server is running in either `STATEMENT` or `MIXED` format and encounters an event in the binary log that is written in `ROW` logging format. In that case, the slave

switches to row-based replication temporarily for that event, and switches back to the previous format afterward.

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the master, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger
- If the `NDB` storage engine is enabled
- If the session is currently in row-based replication mode and has open temporary tables

Trying to switch the format in any of these cases results in an error.

If you are using `InnoDB` tables and the transaction isolation level is `READ COMMITTED` [1469] or `READ UNCOMMITTED` [1470], only row-based logging can be used. It is *possible* to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because `InnoDB` can no longer perform inserts.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with user-defined functions (UDFs) and with the `UUID()` [1280] function.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` [2001] option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 1024.

#### Warning

When using *statement-based logging* for replication, it is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see [Section C.5.8, “Known Issues in MySQL”](#).

For information about logs kept by replication slaves, see [Section 16.2.2, “Replication Relay and Status Logs”](#).

### 5.2.4.3. Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a function contains `UUID()` [1280].
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT` [2010].

For more information, see [Section 16.4.1.1, “Replication and `AUTO\_INCREMENT`”](#).

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` [\[1280\]](#) function.
- When a call to a UDF is involved.
- When any `INSERT DELAYED` is executed for a nontransactional table.
- If a statement is logged by row and the session that executed the statement has any temporary tables, logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that session are dropped.

This is true whether or not any temporary tables are actually logged.

Temporary tables cannot be logged using row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe. The server approximates this condition by treating all statements executed during the session as unsafe until the session no longer holds any temporary tables.

- When `FOUND_ROWS()` [\[1268\]](#) or `ROW_COUNT()` [\[1272\]](#) is used. (Bug #12092, Bug #30244)
- When `USER()` [\[1273\]](#), `CURRENT_USER()` [\[1267\]](#), or `CURRENT_USER` [\[1267\]](#) is used. (Bug #28086)
- When a statement refers to one or more system variables. (Bug #31168)

**Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment` [\[1965\]](#)
- `auto_increment_offset` [\[1968\]](#)
- `character_set_client` [\[467\]](#)
- `character_set_connection` [\[467\]](#)
- `character_set_database` [\[468\]](#)
- `character_set_server` [\[468\]](#)
- `collation_connection` [\[469\]](#)
- `collation_database` [\[469\]](#)
- `collation_server` [\[470\]](#)
- `foreign_key_checks` [\[483\]](#)
- `identity` [\[488\]](#)
- `last_insert_id` [\[495\]](#)
- `lc_time_names` [\[495\]](#)
- `pseudo_thread_id` [\[527\]](#)
- `sql_auto_is_null` [\[543\]](#)
- `time_zone` [\[557\]](#)
- `timestamp` [\[558\]](#)

- [unique\\_checks](#) [561]

For information about determining system variable scope, see [Section 5.1.5, “Using System Variables”](#).

For information about how replication treats [sql\\_mode](#) [545], see [Section 16.4.1.32, “Replication and Variables”](#).

- When one of the tables involved is a log table in the `mysql` database.
- When the `LOAD_FILE()` [1181] function is used. (Bug #39701)

**Note**

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.
- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

Storage Engine	Row Logging Supported	Statement Logging Supported
<a href="#">ARCHIVE</a>	Yes	Yes
<a href="#">BLACKHOLE</a>	Yes	Yes
<a href="#">CSV</a>	Yes	Yes
<a href="#">EXAMPLE</a>	Yes	No
<a href="#">FEDERATED</a>	Yes	Yes
<a href="#">HEAP</a>	Yes	Yes
<a href="#">InnoDB</a>	Yes	Yes when the transaction isolation level is <a href="#">REPEATABLE READ</a> [1469] or <a href="#">SERIALIZABLE</a> [1470]; No otherwise.
<a href="#">MyISAM</a>	Yes	Yes
<a href="#">MERGE</a>	Yes	Yes
<a href="#">NDB</a>	Yes	No

In MySQL 5.6, whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format (`STATEMENT`, `ROW`, or `MIXED`), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). Statements may be logged with or without a warning; failed statements

are not logged, but generate errors in the log. This is shown in the following decision table, where **SLC** stands for “statement-logging capable” and **RLC** stands for “row-logging capable”.

Condition				Action	
Type	<code>binlog_format</code> [2010]	SLC	RLC	Error / Warning	Logged as
*	*	No	No	<code>Error: Cannot execute statement:</code> Binary logging is impossible since at least one engine is involved that is both row-incapable and statement-incapable.	-
Safe	<code>STATEMENT</code>	Yes	No	-	<code>STATEMENT</code>
Safe	<code>MIXED</code>	Yes	No	-	<code>STATEMENT</code>
Safe	<code>ROW</code>	Yes	No	<code>Error: Cannot execute statement:</code> Binary logging is impossible since <code>BINLOG_FORMAT = ROW</code> and at least one table uses a storage engine that is not capable of row-based logging.	-
Unsafe	<code>STATEMENT</code>	Yes	No	<code>Warning: Unsafe statement binlogged in statement format, since BINLOG_FORMAT = STATEMENT</code>	<code>STATEMENT</code>
Unsafe	<code>MIXED</code>	Yes	No	<code>Error: Cannot execute statement:</code> Binary logging of an unsafe statement is impossible when the storage engine is limited to statement-based logging, even if <code>BINLOG_FORMAT = MIXED</code> .	-
Unsafe	<code>ROW</code>	Yes	No	<code>Error: Cannot execute statement:</code> Binary logging is impossible since <code>BINLOG_FORMAT</code>	-

Condition				Action	
Type	binlog_format [2010]	SLC	RLC	Error / Warning	Logged as
				= ROW and at least one table uses a storage engine that is not capable of row-based logging.	
Row Injection	STATEMENT	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	MIXED	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	ROW	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Safe	STATEMENT	No	Yes	Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = STATEMENT and at least one table uses a storage engine that is not capable of statement-based logging.	-
Safe	MIXED	No	Yes	-	ROW
Safe	ROW	No	Yes	-	ROW
Unsafe	STATEMENT	No	Yes	Error: Cannot execute	-

Condition				Action	
Type	<code>binlog_format</code> [2010]	SLC	RLC	Error / Warning	Logged as
				<code>statement:</code> Binary logging is impossible since <code>BINLOG_FORMAT = STATEMENT</code> and at least one table uses a storage engine that is not capable of statement-based logging.	
Unsafe	<code>MIXED</code>	No	Yes	-	<code>ROW</code>
Unsafe	<code>ROW</code>	No	Yes	-	<code>ROW</code>
Row Injection	<code>STATEMENT</code>	No	Yes	<code>Error: Cannot execute row injection:</code> Binary logging is not possible since <code>BINLOG_FORMAT = STATEMENT</code> .	-
Row Injection	<code>MIXED</code>	No	Yes	-	<code>ROW</code>
Row Injection	<code>ROW</code>	No	Yes	-	<code>ROW</code>
Safe	<code>STATEMENT</code>	Yes	Yes	-	<code>STATEMENT</code>
Safe	<code>MIXED</code>	Yes	Yes	-	<code>ROW</code>
Safe	<code>ROW</code>	Yes	Yes	-	<code>ROW</code>
Unsafe	<code>STATEMENT</code>	Yes	Yes	<code>Warning:</code> Unsafe statement binlogged in statement format since <code>BINLOG_FORMAT = STATEMENT</code> .	<code>STATEMENT</code>
Unsafe	<code>MIXED</code>	Yes	Yes	-	<code>ROW</code>
Unsafe	<code>ROW</code>	Yes	Yes	-	<code>ROW</code>
Row Injection	<code>STATEMENT</code>	Yes	Yes	<code>Error: Cannot execute row injection:</code> Binary logging is not possible because <code>BINLOG_FORMAT = STATEMENT</code> .	-
Row Injection	<code>MIXED</code>	Yes	Yes	-	<code>ROW</code>
Row Injection	<code>ROW</code>	Yes	Yes	-	<code>ROW</code>

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a slave server was started with `--log-warnings` [430] enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

#### 5.2.4.4. Logging Format for Changes to `mysql` Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` [2010] system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA INFILE`, `SELECT`, and `TRUNCATE TABLE`.
- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format` [2010]. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format` [2010].

#### 5.2.5. The Slow Query Log

The slow query log consists of SQL statements that took more than `long_query_time` [500] seconds to execute and required at least `min_examined_row_limit` [510] rows to be examined. The minimum and default values of `long_query_time` [500] are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `--log-slow-admin-statements` [429] and `log_queries_not_using_indexes` [498], as described later.

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log[={0|1}]` [541]. With no argument or an argument of 1, `--slow_query_log` [541] enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name` [541]. To specify the log destination, use `--log-output` [427] (as described in Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”).

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` [541] and `slow_query_log_file` [541] system variables.

Set `slow_query_log` [541] to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `slow_query_log_file` [541] to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the slow query log is enabled, the server writes output to any destinations specified by the `--log-output` [427] option or `log_output` [498] system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

The server writes less information to the slow query log (and binary log) if you use the `--log-short-format` [428] option.

To include slow administrative statements in the statements written to the slow query log, use the `--log-slow-admin-statements` [429] server option. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` [498] system variable. When such queries are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` [499] system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `--log-slow-admin-statements` [429] must have been specified.
2. The query must have taken at least `long_query_time` [500] seconds, or `log_queries_not_using_indexes` [498] must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` [510] rows.
4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` [499] setting.

The server does not write queries handled by the query cache to the slow query log, nor queries that would not benefit from the presence of an index because the table has zero rows or one row.

By default, a replication slave does not write replicated queries to the slow query log. To change this, use the `--log-slow-slave-statements` [1972] server option.

As of MySQL 5.6.3, passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. Before MySQL 5.6.3, passwords in statements are not rewritten and the slow query log should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process a slow query log file using the `mysqldumpslow` command to summarize the queries that appear in the log. See [Section 4.6.9, “mysqldumpslow — Summarize Slow Query Log Files”](#).

## 5.2.6. Server Log Maintenance

As described in [Section 5.2, “MySQL Server Logs”](#), MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See [Section 7.2, “Database Backup Methods”](#).

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

For the binary log, you can set the `expire_logs_days` [480] system variable to expire binary log files automatically after a given number of days (see [Section 5.1.4, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#)).

You can force MySQL to start using new log files by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See [Section 13.7.6.3, “FLUSH Syntax”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` [2016] system variable.

`FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`).

A log-flushing operation does the following:

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the general query log file or slow query log file.
- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If the server was started with the `--log-error` [427] option to cause the error log to be written to a file, the server closes and reopens the log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current log files before flushing them. At flush time, the server opens new log files with the original names. For example, if the general and slow query log files are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.old` and `mysql-slow.old` and then remove them from disk.

A similar strategy can be used to back up the error log file, if there is one.

You can rename the general query log or slow query log at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally; for example, from the command line. Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

## 5.3. Managing Disk I/O and File Space for InnoDB Tables

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The [ACID](#) design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, InnoDB tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a [fast shutdown](#).

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as InnoDB tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

### 5.3.1. InnoDB Disk I/O

InnoDB uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, InnoDB uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, InnoDB still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

#### Read-Ahead

If InnoDB can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in InnoDB:

- In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

#### Doublewrite Buffer

InnoDB uses a novel file flush technique involving a structure called the [doublewrite buffer](#). It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, [InnoDB](#) first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does [InnoDB](#) write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write (causing a [torn page](#) condition), [InnoDB](#) can later find a good copy of the page from the doublewrite buffer during recovery.

### 5.3.2. File Space Management

The data files that you define in the configuration file form the [InnoDB system tablespace](#). The files are logically concatenated to form the tablespace. There is no striping in use. Currently, you cannot define where within the tablespace your tables are allocated. In a newly created tablespace, [InnoDB](#) allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can turn on the [innodb\\_file\\_per\\_table](#) configuration option, which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by [InnoDB](#) within the system tablespace.

### Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database [pages](#). Every tablespace in a MySQL instance has the same [page size](#). By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the [innodb\\_page\\_size \[1740\]](#) option when you create the MySQL instance.

The pages are grouped into [extents](#) of size 1MB (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). The “files” inside a tablespace are called [segments](#) in [InnoDB](#). (These segments are different from the [rollback segment](#), which actually contains many tablespace segments.)

When a segment grows inside the tablespace, [InnoDB](#) allocates the first 32 pages to it one at a time. After that, [InnoDB](#) starts to allocate whole extents to the segment. [InnoDB](#) can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in [InnoDB](#). One is for nonleaf nodes of the B-tree, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an [InnoDB](#) tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a [SHOW TABLE STATUS](#) statement, [InnoDB](#) reports the extents that are definitely free in the tablespace. [InnoDB](#) always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, [InnoDB](#) contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the [purge](#) operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 14.2.3.11](#), “[InnoDB Multi-Versioning](#)”.)

To see information about the tablespace, use the Tablespace Monitor. See [Section 14.2.4.4](#), “[SHOW ENGINE INNODB STATUS and the InnoDB Monitors](#)”.

### How Pages Relate to Table Rows

The maximum row length, except for variable-length columns ([VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#)), is slightly less than half of a database page. That is, the maximum row length is about 8000

bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page. For a column chosen for off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored.

### 5.3.3. InnoDB Checkpoints

Making your `log files` very large may reduce disk I/O during `checkpointing`. It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

### How Checkpoint Processing Works

InnoDB implements a `checkpoint` mechanism known as `fuzzy checkpointing`. InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During `crash recovery`, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

### 5.3.4. Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in B-trees, and their `fill factor` may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” `ALTER TABLE` operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the InnoDB filespace management algorithm guarantees that fragmentation in the index does not occur.

## 5.4. Creating and Using InnoDB Tables and Indexes

To create an [InnoDB](#) table, use the `CREATE TABLE` statement without any special clauses. Formerly, you needed the `ENGINE=InnoDB` clause, but not anymore now that [InnoDB](#) is the default storage engine. (You might still use that clause if you plan to use `mysqldump` or replication to replay the `CREATE TABLE` statement on a server running MySQL 5.1 or earlier, where the default storage engine is [MyISAM](#).)

```
-- Default storage engine = InnoDB.
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a));
-- Backwards-compatible with older MySQL.
CREATE TABLE t2 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

Depending on the file-per-table setting, [InnoDB](#) creates each table and associated primary key index either in the [system tablespace](#), or in a separate tablespace (represented by a `.ibd` file) for each table. MySQL creates `t1.frm` and `t2.frm` files in the `test` directory under the MySQL database directory. Internally, [InnoDB](#) adds an entry for the table to its own data dictionary. The entry includes the database name. For example, if `test` is the database in which the `t1` table is created, the entry is for `'test/t1'`. This means you can create a table of the same name `t1` in some other database, and the table names do not collide inside [InnoDB](#).

To see the properties of these tables, issue a `SHOW TABLE STATUS` statement:

```
SHOW TABLE STATUS FROM test LIKE 't%';
```

In the status output, you see the [row format](#) property of these first tables is [Compact](#). Although that setting is fine for basic experimentation, to take advantage of the most powerful [InnoDB](#) performance features, you will quickly graduate to using other row formats such as [Dynamic](#) and [Compressed](#). Using those values requires a little bit of setup first:

```
set global innodb_file_per_table=1;
set global innodb_file_format=barracuda;
CREATE TABLE t3 (a INT, b CHAR (20), PRIMARY KEY (a)) row_format=dynamic;
CREATE TABLE t4 (a INT, b CHAR (20), PRIMARY KEY (a)) row_format=compressed;
```

Always set up a [primary key](#) for each [InnoDB](#) table, specifying the column or columns that:

- Are referenced by the most important queries.
- Are never left blank.
- Never have duplicate values.
- Rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on `(firstname, lastname)` because more than one person can have the same name, some people have blank last names, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an [auto-increment](#) column so that ascending values are filled in automatically as rows are inserted:

```
-- The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));
-- The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

Although the table *works* correctly without you defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. Make a habit of always specifying one in the `CREATE TABLE` statement. (If you create the table, load data, and then do `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table.)

### 5.4.1. Managing InnoDB Tablespaces

Historically, all InnoDB tables and indexes were stored in the [system tablespace](#). This monolithic approach was targeted at machines dedicated entirely to database processing, with carefully planned data growth, where any disk storage allocated to MySQL would never be needed for other purposes. InnoDB's [file-per-table](#) mode is a more flexible alternative, where you store each InnoDB table and its indexes in a separate file. Each such `.ibd` file represents a separate [tablespace](#). This mode is controlled by the `innodb_file_per_table` [1718] configuration option, and is the default in MySQL 5.6.6 and higher.

Multiple tablespaces are useful in a number of situations:

- You can reclaim disk space when truncating or dropping a table. For tables created when file-per-table mode is turned off, truncating or dropping them creates free space internally in the [ibdata files](#). That free space can only be used for new InnoDB data.
- You can store specific tables on separate storage devices, for I/O optimization, space management, or backup purposes. In previous releases, you had to move entire database directories to other drives and create symbolic links in the MySQL data directory, as described in [Section 8.11.3.1, “Using Symbolic Links”](#). In MySQL 5.6 and higher, you can specify the location of each table using the syntax `CREATE TABLE ... DATA DIRECTORY = absolute_path_to_directory`, as explained in [Section 5.4.1.2, “Specifying the Location of a Tablespace”](#).
- You can copy individual InnoDB tables from one MySQL instance to another (known as the [transportable tablespace](#) feature).
- You can enable [compression](#) for table and index data, using the [compressed row format](#).
- You can enable more efficient storage for tables with large BLOB or text columns using the [dynamic row format](#).
- You can back up or restore a single table quickly, without interrupting the use of other InnoDB tables, using the MySQL Enterprise Backup product. See [Backing Up and Restoring a Single .ibd File](#) for the procedure and restrictions.

#### 5.4.1.1. Enabling and Disabling File-Per-Table Mode

To make file-per-table mode the default for a MySQL server, start the server with the `--innodb_file_per_table` [1718] command-line option, or add this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table
```

You can also issue the command while the server is running:

```
SET GLOBAL innodb_file_per_table=1;
```

With file-per-table mode enabled, InnoDB stores each newly created table in its own `tbl_name.ibd` file in the appropriate database directory. Unlike the [MyISAM](#) storage engine, with its separate `tbl_name.MYD` and `tbl_name.MYI` files for indexes and data, InnoDB stores the data and the indexes together in a single `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove `innodb_file_per_table` [1718] from your startup options and restart the server, or turn it off with the `SET GLOBAL` command, InnoDB creates any new tables inside the system tablespace.

You can always read and write any InnoDB tables, regardless of the file-per-table setting.

To move a table from the system tablespace to its own tablespace, or vice versa, change the `innodb_file_per_table` [1718] setting and rebuild the table:

```
-- Move table from system tablespace to its own tablespace.
SET GLOBAL innodb_file_per_table=1;
ALTER TABLE table_name ENGINE=InnoDB;
```

```
-- Move table from its own tablespace to system tablespace.
SET GLOBAL innodb_file_per_table=0;
ALTER TABLE table_name ENGINE=InnoDB;
```

### Note

InnoDB always needs the system tablespace because it puts its internal [data dictionary](#) and [undo logs](#) there. The `.ibd` files are not sufficient for InnoDB to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new InnoDB data, but is not reclaimed for use by the operating system. When moving large InnoDB tables out of the system tablespace, where disk space is limited, you might prefer to turn on `innodb_file_per_table` and then recreate the entire instance using the `mysqldump` command.

## 5.4.1.2. Specifying the Location of a Tablespace

To create a new InnoDB table in a specific location outside the MySQL data directory, use the `DATA DIRECTORY = absolute_path_to_directory` clause of the `CREATE TABLE` statement. (Plan the location in advance, because you cannot use this clause with the `ALTER TABLE` statement.) The directory you specify could be on another storage device with particular performance or capacity characteristics, such as a fast [SSD](#) or a high-capacity [HDD](#).

Within the destination directory, MySQL creates a subdirectory corresponding to the database name, and within that a `.ibd` file for the new table. In the database directory underneath the MySQL `DATADIR` [472] directory, MySQL creates a `table_name.isl` file containing the path name for the table. The `.isl` file is treated by MySQL like a symbolic link. ([Using actual symbolic links](#) has never been supported for InnoDB tables.)

The following example shows how you might run a small development or test instance of MySQL on a laptop with a primary hard drive that is 95% full, and place a new table `EXTERNAL` on a different storage device with more free space. The shell commands show the different paths to the `LOCAL` table in its default location under the `DATADIR` directory, and the `EXTERNAL` table in the location you specified:

```
mysql> \! df -k .
Filesystem      1024-blocks      Used Available Capacity  iused   ifree %used  Mounted on
/dev/disk0s2    244277768 231603532  12418236    95% 57964881 3104559   95%  /

mysql> use test;
Database changed
mysql> show variables like 'innodb_file_per_table';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_file_per_table | ON |
+-----+-----+
1 row in set (0.00 sec)

mysql> \! pwd
/usr/local/mysql
mysql> create table local (x int unsigned not null primary key);
Query OK, 0 rows affected (0.03 sec)

mysql> \! ls -l data/test/local.ibd
-rw-rw----  1 cirrus  staff  98304 Nov 13 15:24 data/test/local.ibd

mysql> create table external (x int unsigned not null primary key) data directory = '/volumes/external1';
Query OK, 0 rows affected (0.03 sec)
```

```
mysql> \! ls -l /volumes/external1/data/test/external.ibd
-rwxrwxrwx 1 cirrus staff 98304 Nov 13 15:34 /volumes/external1/data/test/external.ibd

mysql> select count(*) from local;
+-----+
| count(*) |
+-----+
|          0 |
+-----+
1 row in set (0.01 sec)

mysql> select count(*) from external;
+-----+
| count(*) |
+-----+
|          0 |
+-----+
1 row in set (0.01 sec)
```

#### Notes:

- MySQL initially holds the `.ibd` file open, preventing you from dismounting the device, but might eventually close the table if the server is busy. Be careful not to accidentally dismount the external device while MySQL is running, or to start MySQL while the device is disconnected. Attempting to access a table when the associated `.ibd` file is missing causes a serious error that requires a server restart.

The server restart might fail if the `.ibd` file is still not at the expected path. In this case, manually remove the `table_name.isl` file in the database directory, and after restarting do a `DROP TABLE` to delete the `.frm` file and remove the information about the table from the [data dictionary](#).

- Do not put MySQL tables on an NFS-mounted volume. NFS uses a message-passing protocol to write to files, which could cause data inconsistency if network messages are lost or received out of order.
- If you use an LVM snapshot, file copy, or other file-based mechanism to back up the `.ibd` file, always use the `FLUSH TABLES ... FOR EXPORT` statement first to make sure all changes that were buffered in memory are [flushed](#) to disk before the backup occurs.
- The `DATA DIRECTORY` clause is a supported alternative to [using symbolic links](#), which has always been problematic and was never supported for individual [InnoDB](#) tables.

### 5.4.1.3. Copying Tablespaces to Another Server (Transportable Tablespaces)

There are many reasons why you might copy an [InnoDB](#) table to a different database server:

- To run reports without putting extra load on a production server.
- To set up identical data for a table on a new [slave](#) server.
- To restore a backed-up version of a table after a problem or mistake.
- As a faster way of moving data around than importing the results of a `mysqldump` command. the data is available immediately, rather than having to be re-inserted and the indexes rebuilt.

Use the `FLUSH TABLES` statement with the `FOR EXPORT` clause. This puts the corresponding `.ibd` files into a consistent state so that they can be copied to another server. You copy a `.cfg` file along with the `.ibd` file; this extra file is used by `ALTER TABLE ... IMPORT TABLESPACE` to make any necessary adjustments within the tablespace file during the import process. See [Section 13.7.6.3, “FLUSH Syntax”](#) for the SQL semantics.

#### 5.4.1.4. Moving the Undo Log out of the System Tablespace

Although tablespace management typically involves files holding tables and indexes, you can also divide the [undo log](#) into separate [undo tablespace](#) files. This layout is different from the default configuration where the undo log is part of the [system tablespace](#). See [Section 14.2.4.2.4, “Separate Tablespaces for InnoDB Undo Logs”](#) for details.

#### 5.4.2. Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with [autocommit](#) mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of [DML](#) statements and commit them or roll them back all together.

To use multiple-statement [transactions](#), switch autocommit off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave autocommit on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+-----+-----+
| a    | b      |
+-----+-----+
| 10  | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

#### Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

#### 5.4.3. Converting Tables from MyISAM to InnoDB

If you have existing tables, and applications that use them, that you want to convert to [InnoDB](#) for better reliability and scalability, use the following guidelines and tips. This section assumes most such tables were originally [MyISAM](#), which was formerly the default.

## Reduce Memory Usage for MyISAM, Increase Memory Usage for InnoDB

As you transition away from MyISAM tables, lower the value of the `key_buffer_size` [492] configuration option to free memory no longer needed for caching results. Increase the value of the `innodb_buffer_pool_size` [1708] configuration option, which performs a similar role of allocating cache memory for InnoDB tables. The InnoDB buffer pool caches both table data and index data, so it does double duty in speeding up lookups for queries and keeping query results in memory for reuse.

- Allocate as much memory to this option as you can afford, often up to 80% of physical memory on the server.
- If the operating system runs short of memory for other processes and begins to swap, reduce the `innodb_buffer_pool_size` [1708] value. Swapping is such an expensive operation that it drastically reduces the benefit of the cache memory.
- If the `innodb_buffer_pool_size` [1708] value is several gigabytes or higher, consider increasing the values of `innodb_buffer_pool_instances` [1706]. Doing so helps on busy servers where many connections are reading data into the cache at the same time.
- On a busy server, run benchmarks with the Query Cache turned off. The InnoDB buffer pool provides similar benefits, so the Query Cache might be tying up memory unnecessarily.

## Watch Out for Too-Long Or Too-Short Transactions

Because MyISAM tables do not support [transactions](#), you might not have paid much attention to the `autocommit` [464] configuration option and the `COMMIT` and `ROLLBACK` statements. These keywords are important to allow multiple sessions to read and write InnoDB tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a `mysql` session for interactive experiments, always `COMMIT` (to finalize the changes) or `ROLLBACK` (to undo the changes) when finished. Close down interactive sessions rather than leaving them open for long periods, to avoid keeping transactions open for long periods by accident.
- Make sure that any error handlers in your application also `ROLLBACK` incomplete changes or `COMMIT` completed changes.
- `ROLLBACK` is a relatively expensive operation, because `INSERT`, `UPDATE`, and `DELETE` operations are written to InnoDB tables prior to the `COMMIT`, with the expectation that most changes will be committed successfully and rollbacks will be rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.
- When loading large volumes of data with a sequence of `INSERT` statements, periodically `COMMIT` the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you `TRUNCATE TABLE` and start over from the beginning rather than doing a `ROLLBACK`.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each `COMMIT`, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on InnoDB tables, you should use the setting `autocommit=0` [464]. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive `INSERT`, `UPDATE`, or `DELETE` statements. From a safety perspective, this allows you to issue a `ROLLBACK` statement to recover lost or garbled data if you make a mistake on the `mysql` command line, or in an exception handler in your application.

- The time when `autocommit=1` [464] is suitable for InnoDB tables is when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to `COMMIT` or `ROLLBACK`, and InnoDB can automatically optimize the read-only workload.
- If you make a series of related changes, finalize all those changes at once with a single `COMMIT` at the end. For example, if you insert related pieces of information into several tables, do a single `COMMIT` after making all the changes. Or if you run many consecutive `INSERT` statements, do a single `COMMIT` after all the data is loaded; if you are doing millions of `INSERT` statements, perhaps split up the huge transaction by issuing a `COMMIT` every ten thousand or hundred thousand records, so the transaction does not grow too large.
- Remember that even a `SELECT` statement opens a transaction, so after running some report or debugging queries in an interactive `mysql` session, either issue a `COMMIT` or close the `mysql` session.

## Don't Worry Too Much About Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of `SHOW ENGINE INNODB STATUS`. Despite the scary-sounding name, a **deadlock** is not a serious issue for InnoDB tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. MySQL immediately detects this condition and cancels (rolls back) the “smaller” transaction, allowing the other to proceed.

Your applications do need error-handling logic to restart a transaction that is forcibly cancelled like this. When you re-issue the same SQL statements as before, the original timing issue no longer applies: either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the `innodb_print_all_deadlocks` [1741] option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the `SHOW ENGINE INNODB STATUS` output.

## Plan the Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table` [1718], `innodb_file_format` [1716], and `innodb_page_size` [1740] configuration options, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table` [1718]. Enabling this option before creating new InnoDB tables ensures that the InnoDB system **tablespace** files do not allocate disk space permanently for all the InnoDB data. With `innodb_file_per_table` [1718] enabled, `DROP TABLE` and `TRUNCATE TABLE` free disk space as you would expect.

## Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use `ALTER TABLE`:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

### Important

Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the InnoDB type. This is an unsupported operation. The system tables must always be of the MyISAM type.

## Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than doing the `ALTER TABLE` conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use `show create table table_name\G` to see the full `CREATE TABLE` statement to use. Change the `ENGINE` clause to `ENGINE=INNODB`.

## Transferring Existing Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;... import operation ...
SET unique_checks=1;
```

For big tables, this saves disk I/O because InnoDB can use its `insert buffer` to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` [561] permits but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, you might insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, increase the size of the InnoDB buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the sizes of the InnoDB log files.

## Storage Requirements

By this point, as already mentioned, you should already have the `innodb_file_per_table` [1718] option enabled, so that if you temporarily make several copies of your data in InnoDB tables, you can recover all that disk space by dropping unneeded tables afterward.

Whether you convert the MyISAM table directly or create a cloned InnoDB table, make sure that you have sufficient disk space to hold both the old and new tables during the process. InnoDB tables require more disk space than MyISAM tables. If an `ALTER TABLE` operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 14.2.4.6, “Starting InnoDB on a Corrupted Database”](#).

## Carefully Choose a PRIMARY KEY for Each Table

The `PRIMARY KEY` clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. Perhaps you have phoned a financial institution where you are

asked for an account number. If you do not have the number, you are asked for a dozen different pieces of information to “uniquely identify” yourself. The primary key is like that unique account number that lets you get straight down to business when querying or modifying the information in a table. Every row in the table must have a primary key value, and no two rows can have the same primary key value.

Here are some guidelines for the primary key, followed by more detailed explanations.

- Declare a [PRIMARY KEY](#) for each table. Typically, it is the most important column that you refer to in [WHERE](#) clauses when looking up a single row.
- Declare the [PRIMARY KEY](#) clause in the original [CREATE TABLE](#) statement, rather than adding it later through an [ALTER TABLE](#) statement.
- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.
- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.
- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a [primary key](#) to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any [secondary indexes](#), because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the [buffer pool](#), speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a [VARCHAR](#), consider adding a new unsigned [AUTO\\_INCREMENT](#) column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as [UNIQUE NOT NULL](#) to enforce the same constraints as the [PRIMARY KEY](#) clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the [PRIMARY KEY](#) clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

## Application Performance Considerations

The extra reliability and scalability features of [InnoDB](#) do require more disk storage than equivalent [MyISAM](#) tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you do set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for [join](#) queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned [INT](#) column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer

types, see [Section 11.2.1, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#).

## Understand Files Associated with InnoDB Tables

InnoDB files require more care and planning than MyISAM files do:

- You must not delete the [ibdata files](#) that represent the [InnoDB system tablespace](#).
- Copying InnoDB tables from one server to another requires issuing the `FLUSH TABLES ... FOR EXPORT` statement first, and copying the `table_name.cfg` file along with the `table_name.ibd` file.

### 5.4.4. AUTO\_INCREMENT Handling in InnoDB

InnoDB provides an optimization that significantly improves scalability and performance of SQL statements that insert rows into tables with `AUTO_INCREMENT` columns. To use the `AUTO_INCREMENT` mechanism with an InnoDB table, an `AUTO_INCREMENT` column `ai_col` must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

This section provides background information on the original (“traditional”) implementation of auto-increment locking in InnoDB, explains the configurable locking mechanism, documents the parameter for configuring the mechanism, and describes its behavior and interaction with replication.

#### 5.4.4.1. Traditional InnoDB Auto-Increment Locking

The original implementation of auto-increment handling in InnoDB uses the following strategy to prevent problems when using the binary log for statement-based replication or for certain recovery scenarios.

If you specify an `AUTO_INCREMENT` column for an InnoDB table, the table handle in the InnoDB data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

InnoDB uses the following algorithm to initialize the auto-increment counter for a table `t` that contains an `AUTO_INCREMENT` column named `ai_col`: After a server startup, for the first insert into a table `t`, InnoDB executes the equivalent of this statement:

```
SELECT MAX(ai_col) FROM t FOR UPDATE;
```

InnoDB increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by one. This default can be overridden by the `auto_increment_increment` [1965] configuration setting.

If the table is empty, InnoDB uses the value 1. This default can be overridden by the `auto_increment_offset` [1968] configuration setting.

If a `SHOW TABLE STATUS` statement examines the table `t` before the auto-increment counter is initialized, InnoDB initializes but does not increment the value and stores it for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction.

InnoDB follows the same procedure for initializing the auto-increment counter for a freshly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an `AUTO_INCREMENT` column, InnoDB increments the counter and assigns the new value to the column.

If you insert a row that explicitly specifies the column value, and the value is bigger than the current counter value, the counter is set to the specified column value.

If a user specifies `NULL` or `0` for the `AUTO_INCREMENT` column in an `INSERT`, InnoDB treats the row as if the value was not specified and generates a new value for it.

The behavior of the auto-increment mechanism is not defined if you assign a negative value to the column, or if the value becomes bigger than the maximum integer that can be stored in the specified integer type.

When accessing the auto-increment counter, InnoDB uses a special table-level `AUTO-INC` lock that it keeps to the end of the current SQL statement, not to the end of the transaction. The special lock release strategy was introduced to improve concurrency for inserts into a table containing an `AUTO_INCREMENT` column. Nevertheless, two transactions cannot have the `AUTO-INC` lock on the same table simultaneously, which can have a performance impact if the `AUTO-INC` lock is held for a long time. That might be the case for a statement such as `INSERT INTO t1 ... SELECT ... FROM t2` that inserts all rows from one table into another.

InnoDB uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, InnoDB reinitializes the counter for each table for the first `INSERT` to the table, as described earlier.

A server restart also cancels the effect of the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, which you can use with InnoDB tables to set the initial counter value or alter the current counter value.

You may see gaps in the sequence of values assigned to the `AUTO_INCREMENT` column if you roll back transactions that have generated numbers using the counter.

#### 5.4.4.2. Configurable InnoDB Auto-Increment Locking

As described in the previous section, InnoDB uses a special lock called the table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction), to ensure that auto-increment numbers are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```
CREATE TABLE t1 (
  c1 INT(11) NOT NULL AUTO_INCREMENT,
  c2 VARCHAR(10) DEFAULT NULL,
  PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

InnoDB cannot tell in advance how many rows will be retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the Tx1 `INSERT ... SELECT` statement will be

consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 will either be smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results will be the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

InnoDB can avoid using the table-level `AUTO-INC` lock for a class of `INSERT` statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication. Further, if you are not using the binary log to replay SQL statements as part of recovery or replication, you can entirely eliminate use of the table-level `AUTO-INC` lock for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

For `INSERT` statements where the number of rows to be inserted is known at the beginning of processing the statement, InnoDB quickly allocates the required number of auto-increment values without taking any lock, but only if there is no concurrent session already holding the table-level `AUTO-INC` lock (because that other statement will be allocating auto-increment values one-by-one as it proceeds). More precisely, such an `INSERT` statement obtains auto-increment values under the control of a mutex (a light-weight lock) that is *not* held until the statement completes, but only for the duration of the allocation process.

This new locking scheme enables much greater scalability, but it does introduce some subtle differences in how auto-increment values are assigned compared to the original mechanism. To describe the way auto-increment works in InnoDB, the following discussion defines some terms, and explains how InnoDB behaves using different settings of the `innodb_autoinc_lock_mode` [1705] configuration parameter, which you can set at server startup. Additional considerations are described following the explanation of auto-increment locking behavior.

First, some definitions:

- “`INSERT-like`” statements

All statements that generate new rows in a table, including `INSERT`, `INSERT ... SELECT`, `REPLACE`, `REPLACE ... SELECT`, and `LOAD DATA`.

- “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row `INSERT` and `REPLACE` statements that do not have a nested subquery, but not `INSERT ... ON DUPLICATE KEY UPDATE`.

- “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. InnoDB will assign new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

- “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` [1705] parameter:

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

This lock mode provides the same behavior as before `innodb_autoinc_lock_mode` [1705] existed. For all “`INSERT`-like” statements, a special table-level `AUTO-INC` lock is obtained and held to the end of the statement. This assures that the auto-increment values assigned by any given statement are consecutive.

This lock mode is provided for:

- Backward compatibility.
- Performance testing.
- Working around issues with “mixed-mode inserts”, due to the possible differences in semantics described later.
- `innodb_autoinc_lock_mode = 1` (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute at a time.

With this lock mode, “simple inserts” (only) use a new locking model where a light-weight mutex is used during the allocation of auto-increment values, and no table-level `AUTO-INC` lock is used, unless an `AUTO-INC` lock is held by another transaction. If another transaction does hold an `AUTO-INC` lock, a “simple insert” waits for the `AUTO-INC` lock, as if it too were a “bulk insert”.

This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “`INSERT`-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, the important impact of this lock mode is significantly better scalability. This mode is safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are *consecutive*. In this mode, there is *no change* in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB will allocate more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “`INSERT`-like” statements use the table-level `AUTO-INC` lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is

*not safe* when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “INSERT-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there will be no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

The auto-increment locking modes provided by `innodb_autoinc_lock_mode` [1705] have several usage implications:

- Using auto-increment with replication

If you are using statement-based replication, set `innodb_autoinc_lock_mode` [1705] to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode` [1705] = 2 (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based replication, all of the auto-increment lock modes are safe. Row-based replication is not sensitive to the order of execution of the SQL statements.

- “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “INSERT-like” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an `AUTO_INCREMENT` column of a table.

- Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` [1705] set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement will be consecutive, without gaps, because the table-level `AUTO-INC` lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` [1705] set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “INSERT-like” statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement will behave differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100. Consider the following “mixed-mode insert” statement:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` [1705] set to 0 (“traditional”), the four new rows will be:

c1	c2
1	a
101	b
5	c
102	d

The next available auto-increment value will be 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “INSERT-like” statements (of any type).

With `innodb_autoinc_lock_mode` [1705] set to 1 (“consecutive”), the four new rows will also be:

c1	c2
1	a
101	b
5	c
102	d

However, in this case, the next available auto-increment value will be 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “INSERT-like” statements (of any type).

With `innodb_autoinc_lock_mode` [1705] set to mode 2 (“interleaved”), the four new rows will be:

c1	c2
1	a
<i>x</i>	b
5	c
<i>y</i>	d

The values of *x* and *y* will be unique and larger than any previously generated rows. However, the specific values of *x* and *y* will depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` [1705] setting, this statement will generate a duplicate-key error 23000 (Can't write; duplicate key in table) because 5 will be allocated for the row (NULL, 'b') and insertion of the row (5, 'c') will fail.

### 5.4.5. InnoDB and FOREIGN KEY Constraints

This section describes differences in the InnoDB storage engine's handling of foreign keys as compared with that of the MySQL Server.

#### Foreign Key Definitions

Foreign key definitions for InnoDB tables are subject to the following conditions:

- InnoDB permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.

- InnoDB does not currently support foreign keys for tables with user-defined partitioning. This means that no user-partitioned InnoDB table may contain foreign key references or columns referenced by foreign keys.
- InnoDB allows a foreign key constraint to reference a non-unique key. *This is an InnoDB extension to standard SQL.*

## Referential Actions

Referential actions for foreign keys of InnoDB tables are subject to the following conditions:

- While `SET DEFAULT` is allowed by the MySQL Server, it is rejected as invalid by InnoDB. `CREATE TABLE` and `ALTER TABLE` statements using this clause are not allowed for InnoDB tables.
- If there are several rows in the parent table that have the same referenced key value, InnoDB acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, InnoDB does not permit the deletion of any of those parent rows.
- InnoDB performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.
- Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, InnoDB checks `UNIQUE` and `FOREIGN KEY` constraints row-by-row. When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until InnoDB implements deferred constraint checking, some things will be impossible, such as deleting a record that refers to itself using a foreign key.

## Foreign Key Usage and Error Information

You can obtain general information about foreign keys and their usage from querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table, and more information more specific to InnoDB tables can be found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, also in the `INFORMATION_SCHEMA` database. See also [Section 13.1.14.2, “Using FOREIGN KEY Constraints”](#).

In addition to `SHOW ERRORS`, in the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), you can obtain a detailed explanation of the most recent InnoDB foreign key error by checking the output of `SHOW ENGINE INNODB STATUS`.

### 5.4.6. Working with InnoDB Compressed Tables

By using the SQL syntax and MySQL configuration options for `compression`, you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with `secondary indexes`, because index data is compressed also. Compression can be especially important for `SSD` storage devices, because they tend to have lower capacity than `HDD` devices.

#### 5.4.6.1. Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are `disk-bound`. Data `compression` enables smaller database size, reduced I/O, and

improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An InnoDB table created with `ROW_FORMAT=COMPRESSED` can use a smaller [page size](#) on disk than the usual 16KB default. Smaller pages require less I/O to read from and write to disk, which is especially valuable for [SSD](#) devices.

The page size is specified through the `KEY_BLOCK_SIZE` parameter. The different page size means the table must be in its own `.ibd` file rather than in the [system tablespace](#), which requires enabling the `innodb_file_per_table` option. The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates a 16KB page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are [evicted](#) from the buffer pool when space is needed, and then uncompressed again on the next access.

#### 5.4.6.2. Enabling Compression for a Table

Before creating a compressed table, make sure the `innodb_file_per_table` [\[1718\]](#) configuration option is enabled, and `innodb_file_format` [\[1716\]](#) is set to `Barracuda`. You can set these parameters in the MySQL [configuration file](#) `my.cnf` or `my.ini`, or with the `SET` statement without shutting down the MySQL server.

To enable compression for a table, you use the clauses `ROW_FORMAT=COMPRESSED`, `KEY_BLOCK_SIZE`, or both in a `CREATE TABLE` or `ALTER TABLE` statement.

To create a compressed table, you might use statements like these:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
CREATE TABLE t1
  (c1 INT PRIMARY KEY)
  ROW_FORMAT=COMPRESSED
  KEY_BLOCK_SIZE=8;
```

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the default compressed page size of 8KB is used.
- If you specify `KEY_BLOCK_SIZE`, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.
- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic [workload](#).
- For additional performance-related configuration options, see [Section 5.4.6.3, “Tuning Compression for InnoDB Tables”](#).

The default uncompressed size of InnoDB data [pages](#) is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the `.ibd` file of the table. The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.

Setting `KEY_BLOCK_SIZE=16` typically does not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer overflow pages as described in [Section 5.4.6.5, “How Compression Works for InnoDB Tables”](#).

All indexes of a table (including the [clustered index](#)) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax, and are ignored if they are specified (although you see them in the output of the `SHOW CREATE TABLE` statement).

## Restrictions on Compressed Tables

Because MySQL versions prior to 5.1 cannot process compressed tables, using compression requires specifying the configuration parameter `innodb_file_format=Barracuda` [\[1716\]](#), to avoid accidentally introducing compatibility issues.

Table compression is also not available for the InnoDB [system tablespace](#). The system tablespace (space 0, the `ibdata*` files) can contain user data, but it also contains internal system information, and therefore is never compressed. Thus, compression applies only to tables (and indexes) stored in their own tablespaces, that is, created with the `innodb_file_per_table` [\[1718\]](#) option enabled.

Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.

### 5.4.6.3. Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in [Section 5.4.6.5, “InnoDB Data Storage and Compression”](#) ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a [data warehouse](#) (primarily queries) or an [OLTP](#) system (mix of queries and [DML](#)).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive [compression failures](#) at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see [Section 5.4.6.4, “Monitoring Compression at Runtime”](#) for ways to verify the effectiveness of those choices under real-world conditions.

## When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific [workload](#) and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

## Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in `CHAR`, `VARCHAR`,

**TEXT** or **BLOB** columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) **page size**. It might be that the **primary key** (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in [Section 5.4.8.3, “DYNAMIC and COMPRESSED Row Formats”](#). Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as **gzip** or WinZip) on a copy of the **.ibd file** for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the **page size**, 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) and look at the size of the resulting **.ibd file**. For example:

```
use test;
set global innodb_file_per_table=1;
set global innodb_file_format=Barracuda;
set global autocommit=0;

-- Create an uncompressed table with a million or two rows.
create table big_table as select * from information_schema.columns;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;
alter table big_table add id int unsigned not null primary key auto_increment;

show create table big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd

create table key_block_size_4 like big_table;
alter table key_block_size_4 key_block_size=4 row_format=compressed;

insert into key_block_size_4 select * from big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw---- 1 cirrus staff 310378496 Jan 9 13:44 data/test/big_table.ibd
-rw-rw---- 1 cirrus staff 83886080 Jan 9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular [workload](#):

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the `INFORMATION_SCHEMA.INNODB_CMP` table.
- For more elaborate tests involving workloads with multiple compressed tables, run queries against the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because the statistics in the `INNODB_CMP_PER_INDEX` table are expensive to collect, you must enable the configuration option `innodb_cmp_per_index_enabled` [1712] before querying that table, and you might restrict such testing to a development server or a non-critical [slave server](#).
- Run some typical SQL statements against the compressed table you are testing.
- Examine the ratio of successful compression operations to overall compression operations by querying the `INFORMATION_SCHEMA.INNODB_CMP` or `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.
- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.
- If you get a high proportion of [compression failures](#), you can adjust `innodb_compression_level` [1713], `innodb_compression_failure_threshold_pct` [1713], and `innodb_compression_pad_pct_max` [1713] options as described in [Section 14.2.4.2.2](#), “[Compression Enhancements for OLTP Workloads](#)”, and try further tests.

## Database Compression versus Application Compression

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

## Compressing in the Database

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

## Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

## Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

## Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing `BLOBS` or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are `INSERTs` that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, `DELETE` operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

## Configuration Characteristics and Compression

Reading and writing database pages from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the buffer pool for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

## Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in [Section 5.4.6.5, “Compression of B-Tree Pages”](#).

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the B-tree nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, `KEY_BLOCK_SIZE=8` is usually a safe choice.

### 5.4.6.4. Monitoring Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from [Section 5.4.6.3, “Tuning Compression for InnoDB Tables”](#), and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the [Information Schema](#) tables described in [Example 14.2, “Using the Compression Information Schema Tables”](#). These tables reflect the internal use of memory and the rates of compression used overall.

The `INNODB_CMP` table reports information about compression activity for each compressed page size (`KEY_BLOCK_SIZE`) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The `INNODB_CMP_PER_INDEX` table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each InnoDB table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different workloads, data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` [1712] configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits B-tree nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of `INSERT`, `UPDATE` and `DELETE` operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

#### 5.4.6.5. How Compression Works for InnoDB Tables

This section describes some internal implementation details about MySQL [compression](#) for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

#### Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known [zlib library](#), which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU

utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the `.idb` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the [workload](#), this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the `innodb_compression_level` [\[1713\]](#) configuration option.

## InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a [B-tree](#) index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) [primary key](#) and all the other columns of the table.

[Secondary indexes](#) in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of [overflow pages](#) used to store long `VARCHAR`, `BLOB`, or `TEXT` columns, as explained in the following sections.

## Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a [compression failure](#)), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for [OLTP](#) applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the `innodb_compression_failure_threshold_pct` [\[1713\]](#), and `innodb_compression_pad_pct_max` [\[1713\]](#) configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If

`innodb_strict_mode` [1749] is ON, MySQL checks the maximum row size during `CREATE TABLE` or `CREATE INDEX`. If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when `innodb_strict_mode` [1749] is OFF, and a subsequent `INSERT` or `UPDATE` statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

## Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated [overflow pages](#). We refer to these columns as [off-page columns](#). Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

Tables created in older versions of MySQL use the [Antelope](#) file format, which supports only `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT`. In these formats, MySQL stores the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the `zlib` compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as `JPEG`, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

Using a 16K compressed page size can reduce storage and I/O costs for `BLOB`, `VARCHAR`, or `TEXT` columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form.

## Compression and the InnoDB Buffer Pool

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if `innodb_page_size` [1740] is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the [buffer pool](#), then uncompresses the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can [evict](#) from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that [hot](#) (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an [I/O-bound](#) or [CPU-bound](#) manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

## Compression and the InnoDB Redo Log Files

Before a compressed page is written to a [data file](#), MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for [crash recovery](#), even in the unlikely case that the [zlib](#) library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of [log files](#), or a need for more frequent [checkpoints](#), can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Note that compressed tables use a different file format for the redo log and the per-table tablespaces than in MySQL 5.1 and earlier. The [MySQL Enterprise Backup](#) product supports this latest [Barracuda](#) file format for compressed InnoDB tables. The older InnoDB Hot Backup product can only back up tables using the file format [Antelope](#), and thus does not support compressed InnoDB tables.

### 5.4.6.6. SQL Compression Syntax Warnings and Errors

Specifying [ROW\\_FORMAT=COMPRESSED](#) or [KEY\\_BLOCK\\_SIZE](#) in [CREATE TABLE](#) or [ALTER TABLE](#) statements produces the following warnings if the Barracuda file format is not enabled. You can view them with the [SHOW WARNINGS](#) statement.

Level	Code	Message
Warning	1478	InnoDB: <a href="#">KEY_BLOCK_SIZE</a> requires <a href="#">innodb_file_per_table</a> .
Warning	1478	InnoDB: <a href="#">KEY_BLOCK_SIZE</a> requires <a href="#">innodb_file_format=1</a>
Warning	1478	InnoDB: ignoring <a href="#">KEY_BLOCK_SIZE=4</a> .
Warning	1478	InnoDB: <a href="#">ROW_FORMAT=COMPRESSED</a> requires <a href="#">innodb_file_per_table</a> .
Warning	1478	InnoDB: assuming <a href="#">ROW_FORMAT=COMPACT</a> .

Notes:

- By default, these messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.
- When [innodb\\_strict\\_mode](#) [1749] is enabled, MySQL generates an error, not a warning, for these cases. The table is not created if the current configuration does not permit using compressed tables.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=COMPACT` instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper settings for the configuration parameters `innodb_file_format` [1716] and `innodb_file_per_table` [1718].

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

Level	Code	Message
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.

If you are running with `innodb_strict_mode` [1749] enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 5.6, “Meaning of `CREATE TABLE` and `ALTER TABLE` options” summarizes how the various options on `CREATE TABLE` and `ALTER TABLE` are handled.

**Table 5.6. Meaning of `CREATE TABLE` and `ALTER TABLE` options**

Option	Usage	Description
<code>ROW_FORMAT=REDUNDANT</code>	Storage format used prior to MySQL 5.0.3	Less efficient than <code>ROW_FORMAT=COMPACT</code> ; for backward compatibility
<code>ROW_FORMAT=COMPACT</code>	Default storage format since MySQL 5.0.3	Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page
<code>ROW_FORMAT=DYNAMIC</code>	Available only with <code>innodb_file_format=Barracuda</code>	Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)
<code>ROW_FORMAT=COMPRESSED</code>	Available only with <code>innodb_file_format=Barracuda</code>	Compresses the table and indexes using zlib to default compressed page size of 8K bytes; implies <code>ROW_FORMAT=DYNAMIC</code>
<code>KEY_BLOCK_SIZE=n</code>	Available only with <code>innodb_file_format=Barracuda</code>	Specifies compressed page size of 1, 2, 4, 8 or 16K bytes; implies <code>ROW_FORMAT=DYNAMIC</code> and <code>ROW_FORMAT=COMPRESSED</code>

Table 5.7, “`CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF`” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` [1749] is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` [1749] is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
-> ENGINE=INNODB KEY_BLOCK_SIZE=33333;
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)
```

```
mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333. |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-----+-----+-----+

2 rows in set (0.00 sec)
```

**Table 5.7. CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF**

Syntax	Warning or Error Condition	Resulting ROW_FORMAT, as shown in SHOW TABLE STATUS
ROW_FORMAT=REDUNDANT	None	REDUNDANT
ROW_FORMAT=COMPACT	None	COMPACT
ROW_FORMAT=COMPRESSED or ROW_FORMAT=DYNAMIC or KEY_BLOCK_SIZE is specified	Ignored unless both <code>innodb_file_format [1716]=Barracuda</code> and <code>innodb_file_per_table [1718]</code> are enabled	COMPACT
Invalid KEY_BLOCK_SIZE is specified (not 1, 2, 4, 8 or 16)	KEY_BLOCK_SIZE is ignored	the requested one, or COMPACT by default
ROW_FORMAT=COMPRESSED and valid KEY_BLOCK_SIZE are specified	None; KEY_BLOCK_SIZE specified is used, not the 8K default	COMPRESSED
KEY_BLOCK_SIZE is specified with REDUNDANT, COMPACT or DYNAMIC row format	KEY_BLOCK_SIZE is ignored	REDUNDANT, COMPACT or DYNAMIC
ROW_FORMAT is not one of REDUNDANT, COMPACT, DYNAMIC or COMPRESSED	Ignored if recognized by the MySQL parser. Otherwise, an error is issued.	COMPACT or N/A

When `innodb_strict_mode` is ON, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

Note that it is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

### 5.4.7. InnoDB File-Format Management

As InnoDB evolves, new on-disk data structures are sometimes required to support new features. Features such as compressed tables (see [Section 5.4.6, “Working with InnoDB Compressed Tables”](#)), and long variable-length columns stored off-page (see [Section 5.4.8, “How InnoDB Stores Variable-Length Columns”](#)) require data file formats that are not compatible with prior versions of InnoDB. These features both require use of the new [Barracuda](#) file format.

#### Note

All other new features are compatible with the original [Antelope](#) file format and do not require the [Barracuda](#) file format.

This section discusses how to specify the file format for new InnoDB tables, compatibility of different file formats between MySQL releases,

**Named File Formats.** InnoDB 1.1 has the idea of a named file format and a configuration parameter to enable the use of features that require use of that format. The new file format is the [Barracuda](#) format, and the original InnoDB file format is called [Antelope](#). Compressed tables and the new row format that stores long columns “off-page” require the use of the Barracuda file format or newer. Future versions of InnoDB may introduce a series of file formats, [identified with the names of animals](#), in ascending alphabetic order.

### 5.4.7.1. Enabling File Formats

The configuration parameter `innodb_file_format` [\[1716\]](#) controls whether such statements as `CREATE TABLE` and `ALTER TABLE` can be used to create tables that depend on support for the [Barracuda](#) file format.

Although Oracle recommends using the Barracuda format for new tables where practical, in MySQL 5.5 the default file format is still [Antelope](#), for maximum compatibility with replication configurations containing different MySQL releases.

The file format is a dynamic, global parameter that can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed with the `SET GLOBAL` command.

### 5.4.7.2. Verifying File Format Compatibility

InnoDB 1.1 incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an older release of the MySQL server on InnoDB data files using a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

## Backward Compatibility

Considerations of backward compatibility only apply when using a recent version of InnoDB (the InnoDB Plugin, or MySQL 5.5 and higher with InnoDB 1.1) alongside an older one (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with a prior version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB 1.1 includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with a prior version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported by the currently running software, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to an earlier file format is to copy the data to a new table, in a tablespace that uses the earlier format. This can be done with the `ALTER TABLE` statement, as described in [Section 5.4.7.4, “Downgrading the File Format”](#).

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table `INFORMATION_SCHEMA.TABLES`. If the `Row_format` of the table is reported as `'Compressed'` or `'Dynamic'`, the tablespace containing the table uses the Barracuda format. Otherwise, it uses the prior InnoDB file format, Antelope.

## Internal Details

Every InnoDB per-table tablespace (represented by a `*.ibd` file) file is labeled with a file format identifier. The system tablespace (represented by the `ibdata` files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with `ROW_FORMAT=DYNAMIC`, updates the file header for the corresponding `.ibd` file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support this new file format. To protect against anomalous behavior, InnoDB version 5.0.21 and later performs a compatibility check when the table is opened. (In many cases, the `ALTER TABLE` statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in [Fast Index Creation in the InnoDB Storage Engine](#).)

### Definition of ib-file set

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more `ibdata` files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.
- Zero or more single-table tablespaces (also called “file per table” files, named `*.ibd` files).
- InnoDB log files; usually two, `ib_logfile0` and `ib_logfile1`. Used for crash recovery and in backups.

An “ib-file set” does not include the corresponding `.frm` files that contain metadata about InnoDB tables. The `.frm` files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.

Multiple tables, even from more than one database, can be stored in a single “ib-file set”. (In MySQL, a “database” is a logical collection of tables, what other systems refer to as a “schema” or “catalog”.)

#### 5.4.7.2.1. Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., `innodb_fast_shutdown` [1716] is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter `innodb_file_format_check` [1717], which is `ON` by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` [1717] is `ON`, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a
file format that this version doesn't support
```

You can also set `innodb_file_format` [1716] to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` [1717] will be useful (with future releases of InnoDB) if you manually “downgrade” all of the tables in an ib-file set (as described in [Downgrading the InnoDB Storage Engine](#)). You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a “too new” format (one that is not supported by the software you are using). If you set the configuration parameter `innodb_file_format_check` [1717] to `OFF`, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a
file format that this version doesn't support
```

### Note

This is a very dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was a crash or “fast shutdown”. You should only set `innodb_file_format_check` [1717] to `OFF` if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs. In a future release, this parameter setting may be renamed from `OFF` to `UNSAFE`. (However, until there are newer releases of InnoDB that support additional file formats, even disabling the startup checking is in fact “safe”.)

The parameter `innodb_file_format_check` [1717] affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` [1716] (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in [Section 5.4.7.2.2, “Compatibility Check When a Table Is Opened”](#). Any time the high water mark is updated, the value of `innodb_file_format_check` [1717] is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the newest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

To best illustrate this behavior, consider the scenario described in [Table 5.8, “InnoDB Data File Compatibility and Related InnoDB Parameters”](#). Imagine that some future version of InnoDB supports the Cheetah format and that an ib-file set has been used with that version.

**Table 5.8. InnoDB Data File Compatibility and Related InnoDB Parameters**

innodb file format check	innodb file format	Highest file format used in ib-file set	Highest file format supported by InnoDB	Result
OFF	Antelope or Barracuda	Barracuda	Barracuda	Database can be opened; tables can be created which require Antelope or Barracuda file format
OFF	Antelope or Barracuda	Cheetah	Barracuda	Database can be opened with a warning, since the database contains files in a “too new” format; tables can be created in Antelope or Barracuda file format; tables in Cheetah format cannot be accessed
OFF	Cheetah	Barracuda	Barracuda	Database cannot be opened; <code>innodb_file_format</code> [1716] cannot be set to Cheetah
ON	Antelope or Barracuda	Barracuda	Barracuda	Database can be opened; tables can be created in Antelope or Barracuda file format
ON	Antelope or Barracuda	Cheetah	Barracuda	Database cannot be opened, since the database contains files in a “too new” format (Cheetah)

innodb file format check	innodb file format	Highest file format used in ib-file set	Highest file format supported by InnoDB	Result
ON	Cheetah	Barracuda	Barracuda	Database cannot be opened; <code>innodb_file_format [1716]</code> cannot be set to Cheetah

#### 5.4.7.2.2. Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a “too new” data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format [1716]` can prevent creating a new table that uses specific file formats, even if they are supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses any supported format.

As noted in [Named File Formats](#), versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in [Section 5.4.7.3, “Identifying the File Format in Use”](#).

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a “too new” format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check [1717]` to `OFF`), the table-level checking described in this section still applies.

Users are *strongly* urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It is possible to “downgrade” such tables to the Antelope format with the procedure described in [Section 5.4.7.4, “Downgrading the File Format”](#).

#### 5.4.7.3. Identifying the File Format in Use

After you enable a given `innodb_file_format [1716]`, this change applies only to newly created tables rather than existing ones. If you do create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required for the table’s features. For example, if you enable file format Barracuda, and create a new table that is not compressed and does not use `ROW_FORMAT=DYNAMIC`, the new tablespace that contains the table is tagged as using file format Antelope.

It is easy to identify the file format used by a given tablespace or table. The table uses the Barracuda format if the `Row_format` reported by `SHOW CREATE TABLE` or `INFORMATION_SCHEMA.TABLES` is one of 'Compressed' or 'Dynamic'. (The `Row_format` is a separate column; ignore the contents of the `Create_options` column, which may contain the string `ROW_FORMAT`.) If the table in a tablespace uses neither of those features, the file uses the format supported by prior releases of InnoDB, now called file format Antelope. Then, the `Row_format` is one of 'Redundant' or 'Compact'.

## Internal Details

The file format identifier is written as part of the tablespace flags (a 32-bit number) in the `*.ibd` file in the 4 bytes starting at position 54 of the file, most significant byte first. (The first byte of the file is byte zero.) On some systems, you can display these bytes in hexadecimal with the command `od -t x1 -j 54 -N 4 tablename.ibd`. If all bytes are zero, the tablespace uses the Antelope file format (which is the format used by the standard InnoDB storage engine up to version 5.1). Otherwise, the least significant bit should be set in the tablespace flags, and the file format identifier is written in the bits 5 through 11. (Divide the tablespace flags by 32 and take the remainder after dividing the integer part of the result by 128.)

### 5.4.7.4. Downgrading the File Format

Each InnoDB tablespace file (with a name matching `*.ibd`) is tagged with the file format used to create its table and indexes. The way to downgrade the tablespace is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the command:

```
ALTER TABLE t ROW_FORMAT=COMPACT;
```

on each table that you want to downgrade. The `COMPACT` row format uses the file format Antelope. It was introduced in MySQL 5.0.3.

### 5.4.7.5. Future InnoDB File Formats

The file format used by the standard built-in InnoDB in MySQL 5.1 is the `Antelope` format. The file format introduced with InnoDB Plugin 1.0 is the `Barracuda` format. Although no new features have been announced that would require additional new file formats, the InnoDB file format mechanism allows for future enhancements.

For the sake of completeness, these are the file format names that might be used for future file formats: Antelope, Barracuda, Cheetah, Dragon, Elk, Fox, Gazelle, Hornet, Impala, Jaguar, Kangaroo, Leopard, Moose, Nautilus, Ocelot, Porpoise, Quail, Rabbit, Shark, Tiger, Urchin, Viper, Whale, Xenops, Yak and Zebra. These file formats correspond to the internal identifiers 0..25.

## 5.4.8. How InnoDB Stores Variable-Length Columns

This section discusses how certain InnoDB features, such as table `compression` and off-page storage of long columns, are controlled by the `ROW_FORMAT` clause of the `CREATE TABLE` statement. It discusses considerations for choosing the right row format and compatibility of row formats between MySQL releases.

### 5.4.8.1. Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk `page`, queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

The data in each InnoDB table is divided into `pages`. The pages that make up each table are arranged in a tree data structure called a `B-tree index`. Table data and `secondary indexes` both use this type of structure. The B-tree index that represents an entire table is known as the `clustered index`, which is organized according to the `primary key` columns. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as `BLOB` and `VARCHAR` that are too long to fit on a B-tree page are stored on separately allocated disk pages called [overflow pages](#). We call such columns [off-page columns](#). The values of these columns are stored in singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases, all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

This section describes the clauses you can use with the `CREATE TABLE` and `ALTER TABLE` statements to control how these variable-length columns are represented: `ROW_FORMAT` and `KEY_BLOCK_SIZE`. To use these clauses, you might also need to change the settings for the `innodb_file_per_table` [1718] and `innodb_file_format` [1716] configuration options.

#### 5.4.8.2. Specifying the Row Format for a Table

You specify the row format for a table with the `ROW_FORMAT` clause of the `CREATE TABLE` and `ALTER TABLE` statements.

#### 5.4.8.3. DYNAMIC and COMPRESSED Row Formats

This section discusses the `DYNAMIC` and `COMPRESSED` row formats for InnoDB tables. You can only create these kinds of tables when the `innodb_file_format` [1716] configuration option is set to `Barracuda`. (The Barracuda file format also allows the `COMPACT` and `REDUNDANT` row formats.)

When a table is created with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, long column values are stored fully off-page, and the clustered index record contains only a 20-byte pointer to the overflow page.

Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, InnoDB chooses the longest columns for off-page storage until the clustered index record fits on the B-tree page.

The `DYNAMIC` row format maintains the efficiency of storing the entire row in the index node if it fits (as do the `COMPACT` and `REDUNDANT` formats), but this new format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The `DYNAMIC` format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With `DYNAMIC` format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages needed for any given row.

The `COMPRESSED` row format uses similar internal details for off-page storage as the `DYNAMIC` row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the `COMPRESSED` row format, the option `KEY_BLOCK_SIZE` controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For full details about the `COMPRESSED` row format, see [Section 5.4.6, “Working with InnoDB Compressed Tables”](#).

#### 5.4.8.4. COMPACT and REDUNDANT Row Formats

Early versions of InnoDB used an unnamed file format (now called `Antelope`) for database files. With that file format, tables are defined with `ROW_FORMAT=COMPACT` or `ROW_FORMAT=REDUNDANT`. InnoDB stores up to the first 768 bytes of variable-length columns (such as `BLOB` and `VARCHAR`) in the index record within the B-tree node, with the remainder stored on the overflow pages.

To preserve compatibility with those prior versions, tables created with the newest InnoDB default to the `COMPACT` row format. See [Section 5.4.8.3, “DYNAMIC and COMPRESSED Row Formats”](#) for information about the newer `DYNAMIC` and `COMPRESSED` row formats.

With the Antelope file format, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the B-tree node. This works well for relatively short `BLOBS`, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause B-tree nodes to become too full of data,

and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

## 5.5. Online DDL for InnoDB Tables

You can perform several kinds of [online DDL](#) operations on [InnoDB](#) tables: that is, allowing [DML](#) operations and [queries](#) on the table while the [DDL](#) is in progress, performing the operation “in-place” without rebuilding the entire table, or both. This enhancement has the following benefits:

- It improves responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours whenever you modify its indexes or column definitions is not practical.
- It lets you adjust the balance between performance and concurrency during the DDL operation, by choosing whether to block access to the table entirely ([LOCK=EXCLUSIVE](#) clause), allow queries but not DML ([LOCK=SHARED](#) clause), or allow full query and DML access to the table ([LOCK=NONE](#) clause). When you omit the [LOCK](#) clause or specify [LOCK=DEFAULT](#), MySQL allows as much concurrency as possible depending on the type of operation.
- By doing the changes in-place where possible, rather than creating a new copy of the table, it avoids temporary increases in disk space usage and the I/O overhead of copying the table and reconstructing all the secondary indexes.

### 5.5.1. Overview of Online DDL

Historically, many [DDL](#) operations on [InnoDB](#) tables were expensive. Many [ALTER TABLE](#) operations worked by creating a new, empty table defined with the requested table options and indexes, then copying the existing rows to the new table one-by-one, updating the indexes as the rows were inserted. After all rows from the original table were copied, the old table was dropped and the copy was renamed with the name of the original table.

MySQL 5.5, and MySQL 5.1 with the InnoDB Plugin, optimized [CREATE INDEX](#) and [DROP INDEX](#) to avoid the table-copying behavior. That feature was known as Fast Index Creation. MySQL 5.6 enhances many other types of [ALTER TABLE](#) operations to avoid copying the table. Another enhancement allows [SELECT](#) queries and [INSERT](#), [UPDATE](#), and [DELETE](#) ([DML](#)) statements to proceed while the table is being altered. This combination of features is now known as [online DDL](#).

This new mechanism also means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table with without any secondary indexes, then adding the secondary indexes after the data is loaded.

Although no syntax changes are required in the [CREATE INDEX](#) or [DROP INDEX](#) commands, some factors affect the performance, space usage, and semantics of this operation (see [Section 5.5.9](#), “[Limitations of Online DDL](#)”).

The online DDL enhancements in MySQL 5.6 improve many DDL operations that formerly required a table copy, blocked DML operations on the table, or both. [Table 5.9](#), “[Summary of Online Status for DDL Operations](#)” shows the variations of the [ALTER TABLE](#) statement and shows how the online DDL feature applies to each one.

- The “In-Place?” column shows which operations allow the [ALGORITHM=INPLACE](#) clause; the preferred value is “Yes”.
- The “Copies Table?” column shows which operations are able to avoid the expensive table-copying operation; the preferred value is “No”. This column is mostly the reverse of the “In-Place?” column, except that a few operations allow [ALGORITHM=INPLACE](#) but still involve some amount of table copying.
- The “Allows Concurrent DML?” column shows which operations can be performed fully online; the preferred value is “Yes”. You can specify [LOCK=NONE](#) to assert that full concurrency is allowed

during the DDL, but MySQL automatically allows this level of concurrency when possible. When concurrent DML is allowed, concurrent queries are also always allowed.

- The “Allows Concurrent Queries?” column shows which DDL operations allow queries on the table while the operation is in progress; the preferred value is “Yes”. Concurrent query is allowed during all online DDL operations. It is shown with “Yes” listed for all cells, for reference purposes. You can specify `LOCK=SHARED` to assert that concurrent queries are allowed during the DDL, but MySQL automatically allows this level of concurrency when possible.
- The “Notes” column explains any exceptions to the “yes/no” values of the other columns, such as when the answer depends on the setting of a configuration option or some other clause in the DDL statement. The values “Yes\*” and “No\*” indicate that an answer depends on these additional notes.

**Table 5.9. Summary of Online Status for DDL Operations**

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
<code>CREATE INDEX, ADD INDEX</code>	Yes*	No*	Yes	Yes	Some restrictions for <code>FULLTEXT</code> index; see next row. Currently, the operation is not in-place (that is, it copies the table) if the same index being created was also dropped by an earlier clause in the same <code>ALTER TABLE</code> statement.
<code>ADD FULLTEXT INDEX</code>	Yes	No*	No	Yes	Creating the first <code>FULLTEXT</code> index for a table involves a table copy, unless there is a user-supplied <code>FTS_DOC_ID</code> column. Subsequent <code>FULLTEXT</code> indexes on the same table can be created in-place.
<code>DROP INDEX</code>	Yes	No	Yes	Yes	
Set default value for a column	Yes	No	Yes	Yes	Modifies <code>.frm</code> file only, not the data file.
Change <code>auto-increment</code> value for a column	Yes	No	Yes	Yes	Modifies a value stored in memory, not the data file.
Add a <code>foreign key constraint</code>	Yes*	No*	Yes	Yes	To avoid copying the table, disable <code>foreign_key_checks</code> [483] during constraint creation.
Drop a <code>foreign key constraint</code>	Yes	No	Yes	Yes	The <code>foreign_key_checks</code> [483] option can be enabled or disabled.
Rename a column	Yes*	No*	Yes*	Yes	To allow concurrent DML, keep the same data type and only change the column name.
Add a column	Yes	Yes	Yes*	Yes	Concurrent DML is not allowed when adding an <code>auto-increment</code> column. Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation.

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
Drop a column	Yes	Yes	Yes	Yes	Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Reorder columns	Yes	Yes	Yes	Yes	Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Change <code>ROW_FORMAT</code> property	Yes	Yes	Yes	Yes	Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Change <code>KEY_BLOCK_SIZE</code> property	Yes	Yes	Yes	Yes	Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Make column <code>NULL</code>	Yes	Yes	Yes	Yes	Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Make column <code>NOT NULL</code>	Yes*	Yes	Yes	Yes	When <code>SQL_MODE [545]</code> includes <code>strict_all_tables</code> or <code>strict_all_tables</code> , the operation fails if the column contains any nulls. Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Change data type of column	No	Yes	No	Yes	
Add <code>primary key</code>	Yes*	Yes	Yes	Yes	Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation. <code>ALGORITHM=INPLACE</code> is not allowed under certain conditions if columns have to be converted to <code>NOT NULL</code> . See <a href="#">Example 5.9, "Creating and Dropping the Primary Key"</a> .
Drop <code>primary key</code> and add another	Yes	Yes	Yes	Yes	<code>ALGORITHM=INPLACE</code> is only allowed when you add a new primary key in the same <code>ALTER TABLE</code> ; the data is reorganized substantially, so it is still an expensive operation.
Drop <code>primary key</code>	No	Yes	No	Yes	Restrictions apply when you drop a primary key without adding a new one in the same <code>ALTER TABLE</code> statement.

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
Convert character set	No	Yes	No	Yes	Rebuilds the table if the new character encoding is different.
Specify character set	No	Yes	No	Yes	Rebuilds the table if the new character encoding is different.
Rebuild with <code>FORCE</code> option	No	Yes	No	Yes	Acts like the <code>ALGORITHM=COPY</code> clause or the setting <code>old_alter_table=1</code> [517].

The following sections shows the basic syntax, and usage notes related to online DDL, for each of the major operations that can be performed with concurrent DML, in-place, or both:

## Secondary Indexes

- Create [secondary indexes](#): `CREATE INDEX name ON table (col_list)` or `ALTER TABLE table ADD INDEX name (col_list)`. (Creating a `FULLTEXT` index still requires locking the table.)
- Drop [secondary indexes](#): `DROP INDEX name ON table;` or `ALTER TABLE table DROP INDEX name`

Creating and dropping secondary indexes on [InnoDB](#) tables skips the table-copying behavior, the same as in MySQL 5.5 and MySQL 5.1 with the [InnoDB Plugin](#).

In MySQL 5.6 and higher, the table remains available for read and write operations while the index is being created or dropped. The `CREATE INDEX` or `DROP INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table. Previously, modifying the table while an index was being created or dropped typically resulted in a [deadlock](#) that cancelled the `INSERT`, `UPDATE`, or `DELETE` statement on the table.

## Column Properties

- Set a default value for a column: `ALTER TABLE tbl ALTER COLUMN col SET DEFAULT literal` or `ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT`

The default values for columns are stored in the `.frm` file for the table, not the [InnoDB data dictionary](#).

- Changing the [auto-increment](#) value for a column: `ALTER TABLE table AUTO_INCREMENT=next_value;`

Especially in a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and you can restart the auto-increment sequence from 1.

- Renaming a column: `ALTER TABLE tbl CHANGE old_col_name new_col_name datatype`

When you keep the same data type and `[NOT] NULL` attribute, only changing the column name, this operation can always be performed online.

As part of this enhancement, you can now rename a column that is part of a foreign key constraint, which was not allowed before. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key only works with the in-place mode

of `ALTER TABLE`. If you use the `ALGORITHM=COPY` clause, or some other condition causes the command to use `ALGORITHM=COPY` behind the scenes, the `ALTER TABLE` statement will fail.

## Foreign Keys

- Adding or dropping a [foreign key constraint](#):

```
ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1) REFERENCES tbl2(col2) referential_action
ALTER TABLE tbl DROP FOREIGN KEY fk_name;
```

Dropping a foreign key can be performed online with the `foreign_key_checks [483]` option enabled or disabled. Creating a foreign key online requires `foreign_key_checks [483]` to be disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

```
show create table table\G
```

Or, query the `information_schema.table_constraints` table and use the `constraint_name` and `constraint_type` columns to identify the foreign key names.

As a consequence of this enhancement, you can now also drop a foreign key and its associated index in a single statement, which previously required separate statements in a strict order:

```
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
```

If [foreign keys](#) are already present in the table being altered (that is, it is a [child table](#) containing any `FOREIGN KEY ... REFERENCE` clauses), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

- Concurrent DML is disallowed during online DDL operations on such child tables. (This restriction is being evaluated as a bug and might be lifted.)
- An `ALTER TABLE` on the child table could also wait for another transaction to commit, if a change to the parent table caused associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.

In the same way, if a table is the [parent table](#) in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement caused an `ON UPDATE` or `ON DELETE` action in the child table.

## Notes on `ALGORITHM=COPY`

Any `ALTER TABLE` operation run with the `ALGORITHM=COPY` clause prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of `LOCK=SHARED` (allow queries but not DML). You can further restrict concurrency for such operations by specifying `LOCK=EXCLUSIVE` (prevent DML and queries).

## Concurrent DML but Table Copy Still Required

Some other `ALTER TABLE` operations allow concurrent DML, and are faster than MySQL 5.5 and prior: the table-copying operation is optimized, even though a table copy is still required:

- Adding, dropping, or reordering columns.
- Adding or dropping a [primary key](#).
- Changing the `ROW_FORMAT` or `KEY_BLOCK_SIZE` properties for a table.
- Changing the nullable status for a column.

### Note

As your database schema evolves with new columns, data types, constraints, indexes, and so on, keep your `CREATE TABLE` statements up to date with the latest table definitions. Even with the performance improvements of online DDL, it is more efficient to create stable database structures at the beginning, rather than creating part of the schema and then issuing `ALTER TABLE` statements afterward.

The main exception to this guideline is for [secondary indexes](#) on tables with large numbers of rows. It is typically most efficient to create the table with all details specified except the secondary indexes, load the data, then create the secondary indexes. You can use the same technique with [foreign keys](#) (load the data first, then set up the foreign keys) if you know the initial data is clean and do not need consistency checks during the loading process.

Whatever sequence of `CREATE TABLE`, `CREATE INDEX`, `ALTER TABLE`, and similar statements went into putting a table together, you can capture the SQL needed to reconstruct the current form of the table by issuing the statement `SHOW CREATE TABLE table\G` (uppercase `\G` required for tidy formatting). This output shows clauses such as numeric precision, `NOT NULL`, and `CHARACTER SET` that are sometimes added behind the scenes, and you might otherwise leave out when cloning the table on a new system or setting up foreign key columns with identical type.

## 5.5.2. Performance and Concurrency Considerations for Online DDL

[Online DDL](#) improves several aspects of MySQL operation, such as performance, concurrency, availability, and scalability:

- Because queries and [DML](#) operations on the table can proceed while the DDL is in progress, applications that access the table are more responsive. Reduced [locking](#) and waiting for other resources all throughout the MySQL server leads to greater scalability, even for operations not involving the table being altered.
- For in-place operations, by avoiding the disk I/O and CPU cycles to rebuild the table, you minimize the overall load on the database and maintain good performance and high throughput during the DDL operation.
- For in-place operations, because less data is read into the [buffer pool](#) than if all the data was copied, you avoid purging frequently accessed data from memory, which formerly could cause a temporary performance dip after a DDL operation.

### Locking Options for Online DDL

While an InnoDB table is being changed by a DDL operation, the table may or may not be [locked](#), depending on the internal workings of that operation and the `LOCK` clause of the `ALTER TABLE` statement. By default, MySQL uses as little locking as possible during a DDL operation; you specify the clause either to make the locking more restrictive than it normally would be (thus limiting concurrent DML, or DML and queries), or to ensure that some expected degree of locking is allowed for an operation. If the `LOCK` clause specifies a level of locking that is not available for that specific kind of DDL operation, such as `LOCK=SHARED` or `LOCK=NONE` while creating or dropping a primary key, the clause works like an assertion, causing the statement to fail with an error. The following list shows the different possibilities for the `LOCK` clause, from the most permissive to the most restrictive:

- For DDL operations with `LOCK=NONE`, both queries and concurrent DML are allowed. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=NONE` if keeping the table fully available is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables

involving customer signups or purchases, to avoid making those tables unavailable by mistakenly issuing an expensive `ALTER TABLE` statement.

- For DDL operations with `LOCK=SHARED`, any writes to the table (that is, DML operations) are blocked, but the data in the table can be read. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=SHARED` if keeping the table available for queries is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables in a data warehouse, where it is OK to delay data load operations until the DDL is finished, but queries cannot be delayed for long periods.
- For DDL operations with `LOCK=DEFAULT`, or with the `LOCK` clause omitted, MySQL uses the lowest level of locking that is available for that kind of operation, allowing concurrent queries, DML, or both wherever possible. This is the setting to use when making pre-planned, pre-tested changes that you know will not cause any availability problems based on the workload for that table.
- For DDL operations with `LOCK=EXCLUSIVE`, both queries and DML operations are blocked. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=EXCLUSIVE` if the primary concern is finishing the DDL in the shortest time possible, and it is OK to make applications wait when they try to access the table. You might also use `LOCK=EXCLUSIVE` if the server is supposed to be idle, to avoid unexpected accesses to the table.

An online DDL statement for an InnoDB table always waits for currently executing transactions that are accessing the table to `commit` or `roll back`, because it requires exclusive access to the table for a brief period while the DDL statement is being prepared. Likewise, it requires exclusive access to the table for a brief time before finishing. Thus, an online DDL statement waits for any transactions that are started while the DDL is in progress, and query or modify the table, to `commit` or `roll back` before the DDL completes.

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the old-style mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the ideal techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

A newly created InnoDB secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

## Performance of In-Place versus Table-Copying DDL Operations

The raw performance of an online DDL operation is largely determined by whether the operation is performed in-place, or requires copying and rebuilding the entire table. See [Table 5.9, “Summary of Online Status for DDL Operations”](#) to see what kinds of operations can be performed in-place, and any requirements for avoiding table-copy operations.

The performance speedup from in-place DDL applies to operations on secondary indexes, not to the primary key index. The rows of an InnoDB table are stored in a `clustered index` organized based on the `primary key`, forming what some database systems call an “index-organized table”. Because the table structure is so closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.

- The change buffer is not used, because there are no random-access inserts into the secondary indexes.

To judge the relative performance of online DDL operations, you can run such operations on a big [InnoDB](#) table using current and earlier versions of MySQL. You can also run all the performance tests under the latest MySQL version, simulating the previous DDL behavior for the “before” results, by setting the `old_alter_table` [\[517\]](#) system variable. Issue the statement `set old_alter_table=1` in the session, and measure DDL performance to record the “before” figures. Then `set old_alter_table=0` to re-enable the newer, faster behavior, and run the DDL operations again to record the “after” figures.

For a basic idea of whether a DDL operation does its changes in-place or performs a table copy, look at the “rows affected” value displayed after the command finishes. For example, here are lines you might see after doing different types of DDL operations:

- Changing the default value of a column (super-fast, does not affect the table data at all):

```
Query OK, 0 rows affected (0.07 sec)
```

- Adding an index (takes time, but `0 rows affected` shows that the table is not copied):

```
Query OK, 0 rows affected (21.42 sec)
```

- Changing the data type of a column (takes substantial time and does require rebuilding all the rows of the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

For example, before running a DDL operation on a big table, you might check whether the operation will be fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a tiny amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A non-zero value means the operation will require rebuilding the entire table, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replication slave server one at a time.

For a deeper understanding of the reduction in MySQL processing, examine the [performance\\_schema](#) and [INFORMATION\\_SCHEMA](#) tables related to [InnoDB](#) before and after DDL operations, to see the number of physical reads, writes, memory allocations, and so on.

### 5.5.3. SQL Syntax for Online DDL

Typically, you do not need to do anything special to enable [online DDL](#) when using the `ALTER TABLE` statement for [InnoDB](#) tables. See [Table 5.9, “Summary of Online Status for DDL Operations”](#) for the kinds of DDL operations that can be performed in-place, allowing concurrent DML, or both. Some variations require particular combinations of configuration settings or `ALTER TABLE` clauses.

You can control the various aspects of a particular online DDL operation by using the `LOCK` and `ALGORITHM` clauses of the `ALTER TABLE` statement. These clauses come at the end of the statement, separated from the table and column specifications by commas. The `LOCK` clause is useful for fine-tuning the degree of concurrent access to the table. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues with existing DDL code. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, you could specify a clause on the `ALTER TABLE` statement such as `LOCK=NONE` (allow both reads and writes) or

`LOCK=SHARED` (allow reads). The operation halts immediately if the requested level of concurrency is not available.

- To compare performance, you could run one statement with `ALGORITHM=INPLACE` and another with `ALGORITHM=COPY`, as an alternative to setting the `old_alter_table` [517] configuration option.
- To avoid the chance of tying up the server by running an `ALTER TABLE` that copied the table, you could include `ALGORITHM=INPLACE` so the statement halts immediately if it cannot use the in-place mechanism. See Table 5.9, “Summary of Online Status for DDL Operations” for a list of the DDL operations that can or cannot be performed in-place.

See Section 5.5.2, “Performance and Concurrency Considerations for Online DDL” for more details about the `LOCK` clause. For full examples of using online DDL, see Section 5.5.5, “Examples of Online DDL”.

## 5.5.4. Combining or Separating DDL Statements

Before the introduction of [online DDL](#), it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.

For DDL operations that can be done in-place, as shown in Table 5.9, “Summary of Online Status for DDL Operations”, now you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```
alter table t1 add index i1(c1), add unique index i2(c2), change c4_old_name c4_new_name integer unsigned;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```
alter table t1 add index i1(c1);
alter table t1 add unique index i2(c2);
alter table t1 change c4_old_name c4_new_name integer unsigned not null;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed in-place, that is, that still copy and rebuild the table.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

## 5.5.5. Examples of Online DDL

Here are code examples showing some operations whose performance, concurrency, and scalability are improved by the latest [online DDL](#) enhancements.

- [Example 5.1, “Schema Setup Code for Online DDL Experiments”](#) sets up tables named `BIG_TABLE` and `SMALL_TABLE` used in the subsequent examples.
- [Example 5.2, “Speed and Efficiency of CREATE INDEX and DROP INDEX”](#) illustrates the performance aspects of creating and dropping indexes.

- [Example 5.3, “Concurrent DML During CREATE INDEX and DROP INDEX”](#) shows queries and DML statements running during a `DROP INDEX` operation.
- [Example 5.4, “Renaming a Column”](#) demonstrates the speed improvement for renaming a column, and shows the care needed to keep the data type precisely the same when doing the rename operation.
- [Example 5.5, “Dropping Foreign Keys”](#) demonstrates how foreign keys work with online DDL. Because two tables are involved in foreign key operations, there are extra locking considerations. Thus, tables with foreign keys sometimes have restrictions for online DDL operations.
- [Example 5.6, “Changing Auto-Increment Value”](#) demonstrates how auto-increment columns work with online DDL. Tables with auto-increment columns sometimes have restrictions for online DDL operations.
- [Example 5.7, “Controlling Concurrency with the LOCK Clause”](#) demonstrates the options to permit or restrict concurrent queries and DML operations while an online DDL operation is in progress. It shows the situations when the DDL statement might wait, or the concurrent transaction might wait, or the concurrent transaction might cancel a DML statement due to a deadlock error.
- [Example 5.8, “Schema Setup Code for Online DDL Experiments”](#) demonstrates creating and dropping multiple indexes in a single statement, which can be more efficient than using a separate statement for each index operation.
- [Example 5.9, “Creating and Dropping the Primary Key”](#) demonstrates how it is more efficient to define a `primary key` when creating the table, and relatively expensive to add one later.

### Example 5.1. Schema Setup Code for Online DDL Experiments

Here is the code that sets up the initial tables used in these demonstrations:

```

/*
Setup code for the online DDL demonstration:
- Set up some config variables.
- Create 2 tables that are clones of one of the INFORMATION_SCHEMA tables
  that always has some data. The "small" table has a couple of thousand rows.
  For the "big" table, keep doubling the data until it reaches over a million rows.
- Set up a primary key for the sample tables, since we are demonstrating InnoDB aspects.
*/

set autocommit = 0;
set foreign_key_checks = 1;
set global innodb_file_per_table = 1;
set old_alter_table=0;
prompt mysql:

use test;

\! echo "Setting up 'small' table:"
drop table if exists small_table;
create table small_table as select * from information_schema.columns;
alter table small_table add id int unsigned not null primary key auto_increment;
select count(id) from small_table;

\! echo "Setting up 'big' table:"
drop table if exists big_table;
create table big_table as select * from information_schema.columns;
show create table big_table\G

insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;

```

```
insert into big_table select * from big_table;
commit;

alter table big_table add id int unsigned not null primary key auto_increment;
select count(id) from big_table;
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```
Setting up 'small' table:
Query OK, 0 rows affected (0.01 sec)

Query OK, 1678 rows affected (0.13 sec)
Records: 1678 Duplicates: 0 Warnings: 0

```

### Example 5.2. Speed and Efficiency of CREATE INDEX and DROP INDEX

Here is a sequence of statements demonstrating the relative speed of `CREATE INDEX` and `DROP INDEX` statements. For a small table, the elapsed time is less than a second whether we use the fast or slow technique, so we look at the “rows affected” output to verify which operations can avoid the table rebuild. For a large table, the difference in efficiency is obvious because skipping the table rebuild saves substantial time.

```

\! clear

\! echo "=== Create and drop index (small table, new/fast technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/small_table.ibd
create index i_dtyp_small on small_table (data_type), algorithm=inplace;
\! echo "Data size after index created: "
\! du -k data/test/small_table.ibd
drop index i_dtyp_small on small_table, algorithm=inplace;

-- Compare against the older slower DDL.

\! echo "=== Create and drop index (small table, old/slow technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/small_table.ibd
create index i_dtyp_small on small_table (data_type), algorithm=copy;
\! echo "Data size after index created: "
\! du -k data/test/small_table.ibd
drop index i_dtyp_small on small_table, algorithm=copy;

-- In the above example, we examined the "rows affected" number,
-- ideally looking for a zero figure. Let's try again with a larger
-- sample size, where we'll see that the actual time taken can
-- vary significantly.

\! echo "=== Create and drop index (big table, new/fast technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/big_table.ibd
create index i_dtyp_big on big_table (data_type), algorithm=inplace;
\! echo "Data size after index created: "
\! du -k data/test/big_table.ibd
drop index i_dtyp_big on big_table, algorithm=inplace;

\! echo "=== Create and drop index (big table, old/slow technique) ==="

```

```

\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/big_table.ibd
create index i_dtyp_big on big_table (data_type), algorithm=copy;
\! echo "Data size after index created: "
\! du -k data/test/big_table.ibd
drop index i_dtyp_big on big_table, algorithm=copy;

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

Query OK, 0 rows affected (0.00 sec)

=== Create and drop index (small table, new/fast technique) ===

Data size (kilobytes) before index created:
384 data/test/small_table.ibd

Records: 1718272 Duplicates: 0 Warnings: 0

Data size after index created:
348160 data/test/big_table.ibd
Query OK, 1718272 rows affected (46.59 sec)
Records: 1718272 Duplicates: 0 Warnings: 0

```

### Example 5.3. Concurrent DML During CREATE INDEX and DROP INDEX

Here are some snippets of code that I ran in separate `mysql` sessions connected to the same database, to illustrate DML statements (insert, update, or delete) running at the same time as `CREATE INDEX` and `DROP INDEX`.

```

/*
CREATE INDEX statement to run against a table while
insert/update/delete statements are modifying the
column being indexed.
*/

-- We'll run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

use test;
create index i_concurrent on big_table(table_name);

```

```

/*
DROP INDEX statement to run against a table while
insert/update/delete statements are modifying the
column being indexed.
*/

-- We'll run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

use test;
drop index i_concurrent on big_table;

```

```

/*
Some queries and insert/update/delete statements to run against a table
while an index is being created or dropped. Previously, these operations
would have stalled during the index create/drop period and possibly
timed out or deadlocked.
*/

-- We'll run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

-- In our test instance, that column has about 1.7M rows, with 136 different values.
-- Sample values: COLUMNS (20480), ENGINES (6144), EVENTS (24576), FILES (38912), TABLES (21504), VIEWS

set autocommit = 0;
use test;

select distinct character_set_name from big_table where table_name = 'FILES';
delete from big_table where table_name = 'FILES';
select distinct character_set_name from big_table where table_name = 'FILES';

-- I'll issue the final rollback interactively, not via script,
-- the better to control the timing.
-- rollback;

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

mysql: source concurrent_ddl_create.sql
Database changed
Query OK, 0 rows affected (1 min 25.15 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql: source concurrent_ddl_drop.sql
Database changed
Query OK, 0 rows affected (24.98 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql: source concurrent_dml.sql
Query OK, 0 rows affected (0.00 sec)

Database changed
+-----+
| character_set_name |
+-----+
| NULL               |
| utf8               |
+-----+
2 rows in set (0.32 sec)

```

```
Query OK, 38912 rows affected (1.84 sec)

Empty set (0.01 sec)

mysql: rollback;
Query OK, 0 rows affected (1.05 sec)
```

### Example 5.4. Renaming a Column

Here is a demonstration of using `ALTER TABLE` to rename a column. We use the new, fast DDL mechanism to change the name, then the old, slow DDL mechanism (with `old_alter_table=1`) to restore the original column name.

Notes:

- Because the syntax for renaming a column also involves re-specifying the data type, be very careful to specify exactly the same data type to avoid a costly table rebuild. In this case, we checked the output of `show create table table\G` and copied any clauses such as `CHARACTER SET` and `NOT NULL` from the original column definition.
- Again, renaming a column for a small table is fast enough that we need to examine the “rows affected” number to verify that the new DDL mechanism is more efficient than the old one. With a big table, the difference in elapsed time makes the improvement obvious.

```
/*
Run through a sequence of 'rename column' statements.
Because this operation involves only metadata, not table data,
it is fast for big and small tables, with new or old DDL mechanisms.
*/

\! clear

\! echo "Rename column (fast technique, small table):"
alter table small_table change `IS_NULLABLE` `NULLABLE` varchar(3) character set utf8 not null, algorithm=innodb;
\! echo "Rename back to original name (slow technique):"
alter table small_table change `NULLABLE` `IS_NULLABLE` varchar(3) character set utf8 not null, algorithm=copy;

\! echo "Rename column (fast technique, big table):"
alter table big_table change `IS_NULLABLE` `NULLABLE` varchar(3) character set utf8 not null, algorithm=innodb;
\! echo "Rename back to original name (slow technique):"
alter table big_table change `NULLABLE` `IS_NULLABLE` varchar(3) character set utf8 not null, algorithm=copy;
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```
Rename column (fast technique, small table):
Query OK, 0 rows affected (0.05 sec)

Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

Rename back to original name (slow technique):
Query OK, 0 rows affected (0.00 sec)

Query OK, 1678 rows affected (0.35 sec)
Records: 1678 Duplicates: 0 Warnings: 0

Rename column (fast technique, big table):
Query OK, 0 rows affected (0.00 sec)

Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0

Rename back to original name (slow technique):
Query OK, 0 rows affected (0.00 sec)

Query OK, 1718272 rows affected (1 min 0.00 sec)
Records: 1718272 Duplicates: 0 Warnings: 0

Query OK, 0 rows affected (0.00 sec)
```

**Example 5.5. Dropping Foreign Keys**

Here is a demonstration of foreign keys, including improvement to the speed of dropping a foreign key constraint.

```

/*
Demonstrate aspects of foreign keys that are or aren't affected by the DDL improvements.
- Create a new table with only a few values to serve as the parent table.
- Set up the 'small' and 'big' tables as child tables using a foreign key.
- Verify that the ON DELETE CASCADE clause makes changes ripple from parent to child tables.
- Drop the foreign key constraints, and optionally associated indexes. (This is the operation that is s
*/

\! clear

-- Make sure foreign keys are being enforced, and allow
-- rollback after doing some DELETES that affect both
-- parent and child tables.
set foreign_key_checks = 1;
set autocommit = 0;

-- Create a parent table, containing values that we know are already present
-- in the child tables.
drop table if exists schema_names;
create table schema_names (id int unsigned not null primary key auto_increment, schema_name varchar(64))

show create table schema_names\G
show create table small_table\G
show create table big_table\G

-- Creating the foreign key constraint still involves a table rebuild when foreign_key_checks=1,
-- as illustrated by the "rows affected" figure.
alter table small_table add constraint small_fk foreign key i_table_schema (table_schema) references schema_names (id) on delete cascade;
alter table big_table add constraint big_fk foreign key i_table_schema (table_schema) references schema_names (id) on delete cascade;

show create table small_table\G
show create table big_table\G

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- big_table is the parent table.
-- schema_names is the parent table.
-- big_table is the child table.
-- (One row in the parent table can have many "children" in the child table.)
-- Changes to the parent table can ripple through to the child table.
-- For example, removing the value 'test' from schema_names.schema_name will
-- result in the removal of 20K or so rows from big_table.

delete from schema_names where schema_name = 'test';

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- Because we've turned off autocommit, we can still get back those deleted rows
-- if the DELETE was issued by mistake.
rollback;

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- All of the cross-checking between parent and child tables would be
-- deadly slow if there wasn't the requirement for the corresponding
-- columns to be indexed!

-- But we can get rid of the foreign key using a fast operation
-- that doesn't rebuild the table.
-- If we didn't specify a constraint name when setting up the foreign key, we would
-- have to find the auto-generated name such as 'big_table_ibfk_1' in the

```

```
-- output from 'show create table'.

-- For the small table, we'll drop the foreign key and the associated index.
-- Having an index on a small table is less critical.

\! echo "DROP FOREIGN KEY and INDEX from small_table:"
alter table small_table drop foreign key small_fk, drop index small_fk;

-- For the big table, we'll drop the foreign key and leave the associated index.
-- If we are still doing queries that reference the indexed column, the index is
-- very important to avoid a full table scan of the big table.
\! echo "DROP FOREIGN KEY from big_table:"
alter table big_table drop foreign key big_fk;

show create table small_table\G
show create table big_table\G
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

### Example 5.6. Changing Auto-Increment Value

Here is an illustration of increasing the [auto-increment](#) lower limit for a table column, demonstrating how this operation now avoids a table rebuild, plus some other fun facts about [InnoDB](#) auto-increment columns.

```

/*
If this script is run after foreign_key.sql, the schema_names table is
already set up. But to allow this script to run multiple times without
running into duplicate ID errors, we set up the schema_names table
all over again.
*/

\! clear

\! echo "=== Adjusting the Auto-Increment Limit for a Table ==="
\! echo

drop table if exists schema_names;
create table schema_names (id int unsigned not null primary key auto_increment,
  schema_name varchar(64) character set utf8 not null, index i_schema (schema_name))
as select distinct table_schema schema_name from small_table;

\! echo "Initial state of schema_names table. AUTO_INCREMENT is included in SHOW CREATE TABLE output."
\! echo "Note how MySQL reserved a block of IDs, but only needed 4 of them in this transaction, so the next"
show create table schema_names\G
select * from schema_names order by id;

\! echo "Inserting even a tiny amount of data can produce gaps in the ID sequence."
insert into schema_names (schema_name) values ('eight'), ('nine');

\! echo "Bumping auto-increment lower limit to 20 (fast mechanism):"
alter table schema_names auto_increment=20, algorithm=inplace;

\! echo "Inserting 2 rows that should get IDs 20 and 21:"
insert into schema_names (schema_name) values ('foo'), ('bar');
commit;

\! echo "Bumping auto-increment lower limit to 30 (slow mechanism):"
alter table schema_names auto_increment=30, algorithm=copy;

```

```

\! echo "Inserting 2 rows that should get IDs 30 and 31:"
insert into schema_names (schema_name) values ('bletch'),('baz');
commit;

select * from schema_names order by id;

\! echo "Final state of schema_names table. AUTO_INCREMENT value shows the next inserted row would get
show create table schema_names\G

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

### Example 5.7. Controlling Concurrency with the `LOCK` Clause

This example shows how to use the `LOCK` clause of the `ALTER TABLE` statement to allow or deny concurrent access to the table while an online DDL operation is in progress. The clause has settings that allow queries and DML statements (`LOCK=NONE`), just queries (`LOCK=SHARED`), or no concurrent access at all (`LOCK=EXCLUSIVE`).

In one session, we run a succession of `ALTER TABLE` statements to create and drop an index, using different values for the `LOCK` clause to see what happens with waiting or deadlocking in either session. We are using the same `BIG_TABLE` table as in previous examples, starting with approximately 1.7 million rows. For illustration purposes, we will index and query the `IS_NULLABLE` column. (Although in real life it would be silly to make an index for a tiny column with only 2 distinct values.)

```

mysql: desc big_table;
+-----+-----+-----+-----+-----+-----+
| Field          | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| TABLE_CATALOG | varchar(512)  | NO   |     |         |       |

...
+-----+-----+-----+-----+-----+-----+
21 rows in set (0.14 sec)

mysql: alter table big_table add index i1(is_nullable);
Query OK, 0 rows affected (20.71 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.02 sec)

mysql: alter table big_table add index i1(is_nullable), lock=exclusive;
Query OK, 0 rows affected (19.44 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.03 sec)

mysql: alter table big_table add index i1(is_nullable), lock=shared;
Query OK, 0 rows affected (16.71 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.05 sec)

```

```
mysql: alter table big_table add index i1(is_nullable), lock=none;
Query OK, 0 rows affected (12.26 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.01 sec)

... repeat statements like the above while running queries ...
... and DML statements at the same time in another session ...
```

Nothing dramatic happens in the session running the DDL statements. Sometimes, an `ALTER TABLE` takes unusually long because it is waiting for another transaction to finish, when that transaction modified the table during the DDL or queried the table before the DDL:

```
mysql: alter table big_table add index i1(is_nullable), lock=none;
Query OK, 0 rows affected (59.27 sec)

mysql: -- The previous ALTER took so long because it was waiting for all the concurrent
mysql: -- transactions to commit or roll back.

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (41.05 sec)

mysql: -- Even doing a SELECT on the table in the other session first causes
mysql: -- the ALTER TABLE above to stall until the transaction
mysql: -- surrounding the SELECT is committed or rolled back.
```

Here is the log from another session running concurrently, where we issue queries and DML statements against the table before, during, and after the DDL operations shown in the previous listings. This first listing shows queries only. We expect the queries to be allowed during DDL operations using `LOCK=NONE` or `LOCK=SHARED`, and for the query to wait until the DDL is finished if the `ALTER TABLE` statement includes `LOCK=EXCLUSIVE`.

```
mysql: show variables like 'autocommit';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| autocommit    | ON    |
+-----+-----+
1 row in set (0.01 sec)

mysql: -- A trial query before any ADD INDEX in the other session:
mysql: -- Note: because autocommit is enabled, each
mysql: -- transaction finishes immediately after the query.
mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES        |
+-----+
2 rows in set (4.49 sec)

mysql: -- Index is being created with LOCK=EXCLUSIVE on the ALTER statement.
mysql: -- The query waits until the DDL is finished before proceeding.
mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES        |
+-----+
2 rows in set (17.26 sec)

mysql: -- Index is being created with LOCK=SHARED on the ALTER statement.
mysql: -- The query returns its results while the DDL is in progress.
mysql: -- The same thing happens with LOCK=NONE on the ALTER statement.
mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
```

```

| NO          |
| YES        |
+-----+
2 rows in set (3.11 sec)

mysql: -- Once the index is created, and with no DDL in progress,
mysql: -- queries referencing the indexed column are very fast:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|  411648 |
+-----+
1 row in set (0.20 sec)

mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES        |
+-----+
2 rows in set (0.00 sec)

```

Now in this concurrent session, we run some transactions including DML statements, or a combination of DML statements and queries. We use `DELETE` statements to illustrate predictable, verifiable changes to the table. Because the transactions in this part can span multiple statements, we run these tests with `autocommit` [464] turned off.

```

mysql: set global autocommit = off;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Count the rows that will be involved in our DELETE statements:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|  411648 |
+-----+
1 row in set (0.95 sec)

mysql: -- After this point, any DDL statements back in the other session
mysql: -- stall until we commit or roll back.

mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.14 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|  400000 |
+-----+
1 row in set (1.04 sec)

mysql: rollback;
Query OK, 0 rows affected (0.09 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|  411648 |
+-----+
1 row in set (0.93 sec)

mysql: -- OK, now we're going to try that during index creation with LOCK=NONE.
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.21 sec)

mysql: -- We expect that now there will be 400000 'YES' rows left:

```

```

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (1.25 sec)

mysql: -- In the other session, the ALTER TABLE is waiting before finishing,
mysql: -- because _this_ transaction hasn't committed or rolled back yet.
mysql: rollback;
Query OK, 0 rows affected (0.11 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+
1 row in set (0.19 sec)

mysql: -- The ROLLBACK left the table in the same state we originally found it.
mysql: -- Now let's make a permanent change while the index is being created,
mysql: -- again with ALTER TABLE ... , LOCK=NONE.
mysql: -- First, commit so the DROP INDEX in the other shell can finish;
mysql: -- the previous SELECT started a transaction that accessed the table.
mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Now we add the index back in the other shell, then issue DML in this one
mysql: -- while the DDL is running.
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.23 sec)

mysql: commit;
Query OK, 0 rows affected (0.01 sec)

mysql: -- In the other shell, the ADD INDEX has finished.
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (0.19 sec)

mysql: -- At the point the new index is finished being created, it contains entries
mysql: -- only for the 400000 'YES' rows left when all concurrent transactions are finished.
mysql:
mysql: -- Now we will run a similar test, while ALTER TABLE ... , LOCK=SHARED is running.
mysql: -- We expect a query to complete during the ALTER TABLE, but for the DELETE
mysql: -- to run into some kind of issue.
mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- As expected, the query returns results while the LOCK=SHARED DDL is running:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (2.07 sec)

mysql: -- The DDL in the other session is not going to finish until this transaction
mysql: -- is committed or rolled back. If we tried a DELETE now and it waited because
mysql: -- of LOCK=SHARED on the DDL, both transactions would wait forever (deadlock).
mysql: -- MySQL detects this condition and cancels the attempted DML statement.
mysql: delete from big_table where is_nullable = 'YES' limit 100000;
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
mysql: -- The transaction here is still going, so in the other shell, the ADD INDEX operation
mysql: -- is waiting for this transaction to commit or roll back.

```

```

mysql: rollback;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Now let's try issuing a query and some DML, on one line, while running
mysql: -- ALTER TABLE ... , LOCK=EXCLUSIVE in the other shell.
mysql: -- Notice how even the query is held up until the DDL is finished.
mysql: -- By the time the DELETE is issued, there is no conflicting access
mysql: -- to the table and we avoid the deadlock error.
mysql: select count(*) from big_table where is_nullable = 'YES'; delete from big_table where is_nullable =
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (15.98 sec)

Query OK, 100000 rows affected (2.81 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 300000 |
+-----+
1 row in set (0.17 sec)

mysql: rollback;
Query OK, 0 rows affected (1.36 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (0.19 sec)

mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Next, we try ALTER TABLE ... , LOCK=EXCLUSIVE in the other session
mysql: -- and only issue DML, not any query, in the concurrent transaction here.
mysql: delete from big_table where is_nullable = 'YES' limit 100000;
Query OK, 100000 rows affected (16.37 sec)

mysql: -- That was OK because the ALTER TABLE did not have to wait for the transaction
mysql: -- here to complete. The DELETE in this session waited until the index was ready.
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 300000 |
+-----+
1 row in set (0.16 sec)

mysql: commit;
Query OK, 0 rows affected (0.00 sec)

```

In the preceding example listings, we learned that:

- The `LOCK` clause for `ALTER TABLE` is set off from the rest of the statement by a comma.
- Online DDL operations might wait before starting, until any prior transactions that access the table are committed or rolled back.
- Online DDL operations might wait before completing, until any concurrent transactions that access the table are committed or rolled back.
- While an online DDL operation is running, concurrent queries are relatively straightforward, as long as the `ALTER TABLE` statement uses `LOCK=NONE` or `LOCK=SHARED`.

- Pay attention to whether `autocommit` [464] is turned on or off. If it is turned off, be careful to end transactions in other sessions (even just queries) before performing DDL operations on the table.
- With `LOCK=SHARED`, concurrent transactions that mix queries and DML could encounter deadlock errors and have to be restarted after the DDL is finished.
- With `LOCK=NONE`, concurrent transactions can freely mix queries and DML. The DDL operation waits until the concurrent transactions are committed or rolled back.
- With `LOCK=NONE`, concurrent transactions can freely mix queries and DML, but those transactions wait until the DDL operation is finished before they can access the table.

### Example 5.8. Schema Setup Code for Online DDL Experiments

You can create multiple indexes on a table with one `ALTER TABLE` statement. This is relatively efficient, because the clustered index of the table needs to be scanned only once (although the data is sorted separately for each new index). For example:

```
CREATE TABLE T1(A INT PRIMARY KEY, B INT, C CHAR(1)) ENGINE=InnoDB;
INSERT INTO T1 VALUES (1,2,'a'), (2,3,'b'), (3,2,'c'), (4,3,'d'), (5,2,'e');
COMMIT;
ALTER TABLE T1 ADD INDEX (B), ADD UNIQUE INDEX (C);
```

The above statements create table `T1` with the primary key on column `A`, insert several rows, then build two new indexes on columns `B` and `C`. If there were many rows inserted into `T1` before the `ALTER TABLE` statement, this approach is much more efficient than creating all the secondary indexes before loading the data.

Because dropping InnoDB secondary indexes also does not require any copying of table data, it is equally efficient to drop multiple indexes with a single `ALTER TABLE` statement or multiple `DROP INDEX` statements:

```
ALTER TABLE T1 DROP INDEX B, DROP INDEX C;
```

or:

```
DROP INDEX B ON T1;
DROP INDEX C ON T1;
```

### Example 5.9. Creating and Dropping the Primary Key

Restructuring the `clustered index` for an InnoDB table always requires copying the table data. Thus, it is best to define the `primary key` when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later, to avoid rebuilding the table.

Defining a `PRIMARY KEY` later causes the data to be copied, as in the following example:

```
CREATE TABLE T2 (A INT, B INT);
INSERT INTO T2 VALUES (NULL, 1);
ALTER TABLE T2 ADD PRIMARY KEY (B);
```

When you create a `UNIQUE` or `PRIMARY KEY` index, MySQL must do some extra work. For `UNIQUE` indexes, MySQL checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, MySQL also checks that none of the `PRIMARY KEY` columns contains a `NULL`.

When you add a primary key using the `ALGORITHM=COPY` clause, MySQL actually converts `NULL` values in the associated columns to default values: 0 for numbers, the empty string for character-based columns and BLOBs, and January 1, 1975 for dates. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using `ALGORITHM=INPLACE` is only allowed when the `SQL_MODE` [545] setting includes the `strict_trans_tables` or `strict_all_tables` flags; when the `SQL_MODE` setting is strict, `ADD PRIMARY KEY ... , ALGORITHM=INPLACE` is allowed,

but the statement can still fail if the requested primary key columns contain any `NULL` values. The `ALGORITHM=INPLACE` behavior is more standard-compliant.

The following example shows the different possibilities for the `ADD PRIMARY KEY` clause. With the `ALGORITHM=COPY` clause, the operation succeeds despite the presence of `NULL` values in the primary key columns; the data is silently changed, which could cause problems. With the `ALGORITHM=INPLACE` clause, the operation could fail for different reasons, because this setting considers data integrity a high priority: the statement gives an error if the `SQL_MODE` [545] setting is not “strict” enough, or if the primary key columns contain any `NULL` values. Once we address both of those requirements, the `ALTER TABLE` operation succeeds.

```
CREATE TABLE add_pk_via_copy (c1 INT, c2 VARCHAR(10), c3 DATETIME);
INSERT INTO add_pk_via_copy VALUES (1,'a','...'),(NULL,NULL,NULL);
ALTER TABLE add_pk_via_copy ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=COPY;
SELECT * FROM add_pk_via_copy;

CREATE TABLE add_pk_via_inplace (c1 INT, c2 VARCHAR(10), c3 DATETIME);
INSERT INTO add_pk_via_inplace VALUES (1,'a','...'),(NULL,NULL,NULL);
SET sql_mode = 'strict_trans_tables';
ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=COPY;
SET sql_mode = '';
ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=COPY;
DELETE FROM add_pk_via_inplace WHERE c1 IS NULL OR c2 IS NULL OR c3 IS NULL;
ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=COPY;
SELECT * FROM add_pk_via_inplace;
```

If you create a table without a primary key, InnoDB chooses one for you, which can be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. To avoid any uncertainty and the potential space requirement for an extra hidden column, specify the `PRIMARY KEY` clause as part of the `CREATE TABLE` statement.

## 5.5.6. Implementation Details of Online DDL

Each `ALTER TABLE` operation for an InnoDB table is governed by several aspects:

- Whether there is any change to the physical representation of the table, or whether it purely a change to metadata that can be done without touching the table itself.
- Whether the volume of data in the table stays the same, increases, or decreases.
- Whether a change in table data involves the clustered index, secondary indexes, or both.
- Whether there are any `foreign key` relationships between the table being altered and some other table. The mechanics differ depending on whether the `foreign_key_checks` [483] configuration option is enabled or disabled.
- Whether the table is partitioned. Partitioning clauses of `ALTER TABLE` are turned into low-level operations involving one or more tables, and those operations follow the regular rules for online DDL.
- Whether the table data must be copied, whether the table can be reorganized “in-place”, or a combination of both.
- Whether the table contains any `auto-increment` columns.
- What degree of `locking` is required, either by the nature of the underlying database operations, or a `LOCK` clause that you specify in the `ALTER TABLE` statement.

This section explains how these factors affect the different kinds of `ALTER TABLE` operations on InnoDB tables.

## Error Conditions for Online DDL

Here are the primary reasons why an online DDL operation could fail:

- If a `LOCK` clause specifies a low degree of locking (`SHARED` or `NONE`) that is not compatible with the particular type of DDL operation.
- If a timeout occurs while waiting to get an `exclusive lock` on the table, which is needed briefly during the initial and final phases of the DDL operation.
- If the `tmpdir` [559] file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation.
- If the `ALTER TABLE` takes so long, and concurrent DML modifies the table so much, that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` [1739] configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.
- If concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a `primary key` index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively `rolled back`.

Although the configuration option `innodb_file_per_table` [1718] has a dramatic effect on the representation for an `InnoDB` table, all online DDL operations work equally well whether that option is enabled or disabled, and whether the table is physically located in its own `.ibd file` or inside the `system tablespace`.

`InnoDB` has two types of indexes: the `clustered index` representing all the data in the table, and optional `secondary indexes` to speed up queries. Since the clustered index contains the data values in its B-tree nodes, adding or dropping a clustered index does involve copying the data, and creating a new copy of the table. A secondary index, however, contains only the index key and the value of the primary key. This type of index can be created or dropped without copying the data in the clustered index. Because each secondary index contains copies of the primary key values (used to access the clustered index when needed), when you change the definition of the primary key, all secondary indexes are recreated as well.

Dropping a secondary index is simple. Only the internal `InnoDB` system tables and the MySQL data dictionary tables are updated to reflect the fact that the index no longer exists. `InnoDB` returns the storage used for the index to the tablespace that contained it, so that new indexes or additional table rows can use the space.

To add a secondary index to an existing table, `InnoDB` scans the table, and sorts the rows using memory buffers and temporary files in order by the values of the secondary index key columns. The B-tree is then built in key-value order, which is more efficient than inserting rows into an index in random order. Because the B-tree nodes are split when they fill, building the index in this way results in a higher fill-factor for the index, making it more efficient for subsequent access.

## Primary Key and Secondary Key Indexes

Historically, the MySQL server and `InnoDB` have each kept their own metadata about table and index structures. The MySQL server stores this information in `.frm files` that are not protected by a transactional mechanism, while `InnoDB` has its own `data dictionary` as part of the `system tablespace`. If a DDL operation was interrupted by a crash or other unexpected event partway through, the metadata could be left inconsistent between these two locations, causing problems such as startup errors or inability to access the table that was being altered. Now that `InnoDB` is the default storage engine, addressing such issues is a high priority. These enhancements to DDL operations reduce the window of opportunity for such issues to occur.

### 5.5.7. How Crash Recovery Works with Online DDL

Although no data is lost if the server crashes while an `ALTER TABLE` statement is executing, the `crash recovery` process is different for `clustered indexes` and `secondary indexes`.

If the server crashes while creating an InnoDB secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

When a crash occurs during the creation of an InnoDB clustered index, recovery is more complicated, because the data in the table must be copied to an entirely new clustered index. Remember that all InnoDB tables are stored as clustered indexes. In the following discussion, we use the word table and clustered index interchangeably.

MySQL creates the new clustered index by copying the existing data from the original InnoDB table to a temporary table that has the desired index structure. Once the data is completely copied to this temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

If a system crash occurs while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario.

### 5.5.8. DDL for Partitioned Tables

The mechanism used for DDL operations on partitioned tables is somewhat different from the online DDL discussed throughout this section. The partitioning clauses of the `ALTER TABLE` statement are only allowed in conjunction with `ALGORITHM=DEFAULT` and `LOCK=DEFAULT`. Although these operations do not go through the same internal online DDL API as for non-partitioned tables, MySQL still attempts to minimize data copying and locking where possible:

- `ADD PARTITION` and `DROP PARTITION` for tables partitioned by `RANGE` or `LIST` do not copy any existing data.
- `TRUNCATE PARTITION` does not copy any existing data, for all types of partitioned tables.
- Concurrent queries are allowed during `ADD PARTITION` and `COALESCE PARTITION` for tables partitioned by `HASH` or `LIST`. MySQL copies the data while holding a shared lock.
- For `REORGANIZE PARTITION`, `REBUILD PARTITION`, or `ADD PARTITION` or `COALESCE PARTITION` for a table partitioned by `LINEAR HASH` or `LIST`, concurrent queries are allowed. Data from the affected partitions is copied while holding a shared lock.

### 5.5.9. Limitations of Online DDL

Take the following considerations into account when creating or dropping InnoDB indexes:

- During an online DDL operation that copies the table, files are written to the temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` [559] configuration variable). Each temporary file is large enough to hold one column in the new table or index, and each one is removed as soon as it is merged into the final table or index.
- The table is copied, rather than using Fast Index Creation when you create an index on a `TEMPORARY TABLE`. This has been reported as MySQL Bug #39833.
- InnoDB handles error cases when users attempt to drop indexes needed for foreign keys. See section [Section 14.2.5.9, “Better Error Handling when Dropping Indexes”](#) for details.
- The `ALTER TABLE` clause `LOCK=NONE` is not allowed if there are `ON . . . CASCADE` or `ON . . . SET NULL` constraints on the table.
- During each online DDL `ALTER TABLE` statement, regardless of the `LOCK` clause, there are brief periods at the beginning and end requiring an **exclusive lock** on the table (the same kind of lock specified by the `LOCK=EXCLUSIVE` clause). Thus, an online DDL operation might wait before starting

if there is a long-running transaction performing inserts, updates, deletes, or `SELECT ... FOR UPDATE` on that table; and an online DDL operation might wait before finishing if a similar long-running transaction was started while the `ALTER TABLE` was in progress.

## 5.6. Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.5 and one from MySQL 5.6, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See [Section 4.2.3, “Specifying Program Options”](#). To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=path` [418] option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see [Section 5.6.1, “Setting Up Multiple Data Directories”](#).

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=port_num` [437]

`--port` [437] controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can use `--bind-address` [414] to cause each server to listen to a different address.

- `--socket=path` [442]

`--socket` [442] controls the Unix socket file path on Unix or the named pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=name` [439]

This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=file_name` [435]

This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=file_name` [486]
- `--log-bin[=file_name]` [2002]
- `--slow_query_log_file=file_name` [541]

- `--log-error[=file_name]` [427]

For further discussion of log file options, see [Section 5.2, “MySQL Server Logs”](#).

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

- `--tmpdir=path` [446]

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=path` [414] option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` [442] and `--port` [437] options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` [414] option to pass to `mysqld`, and you need specify only the `--socket` [229] and `--port` [228] options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` [219] option is useful for this purpose.

### 5.6.1. Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the `--datadir=path` [418] option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

#### Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with `MyISAM` and `MERGE` tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a *very bad idea*. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

## Create a New Data Directory

With this method, the data directory will be in the same state as when you first install MySQL. It will have the default set of MySQL accounts and no user data.

On Unix, initialize the data directory by running `mysql_install_db`. See [Section 2.10.1, “Unix Postinstallation Procedures”](#).

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it `data` directory to where you are setting up the new instance.
- Windows MSI package installers create and set up the data directory that the installed server will use, but also create a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

## Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.
2. Copy the data directory to the location where the new data directory should be.
3. Copy the `my.cnf` or `my.ini` option file used by the existing instance. This serves as a basis for the new instance.
4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).
5. Start the new instance, telling it to use the new option file.

## 5.6.2. Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in [Section 2.3, “Installing MySQL on Microsoft Windows”](#). The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

### 5.6.2.1. Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in [Section 2.3.4.5, “Starting MySQL from the Windows Command Line”](#). To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file [219]` option when you run it.

Suppose that you want to run `mysqld` on port 3307 with a data directory of `C:\mydata1`, and `mysqld-debug` on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.
2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

3. Use the `--defaults-file` [219] option to start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld-debug --defaults-file=C:\my-opts2.cnf
```

Each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, use the `mysqld` or `mysqld-debug` server and specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections with the `--shared-memory` [439] option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` [439] option.

### 5.6.2.2. Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.5.9` and `C:\mysql-5.6.12`, respectively. (This might be the case if you are running 5.5.9 as your production server, but also want to conduct tests using 5.6.12.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.5.9 `mysqld` using the service name of `mysqld1` and the 5.6.12 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.5.9 and the `[mysqld2]` group for 5.6.12. For example, you can set up `C:\my.cnf` like this:

```
# options for mysqld1 service
[mysqld1]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-5.6.12
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
C:\> C:\mysql-5.6.12\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or use `NET START` with the appropriate service names:

```
C:\> NET START mysqld1
C:\> NET START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```
C:\> NET STOP mysqld1
C:\> NET STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` [219] when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.5.9 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 5.6.12 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.6.12
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
--defaults-file=C:\my-opts1.cnf
```

```
C:\> C:\mysql-5.6.12\bin\mysqld --install mysqld2
      --defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a `--defaults-file` [219] option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` [437] option. If the service name is the default (MySQL), you can omit it.

### 5.6.3. Running Multiple MySQL Instances on Unix

One way to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.5 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 5.6.12 server to have different operating parameters, use a CMake command something like this:

```
shell> cmake . -DMYSQL_TCP_PORT=port_number \
           -DMYSQL_UNIX_ADDR=file_name \
           -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-5.6.12
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` [132] value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. To explicitly specify the connection protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` [211] option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` [442] and `--port` [437] option values, and pass a `--datadir=path` [418] option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file` [219] option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```

shell> MYSQL_UNIX_PORT=/tmp/mysql-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &

```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

[Section 2.12, “Environment Variables”](#), includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See [Section 4.3.4, “mysqld\\_multi — Manage Multiple MySQL Servers”](#).

## 5.6.4. Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name [211] --port=port_number [211]` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 [211] --port=port_number [211]` to connect using TCP/IP to a local server, or with `--host=localhost [211] --socket=file_name [211]` to connect to a local server using a Unix socket file or a Windows named pipe.
- Start the client with `--protocol=TCP [211]` to connect using TCP/IP, `--protocol=SOCKET [211]` to connect using a Unix socket file, `--protocol=PIPE [211]` to connect using a named pipe, or `--protocol=MEMORY [211]` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host [211]` and `--port [211]` options. For the other types of connections, you may need to specify a `--socket [211]` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name [211]` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See [Section 2.12, “Environment Variables”](#).
- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See [Section 4.2.3.3, “Using Option Files”](#).
- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See [Section 21.8.6, “C API Function Descriptions”](#).
- If you are using the Perl `DBD: :mysql` module, you can read options from MySQL option files. For example:

```

$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
      . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);

```

See [Section 21.10, “MySQL Perl API”](#).

Other programming interfaces may provide similar capabilities for reading option files.

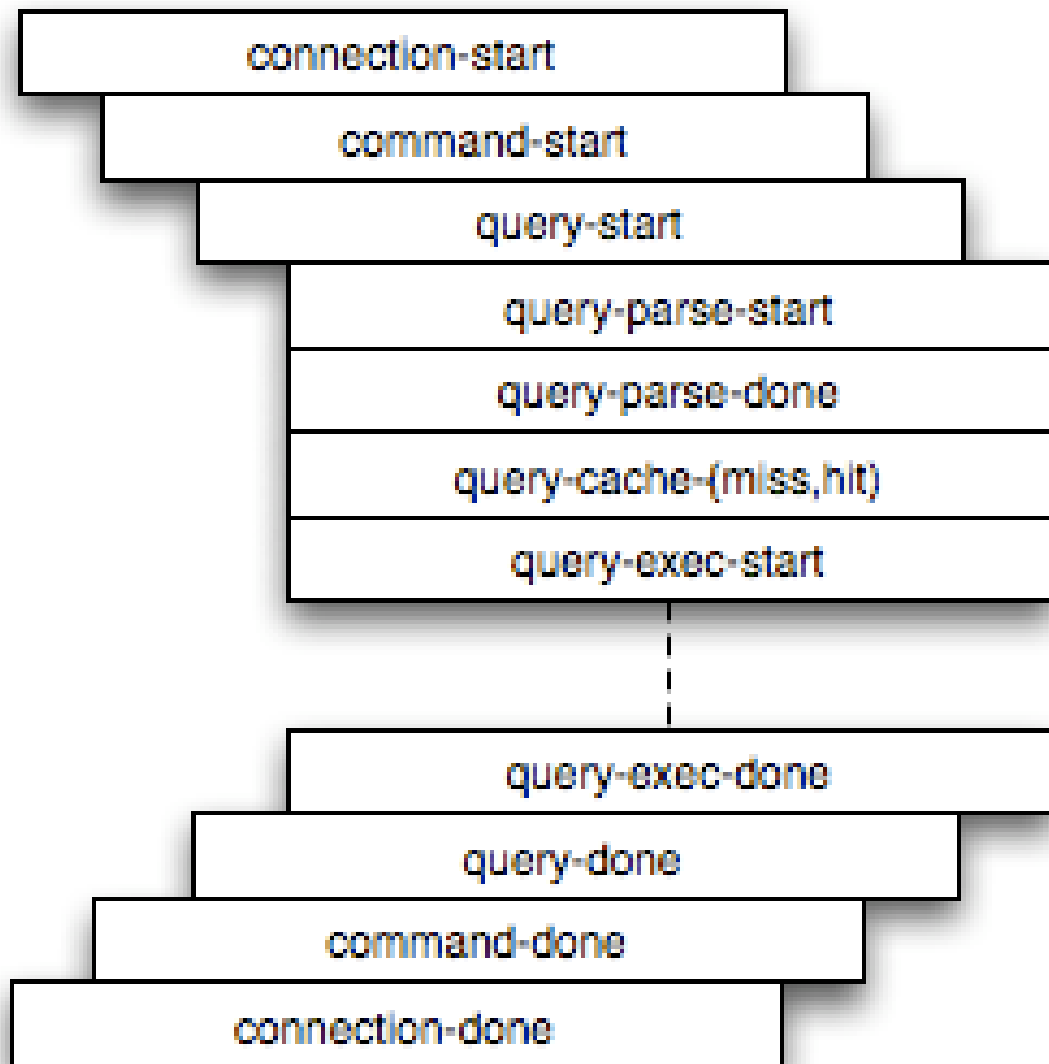

## 5.7. Tracing `mysqld` Using DTrace

The DTrace probes in the MySQL server are designed to provide information about the execution of queries within MySQL and the different areas of the system being utilized during that process. The

organization and triggering of the probes means that the execution of an entire query can be monitored with one level of probes (`query-start` and `query-done`) but by monitoring other probes you can get successively more detailed information about the execution of the query in terms of the locks used, sort methods and even row-by-row and storage-engine level execution information.

The DTrace probes are organized so that you can follow the entire query process, from the point of connection from a client, through the query execution, row-level operations, and back out again. You can think of the probes as being fired within a specific sequence during a typical client connect/execute/disconnect sequence, as shown in the following figure.

**Figure 5.1. The MySQL Architecture Using Pluggable Storage Engines**

Global information is provided in the arguments to the DTrace probes at various levels. Global information, that is, the connection ID and user/host and where relevant the query string, is provided at key levels (`connection-start`, `command-start`, `query-start`, and `query-exec-start`). As you go deeper into the probes, it is assumed either you are only interested in the individual executions (row-level probes provide information on the database and table name only), or that you will combine the row-level probes with the notional parent probes to provide the information about a specific query. Examples of this will be given as the format and arguments of each probe are provided.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

MySQL 5.6 includes support for DTrace probes on Solaris 10 Update 5 (Solaris 5/08) on SPARC, x86 and x86\_64 platforms. Probes are also supported on Mac OS X 10.4 and higher. Enabling the probes should be automatic on these platforms. To explicitly enable or disable the probes during building, use the `-DENABLE_DTRACE=1` [135] or `-DENABLE_DTRACE=0` [135] option to CMake.

### 5.7.1. mysqlld DTrace Probe Reference

MySQL supports the following static probes, organized into groups of functionality.

**Table 5.10. MySQL DTrace Probes**

Group	Probes	Introduced
Connection	<code>connection-start</code> , <code>connection-done</code>	5.4.0
Command	<code>command-start</code> , <code>command-done</code>	5.4.0
Query	<code>query-start</code> , <code>query-done</code>	5.4.0
Query Parsing	<code>query-parse-start</code> , <code>query-parse-done</code>	5.4.0
Query Cache	<code>query-cache-hit</code> , <code>query-cache-miss</code>	5.4.0
Query Execution	<code>query-exec-start</code> , <code>query-exec-done</code>	5.4.0
Row Level	<code>insert-row-start</code> , <code>insert-row-done</code>	5.4.0
	<code>update-row-start</code> , <code>update-row-done</code>	5.4.0
	<code>delete-row-start</code> , <code>delete-row-done</code>	5.4.0
Row Reads	<code>read-row-start</code> , <code>read-row-done</code>	5.4.0
Index Reads	<code>index-read-row-start</code> , <code>index-read-row-done</code>	5.4.0
Lock	<code>handler-rdlock-start</code> , <code>handler-rdlock-done</code>	5.4.0
	<code>handler-wrlock-start</code> , <code>handler-wrlock-done</code>	5.4.0
	<code>handler-unlock-start</code> , <code>handler-unlock-done</code>	5.4.0
Filesort	<code>filesort-start</code> , <code>filesort-done</code>	5.4.0
Statement	<code>select-start</code> , <code>select-done</code>	5.4.0
	<code>insert-start</code> , <code>insert-done</code>	5.4.0
	<code>insert-select-start</code> , <code>insert-select-done</code>	5.4.0
	<code>update-start</code> , <code>update-done</code>	5.4.0
	<code>multi-update-start</code> , <code>multi-update-done</code>	5.4.0
	<code>delete-start</code> , <code>delete-done</code>	5.4.0
	<code>multi-delete-start</code> , <code>multi-delete-done</code>	5.4.0
Network	<code>net-read-start</code> , <code>net-read-done</code> , <code>net-write-start</code> , <code>net-write-done</code>	5.4.0
Keycache	<code>keycache-read-start</code> , <code>keycache-read-block</code> , <code>keycache-read-done</code> , <code>keycache-read-hit</code> , <code>keycache-read-miss</code> , <code>keycache-write-start</code> , <code>keycache-write-block</code> , <code>keycache-write-done</code>	5.4.0

#### Note

When extracting the argument data from the probes, each argument is available as `argN`, starting with `arg0`. To identify each argument within the definitions they are provided with a descriptive name, but you must access the information using the corresponding `argN` parameter.

### 5.7.1.1. Connection Probes

The `connection-start` and `connection-done` probes enclose a connection from a client, regardless of whether the connection is through a socket or network connection.

```
connection-start(connectionid, user, host)
connection-done(status, connectionid)
```

- `connection-start`: Triggered after a connection and successful login/authentication have been completed by a client. The arguments contain the connection information:
  - `connectionid`: An `unsigned long` containing the connection ID. This is the same as the process ID shown as the `Id` value in the output from `SHOW PROCESSLIST`.
  - `user`: The username used when authenticating. The value will be blank for the anonymous user.
  - `host`: The host of the client connection. For a connection made using UNIX sockets, the value will be blank.
- `connection-done`: Triggered just as the connection to the client has been closed. The arguments are:
  - `status`: The status of the connection when it was closed. A logout operation will have a value of 0; any other termination of the connection has a nonzero value.
  - `connectionid`: The connection ID of the connection that was closed.

The following D script will quantify and summarize the average duration of individual connections, and provide a count, dumping the information every 60 seconds:

```
#!/usr/sbin/dtrace -s

mysql*:::connection-start
{
    self->start = timestamp;
}

mysql*:::connection-done
/self->start/
{
    @ = quantize(((timestamp - self->start)/1000000));
    self->start = 0;
}

tick-60s
{
    printa(@);
}
```

When executed on a server with a large number of clients you might see output similar to this:

```
1 57413          :tick-60s

      value  ----- Distribution ----- count
      -1 | 0
      0 | @@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@ 30011
      1 | 59
      2 | 5
      4 | 20
      8 | 29
     16 | 18
     32 | 27
     64 | 30
    128 | 11
    256 | 10
    512 | 1
```

1024	6
2048	8
4096	9
8192	8
16384	2
32768	1
65536	1
131072	0
262144	1
524288	0

### 5.7.1.2. Command Probes

The command probes are executed before and after a client command is executed, including any SQL statement that might be executed during that period. Commands include operations such as the initialization of the DB, use of the `COM_CHANGE_USER` operation (supported by the MySQL protocol), and manipulation of prepared statements. Many of these commands are used only by the MySQL client API from various connectors such as PHP and Java.

```
command-start(connectionid, command, user, host)
command-done(status)
```

- `command-start`: Triggered when a command is submitted to the server.
- `connectionid`: The connection ID of the client executing the command.
- `command`: An integer representing the command that was executed. Possible values are shown in the following table.

Value	Name	Description
00	COM_SLEEP	Internal thread state
01	COM_QUIT	Close connection
02	COM_INIT_DB	Select database ( <code>USE ...</code> )
03	COM_QUERY	Execute a query
04	COM_FIELD_LIST	Get a list of fields
05	COM_CREATE_DB	Create a database (deprecated)
06	COM_DROP_DB	Drop a database (deprecated)
07	COM_REFRESH	Refresh connection
08	COM_SHUTDOWN	Shutdown server
09	COM_STATISTICS	Get statistics
10	COM_PROCESS_INFO	Get processes ( <code>SHOW PROCESSLIST</code> )
11	COM_CONNECT	Initialize connection
12	COM_PROCESS_KILL	Kill process
13	COM_DEBUG	Get debug information
14	COM_PING	Ping
15	COM_TIME	Internal thread state
16	COM_DELAYED_INSERT	Internal thread state
17	COM_CHANGE_USER	Change user
18	COM_BINLOG_DUMP	Used by a replication slave or <code>mysqlbinlog</code> to initiate a binary log read
19	COM_TABLE_DUMP	Used by a replication slave to get the master table information
20	COM_CONNECT_OUT	Used by a replication slave to log a connection to the server
21	COM_REGISTER_SLAVE	Used by a replication slave during registration

Value	Name	Description
22	COM_STMT_PREPARE	Prepare a statement
23	COM_STMT_EXECUTE	Execute a statement
24	COM_STMT_SEND_LONG_DATA	Used when requesting extended data
25	COM_STMT_CLOSE	Close a prepared statement
26	COM_STMT_RESET	Reset a prepared statement
27	COM_SET_OPTIONS	Set a server option
28	COM_STMT_FETCH	Fetch a prepared statement

- `user`: The user executing the command.
- `host`: The client host.
- `command-done`: Triggered when the command execution completes. The `status` argument contains 0 if the command executed successfully, or 1 if the statement was terminated before normal completion.

The `command-start` and `command-done` probes are best used when combined with the statement probes to get an idea of overall execution time.

### 5.7.1.3. Query Probes

The `query-start` and `query-done` probes are triggered when a specific query is received by the server and when the query has been completed and the information has been successfully sent to the client.

```
query-start(query, connectionid, database, user, host)
query-done(status)
```

- `query-start`: Triggered after the query string has been received from the client. The arguments are:
  - `query`: The full text of the submitted query.
  - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
  - `database`: The database name on which the query is being executed.
  - `user`: The username used to connect to the server.
  - `host`: The hostname of the client.
- `query-done`: Triggered once the query has been executed and the information has been returned to the client. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

You can get a simple report of the execution time for each query using the following D script:

```
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %-9s\n", "Who", "Database", "Query", "Time(ms)");
}
mysql*:::query-start
```

```

{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db     = copyinstr(arg2);
    self->who    = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->querystart = timestamp;
}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-9d\n", self->who, self->db, self->query,
        (timestamp - self->querystart) / 1000000);
}

```

When executing the above script you should get a basic idea of the execution time of your queries:

```

shell> ./query.d
Who           Database      Query                                               Time(ms)
root@localhost test         select * from t1 order by i limit 10              0
root@localhost test         set global query_cache_size=0                    0
root@localhost test         select * from t1 order by i limit 10              776
root@localhost test         select * from t1 order by i limit 10              773
root@localhost test         select * from t1 order by i desc limit 10        795

```

#### 5.7.1.4. Query Parsing Probes

The query parsing probes are triggered before the original SQL statement is parsed and when the parsing of the statement and determination of the execution model required to process the statement has been completed:

```

query-parse-start(query)
query-parse-done(status)

```

- **query-parse-start**: Triggered just before the statement is parsed by the MySQL query parser. The single argument, **query**, is a string containing the full text of the original query.
- **query-parse-done**: Triggered when the parsing of the original statement has been completed. The **status** is an integer describing the status of the operation. A **0** indicates that the query was successfully parsed. A **1** indicates that the parsing of the query failed.

For example, you could monitor the execution time for parsing a given query using the following D script:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::query-parse-start
{
    self->parsestart = timestamp;
    self->parsequery = copyinstr(arg0);
}

mysql*:::query-parse-done
/arg0 == 0/
{
    printf("Parsing %s: %d microseconds\n", self->parsequery, ((timestamp - self->parsestart)/1000));
}

mysql*:::query-parse-done
/arg0 != 0/
{
    printf("Error parsing %s: %d microseconds\n", self->parsequery, ((timestamp - self->parsestart)/1000));
}

```

In the above script a predicate is used on **query-parse-done** so that different output is generated based on the status value of the probe.

When running the script and monitoring the execution:

```
shell> ./query-parsing.d
Error parsing select from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 36 ms
Parsing select * from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 176 ms
```

### 5.7.1.5. Query Cache Probes

The query cache probes are fired when executing any query. The `query-cache-hit` query is triggered when a query exists in the query cache and can be used to return the query cache information. The arguments contain the original query text and the number of rows returned from the query cache for the query. If the query is not within the query cache, or the query cache is not enabled, then the `query-cache-miss` probe is triggered instead.

```
query-cache-hit(query, rows)
query-cache-miss(query)
```

- `query-cache-hit`: Triggered when the query has been found within the query cache. The first argument, `query`, contains the original text of the query. The second argument, `rows`, is an integer containing the number of rows in the cached query.
- `query-cache-miss`: Triggered when the query is not found within the query cache. The first argument, `query`, contains the original text of the query.

The query cache probes are best combined with a probe on the main query so that you can determine the differences in times between using or not using the query cache for specified queries. For example, in the following D script, the query and query cache information are combined into the information output during monitoring:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace::BEGIN
{
    printf("%-20s %-20s %-40s %2s %-9s\n", "Who", "Database", "Query", "QC", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->querystart = timestamp;
    self->qc = 0;
}

mysql*:::query-cache-hit
{
    self->qc = 1;
}

mysql*:::query-cache-miss
{
    self->qc = 0;
}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-2s %-9d\n",self->who,self->db,self->query,(self->qc ? "Y" : "N"),
        (timestamp - self->querystart) / 1000000);
}
```

When executing the script you can see the effects of the query cache. Initially the query cache is disabled. If you set the query cache size and then execute the query multiple times you should see that the query cache is being used to return the query data:

```
shell> ./query-cache.d
root@localhost      test                select * from t1 order by i limit 10      N 1072
```

```

root@localhost          set global query_cache_size=262144      N  0
root@localhost test      select * from t1 order by i limit 10      N 781
root@localhost test      select * from t1 order by i limit 10      Y  0

```

### 5.7.1.6. Query Execution Probes

The query execution probe is triggered when the actual execution of the query starts, after the parsing and checking the query cache but before any privilege checks or optimization. By comparing the difference between the start and done probes you can monitor the time actually spent servicing the query (instead of just handling the parsing and other elements of the query).

```

query-exec-start(query, connectionid, database, user, host, exec_type)
query-exec-done(status)

```

#### Note

The information provided in the arguments for `query-start` and `query-exec-start` are almost identical and designed so that you can choose to monitor either the entire query process (using `query-start`) or only the execution (using `query-exec-start`) while exposing the core information about the user, client, and query being executed.

- `query-exec-start`: Triggered when the execution of a individual query is started. The arguments are:
  - `query`: The full text of the submitted query.
  - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
  - `database`: The database name on which the query is being executed.
  - `user`: The username used to connect to the server.
  - `host`: The hostname of the client.
  - `exec_type`: The type of execution. Execution types are determined based on the contents of the query and where it was submitted. The values for each type are shown in the following table.

Value	Description
0	Executed query from <code>sql_parse</code> , top-level query.
1	Executed prepared statement
2	Executed cursor statement
3	Executed query in stored procedure

- `query-exec-done`: Triggered when the execution of the query has completed. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

### 5.7.1.7. Row-Level Probes

The `*row-{start,done}` probes are triggered each time a row operation is pushed down to a storage engine. For example, if you execute an `INSERT` statement with 100 rows of data, then the `insert-row-start` and `insert-row-done` probes will be triggered 100 times each, for each row insert.

```

insert-row-start(database, table)
insert-row-done(status)

```

```

update-row-start(database, table)
update-row-done(status)

delete-row-start(database, table)
delete-row-done(status)

```

- `insert-row-start`: Triggered before a row is inserted into a table.
- `insert-row-done`: Triggered after a row is inserted into a table.
- `update-row-start`: Triggered before a row is updated in a table.
- `update-row-done`: Triggered before a row is updated in a table.
- `delete-row-start`: Triggered before a row is deleted from a table.
- `delete-row-done`: Triggered before a row is deleted from a table.

The arguments supported by the probes are consistent for the corresponding `start` and `done` probes in each case:

- `database`: The database name.
- `table`: The table name.
- `status`: The status; 0 for success or 1 for failure.

Because the row-level probes are triggered for each individual row access, these probes can be triggered many thousands of times each second, which may have a detrimental effect on both the monitoring script and MySQL. The DTrace environment should limit the triggering on these probes to prevent the performance being adversely affected. Either use the probes sparingly, or use counter or aggregation functions to report on these probes and then provide a summary when the script terminates or as part of a `query-done` or `query-exec-done` probes.

The following example script summarizes the duration of each row operation within a larger query:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace::BEGIN
{
    printf("%-2s %-10s %-10s %9s %9s %-s \n",
          "St", "Who", "DB", "ConnID", "Dur ms", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->rowdur = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) /1000000;
    printf("%2d %-10s %-10s %9d %9d %s\n",
          arg0, self->who, self->db,
          self->connid, this->elapsed, self->query);
}

mysql*:::query-done
/ self->rowdur /
{
    printf("%34s %9d %s\n", "", (self->rowdur/1000000), "-> Row ops");
}

```

```

}

mysql*:::insert-row-start
{
    self->rowstart = timestamp;
}

mysql*:::delete-row-start
{
    self->rowstart = timestamp;
}

mysql*:::update-row-start
{
    self->rowstart = timestamp;
}

mysql*:::insert-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql*:::delete-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql*:::update-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

```

Running the above script with a query that inserts data into a table, you can monitor the exact time spent performing the raw row insertion:

St	Who	DB	ConnID	Dur ms	Query
0	@localhost	test	13	20767	insert into t1(select * from t2)
				4827	-> Row ops

### 5.7.1.8. Read Row Probes

The read row probes are triggered at a storage engine level each time a row read operation occurs. These probes are specified within each storage engine (as opposed to the `*row-start` probes which are in the storage engine interface). These probes can therefore be used to monitor individual storage engine row-level operations and performance. Because these probes are triggered around the storage engine row read interface, they may be hit a significant number of times during a basic query.

```

read-row-start(database, table, scan_flag)
read-row-done(status)

```

- `read-row-start`: Triggered when a row is read by the storage engine from the specified `database` and `table`. The `scan_flag` is set to 1 (true) when the read is part of a table scan (that is, a sequential read), or 0 (false) when the read is of a specific record.
- `read-row-done`: Triggered when a row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

### 5.7.1.9. Index Probes

The index probes are triggered each time a a row is read using one of the indexes for the specified table. The probe is triggered within the corresponding storage engine for the table.

```

index-read-row-start(database, table)
index-read-row-done(status)

```

- `index-read-row-start`: Triggered when a row is read by the storage engine from the specified `database` and `table`.

- `index-read-row-done`: Triggered when an indexed row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

### 5.7.1.10. Lock Probes

The lock probes are called whenever an external lock is requested by MySQL for a table using the corresponding lock mechanism on the table as defined by the table's engine type. There are three different types of lock, the read lock, write lock, and unlock operations. Using the probes you can determine the duration of the external locking routine (that is, the time taken by the storage engine to implement the lock, including any time waiting for another lock to become free) and the total duration of the lock/unlock process.

```
handler-rdlock-start(database, table)
handler-rdlock-done(status)

handler-wrlock-start(database, table)
handler-wrlock-done(status)

handler-unlock-start(database, table)
handler-unlock-done(status)
```

- `handler-rdlock-start`: Triggered when a read lock is requested on the specified `database` and `table`.
- `handler-wrlock-start`: Triggered when a write lock is requested on the specified `database` and `table`.
- `handler-unlock-start`: Triggered when an unlock request is made on the specified `database` and `table`.
- `handler-rdlock-done`: Triggered when a read lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.
- `handler-wrlock-done`: Triggered when a write lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.
- `handler-unlock-done`: Triggered when an unlock request completes. The `status` is 0 if the unlock operation succeeded, or `>0` on failure.

You can use arrays to monitor the locking and unlocking of individual tables and then calculate the duration of the entire table lock using the following script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::handler-rdlock-start
{
    self->rdlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0), strjoin("@", copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Read   %s.%s\n", copyinstr(arg0), copyinstr(arg1));
}

mysql*:::handler-wrlock-start
{
    self->wrlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0), strjoin("@", copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Write  %s.%s\n", copyinstr(arg0), copyinstr(arg1));
}

mysql*:::handler-unlock-start
{
    self->unlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0), strjoin("@", copyinstr(arg1)));
    printf("Start: Lock->Unlock %s.%s (%d ms lock duration)\n",
```

```

        copyinstr(arg0),copyinstr(arg1),
        (timestamp - self->lockmap[this->lockref])/1000000);
    }

mysql*:::handler-rdlock-done
{
    printf("End:   Lock->Read   %d ms\n",
        (timestamp - self->rdlockstart)/1000000);
}

mysql*:::handler-wrlock-done
{
    printf("End:   Lock->Write  %d ms\n",
        (timestamp - self->wrlockstart)/1000000);
}

mysql*:::handler-unlock-done
{
    printf("End:   Lock->Unlock %d ms\n",
        (timestamp - self->unlockstart)/1000000);
}

```

When executed, you should get information both about the duration of the locking process itself, and of the locks on a specific table:

```

Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (25743 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms

```

### 5.7.1.11. Filesort Probes

The filesort probes are triggered whenever a filesort operation is applied to a table. For more information on filesort and the conditions under which it occurs, see [Section 8.13.13, "ORDER BY Optimization"](#).

```

filestort-start(database, table)
filestort-done(status, rows)

```

- **filestort-start**: Triggered when the filesort operation starts on a table. The two arguments to the probe, **database** and **table**, will identify the table being sorted.
- **filestort-done**: Triggered when the filesort operation completes. Two arguments are supplied, the **status** (0 for success, 1 for failure), and the number of rows sorted during the filesort process.

An example of this is in the following script, which tracks the duration of the filesort process in addition to the duration of the main query:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %18s %-s \n",
        "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start

```

```

{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->filesort = 0;
    self->fsdb = "";
    self->fstable = "";
}

mysql*:::filesort-start
{
    self->filesort = timestamp;
    self->fsdb = copyinstr(arg0);
    self->fstable = copyinstr(arg1);
}

mysql*:::filesort-done
{
    this->elapsed = (timestamp - self->filesort) /1000;
    printf("%2d %-10s %-10s %9d %18d Filesort on %s\n",
        arg0, self->who, self->fsdb,
        self->connid, this->elapsed, self->fstable);
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) /1000;
    printf("%2d %-10s %-10s %9d %18d %s\n",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
}

```

Executing a query on a large table with an `ORDER BY` clause that triggers a filesort, and then creating an index on the table and then repeating the same query, you can see the difference in execution speed:

St	Who	DB	ConnID	Dur	microsec	Query
0	@localhost	test	14	11335469		Filesort on t1
0	@localhost	test	14	11335787		select * from t1 order by i limit 100
0	@localhost	test	14	466734378		create index t1a on t1 (i)
0	@localhost	test	14	26472		select * from t1 order by i limit 100

### 5.7.1.12. Statement Probes

The individual statement probes are provided to give specific information about different statement types. For the start probes the string of the query is provided as the only argument. Depending on the statement type, the information provided by the corresponding done probe will differ. For all done probes the status of the operation (0 for success, >0 for failure) is provided. For `SELECT`, `INSERT`, `INSERT ... (SELECT FROM ...)`, `DELETE`, and `DELETE FROM t1,t2` operations the number of rows affected is returned.

For `UPDATE` and `UPDATE t1,t2 ...` statements the number of rows matched and the number of rows actually changed is provided. This is because the number of rows actually matched by the corresponding `WHERE` clause, and the number of rows changed can differ. MySQL does not update the value of a row if the value already matches the new setting.

```

select-start(query)
select-done(status,rows)

insert-start(query)
insert-done(status,rows)

insert-select-start(query)
insert-select-done(status,rows)

update-start(query)
update-done(status,rowsmatched,rowschanged)

```

```

multi-update-start(query)
multi-update-done(status, rowsmatched, rowschanged)

delete-start(query)
delete-done(status, rows)

multi-delete-start(query)
multi-delete-done(status, rows)

```

- `select-start`: Triggered before a `SELECT` statement.
- `select-done`: Triggered at the end of a `SELECT` statement.
- `insert-start`: Triggered before a `INSERT` statement.
- `insert-done`: Triggered at the end of an `INSERT` statement.
- `insert-select-start`: Triggered before an `INSERT ... SELECT` statement.
- `insert-select-done`: Triggered at the end of an `INSERT ... SELECT` statement.
- `update-start`: Triggered before an `UPDATE` statement.
- `update-done`: Triggered at the end of an `UPDATE` statement.
- `multi-update-start`: Triggered before an `UPDATE` statement involving multiple tables.
- `multi-update-done`: Triggered at the end of an `UPDATE` statement involving multiple tables.
- `delete-start`: Triggered before a `DELETE` statement.
- `delete-done`: Triggered at the end of a `DELETE` statement.
- `multi-delete-start`: Triggered before a `DELETE` statement involving multiple tables.
- `multi-delete-done`: Triggered at the end of a `DELETE` statement involving multiple tables.

The arguments for the statement probes are:

- `query`: The query string.
- `status`: The status of the query. `0` for success, and `>0` for failure.
- `rows`: The number of rows affected by the statement. This returns the number rows found for `SELECT`, the number of rows deleted for `DELETE`, and the number of rows successfully inserted for `INSERT`.
- `rowsmatched`: The number of rows matched by the `WHERE` clause of an `UPDATE` operation.
- `rowschanged`: The number of rows actually changed during an `UPDATE` operation.

You use these probes to monitor the execution of these statement types without having to monitor the user or client executing the statements. A simple example of this is to track the execution times:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace::BEGIN
{
    printf("%-60s %-8s %-8s %-8s\n", "Query", "RowsU", "RowsM", "Dur (ms)");
}

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,

```

```

mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->query = copyinstr(arg0);
    self->querystart = timestamp;
}

mysql*:::insert-done, mysql*:::select-done,
mysql*:::delete-done, mysql*:::multi-delete-done, mysql*:::insert-select-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
        self->query,
        0,
        arg1,
        this->elapsed);
    self->querystart = 0;
}

mysql*:::update-done, mysql*:::multi-update-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
        self->query,
        arg1,
        arg2,
        this->elapsed);
    self->querystart = 0;
}

```

When executed you can see the basic execution times and rows matches:

Query	RowsU	RowsM	Dur (ms)
select * from t2	0	275	0
insert into t2 (select * from t2)	0	275	9
update t2 set i=5 where i > 75	110	110	8
update t2 set i=5 where i < 25	254	134	12
delete from t2 where i < 5	0	0	0

Another alternative is to use the aggregation functions in DTrace to aggregate the execution time of individual statements together:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->querystart = timestamp;
}

mysql*:::select-done
{
    @statements["select"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::insert-done, mysql*:::insert-select-done
{
    @statements["insert"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::update-done, mysql*:::multi-update-done
{
    @statements["update"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::delete-done, mysql*:::multi-delete-done

```

```

{
    @statements["delete"] = sum(((timestamp - self->querystart)/1000000));
}

tick-30s
{
    printa(@statements);
}

```

The script just shown aggregates the times spent doing each operation, which could be used to help benchmark a standard suite of tests.

```

delete           0
update           0
insert          23
select         2484

delete           0
update           0
insert          39
select        10744

delete           0
update          26
insert          56
select        10944

delete           0
update          26
insert         2287
select        15985

```

### 5.7.1.13. Network Probes

The network probes monitor the transfer of information from the MySQL server and clients of all types over the network. The probes are defined as follows:

```

net-read-start()
net-read-done(status, bytes)
net-write-start(bytes)
net-write-done(status)

```

- **net-read-start**: Triggered when a network read operation is started.
- **net-read-done**: Triggered when the network read operation completes. The `status` is an `integer` representing the return status for the operation, `0` for success and `1` for failure. The `bytes` argument is an integer specifying the number of bytes read during the process.
- **net-start-bytes**: Triggered when data is written to a network socket. The single argument, `bytes`, specifies the number of bytes written to the network socket.
- **net-write-done**: Triggered when the network write operation has completed. The single argument, `status`, is an integer representing the return status for the operation, `0` for success and `1` for failure.

You can use the network probes to monitor the time spent reading from and writing to network clients during execution. The following D script provides an example of this. Both the cumulative time for the read or write is calculated, and the number of bytes. Note that the dynamic variable size has been increased (using the `dynvarsize` option) to cope with the rapid firing of the individual probes for the network reads/writes.

```

#!/usr/sbin/dtrace -s

#pragma D option quiet
#pragma D option dynvarsize=4m

dtrace:::BEGIN

```

```

{
    printf("%-2s %-30s %-10s %9s %18s %-s \n",
           "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->netwrite = 0;
    self->netwritecum = 0;
    self->netwritebase = 0;
    self->netread = 0;
    self->netreadcum = 0;
    self->netreadbase = 0;
}

mysql*:::net-write-start
{
    self->netwrite += arg0;
    self->netwritebase = timestamp;
}

mysql*:::net-write-done
{
    self->netwritecum += (timestamp - self->netwritebase);
    self->netwritebase = 0;
}

mysql*:::net-read-start
{
    self->netreadbase = timestamp;
}

mysql*:::net-read-done
{
    self->netread += arg1;
    self->netreadcum += (timestamp - self->netreadbase);
    self->netreadbase = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) /1000000;
    printf("%2d %-30s %-10s %9d %18d %s\n",
           arg0, self->who, self->db,
           self->connid, this->elapsed, self->query);
    printf("Net read: %d bytes (%d ms) write: %d bytes (%d ms)\n",
           self->netread, (self->netreadcum/1000000),
           self->netwrite, (self->netwritecum/1000000));
}

```

When executing the above script on a machine with a remote client, you can see that approximately a third of the time spent executing the query is related to writing the query results back to the client.

St	Who	DB	ConnID	Dur microsec	Query
0	root@::ffff:192.168.0.108	test	31	3495	select * from t1 limit 100000
Net read: 0 bytes (0 ms) write: 10000075 bytes (1220 ms)					

### 5.7.1.14. Keycache Probes

The keycache probes are triggered when using the index key cache used with the MyISAM storage engine. Probes exist to monitor when data is read into the keycache, cached key data is written from the cache into a cached file, or when accessing the keycache.

Keycache usage indicates when data is read or written from the index files into the cache, and can be used to monitor how efficient the memory allocated to the keycache is being used. A high number of

keycache reads across a range of queries may indicate that the keycache is too small for size of data being accessed.

```
keycache-read-start(filepath, bytes, mem_used, mem_free)
keycache-read-block(bytes)
keycache-read-hit()
keycache-read-miss()
keycache-read-done(mem_used, mem_free)
keycache-write-start(filepath, bytes, mem_used, mem_free)
keycache-write-block(bytes)
keycache-write-done(mem_used, mem_free)
```

When reading data from the index files into the keycache, the process first initializes the read operation (indicated by `keycache-read-start`), then loads blocks of data (`keycache-read-block`), and then the read block is either matches the data being identified (`keycache-read-hit`) or more data needs to be read (`keycache-read-miss`). Once the read operation has completed, reading stops with the `keycache-read-done`.

Data will be read from the index file into the keycache only when the specified key is not already within the keycache.

- `keycache-read-start`: Triggered when the keycache read operation is started. Data is read from the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.
- `keycache-read-block`: Triggered when the keycache reads a block of data, of the specified number of `bytes`, from the index file into the keycache.
- `keycache-read-hit`: Triggered when the block of data read from the index file matches the key data requested.
- `keycache-read-miss`: Triggered when the block of data read from the index file does not match the key data needed.
- `keycache-read-done`: Triggered when the keycache read operation has completed. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

Keycache writes occur when the index information is updated during an `INSERT`, `UPDATE`, or `DELETE` operation, and the cached key information is flushed back to the index file.

- `keycache-write-start`: Triggered when the keycache write operation is started. Data is written to the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.
- `keycache-write-block`: Triggered when the keycache writes a block of data, of the specified number of `bytes`, to the index file from the keycache.
- `keycache-write-done`: Triggered when the keycache write operation has completed. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

---

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See [Section 6.1, “General Security Issues”](#).
- Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see [Section 2.10, “Postinstallation Setup and Testing”](#).
- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see [Section 6.2, “The MySQL Access Privilege System”](#), and [Section 6.3, “MySQL User Account Management”](#).
- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.
- Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See [Chapter 7, Backup and Recovery](#).

## 6.1. General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see [Section 6.2, “The MySQL Access Privilege System”](#).

For answers to some questions that are often asked about MySQL Server security issues, see [Section B.9, “MySQL 5.6 FAQ: Security”](#).

### 6.1.1. Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` database!** This is critical.
- Learn how the MySQL access privilege system works (see [Section 6.2, “The MySQL Access Privilege System”](#)). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

- Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).
- Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.
- Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2 ( )` [1264], `SHA1 ( )` [1264], `MD5 ( )` [1263], or some other one-way hashing function and store the hash value.
- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.
- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

- Try to scan your ports from the Internet using a tool such as [nmap](#). MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where `server_host` is the host name or IP address of the host on which your MySQL server runs:

```
shell> telnet server_host 3306
```

If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

- Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See [Section 6.1.7, “Client Programming Security Guidelines”](#).
- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.
- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

### Warning

If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

## 6.1.2. Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. There is also a discussion of how MySQL uses password hashing internally and of a plugin that you can use to enforce stricter passwords.

### 6.1.2.1. End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use the `mysql_config_editor` utility, which enables you to store authentication credentials in an encrypted login file named `.mylogin.cnf`. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server. See [Section 4.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).
- Use a `-pyour_pass` or `--password=your_pass` option on the command line. For example:

```
shell> mysql -u francis -pfrank db_name
```

This is convenient *but insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `-p` or `--password` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
shell> mysql -u francis -p db_name
Enter password: *****
```

The “\*” characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=your_pass
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
shell> chmod 600 .my.cnf
```

To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` [219] option, where `file_name` is the full path name to the file. For example:

```
shell> mysql --defaults-file=/home/francis/mysql-opts
```

[Section 4.2.3.3, “Using Option Files”](#), discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. See [Section 2.12, “Environment Variables”](#).

This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. On some systems, if you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see [Section 4.5.1.3, “mysql Logging”](#)). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

### 6.1.2.2. Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` table. Access to this table should never be granted to any nonadministrative accounts.

Account passwords can be expired so that users must reset them. See [Section 6.3.6, “Password Expiration and Sandbox Mode”](#).

The `validate_password` plugin can be used to enforce a policy on acceptable password. See [Section 6.1.2.6, “The Password Validation Plugin”](#).

A user who has access to modify the plugin directory (the value of the `plugin_dir` [525] system variable) or the `my.cnf` file that specifies the location of the plugin directory can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

### 6.1.2.3. Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, or statements that invoke the `PASSWORD()` [1263] function. If these statements are logged by the MySQL server as written, such passwords become available to anyone with access to the logs.

Beginning with MySQL 5.6.3, statement logging is modified so that passwords do not appear in plain text for the following statements:

```
CREATE USER ... IDENTIFIED BY ...
GRANT ... IDENTIFIED BY ...
SET PASSWORD ...
SLAVE START ... PASSWORD = ... (as of 5.6.4)
CREATE SERVER ... OPTIONS(... PASSWORD ...) (as of 5.6.9)
ALTER SERVER ... OPTIONS(... PASSWORD ...) (as of 5.6.9)
```

Passwords in those statements are rewritten not to appear literally in statement text, for the general query log, slow query log, and binary log. Rewriting does not apply to other statements.

For the general query log, password rewriting can be suppressed by starting the server with the `--log-raw` [428] option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

Passwords can be written as plain text in SQL statements in the audit log plugin log file (see [Section 6.3.11, “MySQL Enterprise Audit Log Plugin”](#)).

To guard log files against unwarranted exposure, they should be located in a directory that restricts access to only the server and the database administrator. If you log to tables in the `mysql` database, access to those tables should never be granted to any nonadministrative accounts.

Replication slaves store the password for the replication master in the `master.info` file. Restrict this file to be accessible only to the database administrator. As of MySQL 5.6.4, an alternative to storing the password in a file is to use the `START SLAVE` statement to specify credentials for connecting to the master.

Database backups that include tables or log files containing passwords should be protected using a restricted access mode.

### 6.1.2.4. Password Hashing in MySQL

MySQL lists user accounts in the `user` table of the `mysql` database. Each MySQL account can be assigned a password, although the `user` table does not store the cleartext version of the password, but a hash value computed from it.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account the client wants to use.
- After the client connects, it can (if it has sufficient privileges) set or change the password hash for accounts listed in the `user` table. The client can do this by using the `PASSWORD( )` [1263] function to generate a password hash, or by using a password-generating statement (`CREATE USER`, `GRANT`, or `SET PASSWORD`).

In other words, the server *checks* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD( )` [1263] function or uses a password-generating statement to set or change a password.

Password hashing methods in MySQL have the history described following. These changes are illustrated by changes in the result from the `PASSWORD( )` [1263] function that computes password hash values and in the structure of the `user` table where passwords are stored.

#### The Original (Pre-4.1) Hashing Method

The original hashing method produced a 16-byte string. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| 6f8c114b58f2ce9e |
+-----+
```

To store account passwords, the `Password` column of the `user` table was at this point 16 bytes long.

#### The 4.1 Hashing Method

MySQL 4.1 introduced password hashing that provides better security and reduces the risk of passwords being intercepted. There were several aspects to this change:

- Different `PASSWORD( )` [1263] function result format
- Widening of the `Password` column
- Control over the default hashing method
- Control over the permitted hashing methods for clients attempting to connect to the server

The changes in MySQL 4.1 took place in two stages:

- MySQL 4.1.0 used a preliminary version of the 4.1 hashing method. Because this method was so short lived, the following discussion says no more about it.
- In MySQL 4.1.1, the hashing method was modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
```

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

To accommodate longer password hashes, the `Password` column in the `user` table was changed at this point to be 41 bytes, its current length.

A widened `Password` column can store password hashes in both the pre-4.1 and 4.1 formats. The format of any given hash value can be determined two ways:

- The length: 4.1 and pre-4.1 hashes are 41 and 16 bytes, respectively.
- Password hashes in the 4.1 format always begin with a “\*” character, whereas passwords in the pre-4.1 format never do.

To permit explicit generation of pre-4.1 password hashes, two additional changes were made:

- The `OLD_PASSWORD()` [1263] function was added, which returns hash values in the 16-byte format.
- For compatibility purposes, the `old_passwords` [517] system variable was added, to enable DBAs and applications control over the hashing method. The default `old_passwords` [517] value of 0 causes hashing to use the 4.1 method (41-byte hash values), but setting `old_passwords=1` [517] causes hashing to use the pre-4.1 method. In this case, `PASSWORD()` [1263] produces 16-byte values and is equivalent to `OLD_PASSWORD()` [1263]

To permit DBAs control over how clients are permitted to connect, the `secure_auth` [538] system variable was added. Starting the server with this variable disabled or enabled permits or prohibits clients to connect using the older pre-4.1 password hashing method. Before MySQL 5.6.5, `secure_auth` [538] is disabled by default. As of 5.6.5, `secure_auth` [538] is enabled by default to promote a more secure default configuration. (DBAs can disable it at their discretion, but this is not recommended.)

In addition, the `mysql` client supports a `--secure-auth` [253] option that is analogous to `secure_auth` [538], but from the client side. It can be used to prevent connections to less secure accounts that use pre-4.1 password hashing. This option is disabled by default before MySQL 5.6.7, enabled thereafter.

## Compatibility Issues Related to Hashing Methods

The widening of the `Password` column in MySQL 4.1 from 16 bytes to 41 bytes affects installation or upgrade operations as follows:

- If you perform a new installation of MySQL, the `Password` column is made 41 bytes long automatically.
- Upgrades from MySQL 4.1 or later to current versions of MySQL should not give rise to any issues in regard to the `Password` column because both versions use the same column length and password hashing method.
- For upgrades from a pre-4.1 release to 4.1 or later, you must upgrade the system tables after upgrading. (See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).)

The 4.1 hashing method is understood only by MySQL 4.1 (and newer) servers and clients, which can result in some compatibility problems. A 4.1 or newer client can connect to a pre-4.1 server, because the client understands both the pre-4.1 and 4.1 password hashing methods. However, a pre-4.1 client that attempts to connect to a 4.1 or newer server may run into difficulties. For example, a 4.0 `mysql` client may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

This phenomenon also occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or newer. (See [Section 21.9.12, “Common Problems with MySQL and PHP”](#).)

The following discussion describes the differences between the pre-4.1 and 4.1 hashing methods, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. (However, permitting connections by old clients is not recommended and should be avoided if possible.) Additional information can be found in [Section C.5.2.4, “Client does not support authentication protocol”](#). This information is of particular importance to PHP programmers migrating MySQL databases from versions older than 4.1 to 4.1 or higher.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
  - Pre-4.1 clients can connect, but because they know only about the pre-4.1 hashing method, they can authenticate only using accounts that have short hashes.
  - 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `old_passwords [517]` system variable. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and `old_passwords [517]` must not be set to 1.

Those conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using the `PASSWORD( ) [1263]` function or a password-generating statement. This is the behavior that occurs if you have upgraded from a version of MySQL older than 4.1 to 4.1 or later but have not yet run the `mysql_upgrade` program to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, the `PASSWORD( ) [1263]` function and password-generating statements generate long hashes unless the server was started with the `old_passwords [517]` system variable set to 1 to force the server to generate short password hashes instead.

The purpose of the `old_passwords [517]` system variable is to permit backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option does not affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that permitted to occur, the account could no longer be used by pre-4.1 clients. With `old_passwords [517]` disabled, the following undesirable scenario is possible:

- An old pre-4.1 client connects to an account that has a short password hash.

- The client changes its own password. With `old_passwords` [517] disabled, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the 4.1 hashing method during authentication. (Once an account has a long password hash in the user table, only 4.1 and later clients can authenticate for it because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is problematic to run a 4.1 or newer server without `old_passwords` [517] set to 1. By running the server with `old_passwords=1` [517], password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of `old_passwords=1` [517] is that any passwords created or changed use short hashes, even for 4.1 or later clients. Thus, you lose the additional security provided by long password hashes. To create an account that has a long hash (for example, for use by 4.1 clients) or to change an existing account to use a long password hash, an administrator can set the session value of `old_passwords` [517] set to 0 while leaving the global value set to 1:

```
mysql> SET @@session.old_passwords = 0;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@session.old_passwords, @@global.old_passwords;
+-----+-----+
| @@session.old_passwords | @@global.old_passwords |
+-----+-----+
| 0 | 1 |
+-----+-----+
1 row in set (0.00 sec)

mysql> CREATE USER 'newuser'@'localhost' IDENTIFIED BY 'newpass';
Query OK, 0 rows affected (0.03 sec)

mysql> SET PASSWORD FOR 'existinguser'@'localhost' = PASSWORD('existingpass');
Query OK, 0 rows affected (0.00 sec)
```

The following scenarios are possible in MySQL 4.1 or later. The factors are whether the `Password` column is short or long, and, if long, whether the server is started with `old_passwords` [517] enabled or disabled.

**Scenario 1:** Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving the `PASSWORD( )` [1263] function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.
- The value of `old_passwords` [517] is irrelevant because with a short `Password` column, the server generates only short password hashes anyway.

This scenario occurs when a pre-4.1 MySQL installation has been upgraded to 4.1 or later but `mysql_upgrade` has not been run to upgrade the system tables in the `mysql` database. (This is not a recommended configuration because it does not permit use of more secure 4.1 password hashing.)

**Scenario 2:** Long `Password` column; server started with `old_passwords=1` [517]:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only for accounts that have short hashes.

- For connected clients, password hash-generating operations involving the `PASSWORD()` [1263] function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, newly created accounts have short password hashes because `old_passwords=1` [517] prevents generation of long hashes. Also, if you create an account with a long hash before setting `old_passwords` [517] to 1, changing the account's password while `old_passwords=1` [517] results in the account being given a short password, causing it to lose the security benefits of a longer hash.

To create a new account that has a long password hash, or to change the password of any existing account to use a long hash, first set the session value of `old_passwords` [517] set to 0 while leaving the global value set to 1, as described previously.

In this scenario, the server has an up to date `Password` column, but is running with the default password hashing method set to generate pre-4.1 hash values. This is not a recommended configuration but may be useful during a transitional period in which pre-4.1 clients and passwords are upgraded to 4.1 or later. When that has been done, it is preferable to run the server with `old_passwords=0` [517] and `secure_auth=1` [538].

**Scenario 3:** Long `Password` column; server started with `old_passwords=0` [517]:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` [1263] function or password-generating statements use short hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using the `PASSWORD()` [1263] function or a password-generating statement results in the account being given a long password hash. From that point on, no pre-4.1 client can connect to the server using that account. The client must upgrade to 4.1 or later.

If this is a problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` [1263] function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` [1263] is useful for situations in which you explicitly want to generate a short hash.

The disadvantages for each of the preceding scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, `old_passwords=1` [517] prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes unless you take care to change the session value of `old_passwords` [517] to 0 first.

In scenario 3, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()` [1263].

The best way to avoid compatibility problems related to short password hashes is to not use them:

- Upgrade all client programs to MySQL 4.1 or later.
- Run the server with `old_passwords=0` [517].

- Reset the password for any account with a short password hash to use a long password hash.
- For additional security, run the server with `secure_auth=1` [538].

### 6.1.2.5. Implications of Password Hashing Changes in MySQL 4.1 for Application Programs

An upgrade to MySQL version 4.1 or later can cause compatibility issues for applications that use `PASSWORD()` [1263] to generate passwords for their own purposes. Applications really should not do this, because `PASSWORD()` [1263] should be used only to manage passwords for MySQL accounts. But some applications use `PASSWORD()` [1263] for their own purposes anyway.

If you upgrade to 4.1 or later from a pre-4.1 version of MySQL and run the server under conditions where it generates long password hashes, an application using `PASSWORD()` [1263] for its own passwords breaks. The recommended course of action in such cases is to modify the application to use another function, such as `SHA2()` [1264], `SHA1()` [1264], or `MD5()` [1263], to produce hashed values. If that is not possible, you can use the `OLD_PASSWORD()` [1263] function, which is provided for generate short hashes in the old format. However, you should note that `OLD_PASSWORD()` [1263] may one day no longer be supported.

If the server is running with `old_passwords=1` [517], it generates short hashes and `OLD_PASSWORD()` [1263] is equivalent to `PASSWORD()` [1263].

PHP programmers migrating their MySQL databases from version 4.0 or lower to version 4.1 or higher should see [Section 21.9, “MySQL PHP API”](#).

### 6.1.2.6. The Password Validation Plugin

The `validate_password` plugin (available as of MySQL 5.6.6) can be used to test passwords and improve security. This plugin implements two capabilities:

- In statements that assign a password supplied as a cleartext value, the value is checked against the current password policy and rejected if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD` [3714] error). This affects the `CREATE USER`, `GRANT`, and `SET PASSWORD` statements. Passwords given as arguments to the `PASSWORD()` [1263] and `OLD_PASSWORD()` [1263] functions are checked as well.
- The strength of potential passwords can be assessed using the `VALIDATE_PASSWORD_STRENGTH()` [1265] SQL function, which takes a password argument and returns an integer from 0 (weak) to 100 (strong).

For example, the cleartext password in the following statement is checked. Under the default password policy, which requires passwords to be at least 8 characters long, the password is weak and the statement produces an error:

```
mysql> SET PASSWORD = PASSWORD('abc');
ERROR 1819 (HY000): Your password does not satisfy the current policy
requirements
```

Passwords specified as already hashed values are not checked because the original password value is not available:

```
mysql> SET PASSWORD = '*0D3CED9BEC10A777AEC23CCC353A8C08A633045E';
Query OK, 0 rows affected (0.01 sec)
```

The parameters that control password checking are available as the values of the system variables having names of the form `validate_password_xxx`. These variables can be modified to configure password checking; see [Section 6.1.2.6.2, “Password Validation Plugin Options and Variables”](#).

The three levels of password checking are `LOW`, `MEDIUM`, and `STRONG`. The default is `MEDIUM`; to change this, modify the value of `validate_password_policy` [745]. The policies implement increasingly strict password tests. The following descriptions refer to default parameter values; these can be modified by changing the appropriate system variables.

- **LOW** policy tests password length only. Passwords must be at least 8 characters long.
- **MEDIUM** policy adds the conditions that passwords must contain at least 1 numeric character, 1 lowercase and uppercase character, and 1 special (nonalphanumeric) character.
- **STRONG** policy adds the condition that password substrings of length 4 or longer must not match words in the dictionary file, if one has been specified.

If the `validate_password` plugin is not installed, the `validate_password_xxx` system variables are not available, passwords in statements are not checked, and `VALIDATE_PASSWORD_STRENGTH()` [1265] always returns 0. For example, accounts can be assigned passwords shorter than 8 characters.

### 6.1.2.6.1. Password Validation Plugin Installation

The password-validation plugin is named `validate_password`. To be usable by the server, the plugin library object file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` [525] system variable). If necessary, set the value of `plugin_dir` [525] at server startup to tell the server the location of the plugin directory.

To load the plugin at server startup, use the `--plugin-load` [435] option to name the object file that contains the plugin. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in your `my.cnf` file:

```
[mysqld]
plugin-load=validate_password.so
```

If object files have a suffix different from `.so` on your system, substitute the correct suffix (for example, `.dll` on Windows).

Alternatively, to register the plugin at runtime, use this statement (changing the extension as necessary):

```
mysql> INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` table to cause the plugin to be loaded for each subsequent normal server startup.

If the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` [435], you can use the `--validate-password` option at server startup to control plugin activation. For example, to load the plugin and prevent it from being removed at runtime, use these options:

```
[mysqld]
plugin-load=validate_password.so
validate-password=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the password-validation plugin, use `--validate-password` [742] with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

For general information about installing plugins, see [Section 5.1.8, “Server Plugins”](#). To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

### 6.1.2.6.2. Password Validation Plugin Options and Variables

To control the activation of the `validate_password` plugin, use this option:

- `--validate-password[=value]` [742]

<b>Version Introduced</b>	5.6.6
---------------------------	-------

<b>Command-Line Format</b>	<code>--validate-password[=value]</code>
<b>Option-File Format</b>	<code>validate-password[=value]</code>
	<b>Permitted Values</b>
<b>Type</b>	enumeration
<b>Default</b>	ON
<b>Valid Values</b>	ON OFF FORCE FORCE_PLUS_PERMANENT

This option controls how the server loads the `validate_password` plugin at startup. The value should be one of those available for plugin-loading options, as described in [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#). For example, `--validate-password=FORCE_PLUS_PERMANENT` [742] tells the server to load the plugin and prevent it from being removed while the server is running.

This option is available only if the `validate_password` plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` [435]. See [Section 6.1.2.6.1, “Password Validation Plugin Installation”](#).

If the `validate_password` plugin is installed, it exposes several system variables that indicate the parameters that control password checking:

```
mysql> SHOW VARIABLES LIKE 'validate_password%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| validate_password_dictionary_file |      |
| validate_password_length | 8 |
| validate_password_mixed_case_count | 1 |
| validate_password_number_count | 1 |
| validate_password_policy | MEDIUM |
| validate_password_special_char_count | 1 |
+-----+-----+
```

To change how passwords are checked, you can set any of these variables at server startup, and most of them at runtime. The following list describes the meaning of each variable.

- `validate_password_dictionary_file` [743]

<b>Version Introduced</b>	5.6.6
<b>Variable Name</b>	<code>validate_password_dictionary_file</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
<b>Type</b>	file name

The path name of the dictionary file used by the `validate_password` plugin for checking passwords. This variable is unavailable unless that plugin is installed.

By default, this variable has an empty value and dictionary checks are not performed. To enable dictionary checks, you must set this variable to a nonempty value. If the file is named as a relative path, it is interpreted relative to the server data directory. Its contents should be lowercase, one word per line. Contents are treated as having a character set of `utf8`. The maximum permitted file size is 1MB.

For the dictionary file to be used during password checking, the password policy must be set to 2 (`STRONG`); see the description of the `validate_password_policy` [745] system variable. Assuming that is true, each substring of the password of length 4 up to 100 is compared to the words in the dictionary file. Any match causes the password to be rejected. Comparisons are not case sensitive.

For `VALIDATE_PASSWORD_STRENGTH()` [1265] the password is checked against all policies, including `STRONG`, so the strength assessment includes the dictionary check regardless of the `validate_password_policy` [745] value.

Changes to the dictionary file while the server is running require a restart for the server to recognize the changes.

- `validate_password_length` [744]

<b>Version Introduced</b>	5.6.6	
<b>Variable Name</b>	<code>validate_password_length</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	8
	<b>Min Value</b>	0

The minimum number of characters that passwords checked by the `validate_password` plugin must have. This variable is unavailable unless that plugin is installed.

The `validate_password_length` [744] minimum value is a function of several other related system variables. As of MySQL 5.6.10, the server will not set the value less than the value of this expression:

```
validate_password_number_count
+ validate_password_special_char_count
+ (2 * validate_password_mixed_case_count)
```

If the `validate_password` plugin adjusts the value of `validate_password_length` [744] due to the preceding constraint, it writes a message to the error log.

- `validate_password_mixed_case_count` [744]

<b>Version Introduced</b>	5.6.6	
<b>Variable Name</b>	<code>validate_password_mixed_case_count</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	1
	<b>Min Value</b>	0

The minimum number of lowercase and uppercase characters that passwords checked by the `validate_password` plugin must have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless that plugin is installed.

- [validate\\_password\\_number\\_count \[745\]](#)

<b>Version Introduced</b>	5.6.6	
<b>Variable Name</b>	<code>validate_password_number_count</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>
	<b>Min Value</b>	<code>0</code>

The minimum number of numeric (digit) characters that passwords checked by the `validate_password` plugin must have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless that plugin is installed.

- [validate\\_password\\_policy \[745\]](#)

<b>Version Introduced</b>	5.6.6	
<b>Variable Name</b>	<code>validate_password_policy</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>1</code>
	<b>Valid Values</b>	<code>0</code> <code>1</code> <code>2</code>

The password policy enforced by the `validate_password` plugin. This variable is unavailable unless that plugin is installed.

The `validate_password_policy [745]` value can be specified using numeric values 0, 1, 2, or the corresponding symbolic values `LOW`, `MEDIUM`, `STRONG`. The following table describes the tests performed for each policy. For the length test, the required length is the value of the `validate_password_length [744]` system variable. Similarly, the required values for the other tests are given by other `validate_password_xxx` variables.

Policy	Tests Performed
<code>0</code> or <code>LOW</code>	Length
<code>1</code> or <code>MEDIUM</code>	Length; numeric, lowercase/uppercase, and special characters
<code>2</code> or <code>STRONG</code>	Length; numeric, lowercase/uppercase, and special characters; dictionary file

**Note**

Before MySQL 5.6.10, `validate_password_policy` was named `validate_password_policy_number`.

- [validate\\_password\\_special\\_char\\_count \[745\]](#)

<b>Version Introduced</b>	5.6.6	
<b>Variable Name</b>	<code>validate_password_special_char_count</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>
	<b>Min Value</b>	<code>0</code>

The minimum number of nonalphanumeric characters that passwords checked by the `validate_password` plugin must have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless that plugin is installed.

### 6.1.3. Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See [Section 6.1.2.4, “Password Hashing in MySQL”](#), for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See [Section 6.3.9, “Using SSL for Secure Connections”](#). Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at <http://www.openssh.org/>, and a commercial SSH client at <http://www.ssh.com/>.

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

For a discussion of methods for setting passwords, see [Section 6.3.5, “Assigning Account Passwords”](#).

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.
- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE [754]` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root [446]` option.

`mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts.*

- Do not grant the [FILE \[754\]](#) privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. This includes the server's data directory containing the files that implement the privilege tables. To make [FILE \[754\]](#)-privilege operations a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The [FILE \[754\]](#) privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the [secure\\_file\\_priv \[538\]](#) system to a specific directory. See [Section 5.1.4, “Server System Variables”](#).

- Do not grant the [PROCESS \[755\]](#) or [SUPER \[756\]](#) privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

`mysqld` reserves an extra connection for users who have the [SUPER \[756\]](#) privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The [SUPER \[756\]](#) privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links [441]` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See [Section 8.11.3.1.2, “Using Symbolic Links for MyISAM Tables on Unix”](#).
- Stored programs and views should be written using the security guidelines discussed in [Section 18.6, “Access Control for Stored Programs and Views”](#).
- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.
- If you want to restrict the number of connections permitted to a single account, you can do so by setting the [max\\_user\\_connections \[509\]](#) variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use permitted to an account. See [Section 13.7.1.4, “GRANT Syntax”](#).
- If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making [plugin\\_dir \[525\]](#) read only to the server or by setting `--secure-file-priv [438]` to a directory where `SELECT` writes can be made safely.

## 6.1.4. Security-Related `mysqld` Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions of each of these, see [Section 5.1.3, “Server Command Options”](#), and [Section 5.1.4, “Server System Variables”](#).

**Table 6.1. Security Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">allow-suspicious-udfs [413]</a>	Yes	Yes				
<a href="#">automatic_sp_privileges [464]</a>			Yes		Global	Yes
<a href="#">chroot [417]</a>	Yes	Yes				
<a href="#">des-key-file [421]</a>	Yes	Yes				
<a href="#">local_infile [496]</a>			Yes		Global	Yes
<a href="#">old_passwords [517]</a>			Yes		Both	Yes
<a href="#">safe-user-create [438]</a>	Yes	Yes				
<a href="#">secure-auth [438]</a>	Yes	Yes			Global	Yes
- Variable: secure_auth			Yes		Global	Yes
<a href="#">secure-file-priv [438]</a>	Yes	Yes			Global	No
- Variable: secure_file_priv			Yes		Global	No
<a href="#">skip-grant-tables [439]</a>	Yes	Yes				
<a href="#">skip-name-resolve [440]</a>	Yes	Yes			Global	No
- Variable: skip_name_resolve			Yes		Global	No
<a href="#">skip-networking [440]</a>	Yes	Yes			Global	No
- Variable: skip_networking			Yes		Global	No
<a href="#">skip-show-database [441]</a>	Yes	Yes			Global	No
- Variable: skip_show_database			Yes		Global	No

## 6.1.5. How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` [446] option. `mysqld` starts up, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL `root` accounts in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` [254] option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See [Section 2.10, "Postinstallation Setup and Testing"](#).

### 6.1.6. Security Issues with `LOAD DATA LOCAL`

The `LOAD DATA` statement can load a file that is located on the server host, or it can load a file that is located on the client host when the `LOCAL` keyword is specified.

There are two potential security issues with supporting the `LOCAL` version of `LOAD DATA` statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access.
- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the remote program being run by the user who connects to the Web server.

To deal with these problems, we changed how `LOAD DATA LOCAL` is handled as of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows):

- By default, all MySQL clients and libraries in binary distributions are compiled with the `-DENABLED_LOCAL_INFILE=1` [135] option, to be compatible with MySQL 3.23.48 and before.
- If you build MySQL from source but do not invoke `CMake` with the `-DENABLED_LOCAL_INFILE=1` [135] option, `LOAD DATA LOCAL` cannot be used by any client unless it is written explicitly to invoke `mysql_options(... MYSQL_OPT_LOCAL_INFILE, 0)`. See [Section 21.8.6.49, "mysql\\_options\(\)"](#).
- You can disable all `LOAD DATA LOCAL` statements from the server side by starting `mysqld` with the `--local-infile=0` [496] option.
- For the `mysql` command-line client, enable `LOAD DATA LOCAL` by specifying the `--local-infile[=1]` [250] option, or disable it with the `--local-infile=0` [250] option. For

`mysqlimport`, local data file loading is off by default; enable it with the `--local [300]` or `-L` option. In any case, successful use of a local load operation requires that the server permits it.

- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add the `local-infile=1` option to that group. However, to keep this from causing problems for programs that do not understand `local-infile`, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=1
```

- If `LOAD DATA LOCAL` is disabled, either in the server or the client, a client that attempts to issue such a statement receives the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

## 6.1.7. Client Programming Security Guidelines

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like “`;
