DROP DATABASE mysql;`”. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See [Section 5.1.7, “Server SQL Modes”](#).
- Try to enter single and double quotation marks (“’” and “””) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22` (“”), `%23` (“#”), and `%27` (“’”) to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL C API: Use the `mysql_real_escape_string()` API call.
- MySQL++: Use the `escape` and `quote` modifiers for query streams.
- PHP: Use either the `mysqli` or `pdo_mysql` extensions, and not the older `ext/mysql` extension. The preferred API's support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also [Section 21.9.1.3, "Choosing an API"](#).

If the older `ext/mysql` extension must be used, then for escaping use the `mysql_real_escape_string()` function and not `mysql_escape_string()` or `addslashes()` because only `mysql_real_escape_string()` is character set-aware; the other functions can be "bypassed" when using (invalid) multi-byte character sets.

- Perl DBI: Use placeholders or the `quote()` method.
- Ruby DBI: Use placeholders or the `quote()` method.
- Java JDBC: Use a `PreparedStatement` object and placeholders.

Other programming interfaces might have similar capabilities.

## 6.2. The MySQL Access Privilege System

The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as `LOAD DATA INFILE` and administrative operations.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

The user interface to the MySQL privilege system consists of SQL statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See [Section 13.7.1, "Account Management Statements"](#).

Internally, the server stores privilege information in the grant tables of the `mysql` database (that is, in the database named `mysql`). The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the user name you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by `joe` from `office.example.com`, and a different set of privileges for connections by `joe` from

`home.example.com`. To see what privileges a given account has, use the `SHOW GRANTS` statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

MySQL access control involves two stages when you run a client program that connects to the server:

**Stage 1:** The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

**Stage 2:** Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the `SELECT` [755] privilege for the table or the `DROP` [754] privilege for the database.

For a more detailed description of what happens during each stage, see [Section 6.2.4, “Access Control, Stage 1: Connection Verification”](#), and [Section 6.2.5, “Access Control, Stage 2: Request Verification”](#).

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see [Section 6.2.6, “When Privilege Changes Take Effect”](#).

For general security-related advice, see [Section 6.1, “General Security Issues”](#). For help in diagnosing privilege-related problems, see [Section 6.2.7, “Causes of Access-Denied Errors”](#).

## 6.2.1. Privileges Provided by MySQL

MySQL provides privileges that apply in different contexts and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases).

Information about account privileges is stored in the `user`, `db`, `tables_priv`, `columns_priv`, and `procs_priv` tables in the `mysql` database (see [Section 6.2.2, “Privilege System Grant Tables”](#)). The MySQL server reads the contents of these tables into memory when it starts and reloads them under the circumstances indicated in [Section 6.2.6, “When Privilege Changes Take Effect”](#). Access-control decisions are based on the in-memory copies of the grant tables.

Some releases of MySQL introduce changes to the structure of the grant tables to add new access privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

The following table shows the privilege names used at the SQL level in the `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

**Table 6.2. Permissible Privileges for `GRANT` and `REVOKE`**

Privilege	Column	Context
<code>CREATE</code> [754]	<code>Create_priv</code>	databases, tables, or indexes

Privilege	Column	Context
DROP [754]	Drop_priv	databases, tables, or views
GRANT OPTION [755]	Grant_priv	databases, tables, or stored routines
LOCK TABLES [755]	Lock_tables_priv	databases
REFERENCES [755]	References_priv	databases or tables
EVENT [754]	Event_priv	databases
ALTER [753]	Alter_priv	tables
DELETE [754]	Delete_priv	tables
INDEX [755]	Index_priv	tables
INSERT [755]	Insert_priv	tables or columns
SELECT [755]	Select_priv	tables or columns
UPDATE [756]	Update_priv	tables or columns
CREATE TEMPORARY TABLES [754]	Create_tmp_table_priv	tables
TRIGGER [756]	Trigger_priv	tables
CREATE VIEW [754]	Create_view_priv	views
SHOW VIEW [756]	Show_view_priv	views
ALTER ROUTINE [754]	Alter_routine_priv	stored routines
CREATE ROUTINE [754]	Create_routine_priv	stored routines
EXECUTE [754]	Execute_priv	stored routines
FILE [754]	File_priv	file access on server host
CREATE TABLESPACE [754]	Create_tablespace_priv	server administration
CREATE USER [754]	Create_user_priv	server administration
PROCESS [755]	Process_priv	server administration
PROXY [755]	see proxies_priv table	server administration
RELOAD [755]	Reload_priv	server administration
REPLICATION CLIENT [755]	Repl_client_priv	server administration
REPLICATION SLAVE [755]	Repl_slave_priv	server administration
SHOW DATABASES [756]	Show_db_priv	server administration
SHUTDOWN [756]	Shutdown_priv	server administration
SUPER [756]	Super_priv	server administration
ALL [PRIVILEGES] [753]		server administration
USAGE [756]		server administration

The following list provides a general description of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- The `ALL [753]` or `ALL PRIVILEGES [753]` privilege specifier is shorthand. It stands for “all privileges available at a given privilege level” (except `GRANT OPTION [755]`). For example, granting `ALL [753]` at the global or table level grants all global privileges or all table-level privileges.
- The `ALTER [753]` privilege enables use of `ALTER TABLE` to change the structure of tables. `ALTER TABLE` also requires the `CREATE [754]` and `INSERT [755]` privileges. Renaming a table

requires `ALTER` [753] and `DROP` [754] on the old table, `ALTER` [753], `CREATE` [754], and `INSERT` [755] on the new table.

- The `ALTER ROUTINE` [754] privilege is needed to alter or drop stored routines (procedures and functions).
- The `CREATE` [754] privilege enables creation of new databases and tables.
- The `CREATE ROUTINE` [754] privilege is needed to create stored routines (procedures and functions).
- The `CREATE TABLESPACE` [754] privilege is needed to create, alter, or drop tablespaces and log file groups.
- The `CREATE TEMPORARY TABLES` [754] privilege enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.

As of MySQL 5.6.3, after a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` [754] privilege but is able to execute a `DEFINER`-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` [754] and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

Before MySQL 5.6.3, other operations on a temporary table, such as `INSERT`, `UPDATE`, or `SELECT`, require additional privileges for those operations for the database containing the temporary table, or for the nontemporary table of the same name.

To keep privileges for temporary and nontemporary tables separate, a common workaround for this situation is to create a database dedicated to the use of temporary tables. Then for that database, a user can be granted the `CREATE TEMPORARY TABLES` [754] privilege, along with any other privileges required for temporary table operations done by that user.

- The `CREATE USER` [754] privilege enables use of `CREATE USER`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES`.
- The `CREATE VIEW` [754] privilege enables use of `CREATE VIEW`.
- The `DELETE` [754] privilege enables rows to be deleted from tables in a database.
- The `DROP` [754] privilege enables you to drop (remove) existing databases, tables, and views. The `DROP` [754] privilege is required in order to use the statement `ALTER TABLE ... DROP PARTITION` on a partitioned table. The `DROP` [754] privilege is also required for `TRUNCATE TABLE`. *If you grant the `DROP` [754] privilege for the `mysql` database to a user, that user can drop the database in which the MySQL access privileges are stored.*
- The `EVENT` [754] privilege is required to create, alter, drop, or see events for the Event Scheduler.
- The `EXECUTE` [754] privilege is required to execute stored routines (procedures and functions).
- The `FILE` [754] privilege gives you permission to read and write files on the server host using the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` [1181] function. A user who has the `FILE` [754] privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The `FILE` [754] privilege also enables the user to create new files in any directory where the MySQL server has write access.

This includes the server's data directory containing the files that implement the privilege tables. As a security measure, the server will not overwrite existing files.

To limit the location in which files can be read and written, set the `secure_file_priv` [538] system to a specific directory. See [Section 5.1.4, “Server System Variables”](#).

- The `GRANT OPTION` [755] privilege enables you to give to other users or remove from other users those privileges that you yourself possess.
- The `INDEX` [755] privilege enables you to create or drop (remove) indexes. `INDEX` [755] applies to existing tables. If you have the `CREATE` [754] privilege for a table, you can include index definitions in the `CREATE TABLE` statement.
- The `INSERT` [755] privilege enables rows to be inserted into tables in a database. `INSERT` [755] is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.
- The `LOCK TABLES` [755] privilege enables the use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` [755] privilege. This includes the use of write locks, which prevents other sessions from reading the locked table.
- The `PROCESS` [755] privilege pertains to display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of `SHOW PROCESSLIST` or `mysqladmin processlist` to see threads belonging to other accounts; you can always see your own threads.
- The `PROXY` [755] privilege enables a user to impersonate or become known as another user. See [Section 6.3.8, “Proxy Users”](#).
- The `REFERENCES` [755] privilege currently is unused.
- The `RELOAD` [755] privilege enables use of the `FLUSH` statement. It also enables `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

- The `REPLICATION CLIENT` [755] privilege enables the use of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. In MySQL 5.6.6 and later, it also enables the use of the `SHOW BINARY LOGS` statement.
- The `REPLICATION SLAVE` [755] privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server.
- The `SELECT` [755] privilege enables you to select rows from tables in a database. `SELECT` statements require the `SELECT` [755] privilege only if they actually retrieve rows from a table. Some `SELECT` statements do not access tables and can be executed without permission for any database. For example, you can use `SELECT` as a simple calculator to evaluate expressions that make no reference to tables:

```
SELECT 1+1;
SELECT PI()*2;
```

The `SELECT` [755] privilege is also needed for other statements that read column values. For example, `SELECT` [755] is needed for columns referenced on the right hand side of `col_name=expr` assignment in `UPDATE` statements or for columns named in the `WHERE` clause of `DELETE` or `UPDATE` statements.

- The `SHOW DATABASES` [756] privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` [441] option. Note that *any* global privilege is a privilege for the database.
- The `SHOW VIEW` [756] privilege enables use of `SHOW CREATE VIEW`.
- The `SHUTDOWN` [756] privilege enables use of the `mysqladmin shutdown` command. There is no corresponding SQL statement.
- The `SUPER` [756] privilege enables an account to use `CHANGE MASTER TO`, `KILL` or `mysqladmin kill` to kill threads belonging to other accounts (you can always kill your own threads), `PURGE BINARY LOGS`, configuration changes using `SET GLOBAL` to modify global system variables, the `mysqladmin debug` command, enabling or disabling logging, performing updates even if the `read_only` [532] system variable is enabled, starting and stopping replication on slave servers, specification of any account in the `DEFINER` attribute of stored programs and views, and enables you to connect (once) even if the connection limit controlled by the `max_connections` [503] system variable is reached.

To create or alter stored functions if binary logging is enabled, you may also need the `SUPER` [756] privilege, as described in [Section 18.7, “Binary Logging of Stored Programs”](#).

- The `TRIGGER` [756] privilege enables trigger operations. You must have this privilege for a table to create, drop, or execute triggers for that table.
- The `UPDATE` [756] privilege enables rows to be updated in tables in a database.
- The `USAGE` [756] privilege specifier stands for “no privileges.” It is used at the global level with `GRANT` to modify account attributes such as resource limits or SSL characteristics without affecting existing account privileges.

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the `FILE` [754] and administrative privileges:

- The `FILE` [754] privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.
- The `GRANT OPTION` [755] privilege enables users to give their privileges to other users. Two users that have different privileges and with the `GRANT OPTION` [755] privilege are able to combine privileges.
- The `ALTER` [753] privilege may be used to subvert the privilege system by renaming tables.
- The `SHUTDOWN` [756] privilege can be abused to deny service to other users entirely by terminating the server.
- The `PROCESS` [755] privilege can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- The `SUPER` [756] privilege can be used to terminate other sessions or change how the server operates.
- Privileges granted for the `mysql` database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the `user` table `Password` column can change an account's password, and then connect to the MySQL server using that account.

## 6.2.2. Privilege System Grant Tables

Normally, you manipulate the contents of the grant tables in the `mysql` database indirectly by using statements such as `GRANT` and `REVOKE` to set up accounts and control the privileges available to

each one. See [Section 13.7.1, “Account Management Statements”](#). The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

These `mysql` database tables contain grant information:

- `user`: Contains user accounts, global privileges, and other non-privilege columns.
- `db`: Contains database-level privileges.
- `host`: Obsolete. New MySQL installations no longer create this table as of MySQL 5.6.7.
- `tables_priv`: Contains table-level privileges.
- `columns_priv`: Contains column-level privileges.
- `procs_priv`: Contains stored procedure and function privileges.
- `proxies_priv`: Contains proxy-user privileges.

Other tables in the `mysql` database do not hold grant information and are discussed elsewhere:

- `event`: Contains information about Event Scheduler events: See [Section 18.4, “Using the Event Scheduler”](#).
- `func`: Contains information about user-defined functions: See [Section 22.3, “Adding New Functions to MySQL”](#).
- `help_xxx`: These tables are used for server-side help: See [Section 5.1.10, “Server-Side Help”](#).
- `plugin`: Contains information about server plugins: See [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#), and [Section 22.2, “The MySQL Plugin API”](#).
- `proc`: Contains information about stored procedures and functions: See [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#).
- `servers`: Used by the `FEDERATED` storage engine: See [Section 14.9.2.2, “Creating a FEDERATED Table Using CREATE SERVER”](#).
- `time_zone_xxx`: These tables contain time zone information: See [Section 10.6, “MySQL Server Time Zone Support”](#).
- Tables with `_log` in their name are used for logging: See [Section 5.2, “MySQL Server Logs”](#).

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row (entry) in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of `'thomas.loc.gov'` and `'bob'` would be used for authenticating connections made to the server from the host `thomas.loc.gov` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of `'thomas.loc.gov'`, `'bob'` and `'reports'` would be used when `bob` connects from the host `thomas.loc.gov` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.
- Privilege columns indicate which privileges are granted by a table row; that is, what operations can be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. [Section 6.2.5, “Access Control, Stage 2: Request Verification”](#), describes the rules that are used to do this.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user's global privileges. Any privilege granted in this table applies to *all* databases on the server.

**Note**

Because any global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`.

- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine which operations are permitted. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.
- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.
- The `procs_priv` table applies to stored routines. A privilege granted at the routine level applies only to a single routine.
- The `proxies_priv` table indicates which users can act as proxies for other users and whether proxy users can grant the `PROXY [755]` privilege to other users.

The server uses the `user` and `db` tables in the `mysql` database at both the first and second stages of access control (see Section 6.2, “The MySQL Access Privilege System”). The columns in the `user` and `db` tables are shown here.

**Table 6.3. `user` and `db` Table Columns**

Table Name	<code>user</code>	<code>db</code>
<b>Scope columns</b>	Host	Host
	User	Db
	Password	User
<b>Privilege columns</b>	Select_priv	Select_priv
	Insert_priv	Insert_priv
	Update_priv	Update_priv
	Delete_priv	Delete_priv
	Index_priv	Index_priv
	Alter_priv	Alter_priv
	Create_priv	Create_priv
	Drop_priv	Drop_priv
	Grant_priv	Grant_priv
	Create_view_priv	Create_view_priv
	Show_view_priv	Show_view_priv
	Create_routine_priv	Create_routine_priv
	Alter_routine_priv	Alter_routine_priv
	Execute_priv	Execute_priv
	Trigger_priv	Trigger_priv
	Event_priv	Event_priv
	Create_tmp_table_priv	Create_tmp_table_priv

Table Name	user	db
	Lock_tables_priv	Lock_tables_priv
	References_priv	References_priv
	Reload_priv	
	Shutdown_priv	
	Process_priv	
	File_priv	
	Show_db_priv	
	Super_priv	
	Repl_slave_priv	
	Repl_client_priv	
	Create_user_priv	
	Create_tablespace_priv	
<b>Security columns</b>	ssl_type	
	ssl_cipher	
	x509_issuer	
	x509_subject	
	plugin	
	authentication_string	
	password_expired	
<b>Resource control columns</b>	max_questions	
	max_updates	
	max_connections	
	max_user_connections	

The `mysql.user` table `plugin` and `authentication_string` columns store authentication plugin information.

If the `plugin` column for an account row is empty, the server uses native authentication for connection attempts for the account: Clients must match the password in the `Password` column of the account row.

If an account row names a plugin in the `plugin` column, the server uses it to authenticate connection attempts for the account. Whether the plugin uses the value in the `Password` column is up to the plugin.

The `password_expired` column was added in MySQL 5.6.6 to permit DBAs to expire account passwords and require users to reset their password. The default `password_expired` value is 'N', but can be set to 'Y' with the `ALTER USER` statement. After an account's password has been expired, all operations performed by the account in subsequent connections to the server result in an error until the user issues a `SET PASSWORD` statement to establish a new account password. See [Section 13.7.1.1, "ALTER USER Syntax"](#).

It is possible after password expiration to "reset" a password by using `SET PASSWORD` to set it to its current value. As a matter of good policy, it is preferable to choose a different password.

**Caution**

In MySQL 5.6.6, `ALTER USER` also sets the `Password` column to the empty string, so do not use this statement until 5.6.7.

During the second stage of access control, the server performs request verification to make sure that each client has sufficient privileges for each request that it issues. In addition to the `user` and `db` grant tables, the server may also consult the `tables_priv` and `columns_priv` tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

**Table 6.4. `tables_priv` and `columns_priv` Table Columns**

Table Name	<code>tables_priv</code>	<code>columns_priv</code>
<b>Scope columns</b>	<code>Host</code>	<code>Host</code>
	<code>Db</code>	<code>Db</code>
	<code>User</code>	<code>User</code>
	<code>Table_name</code>	<code>Table_name</code>
		<code>Column_name</code>
<b>Privilege columns</b>	<code>Table_priv</code>	<code>Column_priv</code>
	<code>Column_priv</code>	
<b>Other columns</b>	<code>Timestamp</code>	<code>Timestamp</code>
	<code>Grantor</code>	

The `Timestamp` and `Grantor` columns are set to the current timestamp and the `CURRENT_USER` [1267] value, respectively. However, they are unused and are discussed no further here.

For verification of requests that involve stored routines, the server may consult the `procs_priv` table, which has the columns shown in the following table.

**Table 6.5. `procs_priv` Table Columns**

Table Name	<code>procs_priv</code>
<b>Scope columns</b>	<code>Host</code>
	<code>Db</code>
	<code>User</code>
	<code>Routine_name</code>
	<code>Routine_type</code>
<b>Privilege columns</b>	<code>Proc_priv</code>
<b>Other columns</b>	<code>Timestamp</code>
	<code>Grantor</code>

The `Routine_type` column is an `ENUM` column with values of `'FUNCTION'` or `'PROCEDURE'` to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns currently are unused and are discussed no further here.

The `proxies_priv` table records information about proxy users. It has these columns:

- `Host`, `User`: These columns indicate the user account that has the `PROXY` [755] privilege for the proxied account.
- `Proxied_host`, `Proxied_user`: These columns indicate the account of the proxied user.
- `Grantor`: Currently unused.
- `Timestamp`: Currently unused.

- `With_grant`: This column indicates whether the proxy account can grant the `PROXY` [755] privilege to other accounts.

Scope columns in the grant tables contain strings. They are declared as shown here; the default value for each is the empty string.

**Table 6.6. Grant Table Scope Column Types**

Column Name	Type
<code>Host, Proxied_host</code>	<code>CHAR(60)</code>
<code>User, Proxied_user</code>	<code>CHAR(16)</code>
<code>Password</code>	<code>CHAR(41)</code>
<code>Db</code>	<code>CHAR(64)</code>
<code>Table_name</code>	<code>CHAR(64)</code>
<code>Column_name</code>	<code>CHAR(64)</code>
<code>Routine_name</code>	<code>CHAR(64)</code>

For access-checking purposes, comparisons of `User`, `Proxied_user`, `Password`, `Db`, and `Table_name` values are case sensitive. Comparisons of `Host`, `Proxied_host`, `Column_name`, and `Routine_name` values are not case sensitive.

In the `user` and `db` tables, each privilege is listed in a separate column that is declared as `ENUM('N', 'Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

In the `tables_priv`, `columns_priv`, and `procs_priv` tables, the privilege columns are declared as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

**Table 6.7. Set-Type Privilege Column Values**

Table Name	Column Name	Possible Set Elements
<code>tables_priv</code>	<code>Table_priv</code>	<code>'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'</code>
<code>tables_priv</code>	<code>Column_priv</code>	<code>'Select', 'Insert', 'Update', 'References'</code>
<code>columns_priv</code>	<code>Column_priv</code>	<code>'Select', 'Insert', 'Update', 'References'</code>
<code>procs_priv</code>	<code>Proc_priv</code>	<code>'Execute', 'Alter Routine', 'Grant'</code>

Administrative privileges (such as `RELOAD` [755] or `SHUTDOWN` [756]) are specified only in the `user` table. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, to determine whether you can perform an administrative operation, the server need consult only the `user` table.

The `FILE` [754] privilege also is specified only in the `user` table. It is not an administrative privilege as such, but your ability to read or write files on the server host is independent of the database you are accessing.

The `mysqld` server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in Section 6.2.6, “When Privilege Changes Take Effect”.

When you modify an account's privileges, it is a good idea to verify that the changes set up privileges the way you want. To check the privileges for a given account, use the `SHOW GRANTS` statement (see [Section 13.7.5.22, "SHOW GRANTS Syntax"](#)). For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

### 6.2.3. Specifying Account Names

MySQL account names consist of a user name and a host name. This enables creation of accounts for users with the same name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

In SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, write account names using the following rules:

- Syntax for account names is `'user_name'@'host_name'`.
- An account name consisting only of a user name is equivalent to `'user_name'@'%'`. For example, `'me'` is equivalent to `'me'@'%'`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a `user_name` string containing special characters (such as `"-`"), or a `host_name` string containing special characters or wildcard characters (such as `"%"`); for example, `'test-user'@'%.com'`.
- Quote user names and host names as identifiers or as strings, using either backticks (`"`"`), single quotation marks (`"'"`), or double quotation marks (`""`).
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`; the latter is interpreted as `'me@localhost'@'%'`.
- A reference to the `CURRENT_USER [1267]` or `CURRENT_USER() [1267]` function is equivalent to specifying the current client's user name and host name literally.

MySQL stores account names in grant tables in the `mysql` database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.

For additional detail about grant table structure, see [Section 6.2.2, "Privilege System Grant Tables"](#).

User names and host names have certain special values or wildcard conventions, as described following.

A user name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `'@'localhost'`.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name `'localhost'` indicates the local host. The IP address `'127.0.0.1'` indicates the IPv4 loopback interface. The IP address `:::1` indicates the IPv6 loopback interface.
- You can use the wildcard characters `"%"` and `"_"` in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the `LIKE [1190]` operator.

For example, a host value of `'%'` matches any host name, whereas a value of `'%.mysql.com'` matches any host in the `mysql.com` domain. `'192.168.1.%'` matches any host in the 192.168.1 class C network.

Because you can use IP wildcard values in host values (for example, `'192.168.1.%'` to match every host on a subnet), someone could try to exploit this capability by naming a host `192.168.1.somewhere.com`. To foil such attempts, MySQL disallows matching on host names that start with digits and a dot. Thus, if you have a host named something like `1.2.example.com`, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, you can specify a netmask indicating how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'192.58.197.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP address `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 192.58.197.0
```

IP addresses that satisfy this condition and can connect to the MySQL server are those in the range from `192.58.197.0` to `192.58.197.255`.

The netmask can only be used to tell the server to use 8, 16, 24, or 32 bits of the address. Examples:

- `192.0.0.0/255.0.0.0`: Any host on the 192 class A network
- `192.168.0.0/255.255.0.0`: Any host on the 192.168 class B network
- `192.168.1.0/255.255.255.0`: Any host on the 192.168.1 class C network
- `192.168.1.1`: Only the host with this specific IP address

The following netmask will not work because it masks 28 bits, and 28 is not a multiple of 8:

```
192.168.0.1/255.255.255.240
```

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, this comparison is performed as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. But if DNS returns just `host1`, use `host1` instead.
- If DNS returns the IP address for a given host as `192.168.1.2`, that will match an account host value of `192.168.1.2` but not `192.168.01.2`. Similarly, it will match an account host pattern like `192.168.1.%` but not `192.168.01.%`.

To avoid problems like this, it is advisable to check the format in which your DNS returns host names and addresses, and use values in the same format in MySQL account names.

## 6.2.4. Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the server denies access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

Identity checking is performed using the three `user` table scope columns (`Host`, `User`, and `Password`). The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name and the client supplies the password specified in that row. The rules for permissible `Host` and `User` values are given in [Section 6.2.3, “Specifying Account Names”](#).

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `Password` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the `Password` column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank `Password` values in the `user` table represent encrypted passwords. MySQL does not store passwords in plaintext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the `PASSWORD()` [1263] function). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See [Section 6.3.1, “User Names and Passwords”](#).

From MySQL's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give nonadministrative users read access to tables in the `mysql` database*.

The following table shows how various combinations of `Host` and `User` values in the `user` table apply to incoming connections.

Host Value	User Value	Permissible Connections
'thomas.loc.gov'	'fred'	fred, connecting from thomas.loc.gov
'thomas.loc.gov'	' '	Any user, connecting from thomas.loc.gov
'%'	'fred'	fred, connecting from any host
'%'	' '	Any user, connecting from any host
'%.loc.gov'	'fred'	fred, connecting from any host in the loc.gov domain
'x.y.%'	'fred'	fred, connecting from x.y.net, x.y.com, x.y.edu, and so on; this is probably not useful
'144.155.166.177'	'fred'	fred, connecting from the host with IP address 144.155.166.177
'144.155.166.%'	'fred'	fred, connecting from any host in the 144.155.166 class C subnet
'144.155.166.0/255.255.255.0'	'fred'	Same as previous example

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `thomas.loc.gov` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific `Host` values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so `192.168.1.13` and `192.168.1.0/255.255.255.0` are considered equally specific.) The pattern `'%'` means “any host” and is least specific. The empty string `' '` also means “any host” but sorts after `'%'`. Rows with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means “any user” and is least specific).

To see how this works, suppose that the `user` table looks like this:

```
+-----+-----+
| Host      | User      | ...
+-----+-----+
| %         | root      | ...
| %         | jeffrey   | ...
| localhost | root      | ...
| localhost |           | ...
+-----+-----+
```

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

```
+-----+-----+
| Host      | User      | ...
+-----+-----+
| localhost | root      | ...
| localhost |           | ...
| %         | jeffrey   | ...
| %         | root      | ...
+-----+-----+
```

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of `'localhost'` and `' '`, and the one with values of `'%'` and `'jeffrey'`. The `'localhost'` row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

```
+-----+-----+
| Host      | User      | ...
+-----+-----+
| %         | jeffrey   | ...
| thomas.loc.gov |         | ...
+-----+-----+
```

The sorted table looks like this:

```
+-----+-----+
| Host      | User      | ...
+-----+-----+
| thomas.loc.gov |         | ...
| %         | jeffrey   | ...
+-----+-----+
```

A connection by `jeffrey` from `thomas.loc.gov` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

#### Note

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `thomas.loc.gov` by `jeffrey` is first matched not by the row containing `'jeffrey'` as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` [1267] function. (See [Section 12.14, “Information Functions”](#).) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| @localhost     |
+-----+
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

## 6.2.5. Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to [Section 6.2.2, “Privilege System Grant Tables”](#), which lists the columns present in each of the grant tables.)

The `user` table grants privileges that are assigned to you on a global basis and that apply no matter what the default database is. For example, if the `user` table grants you the `DELETE` [754] privilege, you can delete rows from any table in any database on the server host! It is wise to grant privileges in the `user` table only to people who need them, such as database administrators. For other users, you should leave all privileges in the `user` table set to `'N'` and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, columns, or routines.

The `db` table grants database-specific privileges. Values in the scope columns of this table can take the following forms:

- A blank `User` value matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters `“%”` and `“_”` can be used in the `Host` and `Db` columns. These have the same meaning as for pattern-matching operations performed with the `LIKE` [1190] operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (`“_”`) as part of a database name, specify it as `“\_”` in the `GRANT` statement.
- A `'%'` or blank `Host` value means “any host.”
- A `'%'` or blank `Db` value means “any database.”

The server reads the `db` table into memory and sorts it at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching entries, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters “%” and “\_” can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` [1190] operator.
- A ‘%’ or blank `Host` value means “any host.”
- The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` [756] or `RELOAD` [755], the server checks only the `user` table row because that is the only table that specifies administrative privileges. The server grants access if the row permits the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row does not grant the `SHUTDOWN` [756] privilege to you, the server denies access without even checking the `db` table. (It contains no `Shutdown_priv` column, so there is no need to do so.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global privileges by looking in the `user` table row. If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges by checking the `db` table:

The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.

After determining the database-specific privileges granted by the `db` table entries, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global `user` row privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` [755] and the `SELECT` [755] privileges. Your privileges might be such that the `user` table row grants one privilege and the `db` table row grants the other. In this case, you have the necessary privileges to perform the

request, but the server cannot tell that from either table by itself; the privileges granted by the entries in both tables must be combined.

## 6.2.6. When Privilege Changes Take Effect

When `mysqld` starts, it reads all grant table contents into memory. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using account-management statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, or `RENAME USER`, the server notices these changes and loads the grant tables into memory again immediately.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE`, your changes have no effect on privilege checking until you either restart the server or tell it to reload the tables. If you change the grant tables directly but forget to reload them, your changes have *no effect* until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client connection as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

### Note

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database or flushing the privileges.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only for subsequent connections.

If the server is started with the `--skip-grant-tables` [439] option, it does not read the grant tables or implement any access control. Anyone can connect and do anything, *which is insecure*. To cause a server thus started to read the tables and enable access checking, flush the privileges.

## 6.2.7. Causes of Access-Denied Errors

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` [211] option to indicate the proper port number, or a `--socket` [211] option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
shell> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking` [440], it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1` [414], it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.
- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.
- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the `mysql` database containing the grant tables. For distributions that do not do this, you must initialize the grant tables manually by running the `mysql_install_db` script. For details, see [Section 2.10.1, “Unix Postinstallation Procedures”](#).

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, execute the `mysql_install_db` script. After running this script and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root test
```

The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect because the MySQL `root` user has no password initially. That is also a security risk, so setting the password for the `root` accounts is something you should do while you're setting up your other MySQL accounts. For instructions on setting the initial passwords, see [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

- If you have updated an existing MySQL installation to a newer version, did you run the `mysql_upgrade` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).
- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

For information on how to deal with this, see [Section 6.1.2.4, “Password Hashing in MySQL”](#), and [Section C.5.2.4, “Client does not support authentication protocol”](#).

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` [220] option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in [Section 4.2.3.3, “Using Option Files”](#). Environment variables are listed in [Section 2.12, “Environment Variables”](#).

- If you get the following error, it means that you are using an incorrect `root` password:

```
shell> mysqladmin -u root -pxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` [\[220\]](#) option as described in the previous item.

For information on changing passwords, see [Section 6.3.5, “Assigning Account Passwords”](#).

If you have lost or forgotten the `root` password, see [Section C.5.4.1, “How to Reset the Root Password”](#).

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` [\[1263\]](#) function. If you do not use `PASSWORD()` [\[1263\]](#) for these statements, the password will not work. For example, the following statement assigns a password, but fails to encrypt it, so the user is not able to connect afterward:

```
SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The `PASSWORD()` [\[1263\]](#) function is unnecessary when you specify a password using the `CREATE USER` or `GRANT` statements or the `mysqladmin password` command. Each of those automatically uses `PASSWORD()` [\[1263\]](#) to encrypt the password. See [Section 6.3.5, “Assigning Account Passwords”](#), and [Section 13.7.1.2, “CREATE USER Syntax”](#).

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

To avoid this problem on such systems, you can use a `--host=127.0.0.1` [\[211\]](#) option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` [\[211\]](#) option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.
- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the `Host` and `User` columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with '%' as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the '%' in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

```
shell> mysqladmin -u root -pXXXX -h some_hostname ver
Access denied for user 'root'@' ' (using password: YES)
```

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of 'root' and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host cache. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `--skip-name-resolve` [\[440\]](#) option.
- Start `mysqld` with the `--skip-host-cache` [\[439\]](#) option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. Unix connections to `localhost` use a Unix socket file rather than TCP/IP.
- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name `.` (period). Connections to `.` use a named pipe rather than TCP/IP.
- If `mysql -u root test` works but `mysql -h your_hostname -u root test` results in `Access denied` (where `your_hostname` is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have an entry with host 'pluto' in the `user` table, but your DNS tells MySQL that your host name is 'pluto.example.com', the entry does not work. Try adding an entry to the `user` table that contains the IP address of your host as the `Host` column value. (Alternatively, you could add an

entry to the `user` table with a `Host` value that contains a wildcard; for example, `'pluto.%'`. However, use of `Host` values ending with `"%"` is *insecure* and is *not* recommended!)

- If `mysql -u user_name test` works but `mysql -u user_name other_db` does not, you have not granted access to the given user for the database named `other_db`.
- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.
- If you cannot figure out why you get `Access denied`, remove from the `user` table all entries that have `Host` values containing wildcards (entries that contain `'%'` or `'_'` characters). A very common error is to insert a new entry with `Host='%'` and `User='some_user'`, thinking that this enables you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include an entry with `Host='localhost'` and `User=''`. Because that entry has a `Host` value `'localhost'` that is more specific than `'%'`, it is used in preference to the new entry when connecting from `localhost`! The correct procedure is to insert a second entry with `Host='localhost'` and `User='some_user'`, or to delete the entry with `Host='localhost'` and `User=''`. After deleting the entry, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also [Section 6.2.4, "Access Control, Stage 1: Connection Verification"](#).
- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA INFILE` statement, your entry in the `user` table does not have the `FILE [754]` privilege enabled.
- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!
- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in [Section 6.2.6, "When Privilege Changes Take Effect"](#).
- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -p your_pass db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass [211]` syntax to specify the password. If you use the `-p` or `--password [211]` option with no password value, MySQL prompts you for the password.)
- For testing purposes, start the `mysqld` server with the `--skip-grant-tables [439]` option. Then you can change the MySQL grant tables and use the `mysqlaccess` script to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.
- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query [418]`). This prints host and user information about attempted connections, as well as information about each command issued. See [MySQL Internals: Porting to Other Systems](#).
- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at [Section 1.7, "How to Report Bugs or Problems"](#). In some cases, you may need to restart `mysqld` with `--skip-grant-tables [439]` to run `mysqldump`.

## 6.3. MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system
- How to set up new accounts and remove existing accounts
- How to change passwords
- Guidelines for using passwords securely
- How to use secure connections with SSL

See also [Section 13.7.1, “Account Management Statements”](#), which describes the syntax and use for all user-management SQL statements.

### 6.3.1. User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. The account may also have a password. For information about account representation in the `user` table, see [Section 6.2.2, “Privilege System Grant Tables”](#). MySQL 5.6 supports authentication plugins, so it is possible that an account authenticates using some external authentication method. See [Section 6.3.7, “Pluggable Authentication”](#).

There are several distinctions between the way user names and passwords are used by MySQL and the way they are used by your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. Because this means that anyone can attempt to connect to the server using any user name, you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password is able to connect successfully to the server.
- MySQL user names can be up to 16 characters long. Operating system user names, because they are completely unrelated to MySQL user names, may be of a different maximum length. For example, Unix user names typically are limited to eight characters.

#### Warning

The limit on MySQL user name length is hard-coded in the MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.

You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#). Attempting to redefine MySQL's system tables in any other fashion results in undefined (and unsupported!) behavior.

- The server uses MySQL passwords stored in the `user` table to authenticate client connections using MySQL native authentication (against passwords stored in the `mysql.user` table). These passwords have nothing to do with passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the `user` table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- MySQL encrypts passwords stored in the `user` table using its own algorithm. This encryption is the same as that implemented by the `PASSWORD()` [1263] SQL function but differs from that used during the Unix login process. Unix password encryption is the same as that implemented by the `ENCRYPT()` [1262] SQL function. See the descriptions of the `PASSWORD()` [1263] and `ENCRYPT()` [1262] functions in [Section 12.13, “Encryption and Compression Functions”](#).

From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. (In earlier versions, even though passwords are stored in encrypted form in the `user` table, knowledge of the encrypted password value could be used to connect to the MySQL server.) [Section 6.1.2.4, “Password Hashing in MySQL”](#), discusses password encryption further.

- It is possible to connect to the server regardless of character set settings if the user name and password contain only ASCII characters. To connect when the user name or password contain non-ASCII characters, the client should call the `mysql_options()` C API function with the `MYSQL_SET_CHARSET_NAME` option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication will fail unless the server default character set is the same as the encoding in the authentication defaults.

Standard MySQL client programs support a `--default-character-set` option that causes `mysql_options()` to be called as just described. In addition, character set autodetection is supported as described in [Section 10.1.4, “Connection Character Sets and Collations”](#). For programs that use a connector that is not based on the C API, the connector may provide an equivalent to `mysql_options()` that can be used instead. Check the connector documentation.

The preceding notes do not apply for `ucs2`, `utf16`, and `utf32`, which are not permitted as client character sets.

When you install MySQL, the grant tables are populated with an initial set of accounts. The names and access privileges for these accounts are described in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#), which also discusses how to assign passwords to them. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See [Section 13.7.1, “Account Management Statements”](#).

When you connect to a MySQL server with a command-line client, specify the user name and password as necessary for the account that you want to use:

```
shell> mysql --user=monty --password=password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u monty -ppassword db_name
```

There must be *no space* between the `-p` option and the following password value.

If you omit the `password` value following the `--password` [211] or `-p` option on the command line, the client prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

For additional information about specifying user names, passwords, and other connection parameters, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

## 6.3.2. Adding User Accounts

You can create MySQL accounts in two ways:

- By using statements intended for creating accounts, such as `CREATE USER` or `GRANT`. These statements cause the server to make appropriate modifications to the grant tables.
- By manipulating the MySQL grant tables directly with statements such as `INSERT`, `UPDATE`, or `DELETE`.

The preferred method is to use account-creation statements because they are more concise and less error-prone than manipulating the grant tables directly. `CREATE USER` and `GRANT` are described in [Section 13.7.1, “Account Management Statements”](#).

Another option for creating accounts is to use the GUI tool MySQL Workbench. Or one of several available third-party programs that offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that privileges have been set up according to the defaults described in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#). This means that to make changes, you must connect to the MySQL server as the MySQL `root` user, and the `root` account must have the `INSERT [755]` privilege for the `mysql` database and the `RELOAD [755]` administrative privilege.

As noted in the examples where appropriate, some of the statements will fail if the server's SQL mode has been set to enable certain restrictions. In particular, strict mode (`STRICT_TRANS_TABLES [607]`, `STRICT_ALL_TABLES [607]`) and `NO_AUTO_CREATE_USER [604]` will prevent the server from accepting some of the statements. Workarounds are indicated for these cases. For more information about SQL modes and their effect on grant table manipulation, see [Section 5.1.7, “Server SQL Modes”](#), and [Section 13.7.1.4, “GRANT Syntax”](#).

First, use the `mysql` program to connect to the server as the MySQL `root` user:

```
shell> mysql --user=root mysql
```

If you have assigned a password to the `root` account, you will also need to supply a `--password` or `-p` option, both for this `mysql` command and for those later in this section.

After connecting to the server as `root`, you can add new accounts. The following statements use `GRANT` to set up four new accounts:

```
mysql> CREATE USER 'monty'@'localhost' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'localhost'
-> WITH GRANT OPTION;
mysql> CREATE USER 'monty'@'%' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'%'
-> WITH GRANT OPTION;
mysql> CREATE USER 'admin'@'localhost';
mysql> GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
mysql> CREATE USER 'dummy'@'localhost';
```

The accounts created by these statements have the following properties:

- Two of the accounts have a user name of `monty` and a password of `some_pass`. Both accounts are superuser accounts with full privileges to do anything. The `'monty'@'localhost'` account can be used only when connecting from the local host. The `'monty'@'%'` account uses the `'%'` wildcard for the host part, so it can be used to connect from any host.

It is necessary to have both accounts for `monty` to be able to connect from anywhere as `monty`. Without the `localhost` account, the anonymous-user account for `localhost` that is created by `mysql_install_db` would take precedence when `monty` connects from the local host. As a result, `monty` would be treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'monty'@'%'` account and thus comes earlier in the `user` table sort order. (`user` table sorting is discussed in [Section 6.2.4, “Access Control, Stage 1: Connection Verification”](#).)

- The `'admin'@'localhost'` account has no password. This account can be used only by `admin` to connect from the local host. It is granted the `RELOAD [755]` and `PROCESS [755]` administrative privileges. These privileges enable the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges later by issuing other `GRANT` statements.
- The `'dummy'@'localhost'` account has no password. This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account later.

The statements that create accounts with no password will fail if the `NO_AUTO_CREATE_USER [604]` SQL mode is enabled. To deal with this, use an `IDENTIFIED BY` clause that specifies a nonempty password.

To check the privileges for an account, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----+
| Grants for admin@localhost |
+-----+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----+
```

As an alternative to `CREATE USER` and `GRANT`, you can create the same accounts directly by issuing `INSERT` statements and then telling the server to reload the grant tables using `FLUSH PRIVILEGES`:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user
-> VALUES('localhost','monty',PASSWORD('some_pass'),
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user
-> VALUES('%','monty',PASSWORD('some_pass'),
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y',
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y',
-> '','','',0,0,0,0);
mysql> INSERT INTO user SET Host='localhost',User='admin',
-> Reload_priv='Y', Process_priv='Y';
mysql> INSERT INTO user (Host,User>Password)
-> VALUES('localhost','dummy','');
mysql> FLUSH PRIVILEGES;
```

When you create accounts with `INSERT`, it is necessary to use `FLUSH PRIVILEGES` to tell the server to reload the grant tables. Otherwise, the changes go unnoticed until you restart the server. With `CREATE USER`, `FLUSH PRIVILEGES` is unnecessary.

The reason for using the `PASSWORD( ) [1263]` function with `INSERT` is to encrypt the password. The `CREATE USER` statement encrypts the password for you, so `PASSWORD( ) [1263]` is unnecessary.

The `'Y'` values enable privileges for the accounts. Depending on your MySQL version, you may have to use a different number of `'Y'` values in the first two `INSERT` statements. The `INSERT` statement for the `admin` account employs the more readable extended `INSERT` syntax using `SET`.

In the `INSERT` statement for the `dummy` account, only the `Host`, `User`, and `Password` columns in the `user` table row are assigned values. None of the privilege columns are set explicitly, so MySQL assigns them all the default value of `'N'`. This is equivalent to what `CREATE USER` does.

If strict SQL mode is enabled, all columns that have no default value must have a value specified. In this case, `INSERT` statements must explicitly specify values for the `ssl_cipher`, `x509_issuer`, and `x509_subject` columns.

To set up a superuser account, it is necessary only to insert a `user` table row with all privilege columns set to `'Y'`. The `user` table privileges are global, so no entries in any of the other grant tables are needed.

The next examples create three accounts and give them access to specific databases. Each of them has a user name of `custom` and password of `obscure`.

To create the accounts with `CREATE USER` and `GRANT`, use the following statements:

```
shell> mysql --user=root mysql
mysql> CREATE USER 'custom'@'localhost' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON bankaccount.*
-> TO 'custom'@'localhost';
mysql> CREATE USER 'custom'@'host47.example.com' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON expenses.*
-> TO 'custom'@'host47.example.com';
mysql> CREATE USER 'custom'@'server.domain' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON customer.*
-> TO 'custom'@'server.domain';
```

The three accounts can be used as follows:

- The first account can access the `bankaccount` database, but only from the local host.
- The second account can access the `expenses` database, but only from the host `host47.example.com`.
- The third account can access the `customer` database, but only from the host `server.domain`.

To set up the `custom` accounts without `GRANT`, use `INSERT` statements as follows to modify the grant tables directly:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('localhost','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('host47.example.com','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('server.domain','custom',PASSWORD('obscure'));
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv,Delete_priv,Create_priv,Drop_priv)
-> VALUES('localhost','bankaccount','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv,Delete_priv,Create_priv,Drop_priv)
-> VALUES('host47.example.com','expenses','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv,Delete_priv,Create_priv,Drop_priv)
-> VALUES('server.domain','customer','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> FLUSH PRIVILEGES;
```

The first three `INSERT` statements add `user` table entries that permit the user `custom` to connect from the various hosts with the given password, but grant no global privileges (all privileges are set to the default value of `'N'`). The next three `INSERT` statements add `db` table entries that grant privileges to `custom` for the `bankaccount`, `expenses`, and `customer` databases, but only when accessed from the proper hosts. As usual when you modify the grant tables directly, you must tell the server to reload them with `FLUSH PRIVILEGES` so that the privilege changes take effect.

To create a user who has access from all machines in a given domain (for example, `mydomain.com`), you can use the `"%"` wildcard character in the host part of the account name:

```
mysql> CREATE USER 'myname'@'%.mydomain.com' IDENTIFIED BY 'mypass';
```

To do the same thing by modifying the grant tables directly, do this:

```
mysql> INSERT INTO user (Host,User,Password,...)
-> VALUES ('%.mydomain.com','myname',PASSWORD('mypass'),...);
mysql> FLUSH PRIVILEGES;
```

### 6.3.3. Removing User Accounts

To remove an account, use the `DROP USER` statement, which is described in [Section 13.7.1.3](#), “`DROP USER Syntax`”.

### 6.3.4. Setting Account Resource Limits

One means of limiting use of MySQL server resources is to set the global `max_user_connections` [509] system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` [509] does not enable management of individual accounts. Both types of control are of interest to many MySQL administrators, particularly those working for Internet Service Providers.

In MySQL 5.6, you can limit use of the following server resources for individual accounts:

- The number of queries that an account can issue per hour
- The number of updates that an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit (unless its results are served from the query cache). Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `'usera'@'%.example.com'` corresponds to a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0.3, an “account” was assessed against the actual host from which a user connects. This older method accounting may be selected by starting the server with the `--old-style-user-limits` [433] option. In this case, if `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

To set resource limits for an account, use the `GRANT` statement (see [Section 13.7.1.4](#), “`GRANT Syntax`”). Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank';
mysql> GRANT ALL ON customer.* TO 'francis'@'localhost'
-> WITH MAX_QUERIES_PER_HOUR 20
-> MAX_UPDATES_PER_HOUR 10
-> MAX_CONNECTIONS_PER_HOUR 5
-> MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global

`max_user_connections` [509] system variable value determines the number of simultaneous connections. If `max_user_connections` [509] is also zero, there is no limit for the account.

To modify existing limits for an account, use a `GRANT USAGE` statement at the global level (`ON *.*`). The following statement changes the query limit for `francis` to 100:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
->     WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
->     WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` [509] system variable. Suppose that the global `max_user_connections` [509] value is 10 and three accounts have resource limits specified with `GRANT`:

```
GRANT ... TO 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
GRANT ... TO 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
GRANT ... TO 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

`user1` has a connection limit of 10 (the global `max_user_connections` [509] value) because it has a zero `MAX_USER_CONNECTIONS` limit). `user2` and `user3` have connection limits of 5 and 20, respectively, because they have nonzero `MAX_USER_CONNECTIONS` limits.

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits, and the `max_user_connections` column stores the `MAX_USER_CONNECTIONS` limit. (See [Section 6.2.2, "Privilege System Grant Tables"](#).)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, further connections for the account are rejected until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, further queries or updates are rejected until the hour is up. In all such cases, an appropriate error message is issued.

Resource counting is done per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be set to zero by re-granting it any of its limits. To do this, use `GRANT USAGE` as described earlier and specify a limit value equal to the value that the account currently has.

Counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts; counts are not carried over through a restart.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` [3673] or `ER_USER_LIMIT_REACHED` [3675]) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be permitted.

### 6.3.5. Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts. In MySQL 5.6, it is also possible for clients to authenticate using plugins. For information, see [Section 6.3.7, “Pluggable Authentication”](#).

To assign a password when you create a new account with `CREATE USER`, include an `IDENTIFIED BY` clause:

```
mysql> CREATE USER 'jeffrey'@'localhost'
-> IDENTIFIED BY 'mypass';
```

To assign or change a password for an existing account, one way is to issue a `SET PASSWORD` statement:

```
mysql> SET PASSWORD FOR
-> 'jeffrey'@'localhost' = PASSWORD('mypass');
```

MySQL stores passwords in the `user` table in the `mysql` database. Only users such as `root` that have update access to the `mysql` database can change the password for other users. If you are not connected as an anonymous user, you can change your own password by omitting the `FOR` clause:

```
mysql> SET PASSWORD = PASSWORD('mypass');
```

The `old_passwords` [517] system variable value determines the hashing method used by `PASSWORD()` [1263]. If you specify the password using that function and `SET PASSWORD` rejects the password as not being in the correct format, it may be necessary to set `old_passwords` [517] to change the hashing method. For descriptions of the permitted values, see [Section 5.1.4, “Server System Variables”](#).

In MySQL 5.6, enabling the `read_only` [532] system variable prevents the use of the `SET PASSWORD` statement by any user not having the `SUPER` [756] privilege.

You can also use a `GRANT USAGE` statement at the global level (`ON *.*`) to assign a password to an account without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost'
-> IDENTIFIED BY 'mypass';
```

To assign a password from the command line, use the `mysqladmin` command:

```
shell> mysqladmin -u user_name -h host_name password "newpwd"
```

The account for which this command sets the password is the one with a `user` table row that matches `user_name` in the `User` column and the client host *from which you connect* in the `Host` column.

During authentication when a client connects to the server, MySQL treats the password in the `user` table as an encrypted hash value (the value that `PASSWORD()` [1263] would return for the password). When assigning a password to an account, it is important to store an encrypted value, not the plaintext password. Use the following guidelines:

- When you assign a password using `CREATE USER`, `GRANT` with an `IDENTIFIED BY` clause, or the `mysqladmin password` command, they encrypt the password for you. Specify the literal plaintext password:

```
mysql> CREATE USER 'jeffrey'@'localhost'
```

```
-> IDENTIFIED BY 'mypass';
```

- For `CREATE USER` or `GRANT`, you can avoid sending the plaintext password if you know the hash value that `PASSWORD()` [1263] would return for the password. Specify the hash value preceded by the keyword `PASSWORD`:

```
mysql> CREATE USER 'jeffrey'@'localhost'
-> IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
```

- When you assign an account a nonempty password using `SET PASSWORD`, you must use the `PASSWORD()` [1263] function to encrypt the password, otherwise the password is stored as plaintext. Suppose that you assign a password like this:

```
mysql> SET PASSWORD FOR
-> 'jeffrey'@'localhost' = 'mypass';
```

The result is that the literal value `'mypass'` is stored as the password in the `user` table, not the encrypted value. When `jeffrey` attempts to connect to the server using this password, the value is encrypted and compared to the value stored in the `user` table. However, the stored value is the literal string `'mypass'`, so the comparison fails and the server rejects the connection with an `Access denied` error.

#### Note

`PASSWORD()` [1263] encryption differs from Unix password encryption. See [Section 6.3.1, “User Names and Passwords”](#).

It is preferable to assign passwords using `SET PASSWORD`, `GRANT`, or `mysqladmin`, but it is also possible to modify the `user` table directly. In this case, you must also use `FLUSH PRIVILEGES` to cause the server to reread the grant tables. Otherwise, the change remains unnoticed by the server until you restart it.

- To establish a password for a new account, provide a value for the `Password` column:

```
mysql> INSERT INTO mysql.user (Host,User,Password)
-> VALUES('localhost','jeffrey',PASSWORD('mypass'));
mysql> FLUSH PRIVILEGES;
```

- To change the password for an existing account, use `UPDATE` to set the `Password` column value:

```
mysql> UPDATE mysql.user SET Password = PASSWORD('bagel')
-> WHERE Host = 'localhost' AND User = 'francis';
mysql> FLUSH PRIVILEGES;
```

## 6.3.6. Password Expiration and Sandbox Mode

MySQL 5.6 introduces password-expiration capability, to enable database administrators to expire account passwords and require users to reset their password. The immediately following discussion describes how password expiration works currently. Later, the development of this capability is detailed as it occurred over several versions, as background to help you understand what features are available when. However, to ensure that you can take advantage of all features and fixes, you should use the most recent available version of MySQL 5.6 if possible.

### How Password Expiration Works

To expire an account password, use the `ALTER USER` statement. For example:

```
ALTER USER 'myuser'@'localhost' PASSWORD EXPIRE;
```

This statement modifies the row of the `mysql.user` table associated with the named account, setting the `password_expired` column to `'Y'`. This does not affect any current connections the account has open. For each subsequent connection that uses the account, the server either disconnects the client or handles the client in “sandbox mode,” in which the server permits the client only those operations

necessary to reset the expired password. (The action taken by the server depends on both client and server settings.)

If the server disconnects the client, it returns an `ER_MUST_CHANGE_PASSWORD_LOGIN` [3717] error:

```
shell> mysql -u myuser -p
Password: *****
ERROR 1862 (HY000): Your password has expired. To log in you must
change it using a client that supports expired passwords.
```

If the server puts the client in sandbox mode, these operations are permitted within the client session:

- The client can reset the account password with `SET PASSWORD`. This modifies the row of the `mysql.user` table associated with the current account, setting the `password_expired` column to 'N'. After the password has been reset, the server restores normal access for the session, as well as for subsequent connections that use the account.

It is possible to “reset” a password by setting it to its current value. As a matter of good policy, it is preferable to choose a different password.

- The client can use `SET` statements. This might be necessary prior to resetting the password; for example, if the account password uses a hashing format that requires the `old_passwords` [517] system variable to be set to a value different from its default.

For any operation not permitted within the session, the server returns an `ER_MUST_CHANGE_PASSWORD` [3714] error:

```
mysql> USE test;
ERROR 1820 (HY000): You must SET PASSWORD before executing this statement
```

As mentioned previously, whether the server disconnects an expired-password client or puts it in sandbox mode depends on a combination of client and server settings. The following discussion describes the relevant settings and how they interact.

On the client side, a given client indicates whether it can handle sandbox mode for expired passwords. For clients that use the C client library, there are two ways to do this:

- Pass the `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_options()` prior to connecting:

```
arg = 1;
result = mysql_options(mysql,
                        MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS, &arg);
```

- Pass the `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_real_connect()` at connection time:

```
mysql = mysql_real_connect(mysql,
                           host, user, password, "test",
                           port, unix_socket,
                           CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS);
```

Other MySQL Connectors have their own conventions for indicating readiness to handle sandbox mode. See the relevant Connector documentation.

On the server side, if a client indicates that it can handle expired passwords, the server puts it in sandbox mode.

If a client does not indicate that it can handle expired passwords (or uses an older version of the client library that cannot so indicate), the server action depends on the value of the `disconnect_on_expired_passwords` [477] system variable:

- If `disconnect_on_expired_passwords` [477] is enabled (the default), the server disconnects the client with an `ER_MUST_CHANGE_PASSWORD_LOGIN` [3717] error.

- If `disconnect_on_expired_passwords` [477] is disabled, the server puts the client in sandbox mode.

The preceding client and server settings apply only for accounts with expired passwords. If a client connects using a nonexpired password, the server handles the client normally.

## Development of Password-Expiration Capability

The following timeline describes the versions in which various password-expiration features were added.

MySQL 5.6.6: Initial implementation of password expiration

The `password_expired` column is introduced in the `mysql.user` table to enable DBAs to expire account passwords. The column default value is 'N' (not expired).

The `ALTER USER` statement is introduced as the SQL interface for setting the `password_expired` column to 'Y'.

Connections that use an account with an expired password enter “sandbox mode” that permits only `SET PASSWORD` statements. For other statements, the server returns an `ER_MUST_CHANGE_PASSWORD` [3714] error. The intent is to force the client to reset the password before the server permits any other operations. `SET PASSWORD` resets the account password and sets `password_expired` to 'N'.

A bug in the initial implementation is that `ALTER USER` sets the `Password` column in the `mysql.user` table to the empty string. The implication is that users should wait until MySQL 5.6.7 to use this statement.

MySQL 5.6.7:

`ALTER USER` is fixed to not set the `Password` column to the empty string.

MySQL 5.6.8:

`ALTER USER` can be used as a prepared statement.

`mysqladmin password` is made capable of setting passwords for accounts with expired native or old-native passwords.

Sandbox mode is changed to permit clients to execute `SET` statements in addition to `SET PASSWORD`. Prohibiting `SET` prevented clients that needed to set `old_passwords` from resetting their password. It also broke some Connectors, which use `SET` extensively at connect time to initialize the session environment.

MySQL 5.6.9:

Sandbox mode is changed to permit `SET PASSWORD` only if the account named in the statement matches the account the client authenticated as.

MySQL 5.6.10:

Sandbox mode is changed to permit better control over how the server handles client connections for accounts with expired passwords, and to permit clients to signal whether they are capable of handling expired passwords:

- The `disconnect_on_expired_passwords` [477] system variable is added, which controls how the server treats expired-password accounts.
- Two flags are added to the C API client library: `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` for `mysql_options()` and `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` for

`mysql_real_connect()`. Each flag enables a client program to indicate whether it can handle sandbox mode for accounts with expired passwords.

`MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` is enabled for `mysqltest` unconditionally, for `mysql` in interactive mode, and for `mysqladmin` if the first command is `password`.

- The `ER_MUST_CHANGE_PASSWORD_LOGIN` [3717] error is added. The server returns this error when it disconnects a client.

Concurrent with these changes to sandbox mode in MySQL Server and the C API client library, work begins to modify Connectors for conformance to the changes.

## 6.3.7. Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` table. It then uses this row to authenticate the client.

In MySQL 5.6, the server authenticates clients using plugins, as follows:

- The server determines from the account row which authentication plugin applies for the client:
  - If the account row specifies no plugin name, the server uses native authentication; that is, authentication against the password stored in the `Password` column of the account row. This is the same authentication method provided by MySQL servers older than 5.5.7, before pluggable authentication was implemented, but now is implemented using two plugins that are built in and cannot be disabled.
  - If the account row specifies a plugin, the server invokes it to authenticate the user. If the server cannot find the plugin, an error occurs.
- The plugin returns a status to the server indicating whether the user is permitted to connect.

Pluggable authentication enables two important capabilities:

- **External authentication:** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials that are appropriate for authentication methods other than native authentication based on passwords stored in the `mysql.user` table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.
- **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user. While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of a different user. In effect, one user impersonates another. For more information, see [Section 6.3.8, “Proxy Users”](#).

Several authentication plugins are available in MySQL. The following sections provide details about specific plugins.

- Plugins that perform native authentication that matches the password against the `Password` column of the account row. See [Section 6.3.7.1, “The Native Authentication Plugins”](#). Native authentication is the default for accounts that have no plugin named explicitly in their account row.
- A plugin that performs authentication using SHA-256 password hashing. This plugin matches the password against the `authentication_string` column of the account row. This is stronger encryption than that available with native authentication. See [Section 6.3.7.2, “The SHA-256 Authentication Plugin”](#).
- A plugin that performs external authentication against PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See [Section 6.3.7.3, “The PAM Authentication Plugin”](#).

- A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).
- A client-side plugin that sends the password to the server without hashing or encryption. This plugin can be used by server-side plugins that require access to the password exactly as provided by the client user. See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).
- A plugin that authenticates clients that connect from the local host through the Unix socket file. See [Section 6.3.7.6, “The Socket Peer-Credential Authentication Plugin”](#).
- A test plugin that authenticates using MySQL native authentication. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See [Section 6.3.7.7, “The Test Authentication Plugin”](#).

**Note**

For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see [Section E.9, “Restrictions on Pluggable Authentication”](#).

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see [Section 22.2.4.9, “Writing Authentication Plugins”](#).

In general, pluggable authentication uses corresponding plugins on the server and client sides, so you use a given authentication method like this:

- On the server host, install the appropriate library containing the server plugin, if necessary, so that the server can use it to authenticate client connections. Similarly, on each client host, install the appropriate library containing the client plugin for use by client programs.
- Create MySQL accounts that specify use of the plugin for authentication.
- When a client connects, the server plugin tells the client program which client plugin to use for authentication.

The remainder of this section provides general instructions for installing and using authentication plugins. The instructions use an example authentication plugin included in MySQL distributions (see [Section 6.3.7.7, “The Test Authentication Plugin”](#)). The procedure is similar for other authentication plugins; substitute the appropriate plugin and file names.

The example authentication plugin has these characteristics:

- The server-side plugin name is `test_plugin_server`.
- The client-side plugin name is `auth_test_plugin`.
- Both plugins are located in the shared library object file named `auth_test_plugin.so` in the plugin directory (the directory named by the `plugin_dir` [525] system variable). The file name suffix might differ on your system.

Install and use the example authentication plugin as follows:

1. Make sure that the plugin library is installed on the server and client hosts.
2. Install the server-side test plugin at server startup or at runtime:

- To install the plugin at startup, use the `--plugin-load` [435] option. With this plugin-loading method, the option must be given each time you start the server. For example, use these lines in a `my.cnf` option file:

```
[mysqld]
plugin-load=test_plugin_server=auth_test_plugin.so
```

- To install the plugin at runtime, use the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

This installs the plugin permanently and need be done only once.

PAM authentication, when not done through proxy users or groups, requires the MySQL account to have the same user name as the Unix account. Because MySQL user names are limited to 16 characters (see [Section 6.2.2, “Privilege System Grant Tables”](#)), this limits PAM nonproxy authentication to Unix accounts with names of at most 16 characters.

3. Verify that the plugin is installed. For example, use `SHOW PLUGINS`:

```
mysql> SHOW PLUGINS\G
...
***** 21. row *****
Name: test_plugin_server
Status: ACTIVE
Type: AUTHENTICATION
Library: auth_test_plugin.so
License: GPL
```

For other ways to check the plugin, see [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

4. To specify that a MySQL user must be authenticated using the plugin, name it in the `IDENTIFIED WITH` clause of the `CREATE USER` statement that creates the user:

```
CREATE USER 'testuser'@'localhost' IDENTIFIED WITH test_plugin_server;
```

5. Connect to the server using a client program. The test plugin authenticates the same way as native MySQL authentication, so provide the usual `--user` [212] and `--password` [211] options that you normally use to connect to the server. For example:

```
shell> mysql --user=your_name --password=your_pass
```

For connections by `testuser`, the server sees that the account must be authenticated using the server-side plugin named `test_plugin_server` and communicates to the client program which client-side plugin it must use—in this case, `auth_test_plugin`.

In the case that the account uses the authentication method that is the default for both the server and the client program, the server need not communicate to the client which plugin to use, and a round trip in client/server negotiation can be avoided. Currently this is true for accounts that use native MySQL authentication (`mysql_native_password`).

The `--default-auth=plugin_name` [249] option can be specified on the `mysql` command line to make explicit which client-side plugin the program can expect to use, although the server will override this if the user account requires a different plugin.

If `mysql` does not find the plugin, specify a `--plugin-dir=dir_name` [252] option to indicate where the plugin is located.

#### Note

If you start the server with the `--skip-grant-tables` [439] option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is

insecure, you might want to use `--skip-grant-tables` [439] in conjunction with `--skip-networking` [440] to prevent remote clients from connecting.

### 6.3.7.1. The Native Authentication Plugins

MySQL includes two plugins that implement the same kind of native authentication that older servers provide; that is, authentication against passwords stored in the `Password` column of the `mysql.user` table:

- The `mysql_native_password` authentication plugin implements the same default authentication against the `mysql.user` table as used prior to the implementation of pluggable authentication.
- The `mysql_old_password` plugin implements authentication as used before MySQL 4.1.1 that is based on shorter password hash values. For information about this authentication method, see [Section 6.1.2.4, “Password Hashing in MySQL”](#).

The native authentication plugins are backward compatible. Clients older than MySQL 5.5.7 do not support authentication plugins but use native authentication, so they can connect to servers from 5.5.7 and up.

The following tables show the plugin names. Both are considered to implement native authentication even though only one has “native” in the name.

**Table 6.8. MySQL Native Password Authentication Plugin**

Server-side plugin name	<code>mysql_native_password</code>
Client-side plugin name	<code>mysql_native_password</code>
Library object file name	None (plugins are built in)

**Table 6.9. MySQL Native Old-Password Authentication Plugin**

Server-side plugin name	<code>mysql_old_password</code>
Client-side plugin name	<code>mysql_old_password</code>
Library object file name	None (plugins are built in)

Each plugin exists in both client and server form. MySQL client programs use `mysql_native_password` by default. The `--default-auth` [249] option can be used to specify either plugin explicitly:

```
shell> mysql --default-auth=mysql_native_password ...
shell> mysql --default-auth=mysql_old_password ...
```

The server-side plugins are built into the server, need not be loaded explicitly, and cannot be disabled by unloading them. The client-side plugins are built into the `libmysqlclient` client library as of MySQL 5.5.7 and available to any program linked against `libmysqlclient` from that version or newer.

For general information about pluggable authentication in MySQL, see [Section 6.3.7, “Pluggable Authentication”](#).

### 6.3.7.2. The SHA-256 Authentication Plugin

As of MySQL 5.6.6, MySQL provides an authentication plugin that implements SHA-256 hashing for user account passwords. The following table shows the plugin names on the server and client sides.

**Table 6.10. MySQL SHA-256 Authentication Plugin**

Server-side plugin name	<code>sha256_password</code>
Client-side plugin name	<code>sha256_password</code>
Library object file name	None (plugins are built in)

The server-side `sha256_password` plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it. Similarly, clients need not specify the location of the client-side plugin.

### Note

Use of the `sha256_password` plugin requires that MySQL be built with SSL capabilities. See [Section 6.3.9, “Using SSL for Secure Connections”](#).

To set up an account that uses SHA-256 password hashing, use the following procedure.

1. Create the account and specify that it authenticates using the `sha256_password` plugin:

```
CREATE USER 'sha256user'@'localhost' IDENTIFIED WITH sha256_password;
```

2. Set the `old_passwords` system variable to 2 to select SHA-256 hashing of password strings by the `PASSWORD()` function;

```
SET old_passwords = 2;
```

3. Set the account password:

```
SET PASSWORD FOR 'sha256user'@'localhost' = PASSWORD('sha256P@ss');
```

Alternatively, start the server with the default authentication plugin set to `sha256_password`. For example, put these lines in the server option file:

```
[mysqld]
default-authentication-plugin=sha256_password
```

That causes the `sha256_password` plugin to be used by default for new accounts and sets `old_passwords` to 2. As a result, it is possible to set the password at account-creation time with the `CREATE USER` statement:

```
mysql> CREATE USER 'sha256user2'@'localhost' IDENTIFIED BY 'sha256P@ss2';
Query OK, 0 rows affected (0.06 sec)
```

In this case, the server assigns the `sha256_password` plugin to the account and encrypts the password using SHA-256. (Another consequence is that to create an account that uses a different authentication plugin, you must specify that plugin in the `CREATE USER` statement, then set `old_passwords` appropriately for the plugin before using `SET PASSWORD` to set the account password.)

If `old_passwords` has a value other than 2, an error occurs for attempts to set the password for an account that requires a SHA-256 password:

```
mysql> SET old_passwords = 0;
mysql> SET PASSWORD FOR 'sha256user'@'localhost' = PASSWORD('sha256P@ss');
ERROR 1827 (HY000): The password hash doesn't have the expected format.
Check if the correct password algorithm is being used with the
PASSWORD() function.
```

For more information about `old_passwords` [\[517\]](#) and `PASSWORD()` [\[1263\]](#), see [Section 5.1.4, “Server System Variables”](#), and [Section 12.13, “Encryption and Compression Functions”](#).

Accounts in the `mysql.user` table that use SHA-256 passwords can be identified as rows with `'sha256_password'` in the `plugin` column and a SHA-256 password hash in the `authentication_string` column.

MySQL can be built with either yaSSL or OpenSSL and the `sha256_password` plugin works with distributions built using either package. The default is to use yaSSL. If MySQL is built using OpenSSL instead, RSA encryption is available and `sha256_password` implements the additional capabilities in the following list. (To enable these capabilities, you must also follow the RSA configuration procedure given later in this section.)

- It is possible for the client to transmit passwords to the server using RSA encryption during the client connection process, as described later.
- The server exposes two additional system variables, `sha256_password_private_key_path` [539] and `sha256_password_public_key_path` [539]. It is intended that the database administrator will set these to the names of the RSA private and public key files at server startup.
- The server exposes a status variable, `Rsa_public_key` [597], that displays the RSA public key value.
- The `mysql` and `mysqltest` client programs support a `--server-public-key-path` [253] option for specifying an RSA public key file explicitly. (This option was added in MySQL 5.6.6 under the name `--server-public-key` and renamed in 5.6.7 to `--server-public-key-path`.)

For clients that use the `sha256_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether an SSL connection is used and whether RSA encryption is available:

- If an SSL connection is used, the password is sent as cleartext but cannot be snooped because the connection is encrypted using SSL.
- If an SSL connection is not used but RSA encryption is available, the password is sent within an unencrypted connection, but the password is RSA-encrypted to prevent snooping. When the server receives the password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.
- If an SSL connection is not used and RSA encryption is not available, the `sha256_password` plugin causes the connection attempt to fail because the password cannot be sent without being exposed as cleartext.

As mentioned previously, RSA password encryption is available only if MySQL was built using OpenSSL. The implication for MySQL distributions built using yaSSL is that SHA-256 passwords can be used only when clients access the server using an SSL connection. For information about connecting to the server using SSL, see [Section 6.3.9, “Using SSL for Secure Connections”](#).

Assuming that MySQL has been built with OpenSSL, the following procedure describes how to enable RSA encryption of passwords during the client connection process:

1. Create the RSA private and public key files. Run these commands while logged into the system account used to run the MySQL server so the files will be owned by that account:

```
openssl genrsa -out mykey.pem 1024
openssl rsa -in mykey.pem -pubout > mykey.pub
```

2. Set the access modes for the key files. The private key should be readable only by the server:

```
chmod 400 mykey.pem
```

The public key can be freely distributed to client users:

```
chmod 444 mykey.pub
```

3. In the server option file, configure the appropriate system variables with the names of the key files. If you place the files in the server data directory, you need not specify their full path names:

```
[mysqld]
sha256_password_private_key_path=mykey.pem
sha256_password_public_key_path=mykey.pub
```

If the files are not in the data directory, or to make their locations explicit in the option values, use full path names:

```
[mysqld]
```

```
sha256_password_private_key_path=/usr/local/mysql/mykey.pem
sha256_password_public_key_path=/usr/local/mysql/mykey.pub
```

- Restart the server, then connect to it and check the `Rsa_public_key` [597] status variable value. The value will differ from that shown here, but should be nonempty:

```
mysql> SHOW STATUS LIKE 'Rsa_public_key'\G
***** 1. row *****
Variable_name: Rsa_public_key
Value: -----BEGIN PUBLIC KEY-----
MIGfMA0GC斯qGSIB3DQEBAQUAA4GNADCBiQKBgQDO9nRUdd+KvSZgY7cNBZMNpwX6
MvE1PbJFXO7u18nJ91wc99Du/E71w6CVXw7VKrXPehbVQUzGyUNkf45Nz/ckaaJa
aLgJOBcIDmNVnyU54OT/1lcs2xiyfaDMe8fCJ64ZwTnKbY2gkt1IMjUAB5Ogd5kJ
g8aV7EtKwyhHb0c30QIDAQAB
-----END PUBLIC KEY-----
```

If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, clients can connect to it using accounts that authenticate with the `sha256_password` plugin. As mentioned previously, such accounts can use either an SSL connection (in which case RSA is not used) or a plain connection that encrypts the password using RSA. Assume for the following discussion that SSL is not used. Connecting to the server involves no special preparation on the client side. For example:

```
shell> mysql -u sha256user -p
Enter password: sha256P@ss
```

For connection attempts by `sha256user`, the server determines that `sha256_password` is the appropriate authentication plugin and invokes it. The plugin finds that the connection does not use SSL and thus requires the password to be transmitted using RSA encryption. It sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The server sends the public key to the client as needed, but if a copy of the RSA public key is available on the client host, the client can use it to save a round trip in the client/server protocol:

```
shell> mysql -u sha256user -p --server-public-key-path=file_name
```

The public key value in the file named by the `--server-public-key-path` [253] option should be the same as the key value in the server-side file named by the `sha256_password_public_key_path` [539] system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it. In this case, the server sends the public key to the client as if no `--server-public-key-path` [253] option had been specified.

Client users can get the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Rsa_public_key'` statement and save the returned key value in a file.

### 6.3.7.3. The PAM Authentication Plugin

#### Note

The PAM authentication plugin is a commercial extension. To learn more about commercial products (MySQL Enterprise Edition), see <http://www.mysql.com/products/>.

As of MySQL 5.6.10, commercial distributions of MySQL include an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM

enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory.

The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string), plus whatever method is available for PAM lookup. The plugin checks the user credentials against PAM and returns `'Authentication succeeded, Username is user_name'` or `'Authentication failed'`.

The PAM authentication plugin provides these capabilities:

- External authentication: The plugin enables MySQL Server to accept connections from users defined outside the MySQL grant tables.
- Proxy user support: The plugin can return to MySQL a user name different from the login user, based on the groups the external user is in and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, a PAM user named `joe` can connect and have the privileges of the MySQL user named `developer`.

The following table shows the plugin and library file names. The file name suffix might be different on your system. The file location must be the directory named by the `plugin_dir [525]` system variable. For installation information, see [Section 6.3.7.3.1, “Installing the PAM Authentication Plugin”](#).

**Table 6.11. MySQL PAM Authentication Plugin**

Server-side plugin name	<code>authentication_pam</code>
Client-side plugin name	<code>mysql_clear_password</code>
Library object file name	<code>authentication_pam.so</code>

The library file includes only the server-side plugin. The client-side plugin is built into the `libmysqlclient` client library. See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).

The server-side PAM authentication plugin is included only in commercial distributions. It is not included in MySQL community distributions. The client-side clear-text plugin that communicates with the server-side plugin is built into the MySQL client library and is included in all distributions, including community distributions. This permits clients from any 5.6.10 or newer distribution to connect to a server that has the server-side plugin loaded.

The PAM authentication plugin has been tested on Linux and Mac OS X. It requires MySQL Server 5.6.10 or newer.

For general information about pluggable authentication in MySQL, see [Section 6.3.7, “Pluggable Authentication”](#). For proxy user information, see [Section 6.3.8, “Proxy Users”](#).

### 6.3.7.3.1. Installing the PAM Authentication Plugin

The PAM authentication plugin must be located in the MySQL plugin directory (the directory named by the `plugin_dir [525]` system variable). If necessary, set the value of `plugin_dir [525]` at server startup to tell the server the location of the plugin directory.

To enable the plugin, start the server with the `--plugin-load [435]` option. For example, put the following lines in your `my.cnf` file. If object files have a suffix different from `.so` on your system, substitute the correct suffix.

```
[mysqld]
plugin-load=authentication_pam.so
```

Use the plugin name `authentication_pam` in the `IDENTIFIED WITH` clause of `CREATE USER` or `GRANT` statements for MySQL accounts that should be authenticated with this plugin.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

### 6.3.7.3.2. Using the PAM Authentication Plugin

This section describes how to use the PAM authentication plugin to connect from MySQL client programs to the server. It is assumed that the server-side plugin is enabled and that client programs are recent enough to include the client-side plugin.

#### Note

The client-side plugin with which the PAM plugin communicates simply sends the password to the server in clear text so it can be passed to PAM. This may be a security problem in some configurations, but is necessary to use the server-side PAM library. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using SSL. See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_pam`. For example:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'authentication_string';
```

The authentication string specifies the following types of information:

- PAM supports the notion of “service name,” which is a name that the system administrator can use to configure the authentication method for a particular application. There can be several such “applications” associated with a single database server instance, so the choice of service name is left to the SQL application developer. When you define an account that should authenticate using PAM, specify the service name in the authentication string.
- PAM provides a way for a PAM module to return to the server a MySQL user name other than the login name supplied at login time. Use the authentication string to control the mapping between login name and MySQL user name. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if the service name is `mysql` and users in the `root` and `users` PAM groups should be mapped to the `developer` and `data_entry` users, respectively, use a statement like this:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'mysql, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

- The string consists of a PAM service name, optionally followed by a group mapping list consisting of one or more keyword/value pairs each specifying a group name and a SQL user name:

```
pam_service_name[,group_name=sql_user_name]...
```

- Each `group_name=sql_user_name` pair must be preceded by a comma.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `pam_service_name`, `group_name`, and `sql_user_name` values can contain anything except equal sign, comma, or space.
- If a `pam_service_name`, `group_name`, or `sql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (`'\'`). To include either character, escape it with a backslash.

The plugin parses the authentication string on each login check. To minimize overhead, keep the string as short as possible.

If the plugin successfully authenticates a login name, it looks for a group mapping list in the authentication string and uses it to return a different user name to the MySQL server based on the groups the external user is a member of:

- If the authentication string contains no group mapping list, the plugin returns the login name.
- If the authentication string does contain a group mapping list, the plugin examines each `group_name=sql_user_name` pair in the list from left to right and tries to find a match for the `group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `sql_user_name` for the first match it finds. If the plugin finds no match for any group, it returns the login name. If the plugin is not capable of looking up a group in a directory, it ignores the group mapping list and returns the login name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

- No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication. Authentication can be performed by various PAM-supported methods. The discussion shows how to use traditional Unix passwords and LDAP.

PAM authentication, when not done through proxy users or groups, requires the MySQL account to have the same user name as the Unix account. Because MySQL user names are limited to 16 characters (see [Section 6.2.2, “Privilege System Grant Tables”](#)), this limits PAM nonproxy authentication to Unix accounts with names of at most 16 characters.

- Proxy login only and group mapping. For this scenario, create a few MySQL accounts that define different sets of privileges. (Ideally, nobody should log in through these directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually by the external groups the users are in) to map all the external logins to the few MySQL accounts holding the privilege sets. Any user that logs in is mapped to one of the MySQL accounts and uses its privileges. The discussion shows how to set this up using Unix passwords, but other PAM methods such as LDAP could be used instead.

Variations on these scenarios are possible. For example, you can permit some users to log in directly but require others to connect through proxy users.

The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

- The PAM configuration directory is `/etc/pam.d`.
- The PAM service name is `mysql`, which means that you must set up a PAM file named `mysql` in the PAM configuration directory (creating the file if it does not exist). If you use a different service name, the file name will be different and you must use a different name in the `AS` clause of `CREATE USER` and `GRANT` statements.
- The examples use a login name of `antonio` and password of `verysecret`. Change these to correspond to the users you want to authenticate.

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set. If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related problems that occur when the plugin performs authentication. For more information, see [Section 6.3.7.3.3, “PAM Authentication Plugin Debugging”](#).

#### 6.3.7.3.2.1. Unix Password Authentication without Proxy Users

This authentication scenario uses PAM only to check Unix user login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication.

1. Verify that Unix authentication in PAM permits you to log in as `antonio` with password `verysecret`.
2. Set up PAM to authenticate the `mysql` service. Put the following in `/etc/pam.d/mysql`:

```

#%PAM-1.0
auth            include      password-auth
account         include      password-auth

```

3. Create a MySQL account with the same user name as the Unix login name and define it to authenticate using the PAM plugin:

```

CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam AS 'mysql';
GRANT ALL PRIVILEGES ON mydb.* TO 'antonio'@'localhost';

```

4. Try to connect to the MySQL server using the `mysql` command-line client. For example:

```
mysql --user=antonio --password=verysecret mydb
```

The server should permit the connection and the following query should return output as shown:

```

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | antonio@localhost | NULL         |
+-----+-----+-----+

```

This shows that `antonio` uses the privileges granted to the `antonio` MySQL account, and that no proxying has occurred.

#### 6.3.7.3.2.2. LDAP Authentication without Proxy Users

This authentication scenario uses PAM only to check LDAP user login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication.

1. Verify that LDAP authentication in PAM permits you to log in as `antonio` with password `verysecret`.
2. Set up PAM to authenticate the `mysql` service through LDAP. Put the following in `/etc/pam.d/mysql`:

```

#%PAM-1.0
auth            required     pam_ldap.so
account         required     pam_ldap.so

```

If PAM object files have a suffix different from `.so` on your system, substitute the correct suffix.

3. MySQL account creation and connecting to the server is the same as previously described in [Section 6.3.7.3.2.1, “Unix Password Authentication without Proxy Users”](#).

#### 6.3.7.3.2.3. Unix Password Authentication with Proxy Users and Group Mapping

This authentication scheme uses proxying and group mapping to map users who connect to the MySQL server through PAM onto a few MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy user authenticating through PAM that uses a mapping scheme to map all the external logins to the few MySQL accounts holding the privileges. Any user who connects is mapped to one of the MySQL accounts and uses its privileges.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of [Section 6.3.7.3.2.2, “LDAP Authentication without Proxy Users”](#).

1. Verify that Unix authentication in PAM permits you to log in as `antonio` with password `verysecret` and that `antonio` is a member of the `root` or `users` group.
2. Set up PAM to authenticate the `mysql` service. Put the following in `/etc/pam.d/mysql`:

```

#%PAM-1.0
auth            include            password-auth
account        include            password-auth

```

3. Create the default proxy user that maps the external PAM users to the proxied accounts. It maps external users from the `root` PAM group to the `developer` MySQL account and the external users from the `users` PAM group to the `data_entry` MySQL account:

```

CREATE USER ''@'
  IDENTIFIED WITH authentication_pam
  AS 'mysql, root=developer, users=data_entry';

```

The mapping list following the service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to map the name of PAM groups to the proper proxied user name.

4. Create the proxied accounts that will be used to access the databases:

```

CREATE USER 'developer'@'localhost' IDENTIFIED BY 'very secret password';
GRANT ALL PRIVILEGES ON mydevdb.* TO 'developer'@'localhost';
CREATE USER 'data_entry'@'localhost' IDENTIFIED BY 'very secret password';
GRANT ALL PRIVILEGES ON mydb.* TO 'data_entry'@'localhost';

```

If you do not let anyone know the passwords for these accounts, other users cannot use them to connect directly to the MySQL server. Instead, it is expected that users will authenticate using PAM and that they will use the `developer` or `data_entry` account by proxy based on their PAM group.

5. Grant the `PROXY [755]` privilege to the proxy account for the proxied accounts:

```

GRANT PROXY ON 'developer'@'localhost' TO ''@';
GRANT PROXY ON 'data_entry'@'localhost' TO ''@';

```

6. Try to connect to the MySQL server using the `mysql` command-line client. For example:

```
mysql --user=antonio --password=verysecret mydb
```

The server authenticates the connection using the `''@'` account. The privileges `antonio` will have depends on what PAM groups he is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user name and returns that name to the server. The server verifies that `''@'` has the `PROXY [755]` privilege for `developer` and permits the connection. the following query should return output as shown:

```

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER()    | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | developer@localhost | ''@'         |
+-----+-----+-----+

```

This shows that `antonio` uses the privileges granted to the `developer` MySQL account, and that proxying occurred through the default proxy user account.

If `antonio` is not a member of the `root` PAM group but is a member of the `users` group, a similar process occurs, but the plugin maps `user` group membership to the `data_entry` MySQL user name and returns that name to the server. In this case, `antonio` uses the privileges of the `data_entry` MySQL account:

```

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER()    | @@proxy_user |
+-----+-----+-----+

```

```
| antonio@localhost | data_entry@localhost | '@' |
+-----+-----+-----+-----+
```

### 6.3.7.3.3. PAM Authentication Plugin Debugging

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related problems that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

The following transcript demonstrates the kind of information produced by enabling logging. It resulted from a successful proxy authentication attempt.

### 6.3.7.4. The Windows Native Authentication Plugin

#### Note

The Windows authentication plugin is a commercial extension. To learn more about commercial products (MySQL Enterprise Edition), see <http://www.mysql.com/products/>.

As of MySQL 5.6.10, commercial distributions of MySQL for Windows include an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. The Windows authentication plugin uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

The Windows authentication plugin provides these capabilities:

- External authentication: The plugin enables MySQL Server to accept connections from users defined outside the MySQL grant tables.
- Proxy user support: The plugin can return to MySQL a user name different from the client user. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of the MySQL user named `developer`.

The following table shows the plugin and library file names. The file location must be the directory named by the `plugin_dir` [525] system variable. For installation information, see [Section 6.3.7.4.1, “Installing the Windows Authentication Plugin”](#).

**Table 6.12. MySQL Windows Authentication Plugin**

Server-side plugin name	<code>authentication_windows</code>
Client-side plugin name	<code>authentication_windows_client</code>
Library object file name	<code>authentication_windows.dll</code>

The library file includes only the server-side plugin. The client-side plugin is built into the `libmysqlclient` client library.

The server-side Windows authentication plugin is included only in commercial distributions. It is not included in MySQL community distributions. The client-side plugin is included in all distributions,

including community distributions. This permits clients from any distribution to connect to a server that has the server-side plugin loaded.

The Windows authentication plugin should work on Windows 2000 Professional and up. It requires MySQL Server 5.6.10 or newer.

For general information about pluggable authentication in MySQL, see [Section 6.3.7, “Pluggable Authentication”](#). For proxy user information, see [Section 6.3.8, “Proxy Users”](#).

#### 6.3.7.4.1. Installing the Windows Authentication Plugin

The Windows authentication plugin must be installed in the MySQL plugin directory (the directory named by the `plugin_dir` [525] system variable). If necessary, set the value of `plugin_dir` [525] at server startup to tell the server the location of the plugin directory.

To enable the plugin, start the server with the `--plugin-load` [435] option. For example, put these lines in your `my.ini` file:

```
[mysqld]
plugin-load=authentication_windows.dll
```

Use the plugin name `authentication_windows` in the `IDENTIFIED WITH` clause of `CREATE USER` or `GRANT` statements for MySQL accounts that should be authenticated with this plugin.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

#### 6.3.7.4.2. Using the Windows Authentication Plugin

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server-side plugin is enabled and that client programs are recent enough to include the client-side plugin built into `libmysqlclient`. Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_windows`. Suppose that the Windows users `Rafal` and `Tasha` should be permitted to connect to MySQL, as well as any users in the `Administrators` or `Power Users` group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users"');
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named `Rafal` or `Tasha` are permitted to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the `Administrators` or `Power Users` group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```
C:\> mysql --user=sql_admin
```

No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named `Rafal` or `Tasha`, or is in the `Administrators` or `Power Users` group, the server grants access and the client is authenticated as `sql_admin` and has whatever privileges are granted to the `sql_admin` account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.
- Each user mapping associates a Windows user or group name with a MySQL user name:

```
win_user_or_group_name=sql_user_name
win_user_or_group_name
```

For the latter syntax, with no *sql\_user\_name* value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

```
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users"';

CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin,
    "Power Users"=sql_admin';
```

- Each backslash (`'\'`) in a value must be doubled because backslash is the escape character in MySQL strings.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted *win\_user\_or\_group\_name* and *sql\_user\_name* values can contain anything except equal sign, comma, or space.
- If a *win\_user\_or\_group\_name* and or *sql\_user\_name* value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.
- *win\_user\_or\_group\_name* values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```
domain\\user
.\user
domain\group
.\group
BUILTIN\WellKnownGroup
```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding *sql\_user\_name* to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named *win\_user* is a member of *win\_group* and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```

When *win\_user* connects to the MySQL server, there is a match both to *win\_group* and to *win\_user*. The plugin authenticates the user as *sql\_user2* because the more-specific user match takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
  IDENTIFIED WITH authentication_windows
```

```
AS 'SomeDomain\\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see [Section 6.3.8, “Proxy Users”](#)). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.
- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.
- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```
CREATE USER win_proxy
  IDENTIFIED WITH authentication_windows
  AS 'local_user = local_wlad,
     MyDomain\\domain_user = local_wlad,
     MyDomain\\Developers = local_dev,
     BUILTIN\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```
CREATE USER local_wlad IDENTIFIED BY 'wlad_pass';
CREATE USER local_dev IDENTIFIED BY 'dev_pass';
CREATE USER local_admin IDENTIFIED BY 'admin_pass';
```

If you do not let anyone know the passwords for these accounts, other users cannot use them to connect directly to the MySQL server.

You should also issue `GRANT` statements (not shown) that grant each proxied account the privileges it needs.

3. The proxy account must have the `PROXY [755]` privilege for each of the proxied accounts:

```
GRANT PROXY ON local_wlad TO win_proxy;
GRANT PROXY ON local_dev TO win_proxy;
GRANT PROXY ON local_admin TO win_proxy;
```

Now the Windows users `local_user` and `MyDomain\domain_user` can connect to the MySQL server as `win_proxy` and when authenticated have the privileges of the account given in the authentication string—in this case, `local_wlad`. A user in the `MyDomain\Developers` group who connects as `win_proxy` has the privileges of the `local_dev` account. A user in the `BUILTIN\Administrators` group has the privileges of the `local_admin` account.

To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy user (`' '@ '`) for `win_proxy` in the preceding instructions. For information about the default proxy user, see [Section 6.3.8, “Proxy Users”](#).

To use the Windows authentication plugin with Connector/Net connection strings in Connector/Net 6.4.4 and higher, see [Section 21.2.5.5, “Using the Windows Native Authentication Plugin”](#).

Additional control over the Windows authentication plugin is provided by the `authentication_windows_use_principal_name` [464] and `authentication_windows_log_level` [463] system variables. See [Section 5.1.4, “Server System Variables”](#).

### 6.3.7.5. The Cleartext Client-Side Authentication Plugin

As of MySQL 5.6.2, a client-side authentication plugin is available that sends the password to the server without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

**Table 6.13. MySQL Cleartext Authentication Plugin**

Server-side plugin name	None, see discussion
Client-side plugin name	<code>mysql_clear_password</code>
Library object file name	None (plugin is built in)

With native MySQL authentication, the client performs one-way hashing on the password before sending it to the server. This enables the client to avoid sending the password in clear text. See [Section 6.1.2.4, “Password Hashing in MySQL”](#). However, because the hash algorithm is one way, the original password cannot be recovered on the server side.

One-way hashing cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the `mysql_clear_password` client-side plugin can be used to send the password to the server in clear text. There is no corresponding server-side plugin. Rather, the client-side plugin can be used by any server-side plugin that needs a clear text password.

For general information about pluggable authentication in MySQL, see [Section 6.3.7, “Pluggable Authentication”](#).

#### Note

Sending passwords in clear text may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see [Section 6.3.9, “Using SSL for Secure Connections”](#)), IPsec, or a private network.

As of MySQL 5.6.7, to make inadvertent use of this plugin less likely, it is required that clients explicitly enable it. This can be done several ways:

- Set the `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` environment variable to a value that begins with `1`, `Y`, or `y`. This enables the plugin for all client connections.
- The `mysql`, `mysqladmin`, and `mysqlslap` client programs support an `--enable-cleartext-plugin` option that enables the plugin on a per-invocation basis.
- The `mysql_options()` C API function supports a `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option that enables the plugin on a per-connection basis. Also, any program that uses `libmysqlclient` and reads option files can enable the plugin by including an `enable-cleartext-plugin` option in an option group read by the client library.

### 6.3.7.6. The Socket Peer-Credential Authentication Plugin

As of MySQL 5.6.2, a server-side authentication plugin is available that authenticates clients that connect from the local host through the Unix socket file.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file location is the directory named by the `plugin_dir` [525] system variable. For installation information, see [Section 6.3.7, “Pluggable Authentication”](#).

**Table 6.14. MySQL Socket Peer-Credential Authentication Plugin**

Server-side plugin name	<code>auth_socket</code>
Client-side plugin name	None, see discussion
Library object file name	<code>auth_socket.so</code>

The `auth_socket` authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the `SO_PEERCRED` socket option to obtain information about the user running the client program. The plugin checks whether the user name matches the MySQL user name specified by the client program to the server, and permits the connection only if the names match. The plugin can be built only on systems that support the `SO_PEERCRED` option, such as Linux.

Suppose that a MySQL account is created for a user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user's name (`stefanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However, the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.

For general information about pluggable authentication in MySQL, see [Section 6.3.7, “Pluggable Authentication”](#).

### 6.3.7.7. The Test Authentication Plugin

MySQL includes a test plugin that authenticates using MySQL native authentication, but is a loadable plugin (not built in) and must be installed prior to use. It can authenticate against either normal or older (shorter) password hash values.

This plugin is intended for testing and development purposes, and not for use in production environments. The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file location is the directory named by the `plugin_dir` [525] system variable. For installation information, see [Section 6.3.7, “Pluggable Authentication”](#).

**Table 6.15. MySQL Test Authentication Plugin**

Server-side plugin name	<code>test_plugin_server</code>
Client-side plugin name	<code>auth_test_plugin</code>
Library object file name	<code>auth_test_plugin.so</code>

Because the test plugin authenticates the same way as native MySQL authentication, provide the usual `--user` [212] and `--password` [211] options that you normally use for accounts that use native authentication when you connect to the server. For example:

```
shell> mysql --user=your_name --password=your_pass
```

For general information about pluggable authentication in MySQL, see [Section 6.3.7, “Pluggable Authentication”](#).

### 6.3.8. Proxy Users

When authentication to the MySQL server occurs by means of an authentication plugin, the plugin may request that the connecting (external) user be treated as a different user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to have the privileges of the second user. In other words, the external user is a “proxy user” (a user who can impersonate or become known as another user) and the second user is a “proxied user” (a user whose identity can be taken on by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see [Section 6.3.7, “Pluggable Authentication”](#). If you are interested in writing your own authentication plugins that support proxy users, see [Section 22.2.4.9.4, “Implementing Proxy User Support in Authentication Plugins”](#).

For proxying to occur, these conditions must be satisfied:

- When a connecting client should be treated as a proxy user, the plugin must return a different name, to indicate the proxied user name.
- A proxy user account must be set up to be authenticated by the plugin. Use the `CREATE USER` or `GRANT` statement to associate an account with a plugin.
- A proxy user account must have the `PROXY [755]` privilege for the proxied account. Use the `GRANT` statement for this.

Consider the following definitions:

```
CREATE USER 'empl_external'@'localhost'
  IDENTIFIED WITH auth_plugin AS 'auth_string';
CREATE USER 'employee'@'localhost'
  IDENTIFIED BY 'employee_pass';
GRANT PROXY
  ON 'employee'@'localhost'
  TO 'empl_external'@'localhost';
```

When a client connects as `empl_external` from the local host, MySQL uses `auth_plugin` to perform authentication. If `auth_plugin` returns the `employee` user name to the server (based on the content of `'auth_string'` and perhaps by consulting some external authentication system), that serves as a request to the server to treat this client, for purposes of privilege checking, as the `employee` local user.

In this case, `empl_external` is the proxy user and `employee` is the proxied user.

The server verifies that proxy authentication for `employee` is possible for the `empl_external` user by checking whether `empl_external` has the `PROXY [755]` privilege for `employee`. (If this privilege had not been granted, an error would occur.)

When proxying occurs, the `USER()` and `CURRENT_USER()` functions can be used to see the difference between the connecting user and the account whose privileges apply during the current session. For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| empl_external@localhost | employee@localhost |
+-----+-----+
```

The `IDENTIFIED WITH` clause that names the authentication plugin may be followed by an `AS` clause specifying a string that the server passes to the plugin when the user connects. It is up to each plugin

whether the `AS` clause is required. If it is required, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

## Granting the Proxy Privilege

A special `PROXY [755]` privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the `GRANT` statement. For example:

```
GRANT PROXY ON 'proxied_user' TO 'proxy_user';
```

`proxy_user` must represent a valid externally authenticated MySQL user at connection time or connection attempts fail. `proxied_user` must represent a valid locally authenticated user at connection time or connection attempts fail.

The corresponding `REVOKE` syntax is:

```
REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';
```

MySQL `GRANT` and `REVOKE` syntax extensions work as usual. For example:

```
GRANT PROXY ON 'a' TO 'b', 'c', 'd';
GRANT PROXY ON 'a' TO 'd' IDENTIFIED BY ...;
GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;
GRANT PROXY ON 'a' TO '@';
REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';
```

In the preceding example, `'@'` is the default proxy user and means “any user.” The default proxy user is discussed later in this section.

The `PROXY [755]` privilege can be granted in these cases:

- By `proxied_user` for itself: The value of `USER()` must exactly match `CURRENT_USER()` and `proxied_user`, for both the user name and host name parts of the account name.
- By a user that has `GRANT PROXY ... WITH GRANT OPTION` for `proxied_user`.

The `root` account created by default during MySQL installation has the `PROXY ... WITH GRANT OPTION [755]` privilege for `'@'`, that is, for all users. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, `root` can do this:

```
CREATE USER 'admin'@'localhost' IDENTIFIED BY 'test';
GRANT PROXY ON '@' TO 'admin'@'localhost' WITH GRANT OPTION;
```

Now the `admin` user can manage all the specific `GRANT PROXY` mappings. For example, `admin` can do this:

```
GRANT PROXY ON sally TO joe;
```

## Default Proxy Users

To specify that some or all users should connect using a given external plugin, create a “blank” MySQL user, set it up to use that plugin for authentication, and let the plugin return the real authenticated user name (if different from the blank user). For example, suppose that there exists a hypothetical plugin named `ldap_auth` that implements LDAP authentication:

```
CREATE USER '@' IDENTIFIED WITH ldap_auth AS 'O=Oracle, OU=MySQL';
CREATE USER 'developer'@'localhost' IDENTIFIED BY 'developer_pass';
CREATE USER 'manager'@'localhost' IDENTIFIED BY 'manager_pass';
GRANT PROXY ON 'manager'@'localhost' TO '@';
GRANT PROXY ON 'developer'@'localhost' TO '@';
```

Now assume that a client tries to connect as follows:

```
mysql --user=myuser --password='myuser_pass' ...
```

The server will not find `myuser` defined as a MySQL user. But because there is a blank user account (`' '@'`), that matches the client user name and host name, the server authenticates the client against that account: The server invokes `ldap_auth`, passing it `myuser` and `myuser_pass` as the user name and password.

If the `ldap_auth` plugin finds in the LDAP directory that `myuser_pass` is not the correct password for `myuser`, authentication fails and the server rejects the connection.

If the password is correct and `ldap_auth` finds that `myuser` is a developer, it returns the user name `developer` to the MySQL server, rather than `myuser`. The server verifies that `' '@'` can authenticate as `developer` (because it has the `PROXY [755]` privilege to do so) and accepts the connection. The session proceeds with `myuser` having the privileges of `developer`. (These privileges should be set up by the DBA using `GRANT` statements, not shown.) The `USER()` [1273] and `CURRENT_USER()` [1267] functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| myuser@localhost | developer@localhost |
+-----+-----+
```

If the plugin instead finds in the LDAP directory that `myuser` is a manager, it returns `manager` as the user name and the session proceeds with `myuser` having the privileges of `manager`.

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| myuser@localhost | manager@localhost |
+-----+-----+
```

For simplicity, external authentication cannot be multilevel: Neither the credentials for `developer` nor those for `manager` are taken into account in the preceding example. However, they are still used if a client tries to authenticate directly against the `developer` or `manager` account, which is why those accounts should be assigned passwords.

The default proxy account uses `' '@'` in the host part, which matches any host. If you set up a default proxy user, take care to also check for accounts with `' @%'` in the host part, because that also matches any host, but has precedence over `' '@'` by the rules that the server uses to sort account rows internally (see [Section 6.2.4, “Access Control, Stage 1: Connection Verification”](#)).

Suppose that a MySQL installation includes these two accounts:

```
CREATE USER '@' IDENTIFIED WITH some_plugin;
CREATE USER '@%' IDENTIFIED BY 'some_password';
```

The intent of the first account is to serve as the default proxy user, to be used to authenticate connections for users who do not otherwise match a more-specific account. The second account might have been created, for example, to enable users without their own account as the anonymous user.

However, in this configuration, the first account will never be used because the matching rules sort `' @%'` ahead of `' '@'`. For accounts that do not match any more-specific account, the server will attempt to authenticate them against `' @%'` rather than `' '@'`.

If you intend to create a default proxy user, check for other existing “match any user” accounts that will take precedence over the default proxy user and thus prevent that user from working as intended. It may be necessary to remove any such accounts.

## Proxy User System Variables

Two system variables help trace the proxy login process:

- `proxy_user` [526]: This value is `NULL` if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the default proxy account, this variable will be set as follows:

```
mysql> SELECT @@proxy_user;
+-----+
| @@proxy_user |
+-----+
| ''@''        |
+-----+
```

- `external_user` [482]: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that authenticates using the windows API does not need the login ID passed to it. However, it still uses an Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the `external_user` read-only session variable. If the plugin does not set this variable, its value is `NULL`.

### 6.3.9. Using SSL for Secure Connections

MySQL supports secure (encrypted) connections between MySQL clients and the server using the Secure Sockets Layer (SSL) protocol. This section discusses how to use SSL connections. For information on how to require users to use SSL connections, see the discussion of the `REQUIRE` clause of the `GRANT` statement in [Section 13.7.1.4, “GRANT Syntax”](#).

The standard configuration of MySQL is intended to be as fast as possible, so encrypted connections are not used by default. For applications that require the security provided by encrypted connections, the extra computation to encrypt the data is worthwhile.

MySQL enables encryption on a per-connection basis. You can choose an unencrypted connection or a secure encrypted SSL connection according to the requirements of individual applications.

Secure connections are based on the OpenSSL API and are available through the MySQL C API. Replication uses the C API, so secure connections can be used between master and slave servers. See [Section 16.3.7, “Setting Up Replication Using SSL”](#).

Another way to connect securely is from within an SSH connection to the MySQL server host. For an example, see [Section 6.3.10, “Connecting to MySQL Remotely from Windows with SSH”](#).

#### 6.3.9.1. Basic SSL Concepts

To understand how MySQL uses SSL, it is necessary to explain some basic SSL and X509 concepts. People who are familiar with these concepts can skip this part of the discussion.

By default, MySQL uses unencrypted connections between the client and the server. This means that someone with access to the network could watch all your traffic and look at the data being sent or received. They could even change the data while it is in transit between client and server. To improve security a little, you can compress client/server traffic by using the `--compress` option when invoking client programs. However, this does not foil a determined attacker.

When you need to move information over a network in a secure fashion, an unencrypted connection is unacceptable. Encryption is the way to make any kind of data unreadable. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

SSL is a protocol that uses different encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect any data change, loss, or replay. SSL also incorporates algorithms that provide identity verification using the X509 standard.

X509 makes it possible to identify someone on the Internet. It is most commonly used in e-commerce applications. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption

algorithms that have two encryption keys (a public key and a secret key). A certificate owner can show the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted with this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

For more information about SSL, X509, encryption, or public-key cryptography, perform an Internet search for the keywords in which you are interested.

### 6.3.9.2. Configuring MySQL for SSL

To use SSL connections between the MySQL server and client programs, your system must support either OpenSSL or yaSSL, and your version of MySQL must be built with SSL support. To make it easier to use secure connections, MySQL is bundled with yaSSL, which uses the same licensing model as MySQL. (OpenSSL uses an Apache-style license.) yaSSL support is available on all MySQL platforms supported by Oracle Corporation.

To get secure connections to work with MySQL and SSL, you must do the following:

1. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, and you are going to use OpenSSL rather than the bundled yaSSL library, install OpenSSL if it has not already been installed. We have tested MySQL with OpenSSL 1.0.0. To obtain OpenSSL, visit <http://www.openssl.org>.

Building MySQL using OpenSSL requires a shared OpenSSL library, otherwise linker errors occur. Alternatively, build MySQL using yaSSL.

2. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, configure a MySQL source distribution to use SSL. When you configure MySQL, invoke `CMake` like this:

```
shell> cmake . -DWITH_SSL=bundled
```

That command configures the distribution to use the bundled yaSSL library. To use the system SSL library instead, specify the option like this instead:

```
shell> cmake . -DWITH_SSL=system
```

See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

Then compile and install the distribution.

On Unix platforms, yaSSL retrieves true random numbers from either either `/dev/urandom` or `/dev/random`. Bug#13164 lists workarounds for some very old platforms which do not support these devices.

3. To check whether a `mysqld` server supports SSL, examine the value of the `have_ssl` [487] system variable:

```
mysql> SHOW VARIABLES LIKE 'have_ssl';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_ssl      | YES   |
+-----+-----+
```

If the value is `YES`, the server supports SSL connections. If the value is `DISABLED`, the server is capable of supporting SSL connections but was not started with the appropriate `--ssl-xxx` options to enable them to be used; see [Section 6.3.9.3, “Using SSL Connections”](#).

### 6.3.9.3. Using SSL Connections

To enable SSL connections, your MySQL distribution must be built with SSL support, as described in [Section 6.3.9.2, “Configuring MySQL for SSL”](#). In addition, the proper SSL-related options must

be used to specify the appropriate certificate and key files. For a complete list of SSL options, see [Section 6.3.9.4, “SSL Command Options”](#).

To start the MySQL server so that it permits clients to connect using SSL, use the options that identify the certificate and key files the server uses when establishing a secure connection:

- `--ssl-ca` [810] identifies the Certificate Authority (CA) certificate.
- `--ssl-cert` [811] identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key` [811] identifies the server private key.

For example, start the server like this:

```
shell> mysqld --ssl-ca=ca-cert.pem \
             --ssl-cert=server-cert.pem \
             --ssl-key=server-key.pem
```

Each option names a file in PEM format. For instructions on generating the required SSL certificate and key files, see [Section 6.3.9.5, “Setting Up SSL Certificates and Keys for MySQL”](#). If you have a MySQL source distribution, you can also test your setup using the demonstration certificate and key files in the `mysql-test/std_data` directory of the distribution.

Similar options are used on the client side, although in this case, `--ssl-cert` [811] and `--ssl-key` [811] identify the client public and private key. Note that the Certificate Authority certificate, if specified, must be the same as used by the server.

To establish a secure connection to a MySQL server with SSL support, the options that a client must specify depend on the SSL requirements of the MySQL account used by the client. (See the discussion of the `REQUIRE` clause in [Section 13.7.1.4, “GRANT Syntax”](#).)

Suppose that you want to connect using an account that has no special SSL requirements or was created using a `GRANT` statement that includes the `REQUIRE SSL` option. As a recommended set of SSL options, start the server with at least `--ssl-cert` [811] and `--ssl-key` [811], and invoke the client with `--ssl-ca` [810]. A client can connect securely like this:

```
shell> mysql --ssl-ca=ca-cert.pem
```

To require that a client certificate also be specified, create the account using the `REQUIRE X509` option. Then the client must also specify the proper client key and certificate files or the server will reject the connection:

```
shell> mysql --ssl-ca=ca-cert.pem \
             --ssl-cert=client-cert.pem \
             --ssl-key=client-key.pem
```

A client can determine whether the current connection with the server uses SSL by checking the value of the `Ssl_cipher` [599] status variable. The value of `Ssl_cipher` [599] is nonempty if SSL is used, and empty otherwise. For example:

```
mysql> SHOW STATUS LIKE 'Ssl_cipher';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| Ssl_cipher    | DHE-RSA-AES256-SHA                |
+-----+-----+
```

For the `mysql` client, an alternative is to use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
...
SSL:                               Not in use
```

...

Or:

```
mysql> \s
...
SSL:                Cipher in use is DHE-RSA-AES256-SHA
...
```

The C API enables application programs to use SSL:

- To establish a secure connection, program, use the `mysql_ssl_set()` C API function to set the appropriate certificate options before calling `mysql_real_connect()`. See [Section 21.8.6.68](#), “`mysql_ssl_set()`”.
- To determine whether SSL is in use after the connection is established, use `mysql_get_ssl_cipher()`. A non-NULL return value indicates a secure connection and names the SSL cipher used for encryption. A NULL return value indicates that SSL is not being used. See [Section 21.8.6.33](#), “`mysql_get_ssl_cipher()`”.

Replication uses the C API, so secure connections can be used between master and slave servers. See [Section 16.3.7](#), “[Setting Up Replication Using SSL](#)”.

### 6.3.9.4. SSL Command Options

This section describes options that are used to specify whether to use SSL and the names of SSL certificate and key files. These options can be given on the command line or in an option file. They are not available unless MySQL has been built with SSL support. See [Section 6.3.9.2](#), “[Configuring MySQL for SSL](#)”.

**Table 6.16. SSL Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">have_openssl [487]</a>			Yes		Global	No
<a href="#">have_ssl [487]</a>			Yes		Global	No
<a href="#">skip-ssl [810]</a>	Yes	Yes				
<a href="#">ssl [810]</a>	Yes	Yes				
<a href="#">ssl-ca [810]</a>	Yes	Yes			Global	No
- Variable: <code>ssl_ca</code>			Yes		Global	No
<a href="#">ssl-capath [810]</a>	Yes	Yes			Global	No
- Variable: <code>ssl_capath</code>			Yes		Global	No
<a href="#">ssl-cert [811]</a>	Yes	Yes			Global	No
- Variable: <code>ssl_cert</code>			Yes		Global	No
<a href="#">ssl-cipher [811]</a>	Yes	Yes			Global	No
- Variable: <code>ssl_cipher</code>			Yes		Global	No
<a href="#">ssl-crl [811]</a>	Yes	Yes			Global	No
- Variable: <code>ssl_crl</code>			Yes		Global	No
<a href="#">ssl-crlpath [811]</a>	Yes	Yes			Global	No
- Variable: <code>ssl_crlpath</code>			Yes		Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">ssl-key [811]</a>	Yes	Yes			Global	No
- Variable: <code>ssl_key</code>			Yes		Global	No
<a href="#">ssl-verify-server-cert [811]</a>	Yes	Yes				

- [--ssl \[810\]](#)

For the server, this option specifies that the server permits SSL connections. For a client program, it permits the client to connect to the server using SSL, but this option is not sufficient in itself to cause an SSL connection to be used. As a recommended set of options to enable SSL connections, use at least [--ssl-cert \[811\]](#) and [--ssl-key \[811\]](#) on the server side and [--ssl-ca \[810\]](#) on the client side.

[--ssl \[810\]](#) is implied by other [--ssl-xxx](#) options as indicated in the descriptions for those options. For this reason, [--ssl \[810\]](#) is not usually specified explicitly. It is more often used explicitly in its opposite form to override other SSL options and indicate that SSL should *not* be used. To do this, specify the option as [--skip-ssl \[810\]](#) or [--ssl=0 \[810\]](#). For example, you might have SSL options specified in the `[client]` group of your option file to use SSL connections by default when you invoke MySQL client programs. To use an unencrypted connection instead, invoke the client program with [--skip-ssl \[810\]](#) on the command line to override the options in the option file.

Use of [--ssl \[810\]](#) does not *require* an SSL connection to be used, it only permits it. For example, if you specify this option for a client program but the server has not been configured to permit SSL connections, an unencrypted connection is used.

The secure way to require use of an SSL connection is to create a MySQL account that includes at least a `REQUIRE SSL` clause in the `GRANT` statement. In this case, connections for that account will be rejected unless MySQL supports SSL connections and the server and client have been started with the proper SSL options.

The `REQUIRE` clause permits other SSL-related restrictions as well. These can be used for stricter requirements than `REQUIRE SSL`. The description of `REQUIRE` in [Section 13.7.1.4, “GRANT Syntax”](#), provides additional detail about which SSL command options may or must be specified by clients that connect using accounts that are created using the various `REQUIRE` options.

- [--ssl-ca=file\\_name \[810\]](#)

The path to a file in PEM format that contains a list of trusted SSL certificate authorities. This option implies [--ssl \[810\]](#).

If you use SSL when establishing a client connection, you can tell the client not to authenticate the server certificate by specifying neither [--ssl-ca \[810\]](#) nor [--ssl-capath \[810\]](#). The server still verifies the client according to any applicable requirements established using `GRANT` statements for the client, and it still uses any [--ssl-ca \[810\]](#)/[--ssl-capath \[810\]](#) values that were passed to server at startup.

- [--ssl-capath=dir\\_name \[810\]](#)

The path to a directory that contains trusted SSL certificate authority certificates in PEM format. This option implies [--ssl \[810\]](#).

If you use SSL when establishing a client connection, you can tell the client not to authenticate the server certificate by specifying neither [--ssl-ca \[810\]](#) nor [--ssl-capath \[810\]](#). The server still verifies the client according to any applicable requirements established using `GRANT` statements for the client, and it still uses any [--ssl-ca \[810\]](#)/[--ssl-capath \[810\]](#) values that were passed to server at startup.

MySQL distributions built with OpenSSL support the `--ssl-capath [810]` option. Distributions built with yaSSL do not because yaSSL does not look in any directory and does not follow a chained certificate tree. yaSSL requires that all components of the CA certificate tree be contained within a single CA certificate tree and that each certificate in the file has a unique SubjectName value. To work around this yaSSL limitation, concatenate the individual certificate files comprising the certificate tree into a new file. Then specify the new file as the value of the `--ssl-capath [810]` option.

- `--ssl-cert=file_name [811]`

The name of the SSL certificate file in PEM format to use for establishing a secure connection. This option implies `--ssl [810]`.

- `--ssl-cipher=cipher_list [811]`

A list of permissible ciphers to use for SSL encryption. If no cipher in the list is supported, SSL connections will not work. This option implies `--ssl [810]`.

For greatest portability, `cipher_list` should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. Examples:

```
--ssl-cipher=AES128-SHA
--ssl-cipher=DHE-RSA-AES256-SHA:AES128-SHA
```

OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at <http://www.openssl.org/docs/apps/ciphers.html>. However, yaSSL does not, so attempts to use that extended syntax fails for a MySQL distribution built with yaSSL.

- `--ssl-crl=file_name [811]`

The path to a file containing certificate revocation lists in PEM format. This option implies `--ssl [810]`. If neither `--ssl-crl [811]` nor `--ssl-crlpath [811]` is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

MySQL distributions built with OpenSSL support the `--ssl-crl [811]` option. Distributions built with yaSSL do not because yaSSL revocation lists do not work with yaSSL.

This option was added in MySQL 5.6.3.

- `--ssl-crlpath=dir_name [811]`

The path to a directory that contains files containing certificate revocation lists in PEM format. This option implies `--ssl [810]`. If neither `--ssl-crl [811]` nor `--ssl-crlpath [811]` is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

MySQL distributions built with OpenSSL support the `--ssl-crlpath [811]` option. Distributions built with yaSSL do not because yaSSL revocation lists do not work with yaSSL.

This option was added in MySQL 5.6.3.

- `--ssl-key=file_name [811]`

The name of the SSL key file in PEM format to use for establishing a secure connection.

If the MySQL distribution was built using OpenSSL or (as of MySQL 5.6.3) yaSSL and the key file is protected by a passphrase, the program will prompt the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key. Before MySQL 5.6.3, if the MySQL distribution was built using yaSSL and the key file is protected by a passphrase, an error occurs.

- `--ssl-verify-server-cert [811]`

This option is available for client programs only, not the server. It causes the client to check the server's Common Name value in the certificate that the server sends to the client. The client verifies that name against the host name the client uses for connecting to the server, and the connection fails if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default.

### 6.3.9.5. Setting Up SSL Certificates and Keys for MySQL

This section demonstrates how to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

#### Example 1: Creating SSL Files from the Command Line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the `openssl` commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts

# Create CA certificate
shell> openssl genrsa 2048 > ca-key.pem
shell> openssl req -new -x509 -nodes -days 3600 \
    -key ca-key.pem -out ca-cert.pem

# Create server certificate, remove passphrase, and sign it
# server-cert.pem = public key, server-key.pem = private key
shell> openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout server-key.pem -out server-req.pem
shell> openssl rsa -in server-key.pem -out server-key.pem
shell> openssl x509 -req -in server-req.pem -days 3600 \
    -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
# client-cert.pem = public key, client-key.pem = private key
shell> openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout client-key.pem -out client-req.pem
shell> openssl rsa -in client-key.pem -out client-key.pem
shell> openssl x509 -req -in client-req.pem -days 3600 \
    -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

After generating the certificates, verify them:

```
shell> openssl verify -CAfile ca-cert.pem server-cert.pem client-cert.pem
server-cert.pem: OK
client-cert.pem: OK
```

Now you have a set of files that can be used as follows:

- `ca-cert.pem`: Use this as the argument to `--ssl-ca` [810] on the server and client sides. (The CA certificate, if used, must be the same on both sides.)
- `server-cert.pem`, `server-key.pem`: Use these as the arguments to `--ssl-cert` [811] and `--ssl-key` [811] on the server side.
- `client-cert.pem`, `client-key.pem`: Use these as the arguments to `--ssl-cert` [811] and `--ssl-key` [811] on the client side.

To use the files to test SSL connections, see [Section 6.3.9.3, “Using SSL Connections”](#).

**Example 2: Creating SSL Files Using a Script on Unix**

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files to test SSL connections as described in [Section 6.3.9.3, "Using SSL Connections"](#).

```

DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
# Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca-cert.pem \
    -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# .....+++++
# .....+++++
# writing new private key to '/home/monty/openssl/private/cakey.pem'
# Enter PEM pass phrase:
# Verifying password - Enter PEM pass phrase:
# -----
# You are about to be asked to enter information that will be
# incorporated into your certificate request.
# What you are about to enter is what is called a Distinguished Name
# or a DN.
# There are quite a few fields but you can leave some blank
# For some fields there will be a default value,
# If you enter '.', the field will be left blank.
# -----
# Country Name (2 letter code) [AU]:FI
# State or Province Name (full name) [Some-State]:.
# Locality Name (eg, city) []:
# Organization Name (eg, company) [Internet Widgits Pty Ltd]:MySQL AB
# Organizational Unit Name (eg, section) []:
# Common Name (eg, YOUR name) []:MySQL admin
# Email Address []:

#
# Create server request and key
#

openssl req -new -keyout $DIR/server-key.pem -out \
    $DIR/server-req.pem -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# ..+++++
# .....+++++
# writing new private key to '/home/monty/openssl/server-key.pem'
# Enter PEM pass phrase:
# Verifying password - Enter PEM pass phrase:
# -----
# You are about to be asked to enter information that will be
# incorporated into your certificate request.
# What you are about to enter is what is called a Distinguished Name
# or a DN.
# There are quite a few fields but you can leave some blank

```

```

# For some fields there will be a default value,
# If you enter '.', the field will be left blank.
# -----
# Country Name (2 letter code) [AU]:FI
# State or Province Name (full name) [Some-State]:.
# Locality Name (eg, city) []:
# Organization Name (eg, company) [Internet Widgits Pty Ltd]:MySQL AB
# Organizational Unit Name (eg, section) []:
# Common Name (eg, YOUR name) []:MySQL server
# Email Address []:
#
# Please enter the following 'extra' attributes
# to be sent with your certificate request
# A challenge password []:
# An optional company name []:

#
# Remove the passphrase from the key
#
openssl rsa -in $DIR/server-key.pem -out $DIR/server-key.pem

#
# Sign server cert
#
openssl ca -cert $DIR/ca-cert.pem -policy policy_anything \
  -out $DIR/server-cert.pem -config $DIR/openssl.cnf \
  -infile $DIR/server-req.pem

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Enter PEM pass phrase:
# Check that the request matches the signature
# Signature ok
# The Subjects Distinguished Name is as follows
# countryName           :PRINTABLE:'FI'
# organizationName      :PRINTABLE:'MySQL AB'
# commonName            :PRINTABLE:'MySQL admin'
# Certificate is to be certified until Sep 13 14:22:46 2003 GMT
# (365 days)
# Sign the certificate? [y/n]:y
#
#
# 1 out of 1 certificate requests certified, commit? [y/n]y
# Write out database with 1 new entries
# Data Base Updated

#
# Create client request and key
#
openssl req -new -keyout $DIR/client-key.pem -out \
  $DIR/client-req.pem -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# .....++++++
# .....++++++
# writing new private key to '/home/monty/openssl/client-key.pem'
# Enter PEM pass phrase:

#
# Create a my.cnf file that you can use to test the certificates
#

cat <<EOF > $DIR/my.cnf
[client]
ssl-ca=$DIR/ca-cert.pem
ssl-cert=$DIR/client-cert.pem
ssl-key=$DIR/client-key.pem
[mysqld]
ssl-ca=$DIR/ca-cert.pem
ssl-cert=$DIR/server-cert.pem
ssl-key=$DIR/server-key.pem
EOF

```

### Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

<http://www.slproweb.com/products/Win32OpenSSL.html>

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location will be `C:\OpenSSL-Win32` or `C:\OpenSSL-Win64`, depending on which package you downloaded. The following instructions assume a default location of `C:\OpenSSL-Win32`. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating '`...critical component is missing: Microsoft Visual C++ 2008 Redistributables`', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=9B2DA534-3E03-4391-8A4D-074B9F2BC1BF>

- Visual C++ 2008 Redistributables (x64), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=bd2a6171-e2d6-4230-b809-9a8d7548c1b6>

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default `C:\OpenSSL-Win32` as the install path, and also leave the default option '`Copy OpenSSL DLL files to the Windows system directory`' selected.

When the installation has finished, add `C:\OpenSSL-Win32\bin` to the Windows System Path variable of your server:

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Select the Advanced tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
3. Under **System Variables**, select Path, then click the **Edit** button. The **Edit System Variable** dialogue should appear.
4. Add ' `;C:\OpenSSL-Win32\bin`' to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \

C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

Depending on your version of Windows, the preceding path-setting instructions might differ slightly.

After OpenSSL has been installed, use instructions similar to those from from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts
```

On Windows, use these commands instead:

```
# Create clean environment
shell> md c:\newcerts
shell> cd c:\newcerts
```

- When a '`\`' character is shown at the end of a command line, this '`\`' character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them to test SSL connections, see [Section 6.3.9.3, "Using SSL Connections"](#).

### 6.3.10. Connecting to MySQL Remotely from Windows with SSH

This section describes how to get a secure connection to a remote MySQL server with SSH. The information was provided by David Carlson <[dcarlson@mplcomm.com](mailto:dcarlson@mplcomm.com)>.

1. Install an SSH client on your Windows machine. As a user, the best nonfree one I have found is from *SecureCRT* from <http://www.vandyke.com/>. Another option is *f-secure* from <http://www.f-secure.com/>. You can also find some free ones on *Google* at <http://directory.google.com/Top/Computers/Internet/Protocols/SSH/Clients/Windows/>.
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306, remote_host: yourmysqlservername_or_ip, remote_port: 3306`) or a local forward (Set `port: 3306, host: localhost, remote port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.
6. On your Windows machine, start some ODBC application (such as Access).
7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

### 6.3.11. MySQL Enterprise Audit Log Plugin

#### Note

MySQL Enterprise Audit is a commercial extension. To learn more about commercial products (MySQL Enterprise Edition), see <http://www.mysql.com/products/>.

As of MySQL 5.6.10, MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

After you install the plugin (see [Section 6.3.11.1, “Installing the Audit Log Plugin”](#)), it writes an audit log file. By default, the file is named `audit.log` in the server data directory. To change the name of the file, set the `audit_log_file` [825] system variable at server startup.

The audit log file is written in XML format, with auditable events encoded as `<AUDIT_RECORD>` elements. For details on file format and contents, see [Section 6.3.11.2, “The Audit Log File”](#).

To control what information `audit_log` writes to its log file, set the `audit_log_policy` [826] system variable. By default, this variable is set to `ALL` (write all auditable events), but also permits values of `LOGINS` or `QUERIES` to log only login or query events, or `NONE` to disable logging.

For more information about controlling how logging occurs, see [Section 6.3.11.3, “Audit Log Plugin Logging Control”](#). For descriptions of the parameters used to configure the audit log plugin, see [Section 6.3.11.4, “Audit Log Plugin Options and Variables”](#).

The Performance Schema (see [Chapter 20, MySQL Performance Schema](#)) has instrumentation for the audit log plugin. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE '/alog/%';
```

### 6.3.11.1. Installing the Audit Log Plugin

The audit log plugin is named `audit_log`. To be usable by the server, the plugin library object file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` [525] system variable). If necessary, set the value of `plugin_dir` [525] at server startup to tell the server the location of the plugin directory.

To load the plugin at server startup, use the `--plugin-load` [435] option to name the object file that contains the plugin. With this plugin-loading method, the option must be given each time the server starts. For example, put the following lines in your `my.cnf` file:

```
[mysqld]
plugin-load=audit_log.so
```

If object files have a suffix different from `.so` on your system, substitute the correct suffix (for example, `.dll` on Windows).

Alternatively, to register the plugin at runtime, use this statement (changing the suffix as necessary):

```
mysql> INSTALL PLUGIN audit_log SONAME 'audit_log.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` table to cause the plugin to be loaded for each subsequent normal server startup.

If the plugin is loaded with `--plugin-load` [435] or has been previously registered with `INSTALL PLUGIN`, you can use the `--audit-log` option at server startup to control plugin activation. For example, to load the plugin and prevent it from being removed at runtime, use these options:

```
[mysqld]
plugin-load=audit_log.so
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use `--audit-log` [824] with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

For general information about installing plugins, see [Section 5.1.8, “Server Plugins”](#). To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

For security reasons, the audit log file produced by `audit_log` should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. The default file is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` [825] system variable at server startup.

For additional information about the parameters used to configure operation of the `audit_log` plugin, see [Section 6.3.11.4, “Audit Log Plugin Options and Variables”](#).

### 6.3.11.2. The Audit Log File

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The contents are not encrypted. The root element is `<AUDIT>`. The closing `</AUDIT>` tag of the root element is written when the plugin terminates, so the tag is not present in the file while the audit log plugin is active.

The root element contains `<AUDIT_RECORD>` elements. Each `<AUDIT_RECORD>` element has an empty body; all audit record fields are represented by element attributes.

Here is a sample log file, reformatted for readability:

```
<?xml version="1.0" encoding="UTF-8"?>
```

```

<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2012-08-02T14:52:12"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
    OS_VERSION="i686-Linux"
    MYSQL_VERSION="5.6.10-debug-log" />
  <AUDIT_RECORD
    TIMESTAMP="2012-08-02T14:52:41"
    NAME="Connect"
    CONNECTION_ID="1"
    STATUS="0"
    USER="root"
    PRIV_USER="root"
    OS_LOGIN=""
    PROXY_USER=""
    HOST="localhost"
    IP="127.0.0.1"
    DB="" />
  <AUDIT_RECORD
    TIMESTAMP="2012-08-02T14:53:45"
    NAME="Query"
    CONNECTION_ID="1"
    STATUS="0"
    SQLTEXT="INSERT INTO t1 () VALUES()" />
  <AUDIT_RECORD
    TIMESTAMP="2012-08-02T14:53:51"
    NAME="Quit"
    CONNECTION_ID="1"
    STATUS="0" />
  <AUDIT_RECORD
    TIMESTAMP="2012-08-06T14:21:03"
    NAME="NoAudit"
    SERVER_ID="1" />
</AUDIT>

```

Attributes of `<AUDIT_RECORD>` elements have these characteristics:

- Some attributes appear in every element, but most are optional and do not necessarily appear in every element.
- Order of attributes within an element is not guaranteed.
- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. Null bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFF] | [#x10000-#x10FFFF]
```

Every `<AUDIT_RECORD>` element contains a set of mandatory attributes. Other optional attributes may appear depending on the audit record type.

The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- **NAME**

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example: `NAME="Query"`

Some common **NAME** values:

"Audit"	When auditing starts, which may be server startup time
"Connect"	When a client connects, also known as logging in
"Query"	An SQL statement (executed directly)
"Prepare"	Preparation of an SQL statement; usually followed by Execute
"Execute"	Execution of an SQL statement; usually follows Prepare
"Shutdown"	Server shutdown
"Quit"	When a client disconnects
"NoAudit"	Auditing has been turned off

The possible values are "Audit", "Binlog Dump", "Change user", "Close stmt", "Connect Out", "Connect", "Create DB", "Daemon", "Debug", "Delayed insert", "Drop DB", "Execute", "Fetch", "Field List", "Init DB", "Kill", "Long Data", "NoAudit", "Ping", "Prepare", "Processlist", "Query", "Quit", "Refresh", "Register Slave", "Reset stmt", "Set option", "Shutdown", "Sleep", "Statistics", "Table Dump", "Time".

With the exception of "Audit" and "NoAudit", these values correspond to the COM\_xxx command values listed in the `mysql_com.h` header file. For example, "Create DB" and "Shutdown" correspond to `COM_CREATE_DB` and `COM_SHUTDOWN`, respectively.

- **TIMESTAMP**

The date and time that the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a **TIMESTAMP** value occurring after the statement finishes, not when it is received. The value is UTC, in the format `yyyy-mm-ddThh:mm:ss` (with **T**, no decimals).

Example: `TIMESTAMP="2012-08-09T12:55:16"`

The following attributes are optional in `<AUDIT_RECORD>` elements. Many of them occur only for elements with specific values of the **NAME** attribute.

- **CONNECTION\_ID**

An unsigned integer representing the client connection identifier. This is the same as the `CONNECTION_ID()` [1267] function value within the session.

Example: `CONNECTION_ID="1"`

- **DB**

A string representing the default database name. This attribute appears only if the **NAME** value is "Connect" or "Change user".

- **HOST**

A string representing the client host name. This attribute appears only if the **NAME** value is "Connect" or "Change user".

Example: `HOST="localhost"`

- **IP**

A string representing the client IP address. This attribute appears only if the **NAME** value is "Connect" or "Change user".

Example: `IP="127.0.0.1"`

- **MYSQL\_VERSION**

A string representing the MySQL server version. This is the same as the value of the `VERSION()` [1273] function or `version` [563] system variable. This attribute appears only if the **NAME** value is "Audit".

Example: `MYSQL_VERSION="5.6.10-debug-log"`

- `OS_LOGIN`

A string representing the external user (empty if none). The value may differ from `USER`, for example, if the server authenticates the client using an external authentication method. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

- `OS_VERSION`

A string representing the operating system on which the server was built or is running. This attribute appears only if the `NAME` value is `"Audit"`.

Example: `OS_VERSION="x86_64-Linux"`

- `PRIV_USER`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may be different from the `USER` value. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

- `PROXY_USER`

A string representing the proxy user. The value is empty if user proxying is not in effect. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

- `SERVER_ID`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` [539] system variable. This attribute appears only if the `NAME` value is `"Audit"` or `"NoAudit"`.

Example: `SERVER_ID="1"`

- `SQLTEXT`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. This attribute appears only if the `NAME` value is `"Query"` or `"Execute"`.

The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example: `SQLTEXT="DELETE FROM t1"`

- `STARTUP_OPTIONS`

A string representing the options that were given on the command line or in option files when the MySQL server was started. This attribute appears only if the `NAME` value is `"Audit"`.

Example: `STARTUP_OPTIONS="--port=3306 --log-output=FILE"`

- `STATUS`

An unsigned integer representing the command status. The value is zero for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

The audit log does not contain the `SQLSTATE` value or error message. To see the associations between error codes, `SQLSTATE` values, and messages, see [Section C.3, "Server Error Codes and Messages"](#).

Warnings are not logged.

Example: `STATUS="1051"`

- **USER**

A string representing the user name sent by the client. This may be different from the `PRIV_USER` value. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

- **VERSION**

An unsigned integer representing the version of the audit log file format. This attribute appears only if the `NAME` value is `"Audit"`.

Example: `VERSION="1"`

### 6.3.11.3. Audit Log Plugin Logging Control

This section describes how the `audit_log` plugin performs logging and the system variables that control how logging occurs. It assumes familiarity with the log file format described in [Section 6.3.11.2, “The Audit Log File”](#).

When the audit log plugin opens its log file, it checks whether the XML declaration and opening `<AUDIT>` root element tag need to be written and writes them if so. When the audit log plugin terminates, it writes a closing `</AUDIT>` tag to the file.

If the log file exists at open time, the plugin checks whether the file ends with an `</AUDIT>` tag and truncates it if so before writing any `<AUDIT_RECORD>` elements. If the log file exists but does not end with `</AUDIT>` or the `</AUDIT>` tag cannot be truncated, the plugin considers the file malformed and fails to initialize. This can occur if the server crashes or is killed with the audit log plugin running. No logging occurs until the problem is rectified. Check the error log for diagnostic information:

```
[ERROR] Plugin 'audit_log' init function returned error.
```

To deal with this problem, you must either remove or rename the malformed log file and restart the server.

The MySQL server calls the audit log plugin to write an `<AUDIT_RECORD>` element whenever an auditable event occurs, such as when it completes execution of an SQL statement received from a client. Typically the first `<AUDIT_RECORD>` element written after server startup has the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA INFILE` are not logged.

To permit control over how logging occurs, the `audit_log` plugin provides several system variables, described following. For more information, see [Section 6.3.11.4, “Audit Log Plugin Options and Variables”](#).

- `audit_log_file` [825]: The name of the log file. By default, the name is `audit.log` in the server data directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log.
- `audit_log_policy` [826]: What kinds of information the plugin writes. By default, this variable is set to `ALL` (write all auditable events), but also permits values of `LOGINS` or `QUERIES` to log only login or query events, or `NONE` to disable logging.
- `audit_log_strategy` [827]: The method used for log writes. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMISYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. Writes from the buffer to the log file are handled by a separate thread.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, it is more likely that the audit log will be missing events.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host crashes). To reduce this risk, set `audit_log_strategy` [827] use synchronous logging. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

- `audit_log_buffer_size` [824]: The size of the buffer for asynchronous logging. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.
- `audit_log_rotate_on_size` [826], `audit_log_flush` [825]: These variables permit audit log file rotation and flushing. The audit log file has the potential to grow very large and consume a lot of disk space. To manage the space used, either enable automatic log rotation, or manually rename the audit file and flush the log to open a new file. The renamed file can be removed or backed up as desired.

By default, `audit_log_rotate_on_size=0` [826] and there is no log rotation. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` [825] value changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that you want to maintain the three most recent log files, which cycle through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

```
shell> mv audit.log.2 audit.log.3
shell> mv audit.log.1 audit.log.2
shell> mv audit.log audit.log.1
```

At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`.

2. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

```
mysql> SET GLOBAL audit_log_flush = ON;
```

If `audit_log_rotate_on_size` [826] is greater than 0, setting `audit_log_flush` [825] has no effect. In this case, the audit log plugin closes and reopens its log file whenever a write to the file causes its size to exceed the `audit_log_rotate_on_size` [826] value. The plugin renames the original file to have a timestamp extension. For example, `audit.log` might be renamed to `audit.log.13440033615657730`. The last 7 digits are a fractional second part. The first 10 digits are a Unix timestamp value that can be interpreted using the `FROM_UNIXTIME()` [1218] function:

```
mysql> SELECT FROM_UNIXTIME(1344003361);
+-----+
| FROM_UNIXTIME(1344003361) |
+-----+
| 2012-08-03 09:16:01      |
+-----+
```

### 6.3.11.4. Audit Log Plugin Options and Variables

This section describes the command options and system variables that control operation of the audit log plugin. If values specified at startup time are incorrect, the plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it will not recognize them.

To control the activation of the `audit_log` plugin, use this option:

- `--audit-log[=value]` [824]

<b>Version Introduced</b>	5.6.10	
<b>Command-Line Format</b>	<code>--audit-log[=value]</code>	
<b>Option-File Format</b>	<code>audit-log[=value]</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	ON
	<b>Valid Values</b>	ON OFF FORCE FORCE_PLUS_PERMANENT

This option controls how the server loads the `audit_log` plugin at startup. It is available only if the audit log plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` [435]. See Section 6.3.11.1, “Installing the Audit Log Plugin”.

The option value should be one of those available for plugin-loading options, as described in Section 5.1.8.1, “Installing and Uninstalling Plugins”. For example, `--audit-log=FORCE_PLUS_PERMANENT` [824] tells the server to load the plugin and prevent it from being removed while the server is running.

This option was added in MySQL 5.6.10.

If the `audit_log` plugin is installed, it exposes several system variables that permit control over logging:

```
mysql> SHOW VARIABLES LIKE 'audit_log%';
+-----+-----+
| Variable_name | Value          |
+-----+-----+
| audit_log_buffer_size | 1048576       |
| audit_log_file      | audit.log     |
| audit_log_flush     | OFF           |
| audit_log_policy     | ALL           |
| audit_log_rotate_on_size | 0             |
| audit_log_strategy   | ASYNCHRONOUS |
+-----+-----+
```

You can set any of these variables at server startup, and some of them at runtime.

- `audit_log_buffer_size` [824]

<b>Version Introduced</b>	5.6.10
<b>Variable Name</b>	<code>audit_log_buffer_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

	<b>Permitted Values</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	1048576
<b>Range</b>	4096 .. 4294967295
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	1048576
<b>Range</b>	4096 .. 18446744073709547520

When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

This variable was added in MySQL 5.6.10. It is available only if the `audit_log` plugin is enabled.

- [audit\\_log\\_file \[825\]](#)

<b>Version Introduced</b>	5.6.10
<b>Variable Name</b>	<code>audit_log_file</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
<b>Type</b>	string
<b>Default</b>	<code>audit.log</code>

The name of the file to which the audit log plugin writes events. The default value is `audit.log`. If the file name is a relative path, the server interprets it relative to the data directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log.

This variable was added in MySQL 5.6.10. It is available only if the `audit_log` plugin is enabled.

- [audit\\_log\\_flush \[825\]](#)

<b>Version Introduced</b>	5.6.10
<b>Variable Name</b>	<code>audit_log_flush</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	boolean
<b>Default</b>	OFF

When this variable is set to enabled (1 or ON), the audit log plugin closes and reopens its log file to flush it. (The value remains OFF so that you need not disable it explicitly before

enabling it again to perform another flush.) Enabling this variable has no effect unless `audit_log_rotate_on_size` [826] is 0.

This variable was added in MySQL 5.6.10. It is available only if the `audit_log` plugin is enabled.

- `audit_log_policy` [826]

<b>Version Introduced</b>	5.6.10	
<b>Variable Name</b>	<code>audit_log_policy</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>ALL</code>
	<b>Valid Values</b>	<code>ALL</code> <code>NONE</code> <code>LOGINS</code> <code>QUERIES</code>

The policy controlling the information written by the audit log plugin to its log file. The following table shows the permitted values.

Value	Description
<code>ALL</code>	Log all events
<code>NONE</code>	Log nothing (disable the audit stream)
<code>LOGINS</code>	Log only login events
<code>QUERIES</code>	Log only query events

This variable was added in MySQL 5.6.10. It is available only if the `audit_log` plugin is enabled.

- `audit_log_rotate_on_size` [826]

<b>Version Introduced</b>	5.6.10	
<b>Variable Name</b>	<code>audit_log_rotate_on_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>

If the `audit_log_rotate_on_size` [826] value is greater than 0, the audit log plugin closes and reopens its log file if a write to the file causes its size to exceed this value. The original file is renamed to have a timestamp extension.

If the `audit_log_rotate_on_size` [826] value is 0, the plugin does not close and reopen its log based on size. Instead, use `audit_log_flush` [825] to close and reopen the log on demand. In this case, rename the file externally to the server before flushing it.

For more information about audit log file rotation and timestamp interpretation, see [Section 6.3.11.3, “Audit Log Plugin Logging Control”](#).

If you set this variable to a value that is not a multiple of 4096, it is truncated to the nearest multiple.

This variable was added in MySQL 5.6.10. It is available only if the `audit_log` plugin is enabled.

- `audit_log_strategy` [827]

<b>Version Introduced</b>	5.6.10	
<b>Variable Name</b>	<code>audit_log_strategy</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	enumeration
	<b>Default</b>	ASYNCHRONOUS
	<b>Valid Values</b>	ASYNCHRONOUS PERFORMANCE SEMISYNCHRONOUS SYNCHRONOUS

The logging method used by the audit log plugin. The following table describes the permitted values.

**Table 6.17. Audit Log Strategies**

Value	Meaning
ASYNCHRONOUS	Log asynchronously, wait for space in output buffer
PERFORMANCE	Log asynchronously, drop request if insufficient space in output buffer
SEMISYNCHRONOUS	Log synchronously, permit caching by operating system
SYNCHRONOUS	Log synchronously, call <code>sync()</code> after each request

This variable was added in MySQL 5.6.10. It is available only if the `audit_log` plugin is enabled.

### 6.3.11.5. Audit Log Plugin Restrictions

The audit log plugin is subject to these restrictions:

- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.
- Contents of files referenced by statements such as `LOAD DATA INFILE` are not logged.

## 6.3.12. SQL-Based MySQL Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'user_name'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` [1267] function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` [1267] value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` [1267] refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` [1273] function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` [1273] value never contains wildcards, whereas account values (as returned by `CURRENT_USER()` [1267]) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `'@localhost'` enables clients to connect as an anonymous user from the local host with any user name. If this case, if a client connects as `user1` from the local host, `USER()` [1273] and `CURRENT_USER()` [1267] return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user1@localhost | @localhost     |
+-----+-----+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%'` or `'_'` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` [1267] value will not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` [1273] and `CURRENT_USER()` [1267] return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user2@remote.example.com | user2@%.example.com |
+-----+-----+
```

If an application must invoke `USER()` [1273] for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` [1273] value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the `'@localhost'` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```
RENAME USER '@localhost' TO 'user1@localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` [1267] or `USER()` [1273] value, use the `SUBSTRING()` [1185] function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', 1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', 1) |
+-----+
| user1                                     |
+-----+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', -1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', -1) |
+-----+
| localhost                                 |
+-----+
```

---

# Chapter 7. Backup and Recovery

## Table of Contents

7.1. Backup and Recovery Types .....	832
7.2. Database Backup Methods .....	835
7.3. Example Backup and Recovery Strategy .....	837
7.3.1. Establishing a Backup Policy .....	838
7.3.2. Using Backups for Recovery .....	839
7.3.3. Backup Strategy Summary .....	840

7.4.2. Reloading SQL-Format Backups .....	841
7.4.3. Dumping Data in Delimited-Text Format with <code>mysqldump</code> .....	842
7.4.4. Reloading Delimited-Text Format Backups .....	843
7.4.5. <code>mysqldump</code> Tips .....	844
7.5. Point-in-Time (Incremental) Recovery Using the Binary Log .....	845
7.5.1. Point-in-Time Recovery Using Event Times .....	847
7.5.2. Point-in-Time Recovery Using Event Positions .....	847
7.6. <code>MyISAM</code> Table Maintenance and Crash Recovery .....	848
7.6.1. Using <code>myisamchk</code> for Crash Recovery .....	848
7.6.2. How to Check <code>MyISAM</code> Tables for Errors .....	849
7.6.3. How to Repair <code>MyISAM</code> Tables .....	850
7.6.4. <code>MyISAM</code> Table Optimization .....	852
7.6.5. Setting Up a <code>MyISAM</code> Table Maintenance Schedule .....	853

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replication slave servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

- Types of backups: Logical versus physical, full versus incremental, and so forth.
- Methods for creating backups.
- Recovery methods, including point-in-time recovery.
- Backup scheduling, compression, and encryption.
- Table maintenance, to enable recovery of corrupt tables.

## Additional Resources

Resources related to backup or to maintaining data availability include the following:

- Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see [Section 23.2, “MySQL Enterprise Backup”](#).
- A forum dedicated to backup issues is available at <http://forums.mysql.com/list.php?93>.
- Details for `mysqldump`, `mysqlhotcopy`, and other MySQL backup programs can be found in [Chapter 4, MySQL Programs](#).
- The syntax of the SQL statements described here is given in [Chapter 13, SQL Statement Syntax](#).

- For additional information about [InnoDB](#) backup procedures, see [Section 14.2.2.4, “Backing Up and Recovering an InnoDB Database”](#).
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the master by using a slave server. See [Chapter 16, Replication](#).
- MySQL Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See [MySQL Cluster NDB 6.1 - 7.1](#), which provides information about MySQL Cluster NDB 7.0 and 7.1 (based on MySQL 5.1 but containing the latest improvements and fixes for the [NDBCLUSTER](#) storage engine).

**Note**

The [NDBCLUSTER](#) storage engine is currently not supported in MySQL 5.6.

- Distributed Replicated Block Device (DRBD) is another high-availability solution. It works by replicating a block device from a primary server to a secondary server at the block level. See [Chapter 15, High Availability and Scalability](#)

## 7.1. Backup and Recovery Types

This section describes the characteristics of different types of backups.

### Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure ([CREATE DATABASE](#), [CREATE TABLE](#) statements) and content ([INSERT](#) statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

- The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.
- Physical backup methods are faster than logical because they involve only file copying without conversion.
- Output is more compact than for logical backup.
- Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see [Section 23.2, “MySQL Enterprise Backup”](#).
- Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For example, [InnoDB](#) tables can each be in a separate file, or share file storage with other [InnoDB](#) tables; each [MyISAM](#) table corresponds uniquely to a set of files.
- In addition to databases, the backup can include any related files such as log or configuration files.
- Data from [MEMORY](#) tables is tricky to back up this way because their contents are not stored on disk. (The MySQL Enterprise Backup product has a feature where you can retrieve data from [MEMORY](#) tables during a backup.)

- Backups are portable only to other machines that have identical or similar hardware characteristics.
- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.
- Physical backup tools include the `mysqlbackup` of MySQL Enterprise Backup for InnoDB or any other tables, file system-level commands (such as `cp`, `scp`, `tar`, `rsync`), or `mysqlhotcopy` for MyISAM tables.
- For restore:
  - MySQL Enterprise Backup restores InnoDB and other tables that it backed up.
  - `ndb_restore` restores NDB tables.
  - Files copied at the file system level or with `mysqlhotcopy` can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even MEMORY.
- To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA INFILE` statement or the `mysqlimport` client.

## Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

- The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
- Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.

Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replication slave server that can be taken offline without harming availability.
- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely that clients will be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

## Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server. host.

- `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` [291] option), data files are created on the server host.
- `mysqlhotcopy` performs only local backups: It connects to the server to lock it against data modifications and then copies local table files.
- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.
- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

## Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

## Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

## Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are

applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

## Table Maintenance

Data integrity can be compromised if tables become corrupt. For [InnoDB](#) tables, this is not a typical issue. For programs to check [MyISAM](#) tables and repair them if problems are found, see [Section 7.6](#), “[MyISAM Table Maintenance and Crash Recovery](#)”.

## Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress [InnoDB](#) backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

## 7.2. Database Backup Methods

This section summarizes some general methods for making backups.

### Making a Hot Backup with MySQL Enterprise Backup

Customers of MySQL Enterprise Edition can use the [MySQL Enterprise Backup](#) product to do [physical](#) backups of entire instances or selected databases, tables, or both. This product includes features for [incremental](#) and [compressed](#) backups. Backing up the physical database files makes restore much faster than logical techniques such as the `mysqldump` command. [InnoDB](#) tables are copied using a [hot backup](#) mechanism. (Ideally, the [InnoDB](#) tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a [warm backup](#) mechanism. For an overview of the MySQL Enterprise Backup product, see [Section 23.2](#), “[MySQL Enterprise Backup](#)”.

### Making Backups with `mysqldump` or `mysqlhotcopy`

The `mysqldump` program and the `mysqlhotcopy` script can make backups. `mysqldump` is more general because it can back up all kinds of tables. `mysqlhotcopy` works only with some storage engines. (See [Section 7.4](#), “[Using `mysqldump` for Backups](#)”, and [Section 4.6.10](#), “[`mysqlhotcopy` — A Database Backup Program](#)”.)

For [InnoDB](#) tables, it is possible to perform an online backup that takes no locks on tables using the `--single-transaction` [\[295\]](#) option to `mysqldump`. See [Section 7.3.1](#), “[Establishing a Backup Policy](#)”.

### Making Backups by Copying Table Files

For storage engines that represent each table using its own files, tables can be backed up by copying those files. For example, [MyISAM](#) tables are stored as files, so it is easy to do a backup by copying files (`*.frm`, `*.MYD`, and `*.MYI` files). To get a consistent backup, stop the server or lock and flush the relevant tables:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that all active index pages are written to disk before you start the backup. See [Section 13.3.5](#), “[LOCK TABLES and UNLOCK TABLES Syntax](#)”, and [Section 13.7.6.3](#), “[FLUSH Syntax](#)”.

You can also create a binary backup simply by copying all table files, as long as the server isn't updating anything. The `mysqlhotcopy` script uses this method. (But note that table file copying methods do not work if your database contains [InnoDB](#) tables. `mysqlhotcopy` does not work for

InnoDB tables because InnoDB does not necessarily store table contents in database directories. Also, even if the server is not actively updating data, InnoDB may still have modified data cached in memory and not flushed to disk.)

## Making Delimited-Text File Backups

To create a text file containing a table's data, you can use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See [Section 13.2.9, "SELECT Syntax"](#). This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing `CREATE TABLE` statements for the backed up tables) is to use `mysqldump` with the `--tab` [\[291\]](#) option. See [Section 7.4.3, "Dumping Data in Delimited-Text Format with mysqldump"](#).

To reload a delimited-text data file, use `LOAD DATA INFILE` or `mysqlimport`.

## Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the `--log-bin` [\[2002\]](#) option to enable binary logging; see [Section 5.2.4, "The Binary Log"](#). The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in [Section 7.5, "Point-in-Time \(Incremental\) Recovery Using the Binary Log"](#). The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS`, `mysqldump --flush-logs`, or `mysqlhotcopy --flushlog`. See [Section 4.5.4, "mysqldump — A Database Backup Program"](#), and [Section 4.6.10, "mysqlhotcopy — A Database Backup Program"](#).

## Making Backups Using Replication Slaves

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See [Section 16.3.1, "Using Replication for Backups"](#).

If you are backing up a slave replication server, you should back up its `master.info` and `relay-log.info` files when you back up the slave's databases, regardless of the backup method you choose. These information files are always needed to resume replication after you restore the slave's data. If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` [\[1985\]](#) option. If the server was not started with that option, the directory location is the value of the `tmpdir` [\[559\]](#) system variable.

## Recovering Corrupt Tables

If you have to restore MyISAM tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see [Section 7.6, "MyISAM Table Maintenance and Crash Recovery"](#).

## Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.

2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

## 7.3. Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user [212]` and `--password [211]` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the `InnoDB` storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one,

or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

### 7.3.1. Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, [MySQL Enterprise Backup](#) can perform a [physical backup](#) of an entire instance, with optimizations to minimize overhead and avoid disruption when backing up [InnoDB](#) data files; `mysqldump` provides online [logical backup](#). This discussion uses `mysqldump`.

Assume that we make a full backup of all our [InnoDB](#) tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

The resulting `.sql` file produced by `mysqldump` contains a set of SQL `INSERT` statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using `FLUSH TABLES WITH READ LOCK`). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are [InnoDB](#) tables, so `--single-transaction` [295] uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to [InnoDB](#) tables are not seen by the `mysqldump` process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the [MyISAM](#) tables in the `mysql` database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` [2002] option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the `--log-bin` [2002] option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem guilhem 4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem guilhem 79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem guilhem 508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem guilhem 998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem guilhem 361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` [294] option causes the server to flush its logs. The `--master-data` [288] option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or newer.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or newer.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

#### Note

Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

## 7.3.2. Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` [2002] option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

### 7.3.3. Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` [2002] option, or even `--log-bin=log_name` [2002], where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in [Section 7.3.1, “Establishing a Backup Policy”](#), that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

## 7.4. Using `mysqldump` for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replication slaves.
- As a source of data for experimentation:
  - To make a copy of a database that you can use without changing the original data.
  - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` [291] option is given:

- Without `--tab` [291], `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.
- With `--tab` [291], `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

### 7.4.1. Dumping Data in SQL Format with `mysqldump`

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see [Section 7.4.2, “Reloading SQL-Format Backups”](#).

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
shell> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` [\[292\]](#) option:

```
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` [\[292\]](#) option:

```
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` [\[292\]](#) option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` [\[292\]](#) or `--databases` [\[292\]](#), `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` [\[286\]](#) option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` [\[292\]](#) option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases` [\[292\]](#), the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output will contain no `CREATE DATABASE` statement, the `--add-drop-database` [\[286\]](#) option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

### 7.4.2. Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` [\[292\]](#) or `--`

`databases` [292] option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
shell> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
shell> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
shell> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

### 7.4.3. Dumping Data in Delimited-Text Format with `mysqldump`

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see [Section 7.4.4, “Reloading Delimited-Text Format Backups”](#).

If you invoke `mysqldump` with the `--tab=dir_name` [291] option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the basename for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
shell> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` [754] privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` [291] be used only for dumping a local server. If you use it with a remote server, the `--tab` [291] directory must exist on both the local and remote hosts, and the `.txt` files will be written by the server in the remote directory (on the server host), whereas the `.sql` files will be written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=str` [290]

The string for separating column values (default: tab).

- `--fields-enclosed-by=char` [290]

The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=char` [290]

The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=char` [290]

The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=str` [290]

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` [290] option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,
--fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

## 7.4.4. Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA INFILE` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA INFILE` to ensure proper interpretation of the data file contents:

```
shell> mysqlimport --fields-terminated-by=,
--fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
```

```
-> FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY ''''
-> LINES TERMINATED BY '\r\n';
```

## 7.4.5. mysqldump Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

### 7.4.5.1. Making a Copy of a Database

```
shell> mysqldump db1 > dump.sql
shell> mysqladmin create db2
shell> mysql db2 < dump.sql
```

Do not use `--databases [292]` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

### 7.4.5.2. Copy a Database from one Server to Another

On Server 1:

```
shell> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
shell> mysql < dump.sql
```

Use of `--databases [292]` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases [292]` from the `mysqldump` command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
shell> mysqldump db1 > dump.sql
```

On Server 2:

```
shell> mysqladmin create db1
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases [292]` from the `mysqldump` command enables you to dump data from one database and load it into another.

### 7.4.5.3. Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events [293]`: Dump Event Scheduler events
- `--routines [293]`: Dump stored procedures and functions

- `--triggers` [293]: Dump triggers for tables

The `--triggers` [293] option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events` [293], `--skip-routines` [293], or `--skip-triggers` [293].

#### 7.4.5.4. Dumping Table Definitions and Content Separately

The `--no-data` [293] option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` [286] option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` [293] and `--events` [293] options to also include stored routine and event definitions:

```
shell> mysqldump --no-data --routines --events test > dump-defs.sql
```

#### 7.4.5.5. Using `mysqldump` to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

## 7.5. Point-in-Time (Incremental) Recovery Using the Binary Log

Point-in-time recovery refers to recovery of data changes made since a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed

in [Section 7.2, “Database Backup Methods”](#).) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

Point-in-time recovery is based on these principles:

- The source of information for point-in-time recovery is the set of incremental backups represented by the binary log files generated subsequent to the full backup operation. Therefore, the server must be started with the `--log-bin [2002]` option to enable binary logging (see [Section 5.2.4, “The Binary Log”](#)).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin [2002]` option to place the files in a different location. [Section 5.2.4, “The Binary Log”](#).

To see a listing of all binary log files, use this statement:

```
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```
mysql> SHOW MASTER STATUS;
```

- The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be executed or viewed. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).
- Executing events from the binary log causes the data modifications they represent to be redone. This enables recovery of data changes for a given span of time. To execute events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```
shell> mysqlbinlog binlog_files | mysql -u root -p
```

- Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```
shell> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```
shell> mysqlbinlog binlog_files > tmpfile
shell> ... edit tmpfile ...
```

- Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP DATABASE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, execute the contents as follows:

```
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

## 7.5.1. Point-in-Time Recovery Using Event Times

To indicate the start and end times for recovery, specify the `--start-datetime` [353] and `--stop-datetime` [353] options for `mysqlbinlog`, in `DATETIME` format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the `--stop-datetime` [353] option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on.

To use this method of point-in-time recovery, you should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the `/tmp/mysql_restore.sql` file with a text editor to examine it.

Excluding specific changes by specifying times for `mysqlbinlog` does not work well if multiple statements executed at the same time as the one to be excluded.

## 7.5.2. Point-in-Time Recovery Using Event Positions

Instead of specifying dates and times, the `--start-position` [353] and `--stop-position` [354] options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \
--stop-datetime="2005-04-20 10:05:00" \
/var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you do not want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a

number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position=368312 /var/log/mysql/bin.123456 \  
| mysql -u root -p  
  
shell> mysqlbinlog --start-position=368315 /var/log/mysql/bin.123456 \  
| mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

## 7.6. MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). Other table-repair information can be found at [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause MyISAM FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in [Section 4.6.3.1, “myisamchk General Options”](#).

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check MyISAM tables, use `CHECK TABLE`.
- To repair MyISAM tables, use `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.

For additional information about these statements, see [Section 13.7.2, “Table Maintenance Statements”](#).

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server.

### 7.6.1. Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See [Section C.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

For an explanation of how MyISAM tables can become corrupted, see [Section 14.3.4, “MyISAM Table Problems”](#).

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

File	Purpose
<code>tbl_name.frm</code>	Definition (format) file
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick [322]`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick [322]` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick [322]` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

## 7.6.2. How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:

- `myisamchk tbl_name`

This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m tbl_name`

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`

This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a

long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

### 7.6.3. How to Repair MyISAM Tables

The discussion in this section describes how to use `myisamchk` on MyISAM tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), and [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- `tbl_name.frm` is locked against change
- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `pererror nnn`, where `nnn` is the error number. The following example shows how to use `pererror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> pererror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in [Section 7.6.2, “How to Check MyISAM Tables for Errors”](#)), or you want to use the extended features that `myisamchk` provides.

The `myisamchk` options used for table maintenance with are described in [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). `myisamchk` also has variables that you can set to control memory allocation that may improve performance. See [Section 4.6.3.6, “myisamchk Memory Usage”](#).

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still available for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

### Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state [321]` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

#### Note

If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size [542]` and `key_buffer_size [492]` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
```

```
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
mysql> quit
```

- Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

### Important

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

### Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

- Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.
- If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

## 7.6.4. MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#).

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze [323]` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
- `--sort-index [323]` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num [324]` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

## 7.6.5. Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See [Section 13.7.2, “Table Maintenance Statements”](#).

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent` [319]) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check MyISAM tables automatically, start it with the `--myisam-recover-options` [432] option. See [Section 5.1.3, “Server Command Options”](#).

You should also check your tables regularly during normal system operation. For example, you can run a `cron` job to check important tables once a week, using a line like this in a `crontab` file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with `VARCHAR`, `BLOB`, or `TEXT` columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M /*.MYI
```

This chapter explains how to optimize MySQL performance and provides examples. Optimization involves configuring, tuning, and measuring performance, at several levels. Depending on your job role (developer, DBA, or a combination of both), you might optimize at the level of individual SQL statements, entire applications, a single database server, or multiple networked database servers. Sometimes you can be proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.

## 8.1. Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

### Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that

perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.

- Are the right [indexes](#) in place to make queries efficient?
- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and features of each storage engine you use? In particular, the choice of a transactional storage engine such as [InnoDB](#) or a nontransactional one such as [MyISAM](#) can be very important for performance and scalability.

#### Note

In MySQL 5.5 and higher, [InnoDB](#) is the default storage engine for new tables. In practice, the advanced [InnoDB](#) performance features mean that [InnoDB](#) tables often outperform the simpler [MyISAM](#) tables, especially for a busy database.

- Does each table use an appropriate row format? This choice also depends on the storage engine used for the table. In particular, compressed tables use less disk space and so require less disk I/O to read and write the data. Compression is available for all kinds of workloads with [InnoDB](#) tables, and for read-only [MyISAM](#) tables.
- Does the application use an appropriate [locking strategy](#)? For example, by allowing shared access when possible so that database operations can run concurrently, and requesting exclusive access when appropriate so that critical operations get top priority. Again, the choice of storage engine is significant. The [InnoDB](#) storage engine handles most locking issues without involvement from you, allowing for better concurrency in the database and reducing the amount of experimentation and tuning for your code.
- Are all [memory areas used for caching](#) sized correctly? That is, large enough to hold frequently accessed data, but not so large that they overload physical memory and cause paging. The main memory areas to configure are the [InnoDB](#) buffer pool, the [MyISAM](#) key cache, and the MySQL query cache.

## Optimizing at the Hardware Level

Any database application eventually hits hardware limits as the database becomes more and more busy. A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these [bottlenecks](#), or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.
- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When the data is in main memory, we must process it to get our result. Having small tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

## Balancing Portability and Performance

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within `/*! */` comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see [Section 9.6, “Comment Syntax”](#).

## 8.2. Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

### 8.2.1. Optimizing `SELECT` Statements

Queries, in the form of `SELECT` statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

#### 8.2.1.1. Speed of `SELECT` Statements

The main considerations for optimizing queries are:

- To make a slow `SELECT . . . WHERE` query faster, the first thing to check is whether you can add an [index](#). Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.

Indexes are especially important for queries that reference different tables, using features such as [joins](#) and [foreign keys](#). You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See [Section 8.3.1, “How MySQL Uses Indexes”](#) and [Section 8.8.1, “Optimizing Queries with `EXPLAIN`”](#).

- Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.
- Minimize the number of [full table scans](#) in your queries, particularly for big tables.
- Keep table statistics up to date by using the `ANALYZE TABLE` statement periodically, so the optimizer has the information needed to construct an efficient execution plan.
- Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both [InnoDB](#) and [MyISAM](#) have sets of guidelines for enabling and sustaining high performance in queries. For details, see [Section 8.5.5, “Optimizing InnoDB Queries”](#) and [Section 8.6.1, “Optimizing MyISAM Queries”](#).
- In particular, in MySQL 5.6.4 and higher, you can optimize single-query transactions for [InnoDB](#) tables, using the technique in [Section 14.2.4.2.3, “Optimizations for Read-Only Transactions”](#).
- Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.
- If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the `EXPLAIN` plan and adjusting your indexes, `WHERE` clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the `EXPLAIN` plan might be your first step for every query.)
- Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the [InnoDB buffer pool](#), [MyISAM key cache](#), and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.

- Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.
- Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

### 8.2.1.2. How MySQL Optimizes `WHERE` Clauses

This section discusses optimizations that can be made for processing `WHERE` clauses. The examples use `SELECT` statements, but the same optimizations apply for `WHERE` clauses in `DELETE` and `UPDATE` statements.

#### Note

Because work on the MySQL optimizer is ongoing, not all of the optimizations that MySQL performs are documented here.

You might be tempted to rewrite your queries to make arithmetic operations faster, while sacrificing readability. Because MySQL does similar optimizations automatically, you can often avoid this work, and leave the query in a more understandable and maintainable form. Some of the optimizations performed by MySQL follow:

- Removal of unnecessary parentheses:

```
((a AND b) AND c OR (((a AND b) AND (c AND d))))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
(a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal (needed because of constant folding):

```
(B>=5 AND B=5) OR (B=6 AND 5=5) OR (B=7 AND 5=6)
-> B=5 OR B=6
```

- Constant expressions used by indexes are evaluated only once.
- `COUNT(*)` [1283] on a single table without a `WHERE` is retrieved directly from the table information for `MyISAM` and `MEMORY` tables. This is also done for any `NOT NULL` expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some `SELECT` statements are impossible and returns no rows.
- `HAVING` is merged with `WHERE` if you do not use `GROUP BY` or aggregate functions (`COUNT()` [1283], `MIN()` [1284], and so on).
- For each table in a join, a simpler `WHERE` is constructed to get a fast `WHERE` evaluation for the table and also to skip rows as soon as possible.
- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.
- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the `SQL_SMALL_RESULT` option, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the `HAVING` clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
WHERE key_part1=constant;

SELECT ... FROM tbl_name
ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
ORDER BY key_part1,key_part2,... ;

SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

### 8.2.1.3. Optimizing `LIMIT` Queries

If you need only a specified number of rows from a result set, use a `LIMIT` clause in the query, rather than fetching the whole result set and throwing away the extra data.

MySQL sometimes optimizes a query that has a `LIMIT row_count` clause and no `HAVING` clause:

- If you select only a few rows with `LIMIT`, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.

- If you use `LIMIT row_count` with `ORDER BY`, MySQL ends the sorting as soon as it has found the first `row_count` rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the `LIMIT` clause are selected, and most or all of them are sorted, before the first `row_count` are found. After the initial rows have been found, MySQL does not sort any remainder of the result set.
- When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.
- In some cases, a `GROUP BY` can be resolved by reading the key in order (or doing a sort on the key) and then calculating summaries until the key value changes. In this case, `LIMIT row_count` does not calculate any unnecessary `GROUP BY` values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using `SQL_CALC_FOUND_ROWS`.
- `LIMIT 0` quickly returns an empty set. This can be useful for checking the validity of a query. When using one of the MySQL APIs, it can also be employed for obtaining the types of the result columns. (This trick does not work in the MySQL Monitor (the `mysql` program), which merely displays `Empty set` in such cases; instead, use `SHOW COLUMNS` or `DESCRIBE` for this purpose.)
- When the server uses temporary tables to resolve the query, it uses the `LIMIT row_count` clause to calculate how much space is required.

As of MySQL 5.6.2, the optimizer more efficiently handles queries (and subqueries) of the following form:

```
SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M,]N;
```

That type of query is common in web applications that display only a few rows from a larger result set. For example:

```
SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
```

The sort buffer has a size of `sort_buffer_size` [542]. If the sort elements for `N` rows are small enough to fit in the sort buffer (`M+N` rows if `M` was specified), the server can avoid using a merge file and perform the sort entirely in memory by treating the sort buffer as a priority queue:

- Scan the table, inserting the select list columns from each selected row in sorted order in the queue. If the queue is full, bump out the last row in the sort order.
- Return the first `N` rows from the queue. (If `M` was specified, skip the first `M` rows and return the next `N` rows.)

Previously, the server performed this operation by using a merge file for the sort:

- Scan the table, repeating these steps through the end of the table:
  - Select rows until the sort buffer is filled.
  - Write the first `N` rows in the buffer (`M+N` rows if `M` was specified) to a merge file.
- Sort the merge file and return the first `N` rows. (If `M` was specified, skip the first `M` rows and return the next `N` rows.)

The cost of the table scan is the same for the queue and merge-file methods, so the optimizer chooses between methods based on other costs:

- The queue method involves more CPU for inserting rows into the queue in order
- The merge-file method has I/O costs to write and read the file and CPU cost to sort it

The optimizer considers the balance between these factors for particular values of `N` and the row size.

### 8.2.1.4. How to Avoid Full Table Scans

The output from `EXPLAIN` shows `ALL` in the `type` column when MySQL uses a `full table scan` to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.
- There are no usable restrictions in the `ON` or `WHERE` clause for indexed columns.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See [Section 8.2.1.2, “How MySQL Optimizes WHERE Clauses”](#).
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See [Section 13.7.2.1, “ANALYZE TABLE Syntax”](#).
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

See [Section 13.2.9.3, “Index Hint Syntax”](#).

- Start `mysqld` with the `--max-seeks-for-key=1000 [507]` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See [Section 5.1.4, “Server System Variables”](#).

## 8.2.2. Optimizing DML Statements

This section explains how to speed up the data manipulation language (DML) statements, `INSERT`, `UPDATE`, and `DELETE`. Traditional OLTP applications and modern web applications typically do many small DML operations, where concurrency is vital. Data analysis and reporting applications typically run DML operations that affect many rows at once, where the main considerations is the I/O to write large amounts of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the industry as ETL, for “extract-transform-load”), sometimes you use other SQL statements or external commands, that mimic the effects of `INSERT`, `UPDATE`, and `DELETE` statements.

### 8.2.2.1. Speed of INSERT Statements

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a single connection, send the data for many new rows at once, and delay all index updates and consistency checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)

- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by  $\log N$ , assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a nonempty table, you can tune the `bulk_insert_buffer_size` [466] variable to make data insertion even faster. See [Section 5.1.4, “Server System Variables”](#).
- When loading a table from a text file, use `LOAD DATA INFILE`. This is usually 20 times faster than using `INSERT` statements. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).
- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.
- See [Section 8.5.4, “Bulk Data Loading for InnoDB Tables”](#) for tips specific to InnoDB tables.
- See [Section 8.6.2, “Bulk Data Loading for MyISAM Tables”](#) for tips specific to MyISAM tables.

### 8.2.2.2. Speed of `UPDATE` Statements

An update statement is optimized like a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a MyISAM table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#).

### 8.2.2.3. Speed of `DELETE` Statements

The time required to delete individual rows in a MyISAM table is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` [492] system variable. See [Section 8.11.2, “Tuning Server Parameters”](#).

To delete all rows from a MyISAM table, `TRUNCATE TABLE tbl_name` is faster than `DELETE FROM tbl_name`. Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See [Section 13.1.27, “TRUNCATE TABLE Syntax”](#).

## 8.2.3. Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

## 8.2.4. Optimizing `INFORMATION_SCHEMA` Queries

Applications that monitor the database can make frequent use of the `INFORMATION_SCHEMA` tables. Certain types of queries for `INFORMATION_SCHEMA` tables can be optimized to execute more quickly. The goal is to minimize file operations (for example, scanning a directory or opening a table file) to collect the information that makes up these dynamic tables. These optimizations do have an effect on how collations are used for searches in `INFORMATION_SCHEMA` tables. For more information, see [Section 10.1.7.9, “Collation and `INFORMATION\_SCHEMA` Searches”](#).

### 1) Try to use constant lookup values for database and table names in the `WHERE` clause

You can take advantage of this principle as follows:

- To look up databases or tables, use expressions that evaluate to a constant, such as literal values, functions that return a constant, or scalar subqueries.
- Avoid queries that use a nonconstant database name lookup value (or no lookup value) because they require a scan of the data directory to find matching database directory names.
- Within a database, avoid queries that use a nonconstant table name lookup value (or no lookup value) because they require a scan of the database directory to find matching table files.

This principle applies to the `INFORMATION_SCHEMA` tables shown in the following table, which shows the columns for which a constant lookup value enables the server to avoid a directory scan. For example, if you are selecting from `TABLES`, using a constant lookup value for `TABLE_SCHEMA` in the `WHERE` clause enables a data directory scan to be avoided.

Table	Column to specify to avoid data directory scan	Column to specify to avoid database directory scan
<code>COLUMNS</code>	<code>TABLE_SCHEMA</code>	<code>TABLE_NAME</code>
<code>KEY_COLUMN_USAGE</code>	<code>TABLE_SCHEMA</code>	<code>TABLE_NAME</code>
<code>PARTITIONS</code>	<code>TABLE_SCHEMA</code>	<code>TABLE_NAME</code>
<code>REFERENTIAL_CONSTRAINTS</code>	<code>CONSTRAINT_SCHEMA</code>	<code>TABLE_NAME</code>
<code>STATISTICS</code>	<code>TABLE_SCHEMA</code>	<code>TABLE_NAME</code>
<code>TABLES</code>	<code>TABLE_SCHEMA</code>	<code>TABLE_NAME</code>
<code>TABLE_CONSTRAINTS</code>	<code>TABLE_SCHEMA</code>	<code>TABLE_NAME</code>
<code>TRIGGERS</code>	<code>EVENT_OBJECT_SCHEMA</code>	<code>EVENT_OBJECT_TABLE</code>
<code>VIEWS</code>	<code>TABLE_SCHEMA</code>	<code>TABLE_NAME</code>

The benefit of a query that is limited to a specific constant database name is that checks need be made only for the named database directory. Example:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

Use of the literal database name `test` enables the server to check only the `test` database directory, regardless of how many databases there might be. By contrast, the following query is less efficient because it requires a scan of the data directory to determine which database names match the pattern `'test%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA LIKE 'test%';
```

For a query that is limited to a specific constant table name, checks need be made only for the named table within the corresponding database directory. Example:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
```

Use of the literal table name `t1` enables the server to check only the files for the `t1` table, regardless of how many tables there might be in the `test` database. By contrast, the following query requires a scan of the `test` database directory to determine which table names match the pattern `'t%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME LIKE 't%';
```

The following query requires a scan of the database directory to determine matching database names for the pattern `'test%'`, and for each matching database, it requires a scan of the database directory to determine matching table names for the pattern `'t%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test%' AND TABLE_NAME LIKE 't%';
```

## 2) Write queries that minimize the number of table files that must be opened

For queries that refer to certain INFORMATION\_SCHEMA table columns, several optimizations are available that minimize the number of table files that must be opened. Example:

```
SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

In this case, after the server has scanned the database directory to determine the names of the tables in the database, those names become available with no further file system lookups. Thus, `TABLE_NAME` requires no files to be opened. The `ENGINE` (storage engine) value can be determined by opening the table's `.frm` file, without touching other table files such as the `.MYD` or `.MYI` file.

Some values, such as `INDEX_LENGTH` for `MyISAM` tables, require opening the `.MYD` or `.MYI` file as well.

The file-opening optimization types are denoted thus:

- `SKIP_OPEN_TABLE`: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- `OPEN_FRM_ONLY`: Only the table's `.frm` file need be opened.
- `OPEN_TRIGGER_ONLY`: Only the table's `.TRG` file need be opened.
- `OPEN_FULL_TABLE`: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

The following list indicates how the preceding optimization types apply to INFORMATION\_SCHEMA table columns. For tables and columns not named, none of the optimizations apply.

- `COLUMNS`: `OPEN_FRM_ONLY` applies to all columns
- `KEY_COLUMN_USAGE`: `OPEN_FULL_TABLE` applies to all columns
- `PARTITIONS`: `OPEN_FULL_TABLE` applies to all columns
- `REFERENTIAL_CONSTRAINTS`: `OPEN_FULL_TABLE` applies to all columns
- `STATISTICS`:

Column	Optimization type
<code>TABLE_CATALOG</code>	<code>OPEN_FRM_ONLY</code>
<code>TABLE_SCHEMA</code>	<code>OPEN_FRM_ONLY</code>
<code>TABLE_NAME</code>	<code>OPEN_FRM_ONLY</code>
<code>NON_UNIQUE</code>	<code>OPEN_FRM_ONLY</code>
<code>INDEX_SCHEMA</code>	<code>OPEN_FRM_ONLY</code>
<code>INDEX_NAME</code>	<code>OPEN_FRM_ONLY</code>

Column	Optimization type
SEQ_IN_INDEX	OPEN_FRM_ONLY
COLUMN_NAME	OPEN_FRM_ONLY
COLLATION	OPEN_FRM_ONLY
CARDINALITY	OPEN_FULL_TABLE
SUB_PART	OPEN_FRM_ONLY
PACKED	OPEN_FRM_ONLY
NULLABLE	OPEN_FRM_ONLY
INDEX_TYPE	OPEN_FULL_TABLE
COMMENT	OPEN_FRM_ONLY

- TABLES:

Column	Optimization type
TABLE_CATALOG	SKIP_OPEN_TABLE
TABLE_SCHEMA	SKIP_OPEN_TABLE
TABLE_NAME	SKIP_OPEN_TABLE
TABLE_TYPE	OPEN_FRM_ONLY
ENGINE	OPEN_FRM_ONLY
VERSION	OPEN_FRM_ONLY
ROW_FORMAT	OPEN_FULL_TABLE
TABLE_ROWS	OPEN_FULL_TABLE
AVG_ROW_LENGTH	OPEN_FULL_TABLE
DATA_LENGTH	OPEN_FULL_TABLE
MAX_DATA_LENGTH	OPEN_FULL_TABLE
INDEX_LENGTH	OPEN_FULL_TABLE
DATA_FREE	OPEN_FULL_TABLE
AUTO_INCREMENT	OPEN_FULL_TABLE
CREATE_TIME	OPEN_FULL_TABLE
UPDATE_TIME	OPEN_FULL_TABLE
CHECK_TIME	OPEN_FULL_TABLE
TABLE_COLLATION	OPEN_FRM_ONLY
CHECKSUM	OPEN_FULL_TABLE
CREATE_OPTIONS	OPEN_FRM_ONLY
TABLE_COMMENT	OPEN_FRM_ONLY

- TABLE\_CONSTRAINTS: OPEN\_FULL\_TABLE applies to all columns

- TRIGGERS: OPEN\_TRIGGER\_ONLY applies to all columns

- VIEWS:

Column	Optimization type
TABLE_CATALOG	OPEN_FRM_ONLY
TABLE_SCHEMA	OPEN_FRM_ONLY
TABLE_NAME	OPEN_FRM_ONLY

Column	Optimization type
VIEW_DEFINITION	OPEN_FRM_ONLY
CHECK_OPTION	OPEN_FRM_ONLY
IS_UPDATABLE	OPEN_FULL_TABLE
DEFINER	OPEN_FRM_ONLY
SECURITY_TYPE	OPEN_FRM_ONLY
CHARACTER_SET_CLIENT	OPEN_FRM_ONLY
COLLATION_CONNECTION	OPEN_FRM_ONLY

### 3) Use `EXPLAIN` to determine whether the server can use `INFORMATION_SCHEMA` optimizations for a query

This applies particularly for `INFORMATION_SCHEMA` queries that search for information from more than one database, which might take a long time and impact performance. The `Extra` value in `EXPLAIN` output indicates which, if any, of the optimizations described earlier the server can use to evaluate `INFORMATION_SCHEMA` queries. The following examples demonstrate the kinds of information you can expect to see in the `Extra` value.

```
mysql> EXPLAIN SELECT TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS WHERE
-> TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v1'\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
        table: VIEWS
        type: ALL
possible_keys: NULL
      key: TABLE_SCHEMA, TABLE_NAME
      key_len: NULL
       ref: NULL
      rows: NULL
      Extra: Using where; Open_frm_only; Scanned 0 databases
```

Use of constant database and table lookup values enables the server to avoid directory scans. For references to `VIEWS.TABLE_NAME`, only the `.frm` file need be opened.

```
mysql> EXPLAIN SELECT TABLE_NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.TABLES\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
        table: TABLES
        type: ALL
possible_keys: NULL
      key: NULL
      key_len: NULL
       ref: NULL
      rows: NULL
      Extra: Open_full_table; Scanned all databases
```

No lookup values are provided (there is no `WHERE` clause), so the server must scan the data directory and each database directory. For each table thus identified, the table name and row format are selected. `TABLE_NAME` requires no further table files to be opened (the `SKIP_OPEN_TABLE` optimization applies). `ROW_FORMAT` requires all table files to be opened (`OPEN_FULL_TABLE` applies). `EXPLAIN` reports `OPEN_FULL_TABLE` because it is more expensive than `SKIP_OPEN_TABLE`.

```
mysql> EXPLAIN SELECT TABLE_NAME, TABLE_TYPE FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'test'\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
        table: TABLES
        type: ALL
possible_keys: NULL
      key: TABLE_SCHEMA
      key_len: NULL
```

```

      ref: NULL
      rows: NULL
      Extra: Using where; Open_frm_only; Scanned 1 database

```

No table name lookup value is provided, so the server must scan the `test` database directory. For the `TABLE_NAME` and `TABLE_TYPE` columns, the `SKIP_OPEN_TABLE` and `OPEN_FRM_ONLY` optimizations apply, respectively. `EXPLAIN` reports `OPEN_FRM_ONLY` because it is more expensive.

```

mysql> EXPLAIN SELECT B.TABLE_NAME
-> FROM INFORMATION_SCHEMA.TABLES AS A, INFORMATION_SCHEMA.COLUMNS AS B
-> WHERE A.TABLE_SCHEMA = 'test'
-> AND A.TABLE_NAME = 't1'
-> AND B.TABLE_NAME = A.TABLE_NAME\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: A
      type: ALL
possible_keys: NULL
      key: TABLE_SCHEMA, TABLE_NAME
      key_len: NULL
      ref: NULL
      rows: NULL
      Extra: Using where; Skip_open_table; Scanned 0 databases
***** 2. row *****
      id: 1
      select_type: SIMPLE
      table: B
      type: ALL
possible_keys: NULL
      key: NULL
      key_len: NULL
      ref: NULL
      rows: NULL
      Extra: Using where; Open_frm_only; Scanned all databases;
            Using join buffer

```

For the first `EXPLAIN` output row: Constant database and table lookup values enable the server to avoid directory scans for `TABLES` values. References to `TABLES . TABLE_NAME` require no further table files.

For the second `EXPLAIN` output row: All `COLUMNS` table values are `OPEN_FRM_ONLY` lookups, so `COLUMNS . TABLE_NAME` requires the `.frm` file to be opened.

```

mysql> EXPLAIN SELECT * FROM INFORMATION_SCHEMA.COLLATIONS\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: COLLATIONS
      type: ALL
possible_keys: NULL
      key: NULL
      key_len: NULL
      ref: NULL
      rows: NULL
      Extra:

```

In this case, no optimizations apply because `COLLATIONS` is not one of the `INFORMATION_SCHEMA` tables for which optimizations are available.

## 8.2.5. Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- Use persistent connections to the database to avoid connection overhead. If you cannot use persistent connections and you are initiating many new connections to the database, you may want to change the value of the `thread_cache_size` [552] variable. See Section 8.11.2, “Tuning Server Parameters”.

- Always check whether all your queries really use the indexes that you have created in the tables. In MySQL, you can do this with the `EXPLAIN` statement. See [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#).
- Try to avoid complex `SELECT` queries on `MyISAM` tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.
- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` [471] variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See [Section 8.10.3, “Concurrent Inserts”](#).
- To fix any compression issues that may have occurred with `ARCHIVE` tables, you can use `OPTIMIZE TABLE`. See [Section 14.6, “The ARCHIVE Storage Engine”](#).
- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.
- In some cases, it may make sense to introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it may be much faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
WHERE hash_col=MD5(CONCAT(col1,col2))
AND col1='constant' AND col2='constant';
```

- For `MyISAM` tables that change frequently, try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic row format if it includes even a single variable-length column. See [Chapter 14, Storage Engines](#).
- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a `MyISAM` table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See [Chapter 14, Storage Engines](#).
- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use MySQL storage engines such as `MyISAM` that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- If you need to collect statistics from large log tables, use summary tables instead of scanning the entire log table. Maintaining the summaries should be much faster than trying to calculate statistics “live.” Regenerating new summary tables from the logs when things change (depending on business decisions) is faster than changing the running application.
- If possible, classify reports as “live” or as “statistical,” where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.
- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.

- In some cases, it is convenient to pack and store data into a `BLOB` column. In this case, you must provide code in your application to pack and unpack information, but this may save a lot of accesses at some stage. This is practical when you have data that does not conform well to a rows-and-columns table structure.
- Normally, try to keep all data nonredundant (observing what is referred to in database theory as *third normal form*). However, there may be situations in which it can be advantageous to duplicate information or create summary tables to gain more speed.
- Stored routines or UDFs (user-defined functions) may be a good way to gain performance for some tasks. See [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#), and [Section 22.3, “Adding New Functions to MySQL”](#), for more information.
- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. If your database system supports table locks (as does MySQL), this should help to ensure that the index cache is only flushed once after all updates. You can also take advantage of MySQL's query cache to achieve similar results; see [Section 8.9.3, “The MySQL Query Cache”](#).
- Use multiple-row `INSERT` statements to store many rows with one SQL statement. (This is a relatively portable technique.)
- Use `LOAD DATA INFILE` to load large amounts of data. This is faster than using `INSERT` statements.
- Use `AUTO_INCREMENT` columns so that each row in a table can be identified by a single unique value.
- Use `OPTIMIZE TABLE` once in a while to avoid fragmentation with dynamic-format `MyISAM` tables. See [Section 14.3.3, “MyISAM Table Storage Formats”](#).
- Use `MEMORY` tables when possible to get more speed. See [Section 14.4, “The MEMORY Storage Engine”](#). `MEMORY` tables are useful for noncritical data that is accessed often, such as information about the last displayed banner for users who don't have cookies enabled in their Web browser. User sessions are another alternative available in many Web application environments for handling volatile state data.
- With Web servers, images and other binary assets should normally be stored as files. That is, store only a reference to the file rather than the file itself in the database. Most Web servers are better at caching files than database contents, so using files is generally faster.
- Columns with identical information in different tables should be declared to have identical data types so that joins based on the corresponding columns will be faster.
- Try to keep column names simple. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.
- If you need really high speed, look at the low-level interfaces for data storage that the different SQL servers support. For example, by accessing the MySQL `MyISAM` storage engine directly, you could get a speed increase of two to five times compared to using the SQL interface. To be able to do this, the data must be on the same server as the application, and usually it should only be accessed by one process (because external file locking is really slow). One could eliminate these problems by introducing low-level `MyISAM` commands in the MySQL server (this could be one easy way to get more performance if needed). By carefully designing the database interface, it should be quite easy to support this type of optimization.
- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you need not parse your text files to find line and column boundaries.

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See [Chapter 16, Replication](#).
- Declaring a `MyISAM` table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the `--myisam-recover-options` [432] option, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)
- Use `INSERT LOW_PRIORITY` for supported nontransactional tables when you want to give `SELECT` statements higher priority than your inserts.
- Use `SELECT HIGH_PRIORITY` for supported nontransactional tables to get retrievals that jump the queue. That is, the `SELECT` is executed even if there is another client waiting to do a write.

`LOW_PRIORITY` and `HIGH_PRIORITY` have an effect only for nontransactional storage engines that use only table-level locking.

## 8.3. Optimization and Indexes

The best way to improve the performance of `SELECT` operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the `WHERE` clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create an indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. You must find the right balance to achieve fast queries using the optimal set of indexes.

### 8.3.1. How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. If a table has 1,000 rows, this is at least 100 times faster than reading sequentially.

Most MySQL indexes (`PRIMARY KEY`, `UNIQUE`, `INDEX`, and `FULLTEXT`) are stored in [B-trees](#). Exceptions are that indexes on spatial data types use R-trees, and that `MEMORY` tables also support [hash indexes](#).

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in `MEMORY` tables) are described at the end of this section.

MySQL uses indexes for these operations:

- To find the rows matching a `WHERE` clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows (the most [selective](#) index).
- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. For example, `VARCHAR(10)` and `CHAR(10)` are the same size, but `VARCHAR(10)` and `CHAR(15)` are not.

Comparison of dissimilar columns may prevent use of indexes if values cannot be compared directly without conversion. Suppose that a numeric column is compared to a string column. For a given value such as `1` in the numeric column, it might compare equal to any number of values in the string

column such as '1', ' 1', '00001', or '01.e1'. This rules out use of any indexes for the string column.

- To find the `MIN()` [1284] or `MAX()` [1284] value for a specific indexed column `key_col`. This is optimized by a preprocessor that checks whether you are using `WHERE key_part_N = constant` on all key parts that occur before `key_col` in the index. In this case, MySQL does a single key lookup for each `MIN()` [1284] or `MAX()` [1284] expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```
SELECT MIN(key_part2),MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable key (for example, `ORDER BY key_part1, key_part2`). If all key parts are followed by `DESC`, the key is read in reverse order. See [Section 8.13.13, “ORDER BY Optimization”](#), and [Section 8.13.14, “GROUP BY Optimization”](#).
- In some cases, a query can be optimized to retrieve values without consulting the data rows. (An index that provides all the necessary results for a query is called a [covering index](#).) If a query uses only columns from a table that are numeric and that form a leftmost prefix for some key, the selected values can be retrieved from the index tree for greater speed:

```
SELECT key_part3 FROM tbl_name
WHERE key_part1=1
```

Indexes are less important for queries on small tables, or big tables where report queries process most or all of the rows. When a query needs to access most of the rows, reading sequentially is faster than working through an index. Sequential reads minimize disk seeks, even if not all the rows are needed for the query. See [Section 8.2.1.4, “How to Avoid Full Table Scans”](#) for details.

### 8.3.2. Using Primary Keys

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the `NOT NULL` optimization, because it cannot include any `NULL` values. With the `InnoDB` storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key. These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

### 8.3.3. Using Foreign Keys

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

### 8.3.4. Column Indexes

The most common type of index involves a single column, storing copies of the values from that column in a data structure, allowing fast lookups for the rows with the corresponding column values. The B-tree data structure lets the index quickly find a specific value, a set of values, or a range of values, corresponding to operators such as `=`, `>`, `≤`, `BETWEEN`, `IN`, and so on, in a `WHERE` clause.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See [Chapter 14, Storage Engines](#). All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

## Prefix Indexes

With `col_name(N)` syntax in an index specification, you can create an index that uses only the first *N* characters of a string column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a `BLOB` or `TEXT` column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for `InnoDB` tables). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters. *Be sure to take this into account when specifying a prefix length for a column that uses a multi-byte character set.*

## FULLTEXT Indexes

You can also create `FULLTEXT` indexes. These are used for full-text searches. Only the `InnoDB` and `MyISAM` storage engines support `FULLTEXT` indexes and only for `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see [Section 12.9, “Full-Text Search Functions”](#).

Optimizations are applied to certain kinds of `FULLTEXT` queries against single `InnoDB` tables. Queries with these characteristics are particularly efficient:

- `FULLTEXT` queries that only return the document ID, or the document ID and the search rank.
- `FULLTEXT` queries that sort the matching rows in descending order of score and apply a `LIMIT` clause to take the top *N* matching rows. For this optimization to apply, there must be no `WHERE` clauses and only a single `ORDER BY` clause in descending order.
- `FULLTEXT` queries that retrieve only the `COUNT(*)` value of rows matching a search term, with no additional `WHERE` clauses. Code the `WHERE` clause as `WHERE MATCH(text) AGAINST ('other_text')`, without any `> 0` comparison operator.

## Spatial Indexes

You can also create indexes on spatial data types. Currently, only `MyISAM` supports R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for `ARCHIVE`, which does not support spatial type indexing).

## Indexes in the MEMORY Storage Engine

The `MEMORY` storage engine uses `HASH` indexes by default, but also supports `BTREE` indexes.

### 8.3.5. Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see [Section 8.3.4, “Column Indexes”](#)).

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

**Note**

As an alternative to a composite index, you can introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
  WHERE hash_col=MD5(CONCAT(val1,val2))
  AND col1=val1 AND col2=val2;
```

Suppose that a table has the following specification:

```
CREATE TABLE test (
  id          INT NOT NULL,
  last_name   CHAR(30) NOT NULL,
  first_name  CHAR(30) NOT NULL,
  PRIMARY KEY (id),
  INDEX name (last_name,first_name)
);
```

The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for lookups in queries that specify values in a known range for combinations of `last_name` and `first_name` values. It can also be used for queries that specify just a `last_name` value because that column is a leftmost prefix of the index (see [Section 8.3.5, “Multiple-Column Indexes”](#)). Therefore, the `name` index is used for lookups in the following queries:

```
SELECT * FROM test WHERE last_name='Widenius';

SELECT * FROM test
  WHERE last_name='Widenius' AND first_name='Michael';

SELECT * FROM test
  WHERE last_name='Widenius'
  AND (first_name='Michael' OR first_name='Monty');

SELECT * FROM test
  WHERE last_name='Widenius'
  AND first_name >='M' AND first_name < 'N';
```

However, the `name` index is *not* used for lookups in the following queries:

```
SELECT * FROM test WHERE first_name='Michael';

SELECT * FROM test
  WHERE last_name='Widenius' OR first_name='Michael';
```

Suppose that you issue the following `SELECT` statement:

```
mysql> SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer attempts to use the Index Merge optimization (see [Section 8.13.2, “Index Merge Optimization”](#)), or attempts to find the most restrictive index by deciding which index excludes more rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to find rows. For example, if you have a three-column index on (`col1`, `col2`, `col3`), you have indexed search capabilities on (`col1`), (`col1`, `col2`), and (`col1`, `col2`, `col3`).

MySQL cannot use the index to perform lookups if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;

SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve indexed columns, but `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)`.

### 8.3.6. Verifying Index Usage

Always check whether all your queries really use the indexes that you have created in the tables. Use the `EXPLAIN` statement, as described in [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#).

### 8.3.7. InnoDB and MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how many rows must be read for each [ref \[898\]](#) access
- To estimate how many row a partial join will produce; that is, the number of rows that an operation of this form will produce:

```
(...) JOIN tbl_name ON tbl_name.key = expr
```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on  $N/S$ , where  $N$  is the number of rows in the table and  $S$  is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the `<=>` comparison operator, `NULL` is not treated differently from any other value: `NULL <=> NULL`, just as `N <=> N` for any other  $N$ .

However, for a join based on the `=` operator, `NULL` is different from non-`NULL` values: `expr1 = expr2` is not true when `expr1` or `expr2` (or both) are `NULL`. This affects [ref \[898\]](#) accesses for comparisons of the form `tbl_name.key = expr`: MySQL will not access the table if the current value of `expr` is `NULL`, because the comparison cannot be true.

For `=` comparisons, it does not matter how many `NULL` values are in the table. For optimization purposes, the relevant value is the average size of the non-`NULL` value groups. However, MySQL does not currently enable that average size to be collected or used.

For `InnoDB` and `MyISAM` tables, you have some control over collection of table statistics by means of the `innodb_stats_method [1746]` and `myisam_stats_method [513]` system variables, respectively. These variables have three possible values, which differ as follows:

- When the variable is set to `nulls_equal`, all `NULL` values are treated as identical (that is, they all form a single value group).

If the `NULL` value group size is much higher than the average non-`NULL` value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-`NULL` values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for [ref \[898\]](#) accesses when it should.

- When the variable is set to `nulls_unequal`, `NULL` values are not considered the same. Instead, each `NULL` value forms a separate value group of size 1.

If you have many `NULL` values, this method skews the average value group size downward. If the average non-`NULL` value group size is large, counting `NULL` values each as a group of size

1 causes the optimizer to overestimate the value of the index for joins that look for non-NULL values. Consequently, the `nulls_unequal` method may cause the optimizer to use this index for [ref \[898\]](#) lookups when other methods may be better.

- When the variable is set to `nulls_ignored`, NULL values are ignored.

If you tend to use many joins that use `<=>` rather than `=`, NULL values are not special in comparisons and one NULL is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `innodb_stats_method [1746]` system variable has a global value; the `myisam_stats_method [513]` system variable has both global and session values. Setting the global value affects statistics collection for tables from the corresponding storage engine. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table's statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method [513]`.

To regenerate table statistics, you can use any of the following methods:

- Execute `myisamchk --stats_method=method_name --analyze`
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method [513]` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `innodb_stats_method [1746]` and `myisam_stats_method [513]`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `innodb_stats_method [1746]` or `myisam_stats_method [513]` has at the time. Thus, if you collect statistics using one method, but the system variable is set to the other method when a table's statistics are collected automatically later, the other method will be used.
- There is no way to tell which method was used to generate statistics for a given table.
- These variables apply only to InnoDB and MyISAM tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

### 8.3.8. Comparison of B-Tree and Hash Indexes

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the `MEMORY` storage engine that lets you choose B-tree or hash indexes.

#### B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the `= [1166]`, `> [1167]`, `>= [1167]`, `< [1167]`, `<= [1167]`, or `BETWEEN [1168]` operators. The index also can be used for `LIKE [1190]` comparisons if the argument to `LIKE [1190]` is a constant string that does not start with a wildcard character. For example, the following `SELECT` statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%ck%';
```

In the first statement, only rows with `'Patrick' <= key_col < 'Patricl'` are considered. In the second statement, only rows with `'Pat' <= key_col < 'Pau'` are considered.

The following `SELECT` statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the `LIKE [1190]` value begins with a wildcard character. In the second statement, the `LIKE [1190]` value is not a constant.

If you use `... LIKE '%string%'` and `string` is longer than three characters, MySQL uses the *Turbo Boyer-Moore algorithm* to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using `col_name IS NULL` employs indexes if `col_name` is indexed.

Any index that does not span all `AND [1171]` levels in the `WHERE` clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every `AND [1171]` group.

The following `WHERE` clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3
/* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2
/* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5
/* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These `WHERE` clauses do *not* use indexes:

```
/* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2

/* Index is not used in both parts of the WHERE clause */
... WHERE index=1 OR A=10

/* No index spans all rows */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses `LIMIT` to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

## Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the `=` or `<=>` operators (but are *very* fast). They are not used for comparison operators such as `<` that find a range of values. Systems that rely on this type of single-value lookup are known as “key-value stores”; to use MySQL for such applications, use hash indexes wherever possible.
- The optimizer cannot use a hash index to speed up `ORDER BY` operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a `MyISAM` table to a hash-indexed `MEMORY` table.
- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

## 8.4. Optimizing Database Structure

In your role as a database designer, look for the most efficient way to organize your schemas, tables, and columns. As when tuning application code, you minimize I/O, keep related items together, and plan

ahead so that performance stays high as the data volume increases. Starting with an efficient database design makes it easier for team members to write high-performing application code, and makes the database likely to endure as applications evolve and are rewritten.

### 8.4.1. Optimizing Data Size

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application can give you a big performance gain. See [Chapter 14, Storage Engines](#).

You can get better performance for a table and minimize storage space by using the techniques listed here:

#### Table Columns

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.
- Declare columns to be `NOT NULL` if possible. It makes SQL operations faster, by enabling better use of indexes and eliminating overhead for testing whether each value is `NULL`. You also save some storage space, one bit per column. If you really need `NULL` values in your tables, use them. Just avoid the default setting that allows `NULL` values in every column.

#### Row Format

- `InnoDB` tables use a compact storage format. In versions of MySQL earlier than 5.0.3, `InnoDB` rows contain some redundant information, such as the number of columns and the length of each column, even for fixed-size columns. By default, tables are created in the compact format (`ROW_FORMAT=COMPACT`). If you wish to downgrade to older versions of MySQL, you can request the old format with `ROW_FORMAT=REDUNDANT`.

The presence of the compact row format decreases row storage space by about 20% at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

The compact `InnoDB` format also changes how `CHAR` columns containing UTF-8 data are stored. With `ROW_FORMAT=REDUNDANT`, a UTF-8 `CHAR(N)` occupies  $3 \times N$  bytes, given that the maximum length of a UTF-8 encoded character is three bytes. Many languages can be written primarily using single-byte UTF-8 characters, so a fixed storage length often wastes space. With `ROW_FORMAT=COMPACT` format, `InnoDB` allocates a variable amount of storage in the range from  $N$  to  $3 \times N$  bytes for these columns by stripping trailing spaces if necessary. The minimum storage length is kept as  $N$  bytes to facilitate in-place updates in typical cases.

- To minimize space even further by storing table data in compressed form, specify `ROW_FORMAT=COMPRESSED` when creating `InnoDB` tables, or run the `myisampack` command on an existing `MyISAM` table. (`InnoDB` tables compressed tables are readable and writable, while `MyISAM` compressed tables are read-only.)
- For `MyISAM` tables, if you do not have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size row format is used. This is faster but may waste some space. See [Section 14.3.3, “MyISAM Table Storage Formats”](#). You can hint that you want to have fixed length rows even if you have `VARCHAR` columns with the `CREATE TABLE` option `ROW_FORMAT=FIXED`.

## Indexes

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient. For `InnoDB` tables, the primary key columns are duplicated in each secondary index entry, so a short primary key saves considerable space if you have many secondary indexes.
- Create only the indexes that you need to improve query performance. Indexes are good for retrieval, but slow down insert and update operations. If you access a table mostly by searching on a combination of columns, create a single composite index on them rather than a separate index for each column. The first part of the index should be the column most used. If you *always* use many columns when selecting from the table, the first column in the index should be the one with the most duplicates, to obtain better compression of the index.
- If it is very likely that a long string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see [Section 13.1.11, "CREATE INDEX Syntax"](#)). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See [Section 8.11.2, "Tuning Server Parameters"](#).

## Joins

- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.
- Declare columns with identical information in different tables with identical data types, to speed up joins based on the corresponding columns.
- Keep column names simple, so that you can use the same name across different tables and simplify join queries. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.

## Normalization

- Normally, try to keep all data nonredundant (observing what is referred to in database theory as *third normal form*). Instead of repeating lengthy values such as names and addresses, assign them unique IDs, repeat these IDs as needed across multiple smaller tables, and join the tables in queries by referencing the IDs in the join clause.
- If speed is more important than disk space and the maintenance costs of keeping multiple copies of data, for example in a business intelligence scenario where you analyze all the data from large tables, you can relax the normalization rules, duplicating information or creating summary tables to gain more speed.

## 8.4.2. Optimizing MySQL Data Types

### 8.4.2.1. Optimizing for Numeric Data

- For unique IDs or other values that can be represented as either strings or numbers, prefer numeric columns to string columns. Since large numeric values can be stored in fewer bytes than the corresponding strings, it is faster and takes less memory to transfer and compare them.
- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you can avoid parsing the text file to find line and column boundaries.

### 8.4.2.2. Optimizing for Character and String Types

For character and string columns, follow these guidelines:

- Use binary collation order for fast comparison and sort operations, when you do not need language-specific collation features. You can use the [BINARY](#) operator to use binary collation within a particular query.
- When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.
- For column values less than 8KB in size, use binary [VARCHAR](#) instead of [BLOB](#). The [GROUP BY](#) and [ORDER BY](#) clauses can generate temporary tables, and these temporary tables can use the [MEMORY](#) storage engine if the original table does not contain any [BLOB](#) columns.
- If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.
- When you use a randomly generated value as a primary key in an [InnoDB](#) table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, [InnoDB](#) can insert and retrieve them faster.
- See [Section 8.4.2.1, “Optimizing for Numeric Data”](#) for reasons why a numeric column is usually preferable to an equivalent string column.

### 8.4.2.3. Optimizing for BLOB Types

- When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by [InnoDB](#) or [MyISAM](#).
- For a table with several columns, to reduce memory requirements for queries that do not use the BLOB column, consider splitting the BLOB column into a separate table and referencing it with a join query when needed.
- Since the performance requirements to retrieve and display a BLOB value might be very different from other data types, you could put the BLOB-specific table on a different storage device or even a separate database instance. For example, to retrieve a BLOB might require a large sequential disk read that is better suited to a traditional hard drive than to an [SSD device](#).
- See [Section 8.4.2.2, “Optimizing for Character and String Types”](#) for reasons why a binary [VARCHAR](#) column is sometimes preferable to an equivalent BLOB column.
- Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the [MD5\(\)](#) or [CRC32\(\)](#) function to produce the hash value.) Since hash functions can produce duplicate results for different inputs, you still include a clause `AND blob_column = long_string_value` in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

### 8.4.2.4. Using [PROCEDURE ANALYSE](#)

```
ANALYSE([max_elements[,max_memory]])
```

[ANALYSE\(\)](#) examines the result from a query and returns an analysis of the results that suggests optimal data types for each column that may help reduce table sizes. To obtain this analysis, append [PROCEDURE ANALYSE](#) to the end of a [SELECT](#) statement:

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])
```

For example:

```
SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
```

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that `PROCEDURE ANALYSE()` does not suggest the `ENUM` data type when it is not appropriate.

The arguments are optional and are used as follows:

- `max_elements` (default 256) is the maximum number of distinct values that `ANALYSE()` notices per column. This is used by `ANALYSE()` to check whether the optimal data type should be of type `ENUM`; if there are more than `max_elements` distinct values, then `ENUM` is not a suggested type.
- `max_memory` (default 8192) is the maximum amount of memory that `ANALYSE()` should allocate per column while trying to find all distinct values.

### 8.4.3. Optimizing for Many Tables

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

#### 8.4.3.1. How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have only six tables.

MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The `table_open_cache` [551] and `max_connections` [503] system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_open_cache` [551] is related to `max_connections` [503]. For example, for 200 concurrent running connections, specify a table cache size of at least  $200 * N$ , where  $N$  is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_open_cache` [551] setting. If `table_open_cache` [551] is set too high, MySQL may run out of file descriptors and refuse connections, fail to perform queries, and be very unreliable. You also have to take into account that the `MyISAM` storage engine needs two file descriptors for each unique open table. You can increase the number of file descriptors available to MySQL using the `--open-files-limit` [434] startup option to `mysqld`. See [Section C.5.2.18, “'File' Not Found and Similar Errors”](#).

The cache of open tables is kept at a level of `table_open_cache` [551] entries. The default value is 400; this can be changed with the `--table_open_cache` [551] option to `mysqld`. Note that MySQL may temporarily open more tables than this to execute queries.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_open_cache` [551] entries and a table in the cache is no longer being used by any threads.
- When a table flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables that are not currently in use are released, beginning with the table least recently used.
- If a new table needs to be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A `MyISAM` table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any `MyISAM` table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See [Section 13.2.4, “HANDLER Syntax”](#).

You can determine whether your table cache is too small by checking the `mysqld` status variable `Opened_tables` [595], which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Opened_tables | 2741  |
+-----+-----+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, increase the table cache size. See [Section 5.1.4, “Server System Variables”](#), and [Section 5.1.6, “Server Status Variables”](#).

### 8.4.3.2. Disadvantages of Creating Many Tables in the Same Database

If you have many `MyISAM` tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

### 8.4.3.3. How MySQL Uses Internal Temporary Tables

In some cases, the server creates internal temporary tables while processing queries. Such a table can be held in memory and processed by the `MEMORY` storage engine, or stored on disk and processed by the `MyISAM` storage engine. The server may create a temporary table initially as an in-memory table, then convert it to an on-disk table if it becomes too large. Users have no direct control over when the server creates an internal temporary table or which storage engine the server uses to manage it.

Temporary tables can be created under conditions such as these:

- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.

- `DISTINCT` combined with `ORDER BY` may require a temporary table.
- If you use the `SQL_SMALL_RESULT` option, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.
- Derived tables (subqueries in the `FROM` clause).
- Tables created for subquery or semi-join materialization.

To determine whether a query requires a temporary table, use `EXPLAIN` and check the `Extra` column to see whether it says `Using temporary`. See Section 8.8.1, “Optimizing Queries with `EXPLAIN`”. `EXPLAIN` will not necessarily say `Using temporary` for derived or materialized temporary tables.

Some conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a `BLOB` or `TEXT` column in the table
- Presence of any column in a `GROUP BY` or `DISTINCT` clause larger than 512 bytes
- Presence of any column larger than 512 bytes in the `SELECT` list, if `UNION` or `UNION ALL` is used

If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` [558] and `max_heap_table_size` [504] values. This differs from `MEMORY` tables explicitly created with `CREATE TABLE`: For such tables, the `max_heap_table_size` [504] system variable determines how large the table is permitted to grow and there is no conversion to on-disk format.

When the server creates an internal temporary table (either in memory or on disk), it increments the `Created_tmp_tables` [588] status variable. If the server creates the table on disk (either initially or by converting an in-memory table) it increments the `Created_tmp_disk_tables` [587] status variable.

## 8.5. Optimizing for InnoDB Tables

`InnoDB` is the storage engine that MySQL customers typically use in production databases where reliability and concurrency are important. Because `InnoDB` is the default storage engine in MySQL 5.5 and higher, you can expect to see `InnoDB` tables more often than before. This section explains how to optimize database operations for `InnoDB` tables.

### 8.5.1. Optimizing Storage Layout for InnoDB Tables

- Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the `OPTIMIZE TABLE` statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.

`OPTIMIZE TABLE` copies the data part of the table and rebuilds the indexes. The benefits come from improved packing of data within indexes, and reduced fragmentation within the tablespaces and on disk. The benefits vary depending on the data in each table. You may find that there are significant gains for some and not for others, or that the gains decrease over time until you next optimize the table. This operation can be slow if the table is large or if the indexes being rebuilt don't fit into the buffer pool. The first run after adding a lot of data to a table is often much slower than later runs.

- In `InnoDB`, having a long `PRIMARY KEY` (either a single column with a lengthy value, or several columns that form a long composite value) wastes a lot of disk space. The primary key value for a row is duplicated in all the secondary index records that point to the same row. (See Section 14.2.3.12, “`InnoDB` Table and Index Structures”.) Create an `AUTO_INCREMENT` column as

the primary key if your primary key is long, or index a prefix of a long `VARCHAR` column instead of the entire column.

- Use the `VARCHAR` data type instead of `CHAR` to store variable-length strings or for columns with many `NULL` values. A `CHAR(N)` column always takes `N` characters to store data, even if the string is shorter or its value is `NULL`. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using `COMPACT` row format (the default InnoDB format in MySQL 5.6) and variable-length character sets, such as `utf8` or `sjis`, `CHAR(N)` columns occupy a variable amount of space, but still at least `N` bytes.

- For tables that are big, or contain lots of repetitive text or numeric data, consider using `COMPRESSED` row format. Less disk I/O is required to bring data into the buffer pool, or to perform full table scans. Before making a permanent decision, measure the amount of compression you can achieve by using `COMPRESSED` versus `COMPACT` row format.

## 8.5.2. Optimizing InnoDB Transaction Management

To optimize InnoDB transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting `AUTOCOMMIT=1` can impose performance limitations on a busy database server. Where practical, wrap several related DML operations into a single transaction, by issuing `SET AUTOCOMMIT=0` or a `START TRANSACTION` statement, followed by a `COMMIT` statement after making all the changes.

InnoDB must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Alternatively, for transactions that consist only of a single `SELECT` statement, turning on `AUTOCOMMIT` helps InnoDB to recognize read-only transactions and optimize them. See [Section 14.2.4.2.3, “Optimizations for Read-Only Transactions”](#) for requirements.
- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original DML operations. Killing the database process does not help, because the rollback starts again on server startup.

To minimize the chance of this issue occurring: increase the size of the `buffer pool` so that all the DML changes can be cached rather than immediately written to disk; set `innodb_change_buffering=all` [1709] so that update and delete operations are buffered in addition to inserts; and consider issuing `COMMIT` statements periodically during the big DML operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with `innodb_force_recovery=3` [1722], as explained in [Section 14.2.3.13, “The InnoDB Recovery Process”](#).

This issue is expected to be less prominent in MySQL 5.5 and up, or in MySQL 5.1 with the InnoDB Plugin, because the default setting `innodb_change_buffering=all` [1709] allows update and delete operations to be cached in memory, making them faster to perform in the first place, and also faster to roll back if needed. Make sure to use this parameter setting on servers that process long-running transactions with many inserts, updates, or deletes.

- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the `innodb_flush_log_at_trx_commit` [1718] parameter to 0. InnoDB tries to

flush the log once per second anyway, although the flush is not guaranteed. Also, set the value of `innodb_support_xa` [1749] to 0, which will reduce the number of disk flushes due to synchronizing on disk data and the binary log.

- When rows are modified or deleted, the rows and associated [undo logs](#) are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent [InnoDB](#) from purging data that was changed by a different transaction.
- When rows are modified or deleted within a long-running transaction, other transactions using the [READ COMMITTED](#) [1469] and [REPEATABLE READ](#) [1469] isolation levels have to do more work to reconstruct the older data if they read those same rows.
- When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the [covering index](#) technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

### 8.5.3. Optimizing InnoDB Logging

- Make your log files big, even as big as the buffer pool. When [InnoDB](#) has written the log files full, it must write the modified contents of the buffer pool to disk in a checkpoint. Small log files cause many unnecessary disk writes. Although historically big log files caused lengthy recovery times, recovery is now much faster and you can confidently use large log files.
- Make the log buffer quite large as well (on the order of 8MB).

### 8.5.4. Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in [Section 8.2.2.1, “Speed of INSERT Statements”](#).

- When importing data into [InnoDB](#), turn off autocommit mode, because it performs a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

```
SET autocommit=0;... SQL import statements ...
COMMIT;
```

The `mysqldump` option `--opt` [294] creates dump files that are fast to import into an [InnoDB](#) table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- If you have [UNIQUE](#) constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET unique_checks=0;... SQL import statements ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because [InnoDB](#) can use its insert buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have [FOREIGN KEY](#) constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

```
SET foreign_key_checks=0;... SQL import statements ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

- Use the multiple-row [INSERT](#) syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just InnoDB tables.

- When doing bulk inserts into tables with auto-increment columns, set `innodb_autoinc_lock_mode` [1705] to 2 instead of the default value 1. See [Section 5.4.4.2, “Configurable InnoDB Auto-Increment Locking”](#) for details.
- For optimal performance when loading data into an InnoDB FULLTEXT index, follow this set of steps:
  - Define a column `FTS_DOC_ID` at table creation time, of type `BIGINT UNSIGNED NOT NULL`, with a unique index named `FTS_DOC_ID_INDEX`.
  - Load the data into the table.
  - Create the FULLTEXT index after the data is loaded.

### 8.5.5. Optimizing InnoDB Queries

To tune queries for InnoDB tables, create an appropriate set of indexes on each table. See [Section 8.3.1, “How MySQL Uses Indexes”](#) for details. Follow these guidelines for InnoDB indexes:

- Because each InnoDB table has a **primary key** (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.
- Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.
- Do not create a separate **secondary index** for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of **concatenated indexes** rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a **covering index**), the query might be able to avoid reading the table data at all.
- If an indexed column cannot contain any `NULL` values, declare it as `NOT NULL` when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains `NULL` values or not.
- In MySQL 5.6.4 and higher, you can optimize single-query transactions for InnoDB tables, using the technique in [Section 14.2.4.2.3, “Optimizations for Read-Only Transactions”](#).
- If you often have recurring queries for tables that are not updated frequently, enable the query cache:

```
[mysqld]
query_cache_type = 1
query_cache_size = 10M
```

### 8.5.6. Optimizing InnoDB DDL Operations

- For DDL operations on tables and indexes (`CREATE`, `ALTER`, and `DROP` statements), the most significant aspect for InnoDB tables is that creating and dropping secondary indexes is much faster in MySQL 5.5 and higher, than in MySQL 5.1 and before. See [Fast Index Creation in the InnoDB Storage Engine](#) for details.
- “Fast index creation” makes it faster in some cases to drop an index before loading data into a table, then re-create the index after loading the data.
- Use `TRUNCATE TABLE` to empty a table, not `DELETE FROM tbl_name`. Foreign key constraints can make a `TRUNCATE` statement work like a regular `DELETE` statement, in which case a sequence of commands like `DROP TABLE` and `CREATE TABLE` might be fastest.

- Because the primary key is integral to the storage layout of each InnoDB table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the CREATE TABLE statement, and plan ahead so that you do not need to ALTER or DROP the primary key afterward.

### 8.5.7. Optimizing InnoDB Disk I/O

If you follow the best practices for database design and the tuning techniques for SQL operations, but your database is still slowed by heavy disk I/O activity, explore these low-level techniques related to disk I/O. If the Unix `top` tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

- When table data is cached in the InnoDB buffer pool, it can be processed over and over by queries without requiring any disk I/O. Specify the size of the buffer pool with the `innodb_buffer_pool_size` [1708] option. This memory area is important enough that busy databases often specify a size approximately 80% of the amount of physical memory. For more information, see Section 8.9.1, “The InnoDB Buffer Pool”.
- In some versions of GNU/Linux and Unix, flushing files to disk with the Unix `fsync()` call (which InnoDB uses by default) and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the `innodb_flush_method` [1719] parameter set to `O_DSYNC`.
- When using the InnoDB storage engine on Solaris 10 for x86\_64 architecture (AMD Opteron), use direct I/O for InnoDB-related files, to avoid degradation of InnoDB performance. To use direct I/O for an entire UFS file system used for storing InnoDB-related files, mount it with the `forcedirectio` option; see `mount_ufs(1M)`. (The default on Solaris 10/x86\_64 is *not* to use this option.) To apply direct I/O only to InnoDB file operations rather than the whole file system, set `innodb_flush_method = O_DIRECT` [1719]. With this setting, InnoDB calls `directio()` instead of `fcntl()` for I/O to data files (not for I/O to log files).
- When using the InnoDB storage engine with a large `innodb_buffer_pool_size` [1708] value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with InnoDB data files and log files on raw devices or on a separate direct I/O UFS file system, using the `forcedirectio` mount option as described earlier. (It is necessary to use the mount option rather than setting `innodb_flush_method` [1719] if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the `convosync=direct` mount option.

Do not place other MySQL data files, such as those for MyISAM tables, on a direct I/O file system. Executables or libraries *must not* be placed on a direct I/O file system.

- If you have additional storage devices available to set up a RAID configuration or symbolic links to different disks, Section 8.11.3, “Optimizing Disk I/O” for additional low-level I/O tips.
- If throughput drops periodically because of InnoDB checkpoint operations, consider increasing the value of the `innodb_io_capacity` [1727] configuration option. Higher values cause more frequent flushing, avoiding the backlog of work that can cause dips in throughput.
- If the system is not falling behind with InnoDB flushing operations, consider lowering the value of the `innodb_io_capacity` [1727] configuration option. Typically, you keep this option value as low as practical, but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from `SHOW ENGINE INNODB STATUS`:
  - History list length low, below a few thousand.
  - Insert buffer merges close to rows inserted.
  - Modified pages in buffer pool consistently well below `innodb_max_dirty_pages_pct` [1734] of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)

- `log_sequence_number` - Last checkpoint is at less than 7/8 or ideally less than 6/8 of the total size of the InnoDB log files.
- Other InnoDB configuration options to consider when tuning I/O-bound workloads include `innodb_adaptive_flushing` [1700], `innodb_change_buffer_max_size` [1709], `innodb_change_buffering` [1709], `innodb_flush_neighbors` [1721], `innodb_log_buffer_size` [1732], `innodb_log_file_size` [1732], `innodb_lru_scan_depth` [1734], `innodb_max_dirty_pages_pct` [1734], `innodb_max_purge_lag` [1735], `innodb_open_files` [1739], `innodb_page_size` [1740], `innodb_random_read_ahead` [1742], `innodb_read_ahead_threshold` [1742], `innodb_read_io_threads` [1743], `innodb_rollback_segments` [1744], `innodb_write_io_threads` [1754], and `sync_binlog` [2017].

## 8.5.8. Optimizing InnoDB Configuration Variables

Different settings work best for servers with light, predictable loads, versus servers that are running near full capacity all the time, or that experience spikes of high activity.

Because the InnoDB storage engine performs many of its optimizations automatically, many performance-tuning tasks involve monitoring to ensure that the database is performing well, and changing configuration options when performance drops. See [Section 14.2.4.2.26, “Integration with the MySQL Performance Schema”](#) for information about detailed InnoDB performance monitoring.

For information about the most important and most recent InnoDB performance features, see [Section 14.2.4.2, “InnoDB Performance and Scalability Enhancements”](#). Even if you have used InnoDB tables in prior versions, these features might be new to you, because they are from the “InnoDB Plugin”. The Plugin co-existed alongside the built-in InnoDB in MySQL 5.1, and becomes the default storage engine in MySQL 5.5 and higher.

The main configuration steps you can perform include:

- Enabling InnoDB to use high-performance memory allocators on systems that include them. See [Section 14.2.4.2.12, “Using Operating System Memory Allocators”](#).
- Controlling the types of DML operations for which InnoDB buffers the changed data, to avoid frequent small disk writes. See [Section 14.2.4.2.13, “Controlling InnoDB Change Buffering”](#). Because the default is to buffer all types of DML operations, only change this setting if you need to reduce the amount of buffering.
- Turning the adaptive hash indexing feature on and off. See [Section 14.2.4.2.14, “Controlling Adaptive Hash Indexing”](#). You might change this setting during periods of unusual activity, then restore it to its original setting.
- Setting a limit on the number of concurrent threads that InnoDB processes, if context switching is a bottleneck. See [Section 14.2.4.2.15, “Changes Regarding Thread Concurrency”](#).
- Controlling the amount of prefetching that InnoDB does with its read-ahead operations. When the system has unused I/O capacity, more read-ahead can improve the performance of queries. Too much read-ahead can cause periodic drops in performance on a heavily loaded system. See [Section 14.2.4.2.16, “Changes in the Read-Ahead Algorithm”](#).
- Increasing the number of background threads for read or write operations, if you have a high-end I/O subsystem that is not fully utilized by the default values. See [Section 14.2.4.2.17, “Multiple Background InnoDB I/O Threads”](#).
- Controlling how much I/O InnoDB performs in the background. See [Section 14.2.4.2.20, “Controlling the InnoDB Master Thread I/O Rate”](#). The amount of background I/O is higher than in MySQL 5.1, so you might scale back this setting if you observe periodic drops in performance.
- Controlling the algorithm that determines when InnoDB performs certain types of background writes. See [Section 14.2.4.2.21, “Controlling the Flushing Rate of Dirty Pages from the InnoDB Buffer Pool”](#).

The algorithm works for some types of workloads but not others, so might turn off this setting if you observe periodic drops in performance.

- Taking advantage of multicore processors and their cache memory configuration, to minimize delays in context switching. See [Section 14.2.4.2.23, “Control of Spin Lock Polling”](#).
- Preventing one-time operations such as table scans from interfering with the frequently accessed data stored in the InnoDB buffer cache. See [Section 14.2.4.2.24, “Making the Buffer Pool Scan Resistant”](#).
- Adjusting your log files to a size that makes sense for reliability and crash recovery. See [Section 14.2.4.2.25, “Improvements to Crash Recovery Performance”](#). Historically, people have kept their InnoDB log files small to avoid long startup times after a crash. Internal improvements in InnoDB make startup much faster, so the log file size is not such a performance factor anymore. If your log files are artificially small, increasing the size can help performance by reducing the I/O that occurs as redo log records are recycled.
- Configuring the size and number of instances for the InnoDB buffer pool, especially important for systems with multi-gigabyte buffer pools. See [Section 14.2.4.2.27, “Improvements to Performance from Multiple Buffer Pools”](#).
- Increasing the maximum number of concurrent transactions, which dramatically improves scalability for the busiest databases. See [Section 14.2.4.2.28, “Better Scalability with Multiple Rollback Segments”](#). Although this feature does not require any action during day-to-day operation, you must perform a [slow shutdown](#) during or after upgrading the database to MySQL 5.5 to enable the higher limit.
- Moving purge operations (a type of garbage collection) into a background thread. See [Section 14.2.4.2.29, “Better Scalability with Improved Purge Scheduling”](#). To effectively measure the results of this setting, tune the other I/O-related and thread-related configuration settings first.
- Reducing the amount of switching that InnoDB does between concurrent threads, so that SQL operations on a busy server do not queue up and form a “traffic jam”. Set a value for the `innodb_thread_concurrency [1751]` option, up to approximately 32 for a high-powered modern system. Increase the value for the `innodb_concurrency_tickets [1714]` option, typically to 5000 or so. This combination of options sets a cap on the number of threads that InnoDB processes at any one time, and allows each thread to do substantial work before being swapped out, so that the number of waiting threads stays low and operations can complete without excessive context switching.

## 8.5.9. Optimizing InnoDB for Systems with Many Tables

- InnoDB computes index [cardinality](#) values for a table the first time that table is accessed after startup, instead of storing such values in the table. This step can take significant time on systems that partition the data into many tables. Since this overhead only applies to the initial table open operation, to “warm up” a table for later use, access it immediately after startup by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

## 8.6. Optimizing for MyISAM Tables

The MyISAM storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates. In MySQL 5.6, InnoDB is the default storage engine rather than MyISAM.

### 8.6.1. Optimizing MyISAM Queries

Some general tips for speeding up queries on MyISAM tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.)

MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.

- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.
- Try to avoid complex `SELECT` queries on MyISAM tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.
- MyISAM supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` [471] variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See Section 8.10.3, “Concurrent Inserts”.
- For MyISAM tables that change frequently, try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic row format if it includes even a single variable-length column. See Chapter 14, *Storage Engines*.
- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a MyISAM table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See Chapter 14, *Storage Engines*.
- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.
- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use MySQL storage engines such as MyISAM that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use `INSERT DELAYED` for MyISAM (or other supported nontransactional tables) when you do not need to know when your data is written. This reduces the overall insertion impact because many rows can be written with a single disk write.

#### Note

As of MySQL 5.6.6, `INSERT DELAYED` is deprecated, and will be removed in a future release. Use `INSERT` (without `DELAYED`) instead.

- Use `OPTIMIZE TABLE` periodically to avoid fragmentation with dynamic-format MyISAM tables. See Section 14.3.3, “MyISAM Table Storage Formats”.
- Declaring a MyISAM table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the `--myisam-recover-options` [432] option, or by running `myisamchk` before restarting

the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

- Strings are automatically prefix- and end-space compressed in MyISAM indexes. See [Section 13.1.11, “CREATE INDEX Syntax”](#).
- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates. You can also take advantage of MySQL's query cache to achieve similar results; see [Section 8.9.3, “The MySQL Query Cache”](#).

## 8.6.2. Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in [Section 8.2.2.1, “Speed of INSERT Statements”](#).

- To improve performance when multiple clients insert a lot of rows, use the `INSERT DELAYED` statement. See [Section 13.2.5.2, “INSERT DELAYED Syntax”](#). This technique works for MyISAM and some other storage engines, but not InnoDB.

### Note

As of MySQL 5.6.6, `INSERT DELAYED` is deprecated, and will be removed in a future release. Use `INSERT` (without `DELAYED`) instead.

- For a MyISAM table, you can use concurrent inserts to add rows at the same time that `SELECT` statements are running, if there are no deleted rows in middle of the data file. See [Section 8.10.3, “Concurrent Inserts”](#).
- With some extra work, it is possible to make `LOAD DATA INFILE` run even faster for a MyISAM table when the table has many indexes. Use the following procedure:
  1. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.
  2. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name` to remove all use of indexes for the table.
  3. Insert data into the table with `LOAD DATA INFILE`. This does not update any indexes and therefore is very fast.
  4. If you intend only to read from the table in the future, use `myisampack` to compress it. See [Section 14.3.3.3, “Compressed Table Characteristics”](#).
  5. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during `LOAD DATA INFILE` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
  6. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

`LOAD DATA INFILE` performs the preceding optimization automatically if the MyISAM table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA INFILE` statement.

You can also disable or enable the nonunique indexes for a MyISAM table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the `FLUSH TABLE` operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
```

```
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up `INSERT` operations that are performed with multiple statements for nontransactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all `INSERT` statements have completed. Normally, there would be as many index buffer flushes as there are `INSERT` statements. Explicit locking statements are not needed if you can insert all rows with a single `INSERT`.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert
- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA INFILE`, even when using the strategies just outlined.

- To increase performance for `MyISAM` tables, for both `LOAD DATA INFILE` and `INSERT`, enlarge the key cache by increasing the `key_buffer_size` [492] system variable. See [Section 8.11.2, “Tuning Server Parameters”](#).

### 8.6.3. Speed of `REPAIR TABLE` Statements

`REPAIR TABLE` for `MyISAM` tables is similar to using `myisamchk` for repair operations, and some of the same performance optimizations apply:

- `myisamchk` has variables that control memory allocation. You may be able to improve performance by setting these variables, as described in [Section 4.6.3.6, “myisamchk Memory Usage”](#).
- For `REPAIR TABLE`, the same principle applies, but because the repair is done by the server, you set server system variables instead of `myisamchk` variables. Also, in addition to setting memory-allocation variables, increasing the `myisam_max_sort_file_size` [511] system variable increases the likelihood that the repair will use the faster filesort method and avoid the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a `myisamchk` table-repair operation is done using the following options to set its memory-allocation variables:

```
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those `myisamchk` variables correspond to server system variables:

<code>myisamchk</code> Variable	System Variable
<code>key_buffer_size</code>	<code>key_buffer_size</code> [492]
<code>myisam_sort_buffer_size</code>	<code>myisam_sort_buffer_size</code> [513]
<code>read_buffer_size</code>	<code>read_buffer_size</code> [532]
<code>write_buffer_size</code>	none

Each of the server system variables can be set at runtime, and some of them (`myisam_sort_buffer_size` [513], `read_buffer_size` [532]) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (`key_buffer_size` [492], `myisam_max_sort_file_size` [511]) affects other users as well. For `key_buffer_size` [492], you must take into account that the buffer is shared with those users. For example, if you set the `myisamchk key_buffer_size` variable to 128MB, you could set the corresponding `key_buffer_size` [492] system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See [Section 8.9.2.2, “Multiple Key Caches”](#).

Based on the preceding remarks, a `REPAIR TABLE` operation can be done as follows to use settings similar to the `myisamchk` command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
REPAIR TABLE tbl_name ;
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a `REPAIR TABLE` operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```
SET @old_myisam_sort_buffer_size = @@global.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE tbl_name ;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```

The system variables that affect `REPAIR TABLE` can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server `my.cnf` file:

```
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include `read_buffer_size` [532]. Setting `read_buffer_size` [532] globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.

## 8.7. Optimizing for MEMORY Tables

Consider using `MEMORY` tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent `InnoDB` or `MyISAM` tables under a realistic

workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with `MEMORY` tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the `CREATE INDEX` statement, use the clause `USING BTREE` or `USING HASH`. B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as `>` or `BETWEEN`. Hash indexes are only fast for queries that look up single values through the `=` operator, or a restricted set of values through the `IN` operator. For why `USING BTREE` is often a better choice than the default `USING HASH`, see [Section 8.2.1.4, “How to Avoid Full Table Scans”](#). For implementation details of the different types of `MEMORY` indexes, see [Section 8.3.8, “Comparison of B-Tree and Hash Indexes”](#).

## 8.8. Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your `WHERE` clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform the most efficient query is called the “query execution plan”, also known as the `EXPLAIN` plan. Your goals are to recognize the aspects of the `EXPLAIN` plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

### 8.8.1. Optimizing Queries with `EXPLAIN`

The `EXPLAIN` statement can be used either as a way to obtain information about how MySQL executes a statement, or as a synonym for `DESCRIBE`:

- When you precede a statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the query execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. See [Section 8.8.2, “EXPLAIN Output Format”](#).
- `EXPLAIN EXTENDED` can be used to obtain additional information; see [Section 8.8.3, “EXPLAIN EXTENDED Output Format”](#).

As of MySQL 5.6.3, `EXPLAIN` provides information about `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements. Before MySQL 5.6.3, `EXPLAIN` provides information only about `SELECT` statements.

The following sections describe how to use `EXPLAIN` and `EXPLAIN EXTENDED` to obtain query execution plan information.

- `EXPLAIN PARTITIONS` is useful only when examining queries involving partitioned tables. For details, see [Section 17.3.5, “Obtaining Information About Partitions”](#).
- `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` or `SHOW COLUMNS FROM tbl_name`. For information about `DESCRIBE` and `SHOW COLUMNS`, see [Section 13.8.1, “DESCRIBE Syntax”](#), and [Section 13.7.5.6, “SHOW COLUMNS Syntax”](#).

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 13.2.9, “SELECT Syntax”](#).)

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions”. For details, see [MySQL Internals: Tracing the Optimizer](#).

If you have a problem with indexes not being used when you believe that they should be, run [ANALYZE TABLE](#) to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 13.7.2.1, “ANALYZE TABLE Syntax”](#).

## 8.8.2. EXPLAIN Output Format

The [EXPLAIN](#) statement provides information about the execution plan for a [SELECT](#) statement.

[EXPLAIN](#) returns a row of information for each table used in the [SELECT](#) statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. MySQL resolves all joins using a nested-loop join method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

When the [EXTENDED](#) keyword is used, [EXPLAIN](#) produces extra information that can be viewed by issuing a [SHOW WARNINGS](#) statement following the [EXPLAIN](#) statement. [EXPLAIN EXTENDED](#) also displays the [filtered](#) column. See [Section 8.8.3, “EXPLAIN EXTENDED Output Format”](#).

### Note

You cannot use the [EXTENDED](#) and [PARTITIONS](#) keywords together in the same [EXPLAIN](#) statement.

- [EXPLAIN Output Columns](#)
- [EXPLAIN Join Types](#)
- [EXPLAIN Extra Information](#)
- [EXPLAIN Output Interpretation](#)

### EXPLAIN Output Columns

This section describes the output columns produced by [EXPLAIN](#). Later sections provide additional information about the [type](#) and [Extra](#) columns.

Each output row from [EXPLAIN](#) provides information about one table. Each row contains the values summarized in [Table 8.1, “EXPLAIN Output Columns”](#), and described in more detail following the table.

**Table 8.1. EXPLAIN Output Columns**

Column	Meaning
<a href="#">id</a> [895]	The <a href="#">SELECT</a> identifier
<a href="#">select_type</a> [896]	The <a href="#">SELECT</a> type
<a href="#">table</a> [896]	The table for the output row
<a href="#">partitions</a> [896]	The matching partitions
<a href="#">type</a> [897]	The join type
<a href="#">possible_keys</a> [897]	The possible indexes to choose
<a href="#">key</a> [897]	The index actually chosen
<a href="#">key_len</a> [897]	The length of the chosen key
<a href="#">ref</a> [897]	The columns compared to the index
<a href="#">rows</a> [897]	Estimate of rows to be examined
<a href="#">filtered</a> [897]	Percentage of rows filtered by table condition
<a href="#">Extra</a> [898]	Additional information

- [id](#)

The `SELECT` identifier. This is the sequential number of the `SELECT` within the query. The value can be `NULL` if the row refers to the union result of other rows. In this case, the `table` column shows a value like `<unionM,N>` to indicate that the row refers to the union of the rows with `id` values of `M` and `N`.

- `select_type`

The type of `SELECT`, which can be any of those shown in the following table.

<code>select_type</code> Value	Meaning
<code>SIMPLE</code>	Simple <code>SELECT</code> (not using <code>UNION</code> or subqueries)
<code>PRIMARY</code>	Outermost <code>SELECT</code>
<code>UNION</code>	Second or later <code>SELECT</code> statement in a <code>UNION</code>
<code>DEPENDENT UNION</code>	Second or later <code>SELECT</code> statement in a <code>UNION</code> , dependent on outer query
<code>UNION RESULT</code>	Result of a <code>UNION</code> .
<code>SUBQUERY</code>	First <code>SELECT</code> in subquery
<code>DEPENDENT SUBQUERY</code>	First <code>SELECT</code> in subquery, dependent on outer query
<code>DERIVED</code>	Derived table <code>SELECT</code> (subquery in <code>FROM</code> clause)
<code>MATERIALIZED</code>	Materialized subquery
<code>UNCACHEABLE SUBQUERY</code>	A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query
<code>UNCACHEABLE UNION</code>	The second or later select in a <code>UNION</code> that belongs to an uncacheable subquery (see <code>UNCACHEABLE SUBQUERY</code> )

`DEPENDENT` typically signifies the use of a correlated subquery. See [Section 13.2.10.7, “Correlated Subqueries”](#).

`DEPENDENT SUBQUERY` evaluation differs from `UNCACHEABLE SUBQUERY` evaluation. For `DEPENDENT SUBQUERY`, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For `UNCACHEABLE SUBQUERY`, the subquery is re-evaluated for each row of the outer context.

Cacheability of subqueries differs from caching of query results in the query cache (which is described in [Section 8.9.3.1, “How the Query Cache Operates”](#)). Subquery caching occurs during query execution, whereas the query cache is used to store results only after query execution finishes.

- `table`

The name of the table to which the row of output refers. This can also be one of the following values:

- `<unionM,N>`: The row refers to the union of the rows with `id` values of `M` and `N`.
- `<derivedN>`: The row refers to the derived table result for the row with an `id` value of `N`. A derived table may result, for example, from a subquery in the `FROM` clause.
- `<subqueryN>`: The row refers to the result of a materialized subquery for the row with an `id` value of `N`. See [Section 8.13.16.2, “Optimizing Subqueries with Subquery Materialization”](#).

- `partitions`

The partitions from which records would be matched by the query. This column is displayed only if the `PARTITIONS` keyword is used. The value is `NULL` for nonpartitioned tables. See [Section 17.3.5, “Obtaining Information About Partitions”](#).

- `type`

The `type` join type. For descriptions of the different types, see [EXPLAIN Join Types](#).

- `possible_keys`

The `possible_keys` column indicates which indexes MySQL can choose from use to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

If this column is `NULL`, there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See [Section 13.1.6, “ALTER TABLE Syntax”](#).

To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key`

The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

It is possible that `key` will name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

For `InnoDB`, a secondary index might cover the selected columns even if the query also selects the primary key because `InnoDB` stores the primary key value with each secondary index. If `key` is `NULL`, MySQL found no index to use for executing the query more efficiently.

To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See [Section 13.2.9.3, “Index Hint Syntax”](#).

For `MyISAM` tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For `MyISAM` tables, `myisamchk --analyze` does the same. See [Section 13.7.2.1, “ANALYZE TABLE Syntax”](#), and [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

- `key_len`

The `key_len` column indicates the length of the key that MySQL decided to use. The length is `NULL` if the `key` column says `NULL`. Note that the value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses.

- `ref`

The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

- `rows`

The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

For `InnoDB` tables, this number is an estimate, and may not always be exact.

- `filtered`

The `filtered` column indicates an estimated percentage of table rows that will be filtered by the table condition. That is, `rows` shows the estimated number of rows examined and `rows × filtered`

/ 100 shows the number of rows that will be joined with previous tables. This column is displayed if you use `EXPLAIN EXTENDED`.

- `Extra`

This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see `EXPLAIN Extra Information`.

## EXPLAIN Join Types

The `type` column of `EXPLAIN` output describes how tables are joined. The following list describes the join types, ordered from the best type to the worst:

- `system` [898]

The table has only one row (= system table). This is a special case of the `const` [898] join type.

- `const` [898]

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` [898] tables are very fast because they are read only once.

`const` [898] is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, `tbl_name` can be used as a `const` [898] table:

```
SELECT * FROM tbl_name WHERE primary_key=1;

SELECT * FROM tbl_name
WHERE primary_key_part1=1 AND primary_key_part2=2;
```

- `eq_ref` [898]

One row is read from this table for each combination of rows from the previous tables. Other than the `system` [898] and `const` [898] types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE NOT NULL` index.

`eq_ref` [898] can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` [898] join to process `ref_table`:

```
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `ref` [898]

All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` [898] is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` [898] can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` [898] join to process `ref_table`:

```
SELECT * FROM ref_table WHERE key_column=expr;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
```

```
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- [fulltext \[899\]](#)

The join is performed using a `FULLTEXT` index.

- [ref\\_or\\_null \[899\]](#)

This join type is like [ref \[898\]](#), but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a [ref\\_or\\_null \[899\]](#) join to process *ref\_table*:

```
SELECT * FROM ref_table
WHERE key_column=expr OR key_column IS NULL;
```

See [Section 8.13.6, “IS NULL Optimization”](#).

- [index\\_merge \[899\]](#)

This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see [Section 8.13.2, “Index Merge Optimization”](#).

- [unique\\_subquery \[899\]](#)

This type replaces [ref \[898\]](#) for some `IN` subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

[unique\\_subquery \[899\]](#) is just an index lookup function that replaces the subquery completely for better efficiency.

- [index\\_subquery \[899\]](#)

This join type is similar to [unique\\_subquery \[899\]](#). It replaces `IN` subqueries, but it works for nonunique indexes in subqueries of the following form:

```
value IN (SELECT key_column FROM single_table WHERE some_expr)
```

- [range \[899\]](#)

Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column in the output row indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

[range \[899\]](#) can be used when a key column is compared to a constant using any of the `= [1166]`, `<> [1167]`, `> [1167]`, `>= [1167]`, `< [1167]`, `<= [1167]`, `IS NULL [1168]`, `<=> [1167]`, `BETWEEN [1168]`, or `IN() [1169]` operators:

```
SELECT * FROM tbl_name
  WHERE key_column = 10;

SELECT * FROM tbl_name
  WHERE key_column BETWEEN 10 and 20;

SELECT * FROM tbl_name
  WHERE key_column IN (10,20,30);

SELECT * FROM tbl_name
  WHERE key_part1 = 10 AND key_part2 IN (10,20,30);
```

- [index \[899\]](#)

The `index` join type is the same as `ALL`, except that the index tree is scanned. This occurs two ways:

- If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the `Extra` column says `Using index`. An index-only scan usually is faster than `ALL` because the size of the index usually is smaller than the table data.
- A full table scan is performed using reads from the index to look up data rows in index order. `Uses index` does not appear in the `Extra` column.

MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const` [898], and usually very bad in all other cases. Normally, you can avoid `ALL` by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

## EXPLAIN Extra Information

The `Extra` column of `EXPLAIN` output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. If you want to make your queries as fast as possible, look out for `Extra` values of `Using filesort` and `Using temporary`.

- `const row not found`

For a query such as `SELECT ... FROM tbl_name`, the table was empty.

- `Deleting all rows`

For `DELETE`, some storage engines (such as `MyISAM`) support a handler method that removes all table rows in a simple and fast way. This `Extra` value is displayed if the engine uses this optimization.

- `Distinct`

MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- `FirstMatch(tbl_name)`

The semi-join `FirstMatch` join shortcutting strategy is used for `tbl_name`.

- `Full scan on NULL key`

This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- `Impossible HAVING`

The `HAVING` clause is always false and cannot select any rows.

- `Impossible WHERE`

The `WHERE` clause is always false and cannot select any rows.

- `Impossible WHERE noticed after reading const tables`

MySQL has read all `const` [898] (and `system` [898]) tables and notice that the `WHERE` clause is always false.

- `LooseScan(m..n)`

The semi-join LooseScan strategy is used. *m* and *n* are key part numbers.

- **Materialize, Scan**

Before MySQL 5.6.7, this indicates use of a single materialized temporary table. If `Scan` is present, no temporary table index is used for table reads. Otherwise, an index lookup is used. See also the `Start materialize` entry.

As of MySQL 5.6.7, materialization is indicated by rows with a `select_type` value of `MATERIALIZED` and rows with a `table` value of `<subqueryN>`.

- **No matching min/max row**

No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- **no matching row in const table**

For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- **No matching rows after partition pruning**

For `DELETE` or `UPDATE`, the optimizer found nothing to delete or update after partition pruning. It is similar in meaning to `Impossible WHERE` for `SELECT` statements.

- **No tables used**

The query has no `FROM` clause, or has a `FROM DUAL` clause.

For `INSERT` or `REPLACE` statements, `EXPLAIN` displays this value when there is no `SELECT` part. For example, it appears for `EXPLAIN INSERT INTO t VALUES(10)` because that is equivalent to `EXPLAIN INSERT INTO t SELECT 10 FROM DUAL`.

- **Not exists**

MySQL was able to do a `LEFT JOIN` optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the `LEFT JOIN` criteria. Here is an example of the type of query that can be optimized this way:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
WHERE t2.id IS NULL;
```

Assume that `t2.id` is defined as `NOT NULL`. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be `NULL`, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

- **Range checked for each record (index map: N)**

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a `range [899]` or `index_merge [899]` access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in [Section 8.13.1, “Range Optimization”](#), and [Section 8.13.2, “Index Merge Optimization”](#), with the exception that all column values for the preceding table are known and considered to be constants.

Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value *N* is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 will be considered.

- `Scanned N databases`

This indicates how many directory scans the server performs when processing a query for `INFORMATION_SCHEMA` tables, as described in [Section 8.2.4, “Optimizing `INFORMATION\_SCHEMA` Queries”](#). The value of `N` can be 0, 1, or `all`.

- `Select tables optimized away`

The query contained only aggregate functions (`MIN()` [1284], `MAX()` [1284]) that were all resolved using an index, or `COUNT(*)` [1283] for `MyISAM`, and no `GROUP BY` clause. The optimizer determined that only one row should be returned.

- `Skip_open_table`, `Open_frm_only`, `Open_trigger_only`, `Open_full_table`

These values indicate file-opening optimizations that apply to queries for `INFORMATION_SCHEMA` tables, as described in [Section 8.2.4, “Optimizing `INFORMATION\_SCHEMA` Queries”](#).

- `Skip_open_table`: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- `Open_frm_only`: Only the table's `.frm` file need be opened.
- `Open_trigger_only`: Only the table's `.TRG` file need be opened.
- `Open_full_table`: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

- `Start materialize`, `End materialize`, `Scan`

Before MySQL 5.6.7, this indicates use of multiple materialized temporary tables. If `Scan` is present, no temporary table index is used for table reads. Otherwise, an index lookup is used. See also the [Materialize](#) entry.

As of MySQL 5.6.7, materialization is indicated by rows with a `select_type` value of `MATERIALIZED` and rows with a `table` value of `<subqueryN>`.

- `Start temporary`, `End temporary`

This indicates temporary table use for the semi-join Duplicate Weedout strategy.

- `unique row not found`

For a query such as `SELECT ... FROM tbl_name`, no rows satisfy the condition for a `UNIQUE` index or `PRIMARY KEY` on the table.

- `Using filesort`

MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order. See [Section 8.13.13, “ORDER BY Optimization”](#).

- `Using index`

The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

If the `Extra` column also says `Using where`, it means the index is being used to perform lookups of key values. Without `Using where`, the optimizer may be reading the index to avoid reading data rows but not using it for lookups. For example, if the index is a covering index for the query, the optimizer may scan it without using it for lookups.

For InnoDB tables that have a user-defined clustered index, that index can be used even when `Using index` is absent from the `Extra` column. This is the case if `type` is `index` [899] and `key` is `PRIMARY`.

- `Using index condition`

Tables are read by accessing index tuples and testing them first to determine whether to read full table rows. In this way, index information is used to defer (“push down”) reading full table rows unless it is necessary. See [Section 8.13.4, “Index Condition Pushdown Optimization”](#).

- `Using index for group-by`

Similar to the `Using index` table access method, `Using index for group-by` indicates that MySQL found an index that can be used to retrieve all columns of a `GROUP BY` or `DISTINCT` query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see [Section 8.13.14, “GROUP BY Optimization”](#).

- `Using join buffer (Block Nested Loop)`, `Using join buffer (Batched Key Access)`

Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table. `(Block Nested Loop)` indicates use of the Block Nested-Loop algorithm and `(Batched Key Access)` indicates use of the Batched Key Access algorithm. That is, the keys from the table on the preceding line of the `EXPLAIN` output will be buffered, and the matching rows will be fetched in batches from the table represented by the line in which `Using join buffer` appears.

- `Using MRR`

Tables are read using the Multi-Range Read optimization strategy. See [Section 8.13.11, “Multi-Range Read Optimization”](#).

- `Using sort_union(...)`, `Using union(...)`, `Using intersect(...)`

These indicate how index scans are merged for the `index_merge` [899] join type. See [Section 8.13.2, “Index Merge Optimization”](#).

- `Using temporary`

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- `Using where`

A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index` [899].

- `Using where with pushed condition`

This item applies to `NDB` tables *only*. It means that MySQL Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster’s data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see [Section 8.13.3, “Engine Condition Pushdown Optimization”](#).

## EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the `EXPLAIN` output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` [505] system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See [Section 8.11.2, “Tuning Server Parameters”](#).

The following example shows how a multiple-table join can be optimized progressively based on the information provided by `EXPLAIN`.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using `EXPLAIN`:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
              tt.ProjectReference, tt.EstimatedShipDate,
              tt.ActualShipDate, tt.ClientID,
              tt.ServiceCodes, tt.RepetitiveID,
              tt.CurrentProcess, tt.CurrentDPPerson,
              tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
              et_1.COUNTRY, do.CUSTNAME
FROM tt, et, et AS et_1, do
WHERE tt.SubmitTime IS NULL
      AND tt.ActualPC = et.EMPLOYID
      AND tt.AssignedPC = et_1.EMPLOYID
      AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

Table	Column	Data Type
tt	ActualPC	CHAR(10)
tt	AssignedPC	CHAR(10)
tt	ClientID	CHAR(10)
et	EMPLOYID	CHAR(15)
do	CUSTNMBR	CHAR(15)

- The tables have the following indexes.

Table	Index
tt	ActualPC
tt	AssignedPC
tt	ClientID
et	EMPLOYID (primary key)
do	CUSTNMBR (primary key)

- The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

```
table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
do ALL PRIMARY NULL NULL NULL 2135
et_1 ALL PRIMARY NULL NULL NULL 74
tt ALL AssignedPC, NULL NULL NULL 3872
    ClientID,
    ActualPC
    Range checked for each record (index map: 0x23)
```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is  $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$  rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

table	type	possible_keys	key	key_len	ref	rows	Extra	
tt	ALL	AssignedPC, ClientID, ActualPC	NULL	NULL	NULL	3872	Using where	
do	ALL	PRIMARY	NULL	NULL	NULL	2135		
		Range checked for each record (index map: 0x1)						
et_1	ALL	PRIMARY	NULL	NULL	NULL	74		
		Range checked for each record (index map: 0x1)						
et	eq_ref	PRIMARY	PRIMARY	15	tt.ActualPC	1		

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
->      MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

table	type	possible_keys	key	key_len	ref	rows	Extra
et	ALL	PRIMARY	NULL	NULL	NULL	74	
tt	ref	AssignedPC, ClientID, ActualPC	ActualPC	15	et.EMPLOYID	52	Using where
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

table	type	possible_keys	key	key_len	ref	rows	Extra
tt	ALL	AssignedPC, ClientID, ActualPC	NULL	NULL	NULL	3872	Using where
et	eq_ref	PRIMARY	PRIMARY	15	tt.ActualPC	1	
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

Note that the `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. Check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better

performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause.

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see [Section 13.2.10.8, “Subqueries in the FROM Clause”](#).

### 8.8.3. EXPLAIN EXTENDED Output Format

When `EXPLAIN` is used with the `EXTENDED` keyword, the output includes a `filtered` column not otherwise displayed. This column indicates the estimated percentage of table rows that will be filtered by the table condition. In addition, the statement produces extra information that can be viewed by issuing a `SHOW WARNINGS` statement following the `EXPLAIN` statement. The `Message` value in `SHOW WARNINGS` output displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process. Here is an example:

```
mysql> EXPLAIN EXTENDED
-> SELECT t1.a, t1.a IN (SELECT t2.a FROM t2) FROM t1\G
***** 1. row *****
      id: 1
  select_type: PRIMARY
      table: t1
      type: index
possible_keys: NULL
      key: PRIMARY
     key_len: 4
      ref: NULL
      rows: 4
  filtered: 100.00
     Extra: Using index
***** 2. row *****
      id: 2
  select_type: SUBQUERY
      table: t2
      type: index
possible_keys: a
      key: a
     key_len: 5
      ref: NULL
      rows: 3
  filtered: 100.00
     Extra: Using index
2 rows in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select `test`.`t1`.`a` AS `a`,
<in_optimizer>(`test`.`t1`.`a`,`test`.`t1`.`a` in
( <materialize> (/* select#2 */ select `test`.`t2`.`a`
from `test`.`t2` where 1 having 1 ),
<primary_index_lookup>(`test`.`t1`.`a` in
<temporary table> on <auto_key>
where ((`test`.`t1`.`a` = `materialized-subquery`.`a`)))) AS `t1.a`
IN (SELECT t2.a FROM t2)` from `test`.`t1`
1 row in set (0.00 sec)
```

As of MySQL 5.6.3, `EXPLAIN EXTENDED` can be used with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements. However, the following `SHOW WARNINGS` statement displays a nonempty result only for `SELECT` statements. Before MySQL 5.6.3, `EXPLAIN EXTENDED` can be used only with `SELECT` statements.

Because the statement displayed by `SHOW WARNINGS` may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with `Message` values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in `EXTENDED` output displayed by `SHOW WARNINGS`:

- `<auto_key>`  
An automatically generated key for a temporary table.
- `<cache>(expr)`  
The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use. For results consisting of multiple values, a temporary table may be created and you will see `<temporary table>` instead.
- `<exists>(query fragment)`  
The subquery predicate is converted to an `EXISTS` predicate and the subquery is transformed so that it can be used together with the `EXISTS` predicate.
- `<in_optimizer>(query fragment)`  
This is an internal optimizer object with no user significance.
- `<index_lookup>(query fragment)`  
The query fragment is processed using an index lookup to find qualifying rows.
- `<if>(condition, expr1, expr2)`  
If the condition is true, evaluate to `expr1`, otherwise `expr2`.
- `<is_not_null_test>(expr)`  
A test to verify that the expression does not evaluate to `NULL`.
- `<materialize>(query fragment)`  
Subquery materialization is used.
- ``materialized-subquery`.col_name, `materialized subselect`.col_name`  
A reference to the column `col_name` in an internal temporary table materialized to hold the result from evaluating a subquery.
- `<primary_index_lookup>(query fragment)`  
The query fragment is processed using a primary key lookup to find qualifying rows.
- `<ref_null_helper>(expr)`  
This is an internal optimizer object with no user significance.
- `/* select#N */ select_stmt`  
The `SELECT` is associated with the row in non-`EXTENDED EXPLAIN` output that has an `id` value of `N`.
- `outer_tables semi join (inner_tables)`  
A semi-join operation. `inner_tables` shows the tables that were not pulled out. See [Section 8.13.16.1, “Optimizing Subqueries with Semi-Join Transformations”](#).
- `<temporary table>`  
This represents an internal temporary table created to cache an intermediate result.

## 8.8.4. Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row:  $\log(\text{row\_count}) / \log(\text{index\_block\_length} / 3 * 2 / (\text{index\_length} + \text{data\_pointer\_length})) + 1$ .

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates  $\log(500,000) / \log(1024 / 3 * 2 / (3 + 4)) + 1 = 4$  seeks.

This index would require storage of about  $500,000 * 7 * 3/2 = 5.2\text{MB}$  (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

Note that the preceding discussion does not mean that your application performance slowly degenerates by  $\log N$ . As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by  $\log N$ ). To avoid this, increase the key cache size as the data grows. For `MyISAM` tables, the key cache size is controlled by the `key_buffer_size` [492] system variable. See Section 8.11.2, “Tuning Server Parameters”.

## 8.8.5. Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated and which switchable optimizations are enabled.

### 8.8.5.1. Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server's performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two system variables:

- The `optimizer_prune_level` [519] variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of “educated guess” rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.
- The `optimizer_search_depth` [520] variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values

of `optimizer_search_depth` [520] may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` [520] is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` [520] equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth` [520], this variable can be set to 0 to tell the optimizer to determine the value automatically.

### 8.8.5.2. Controlling Switchable Optimizations

The `optimizer_switch` [520] system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semi_join=on,loosescan=on,
                    firstmatch=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on
```

To change the value of `optimizer_switch` [520], assign a value consisting of a comma-separated list of one or more commands:

```
SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';
```

Each `command` value should have one of the forms shown in the following table.

Command Syntax	Meaning
<code>default</code>	Reset every optimization to its default value
<code>opt_name=default</code>	Set the named optimization to its default value
<code>opt_name=off</code>	Disable the named optimization
<code>opt_name=on</code>	Enable the named optimization

The order of the commands in the value does not matter, although the `default` command is executed first if present. Setting an `opt_name` flag to `default` sets it to whichever of `on` or `off` is its default value. Specifying any given `opt_name` more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of `optimizer_switch` [520] unchanged.

The following table lists the permissible `opt_name` flag names, grouped by optimization strategy.

Optimization	Flag Name	Meaning
Batched Key Access	<code>batched_key_access</code>	Controls use of BKA join algorithm
Block Nested-Loop	<code>block_nested_loop</code>	Controls use of BNL join algorithm
Engine Condition Pushdown	<code>engine_condition_pushdown</code>	Controls engine condition pushdown
Index Condition Pushdown	<code>index_condition_pushdown</code>	Controls index condition pushdown

Optimization	Flag Name	Meaning
Index Extensions	<code>use_index_extensions</code>	Controls use of index extensions
Index Merge	<code>index_merge</code>	Controls all Index Merge optimizations
	<code>index_merge_intersection</code>	Controls the Index Merge Intersection Access optimization
	<code>index_merge_sort_union</code>	Controls the Index Merge Sort-Union Access optimization
	<code>index_merge_union</code>	Controls the Index Merge Union Access optimization
Multi-Range Read	<code>mrr</code>	Controls the Multi-Range Read strategy
	<code>mrr_cost_based</code>	Controls use of cost-based MRR if <code>mrr=on</code>
Semi-join	<code>semi_join</code>	Controls all semi-join strategies
	<code>firstmatch</code>	Controls the semi-join FirstMatch strategy
	<code>loosescan</code>	Controls the semi-join LooseScan strategy (not to be confused with LooseScan for <code>GROUP BY</code> )
Subquery materialization	<code>materialization</code>	Controls materialization (including semi-join materialization)
	<code>subquery_materialization_cost_based</code>	Used cost-based materialization choice

The `block_nested_loop` and `batched_key_access` flags were added in MySQL 5.6.3. For `batched_key_access` to have any effect when set to `on`, the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used.

`semi_join`, `firstmatch`, `loosescan`, and `materialization` flags were added in MySQL 5.6.5 to enable control over semi-join and subquery materialization strategies. The `semi_join` flag controls whether semi-joins are used. If it is set to `on`, the `firstmatch` and `loosescan` flags enable finer control over the permitted semi-join strategies. The `materialization` flag controls whether subquery materialization is used. If `semi_join` and `materialization` are both `on`, semi-joins also use materialization where applicable. These flags are `on` by default.

The `subquery_materialization_cost_based` was added in MySQL 5.6.7 to enable control over the choice between subquery materialization and `IN -> EXISTS` subquery transformation. If the flag is `on` (the default), the optimizer performs a cost-based choice between subquery materialization and `IN -> EXISTS` subquery transformation if either method could be used. If the flag is `off`, the optimizer chooses subquery materialization over `IN -> EXISTS` subquery transformation, which was the previous behavior before MySQL 5.6.7.

For more information about individual optimization strategies, see the following sections:

- [Section 8.13.12, “Block Nested-Loop and Batched Key Access Joins”](#)
- [Section 8.13.3, “Engine Condition Pushdown Optimization”](#)
- [Section 8.13.5, “Use of Index Extensions”](#)
- [Section 8.13.4, “Index Condition Pushdown Optimization”](#)
- [Section 8.13.2, “Index Merge Optimization”](#)
- [Section 8.13.11, “Multi-Range Read Optimization”](#)
- [Section 8.13.16, “Subquery Optimization”](#)

When you assign a value to `optimizer_switch` [520], flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer will perform better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';

mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=off,
                    index_merge_sort_union=off,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on
```

## 8.9. Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

### 8.9.1. The InnoDB Buffer Pool

InnoDB maintains a storage area called the **buffer pool** for caching data and indexes in memory. Knowing how the InnoDB buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.

#### Guidelines

Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more InnoDB acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. The buffer pool even caches data changed by insert and update operations, so that disk writes can be grouped together for better performance.

Depending on the typical workload on your system, you might adjust the proportions of the parts within the buffer pool. You can tune the way the buffer pool chooses which blocks to cache once it fills up, to keep frequently accessed data in memory despite sudden spikes of activity for operations such as backups or reporting.

With 64-bit systems with large memory sizes, you can split the buffer pool into multiple parts, to minimize contention for the memory structures among concurrent operations. For details, see [Section 14.2.4.2.27, “Improvements to Performance from Multiple Buffer Pools”](#).

## Internal Details

`InnoDB` manages the pool as a list, using a variation of the least recently used (LRU) algorithm. When room is needed to add a new block to the pool, `InnoDB` evicts the least recently used block and adds the new block to the middle of the list. This “midpoint insertion strategy” treats the list as two sublists:

- At the head, a sublist of “new” (or “young”) blocks that were accessed recently.
- At the tail, a sublist of “old” blocks that were accessed less recently.

This algorithm keeps blocks that are heavily used by queries in the new sublist. The old sublist contains less-used blocks; these blocks are candidates for [eviction](#).

The LRU algorithm operates as follows by default:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When `InnoDB` reads a block into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A block can be read in because it is required for a user-specified operation such as an SQL query, or as part of a [read-ahead](#) operation performed automatically by `InnoDB`.
- Accessing to a block in the old sublist makes it “young”, moving it to the head of the buffer pool (the head of the new sublist). If the block was read in because it was required, the first access occurs immediately and the block is made young. If the block was read in due to read-ahead, the first access does not occur immediately (and might not occur at all before the block is evicted).
- As the database operates, blocks in the buffer pool that are not accessed “age” by moving toward the tail of the list. Blocks in both the new and old sublists age as other blocks are made new. Blocks in the old sublist also age as blocks are inserted at the midpoint. Eventually, a block that remains unused for long enough reaches the tail of the old sublist and is evicted.

By default, blocks read by queries immediately move into the new sublist, meaning they will stay in the buffer pool for a long time. A table scan (such as performed for a `mysqldump` operation, or a `SELECT` statement with no `WHERE` clause) can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, blocks that are loaded by the read-ahead background thread and then accessed only once move to the head of the new list. These situations can push frequently used blocks to the old sublist, where they become subject to eviction.

## Configuration Options

Several `InnoDB` system variables control the size of the buffer pool and let you tune the LRU algorithm:

- [innodb\\_buffer\\_pool\\_size \[1708\]](#)

Specifies the size of the buffer pool. If your buffer pool is small and you have sufficient memory, making the pool larger can improve performance by reducing the amount of disk I/O needed as queries access `InnoDB` tables.

- [innodb\\_buffer\\_pool\\_instances \[1706\]](#)

Divides the buffer pool into a user-specified number of separate regions, each with its own LRU list and related data structures, to reduce contention during concurrent memory read and write operations. This option takes effect only when you set the [innodb\\_buffer\\_pool\\_size](#) to a size of 1 gigabyte or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of [innodb\\_buffer\\_pool\\_instances \[1706\]](#) and [innodb\\_buffer\\_pool\\_size \[1708\]](#) so that each buffer pool instance is at least 1 gigabyte.

- [innodb\\_old\\_blocks\\_pct \[1738\]](#)

Specifies the approximate percentage of the buffer pool that InnoDB uses for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool).

- [innodb\\_old\\_blocks\\_time \[1738\]](#)

Specifies how long in milliseconds (ms) a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. The default value is 0: A block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many ms after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

Setting [innodb\\_old\\_blocks\\_time \[1738\]](#) greater than 0 prevents one-time table scans from flooding the new sublist with blocks used only for the scan. Rows in a block read in for a scan are accessed many times in rapid succession, but the block is unused after that. If [innodb\\_old\\_blocks\\_time \[1738\]](#) is set to a value greater than time to process the block, the block remains in the “old” sublist and ages to the tail of the list to be evicted quickly. This way, blocks used only for a one-time scan do not act to the detriment of heavily used blocks in the new sublist.

[innodb\\_old\\_blocks\\_time \[1738\]](#) can be set at runtime, so you can change it temporarily while performing operations such as table scans and dumps:

```
SET GLOBAL innodb_old_blocks_time = 1000;... perform queries that scan tables ...
SET GLOBAL innodb_old_blocks_time = 0;
```

This strategy does not apply if your intent is to “warm up” the buffer pool by filling it with a table's content. For example, benchmark tests often perform a table or index scan at server startup, because that data would normally be in the buffer pool after a period of normal use. In this case, leave [innodb\\_old\\_blocks\\_time \[1738\]](#) set to 0, at least until the warmup phase is complete.

## Monitoring the Buffer Pool

The output from the InnoDB Standard Monitor contains several fields in the [BUFFER POOL AND MEMORY](#) section that pertain to operation of the buffer pool LRU algorithm:

- [Old database pages](#): The number of pages in the old sublist of the buffer pool.
- [Pages made young, not young](#): The number of old pages that were moved to the head of the buffer pool (the new sublist), and the number of pages that have remained in the old sublist without being made new.
- [young/s non-young/s](#): The number of accesses to old pages that have resulted in making them young or not. This metric differs from that of the previous item in two ways. First, it relates only to old pages. Second, it is based on number of accesses to pages and not the number of pages. (There can be multiple accesses to a given page, all of which are counted.)
- [young-making rate](#): Hits that cause blocks to move to the head of the buffer pool.
- [not](#): Hits that do not cause blocks to move to the head of the buffer pool (due to the delay not being met).

The [young-making](#) rate and [not](#) rate will not normally add up to the overall buffer pool hit rate. Hits for blocks in the old sublist cause them to move to the new sublist, but hits to blocks in the new sublist cause them to move to the head of the list only if they are a certain distance from the head.

The preceding information from the Monitor can help you make LRU tuning decisions:

- If you see very low [young/s](#) values when you do not have large scans going on, that indicates that you might need to either reduce the delay time, or increase the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger, so blocks in that sublist

take longer to move to the tail and be evicted. This increases the likelihood that they will be accessed again and be made young.

- If you do not see a lot of `non-youngs/s` when you are doing large table scans (and lots of `youngs/s`), to tune your delay value to be larger.

For more information about InnoDB Monitors, see [Section 14.2.4.4, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#).

## 8.9.2. The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the `key_buffer_size` [492] system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the `key_buffer_size` [492] value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one of these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an *LRU* (*Least Recently Used*) strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (*LRU chain*) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The InnoDB storage engine also uses an LRU algorithm, to manage its buffer pool. See [Section 8.9.1, “The InnoDB Buffer Pool”](#).

### 8.9.2.1. Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

### 8.9.2.2. Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given `MyISAM` table. By default, all `MyISAM` table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the `CACHE INDEX` statement (see [Section 13.7.6.2, “CACHE INDEX Syntax”](#)). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

Table	Op	Msg_type	Msg_text
test.t1	assign_to_keycache	status	OK
test.t2	assign_to_keycache	status	OK
test.t3	assign_to_keycache	status	OK

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a `SET GLOBAL` parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

Note that you cannot destroy the default key cache. Any attempt to do this will be ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;
```

```
mysql> SHOW VARIABLES LIKE 'key_buffer_size';
```

Variable_name	Value
key_buffer_size	8384512

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size [492]` is the cache component. See [Section 5.1.5.1, “Structured System Variables”](#), for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read in from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The `CACHE INDEX` statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init-file` option that names a file containing `CACHE INDEX` statements to be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysql_d_init.sql
```

The statements in `mysql_d_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

### 8.9.2.3. Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the *midpoint insertion strategy*.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least `key_cache_division_limit` [494] percent of the key cache blocks. `key_cache_division_limit` [494] is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` [493] component of the key cache.

The threshold value prescribes that, for a key cache containing  $N$  blocks, the block at the beginning of the hot sublist not accessed within the last  $N * \text{key\_cache\_age\_threshold} / 100$  hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` [494] value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` [494] set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

#### 8.9.2.4. Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op          | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+
```

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

#### 8.9.2.5. Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` [493] variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of MyISAM tables, use the `--myisam-block-size` [432] option at server startup.

### 8.9.2.6. Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` [492] or `key_cache_block_size` [493] key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

### 8.9.3. The MySQL Query Cache

The query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again. The query cache is shared among sessions, so a result set generated by one client can be sent in response to the same query issued by another client.

The query cache can be useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content.

The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

#### Note

The query cache does not work in an environment where you have multiple `mysqld` servers updating the same `MyISAM` tables.

The query cache is used for prepared statements under the conditions described in [Section 8.9.3.1, "How the Query Cache Operates"](#).

#### Note

As of MySQL 5.6.5, the query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries. (Bug #53775)

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2x500MHz system with 2GB RAM and a 64MB query cache.

- If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.
- Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` [528] system variable to 0. By disabling the query cache code, there is no noticeable overhead.

The query cache offers the potential for substantial performance improvement, but do not assume that it will do so under all circumstances. With some query cache configurations or server workloads, you might actually see a performance decrease:

- Be cautious about sizing the query cache excessively large, which increases the overhead required to maintain the cache, possibly beyond the benefit of enabling it. Sizes in tens of megabytes are usually beneficial. Sizes in the hundreds of megabytes might not be.
- Server workload has a significant effect on query cache efficiency. A query mix consisting almost entirely of a fixed set of `SELECT` statements is much more likely to benefit from enabling the cache than a mix in which frequent `INSERT` statements cause continual invalidation of results in the cache. In some cases, a workaround is to use the `SQL_NO_CACHE` option to prevent results from even entering the cache for `SELECT` statements that use frequently modified tables. (See [Section 8.9.3.2, “Query Cache `SELECT` Options”](#).)

To verify that enabling the query cache is beneficial, test the operation of your MySQL server with the cache enabled and disabled. Then retest periodically because query cache efficiency may change as server workload changes.

### 8.9.3.1. How the Query Cache Operates

This section describes how the query cache works when it is operational. [Section 8.9.3.3, “Query Cache Configuration”](#), describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be *exactly* the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

The cache is not used for queries of the following types:

- Queries that are a subquery of an outer query
- Queries executed within the body of a stored function, trigger, or event

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` [595] status variable, not `Com_select`. See [Section 8.9.3.4, “Query Cache Status and Maintenance”](#).

If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

The query cache also works within transactions when using `InnoDB` tables.

In MySQL 5.6, the result from a `SELECT` query on a view is cached.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS . . .` queries and stores a value that is returned by a following `SELECT FOUND_ROWS()` query. `FOUND_ROWS()` [1268] returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache. The `SELECT FOUND_ROWS()` query itself cannot be cached.

Prepared statements that are issued using the binary protocol using `mysql_stmt_prepare()` and `mysql_stmt_execute()` (see [Section 21.8.7, “C API Prepared Statements”](#)), are subject to

limitations on caching. Comparison with statements in the query cache is based on the text of the statement after expansion of ? parameter markers. The statement is compared only with other cached statements that were executed using the binary protocol. That is, for query cache purposes, prepared statements issued using the binary protocol are distinct from prepared statements issued using the text protocol (see [Section 13.5, “SQL Syntax for Prepared Statements”](#)).

A query cannot be cached if it contains any of the functions shown in the following table.

<a href="#">BENCHMARK() [1266]</a>	<a href="#">CONNECTION_ID() [1267]</a>	<a href="#">CONVERT_TZ() [1212]</a>
<a href="#">CURDATE() [1212]</a>	<a href="#">CURRENT_DATE() [1212]</a>	<a href="#">CURRENT_TIME() [1212]</a>
<a href="#">CURRENT_TIMESTAMP() [1213]</a>	<a href="#">CURTIME() [1213]</a>	<a href="#">DATABASE() [1268]</a>
<a href="#">ENCRYPT() [1262]</a> with one parameter	<a href="#">FOUND_ROWS() [1268]</a>	<a href="#">GET_LOCK() [1275]</a>
<a href="#">LAST_INSERT_ID() [1269]</a>	<a href="#">LOAD_FILE() [1181]</a>	<a href="#">MASTER_POS_WAIT() [1279]</a>
<a href="#">NOW() [1220]</a>	<a href="#">PASSWORD() [1263]</a>	<a href="#">RAND() [1206]</a>
<a href="#">RELEASE_LOCK() [1280]</a>	<a href="#">SLEEP() [1280]</a>	<a href="#">SYSDATE() [1223]</a>
<a href="#">UNIX_TIMESTAMP() [1226]</a> with no parameters	<a href="#">USER() [1273]</a>	<a href="#">UUID() [1280]</a>
<a href="#">UUID_SHORT() [1281]</a>		

A query also is not cached under these conditions:

- It refers to user-defined functions (UDFs) or stored functions.
- It refers to user variables or local stored program variables.
- It refers to tables in the `mysql`, `INFORMATION_SCHEMA`, or `performance_schema` database.
- (*MySQL 5.6.5 and later.*) It refers to any partitioned tables.
- It is of any of the following forms:

```
SELECT ... LOCK IN SHARE MODE
SELECT ... FOR UPDATE
SELECT ... INTO OUTFILE ...
SELECT ... INTO DUMPFILE ...
SELECT * FROM ... WHERE autoincrement_col IS NULL
```

The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See the Connector/ODBC section of [Chapter 21, Connectors and APIs](#).

Statements within transactions that use `SERIALIZABLE [1470]` isolation level also cannot be cached because they use `LOCK IN SHARE MODE` locking.

- It uses `TEMPORARY` tables.
- It does not use any tables.
- It generates warnings.
- The user has a column-level privilege for any of the involved tables.

### 8.9.3.2. Query Cache `SELECT` Options

Two query cache-related options may be specified in `SELECT` statements:

- `SQL_CACHE`

The query result is cached if it is cacheable and the value of the `query_cache_type [529]` system variable is `ON` or `DEMAND`.

- [SQL\\_NO\\_CACHE](#)

The server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the [SQL\\_NO\\_CACHE](#) keyword; a non-space such as a newline causes the server to check the query cache to see whether the result is already cached.)

Examples:

```
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

### 8.9.3.3. Query Cache Configuration

The [have\\_query\\_cache](#) [487] server system variable indicates whether the query cache is available:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES |
+-----+-----+
```

When using a standard MySQL binary, this value is always [YES](#), even if query caching is disabled.

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting `mysqld`. The query cache system variables all have names that begin with [query\\_cache\\_](#). They are described briefly in [Section 5.1.4, “Server System Variables”](#), with additional configuration information given here.

To set the size of the query cache, set the [query\\_cache\\_size](#) [528] system variable. Setting it to 0 disables the query cache, as does setting [query\\_cache\\_type=0](#) [529]. By default, the query cache is disabled. This is achieved using a default size of 1M, with a default for [query\\_cache\\_type](#) of 0. (Before MySQL 5.6.8, the default size is 0, with a default [query\\_cache\\_type](#) of 1.)

To reduce overhead significantly, also start the server with [query\\_cache\\_type=0](#) [529] if you will not be using the query cache.

#### Note

When using the Windows Configuration Wizard to install or configure MySQL, the default value for [query\\_cache\\_size](#) [528] will be configured automatically for you based on the different configuration types available. When using the Windows Configuration Wizard, the query cache may be enabled (that is, set to a nonzero value) due to the selected configuration. The query cache is also controlled by the setting of the [query\\_cache\\_type](#) [529] variable. Check the values of these variables as set in your `my.ini` file after configuration has taken place.

When you set [query\\_cache\\_size](#) [528] to a nonzero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1282
Message: Query cache failed to set size 39936;
        new query cache size is 0

mysql> SET GLOBAL query_cache_size = 41984;
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 41984 |
+-----+-----+
```

For the query cache to actually be able to hold any query results, its size must be set larger:

```
mysql> SET GLOBAL query_cache_size = 1000000;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 999424 |
+-----+-----+
1 row in set (0.00 sec)
```

The `query_cache_size` [528] value is aligned to the nearest 1024 byte block. The value reported may therefore be different from the value that you assign.

If the query cache size is greater than 0, the `query_cache_type` [529] variable influences how it works. This variable can be set to the following values:

- A value of 0 or `OFF` prevents caching or retrieval of cached results.
- A value of 1 or `ON` enables caching except of those statements that begin with `SELECT SQL_NO_CACHE`.
- A value of 2 or `DEMAND` causes caching of only those statements that begin with `SELECT SQL_CACHE`.

If `query_cache_size` [528] is 0, you should also set `query_cache_type` [529] variable to 0. In this case, the server does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

Setting the `GLOBAL query_cache_type` [529] value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the `SESSION query_cache_type` [529] value. For example, a client can disable use of the query cache for its own queries like this:

```
mysql> SET SESSION query_cache_type = OFF;
```

If you set `query_cache_type` [529] at server startup (rather than at runtime with a `SET` statement), only the numeric values are permitted.

To control the maximum size of individual query results that can be cached, set the `query_cache_limit` [527] system variable. The default value is 1MB.

Be careful not to set the size of the cache too large. Due to the need for threads to lock the cache during updates, you may see lock contention issues with a very large cache.

#### Note

You can set the maximum size that can be specified for the query cache at runtime with the `SET` statement by using the `--maximum-query_cache_size=32M` option on the command line or in the configuration file.

When a query is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated.

Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the `query_cache_min_res_unit` [528] system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed. Depending on the types of queries your server executes, you might find it helpful to tune the value of `query_cache_min_res_unit` [528]:

- The default value of `query_cache_min_res_unit` [528] is 4KB. This should be adequate for most cases.
- If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, decrease the value of `query_cache_min_res_unit` [528]. The number of free blocks and queries removed due to pruning are given by the values of the `Qcache_free_blocks` [595] and `Qcache_lowmem_prunes` [595] status variables.
- If most of your queries have large results (check the `Qcache_total_blocks` [596] and `Qcache_queries_in_cache` [596] status variables), you can increase performance by increasing `query_cache_min_res_unit` [528]. However, be careful to not make it too large (see the previous item).

### 8.9.3.4. Query Cache Status and Maintenance

To check whether the query cache is present in your MySQL server, use the following statement:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES |
+-----+-----+
```

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Qcache_free_blocks | 36 |
| Qcache_free_memory | 138488 |
| Qcache_hits | 79570 |
| Qcache_inserts | 27087 |
| Qcache_lowmem_prunes | 3114 |
| Qcache_not_cached | 22989 |
| Qcache_queries_in_cache | 415 |
| Qcache_total_blocks | 912 |
+-----+-----+
```

Descriptions of each of these variables are given in [Section 5.1.6, “Server Status Variables”](#). Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

```
Com_select
+ Qcache_hits
+ queries with errors found by parser
```

The `Com_select` value is given by this formula:

```
Qcache_inserts
+ Qcache_not_cached
```

```
+ queries with errors found during the column-privileges check
```

The query cache uses variable-length blocks, so `Qcache_total_blocks` [596] and `Qcache_free_blocks` [595] may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` [595] status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in [Section 8.9.3.3, “Query Cache Configuration”](#).

## 8.9.4. Caching of Prepared Statements and Stored Programs

For certain statements that a client might execute multiple times during a session, the server converts the statement to an internal structure and caches that structure to be used during execution. Caching enables the server to perform more efficiently because it avoids the overhead of reconverting the statement should it be needed again during the session. Conversion and caching occurs for these statements:

- Prepared statements, both those processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function). The `max_prepared_stmt_count` [506] system variable controls the total number of statements the server caches. (The sum of the number of prepared statements across all sessions.)
- Stored programs (stored procedures and functions, triggers, and events). In this case, the server converts and caches the entire program body. The `stored_program_cache` [549] system variable indicates the approximate number of stored programs the the server caches per session.

The server maintains caches for prepared statements and stored programs on a per-session basis. Statements cached for one session are not accessible to other sessions. When a session ends, the server discards any statements cached for it.

When the server uses a cached internal statement structure, it must take care that the structure does not go out of date. Metadata changes can occur for an object used by the statement, causing a mismatch between the current object definition and the definition as represented in the internal statement structure. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Table content changes (for example, with `INSERT` or `UPDATE`) do not change metadata, nor do `SELECT` statements.

Here is an illustration of the problem. Suppose that a client prepares this statement:

```
PREPARE s1 FROM 'SELECT * FROM t1';
```

The `SELECT *` expands in the internal structure to the list of columns in the table. If the set of columns in the table is modified with `ALTER TABLE`, the prepared statement goes out of date. If the server does not detect this change the next time the client executes `s1`, the prepared statement will return incorrect results.

To avoid problems caused by metadata changes to tables or views referred to by the prepared statement, the server detects these changes and automatically reprepares the statement when it is next executed. That is, the server reparses the statement and rebuilds the internal structure. Reparsing also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Similarly, if changes occur to objects used by a stored program, the server reparses affected statements within the program. (Before MySQL 5.6.6, the server does not detect metadata changes affecting stored programs, so such changes can cause incorrect results or errors.)

The server also detects metadata changes for objects in expressions. These might be used in statements specific to stored programs, such as `DECLARE CURSOR` or flow-control statements such as `IF`, `CASE`, and `RETURN`.

To avoid reparsing entire stored programs, the server reparses affected statements or expressions within a program only as needed. Examples:

- Suppose that metadata for a table or view is changed. Reparsing occurs for a `SELECT *` within the program that accesses the table or view, but not for a `SELECT *` that does not access the table or view.
- When a statement is affected, the server reparses it only partially if possible. Consider this `CASE` statement:

```
CASE case_expr
  WHEN when_expr1 ...
  WHEN when_expr2 ...
  WHEN when_expr3 ...
  ...
END CASE
```

If a metadata change affects only `WHEN when_expr3`, that expression is reparsed. `case_expr` and the other `WHEN` expressions are not reparsed.

Reparsing uses the default database and SQL mode that were in effect for the original conversion to internal form.

The server attempts reparsing up to three times. An error occurs if all attempts fail.

Reparsing is automatic, but to the extent that it occurs, diminishes prepared statement and stored program performance.

For prepared statements, the `Com_stmt_reprepare` [586] status variable tracks the number of reparsings.

## 8.10. Optimizing Locking Operations

MySQL manages contention for table contents using [locking](#):

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See [Section 8.10.1, “Internal Locking Methods”](#).
- External locking occurs when the server and other programs lock `MyISAM` table files to coordinate among themselves which program can access the tables at which time. See [Section 8.10.5, “External Locking”](#).

### 8.10.1. Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see [Section 8.10.5, “External Locking”](#).

#### Row-Level Locking

MySQL uses [row-level locking](#) for `InnoDB` tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid [deadlocks](#) when performing multiple concurrent write operations on a single `InnoDB` table, acquire necessary locks at the start of the transaction by issuing a `SELECT ... FOR UPDATE` statement for each group of rows expected to be modified, even if the `DML` statements come later in

the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because [InnoDB](#) automatically [detects](#) deadlock conditions and rolls back one of the affected transactions.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows.
- Fewer changes for rollbacks.
- Possible to lock a single row for a long time.

## Table-Level Locking

MySQL uses [table-level locking](#) for [MyISAM](#), [MEMORY](#), and [MERGE](#) tables, allowing only one session to update those tables at a time, making them more suitable for read-only, read-mostly, or single-user applications.

These storage engines avoid [deadlocks](#) by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current [DML](#) statement finishes.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even if there is heavy [SELECT](#) activity for the table. However, if you have many updates for a table, [SELECT](#) statements wait until there are no more updates.

For information on altering the priority of reads and writes, see [Section 8.10.2, “Table Locking Issues”](#).

You can analyze the table lock contention on your system by checking the [Table\\_locks\\_immediate \[600\]](#) and [Table\\_locks\\_waited \[600\]](#) status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Table_locks_immediate | 1151552 |
| Table_locks_waited | 15324 |
+-----+-----+
```

The [MyISAM](#) storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a [MyISAM](#) table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent [INSERT](#) and [SELECT](#) statements for a [MyISAM](#) table without locks. That is, you can insert rows into a [MyISAM](#) table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are

enabled again automatically when all holes have been filled with new data.. This behavior is altered by the `concurrent_insert` [471] system variable. See [Section 8.10.3, “Concurrent Inserts”](#).

If you acquire a table lock explicitly with `LOCK TABLES`, you can request a `READ LOCAL` lock rather than a `READ` lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many `INSERT` and `SELECT` operations on a table `real_table` when concurrent inserts are not possible, you can insert rows into a temporary table `temp_table` and update the real table with the rows from the temporary table periodically. This can be done with the following code:

```
mysql> LOCK TABLES real_table WRITE, temp_table WRITE;
mysql> INSERT INTO real_table SELECT * FROM temp_table;
mysql> DELETE FROM temp_table;
mysql> UNLOCK TABLES;
```

Advantages of table-level locking:

- Requires relatively little memory.
- Fast when used on a large part of the table because only a single lock is involved.
- Fast if you often do `GROUP BY` operations on a large part of the data or if you must scan the entire table frequently.

Generally, table locks are suited to the following cases:

- Most statements for the table are reads.
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

```
UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
DELETE FROM tbl_name WHERE unique_key_col=key_value;
```

- `SELECT` combined with concurrent `INSERT` statements, and very few `UPDATE` or `DELETE` statements.
- Many scans or `GROUP BY` operations on the entire table without any writers.

## 8.10.2. Table Locking Issues

`InnoDB` tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this storage engine, avoid using the `LOCK TABLES` statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the `InnoDB` storage engine is the default in MySQL 5.6.

MySQL uses table locking (instead of page, row, or column locking) for all storage engines except `InnoDB`. The locking operations themselves do not have much overhead. But because only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

### Performance Considerations Favoring `InnoDB`

When choosing whether to create a table using `InnoDB` or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.

- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.
- A `SELECT` statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue `SELECT` statements will queue up behind it, reducing concurrency even for read-only sessions.

## Workarounds for Locking Performance Issues

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the `InnoDB` storage engine, either using `CREATE TABLE ... ENGINE=INNODB` during setup, or using `ALTER TABLE ... ENGINE=INNODB` for an existing table. See [Section 14.2, “The InnoDB Storage Engine”](#) for more details about this storage engine.
- Optimize `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.
- Start `mysqld` with `--low-priority-updates [430]`. For storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`), this gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not wait for the first `SELECT` to finish.
- To specify that all updates issued in a specific connection should be done with low priority, set the `low_priority_updates [500]` server system variable equal to 1.
- To give a specific `INSERT`, `UPDATE`, or `DELETE` statement lower priority, use the `LOW_PRIORITY` attribute.
- To give a specific `SELECT` statement higher priority, use the `HIGH_PRIORITY` attribute. See [Section 13.2.9, “SELECT Syntax”](#).
- Start `mysqld` with a low value for the `max_write_lock_count [509]` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of inserts to the table occur. This permits `READ` locks after a certain number of `WRITE` locks.
- If you have problems with `INSERT` combined with `SELECT`, consider switching to `MyISAM` tables, which support concurrent `SELECT` and `INSERT` statements. (See [Section 8.10.3, “Concurrent Inserts”](#).)
- If you mix inserts and deletes on the same nontransactional table, `INSERT DELAYED` may help. See [Section 13.2.5.2, “INSERT DELAYED Syntax”](#).

### Note

As of MySQL 5.6.6, `INSERT DELAYED` is deprecated, and will be removed in a future release. Use `INSERT` (without `DELAYED`) instead.

- If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See [Section 13.2.2, “DELETE Syntax”](#).
- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See [Section 13.2.9, “SELECT Syntax”](#).
- Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.
- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

### 8.10.3. Concurrent Inserts

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` [471] system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If `concurrent_insert` [471] is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` [471] system variable.

Under circumstances where concurrent inserts can be used, there is seldom any need to use the `DELAYED` modifier for `INSERT` statements. See [Section 13.2.5.2, “INSERT DELAYED Syntax”](#).

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See [Section 5.2.4, “The Binary Log”](#). In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA INFILE`, if you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` [430] option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

### 8.10.4. Metadata Locking

MySQL uses metadata locking to manage access to objects (tables, triggers, and so forth). Metadata locking is used to ensure data consistency but does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition case, and its mutexes and locks differ from the `LOCK_open` mutex. The following discussion provides some information about how metadata locking works.

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted transaction in another session. The server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table `t` and nontransactional table `nt` as follows:

```
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

Metadata locks are held on both `t` and `nt` until the transaction ends. If another session attempts a DDL operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:

```
DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
```

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

Before MySQL 5.5, when a transaction acquired the equivalent of a metadata lock for a table used within a statement, it released the lock at the end of the statement. This approach had the disadvantage that if a DDL statement occurred for a table that was being used by another session in an active transaction, statements could be written to the binary log in the wrong order.

## 8.10.5. External Locking

External locking is the use of file system locking to manage contention for `MyISAM` database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.
- If you use `myisamchk` to perform table maintenance operations on `MyISAM` tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `myisampack` to pack `MyISAM` tables.

If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such as checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `myisampack` to pack tables, you *must* always ensure that the `mysqld` server is not using the table. If you don't stop `mysqld`, at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is running. If you only *read* tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. (See [Section 8.11.1](#), “System

Factors and Startup Parameter Tuning".) To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables.

For `mysqld`, external locking is controlled by the value of the `skip_external_locking` [540] system variable. When this variable is enabled, external locking is disabled, and vice versa. From MySQL 4.0 on, external locking is disabled by default.

Use of external locking can be controlled at server startup by using the `--external-locking` [422] or `--skip-external-locking` [439] option.

If you do use external locking option to enable updates to `MyISAM` tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- Do not use the query cache for queries that use tables that are updated by another process.
- Do not start the server with the `--delay-key-write=ALL` [421] option or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy these conditions is to always use `--external-locking` [422] together with `--delay-key-write=OFF` [421] and `--query-cache-size=0` [528]. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

## 8.11. Optimizing the MySQL Server

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

### 8.11.1. System Factors and Startup Parameter Tuning

We start with system-level factors, because some of these decisions must be made very early to achieve large performance gains. In other cases, a quick look at this section may suffice. However, it is always nice to have a sense of how much can be gained by changing factors that apply at this level.

The operating system to use is very important. To get the best use of multiple-CPU machines, you should use Solaris (because its threads implementation works well) or Linux (because the 2.4 and later kernels have good SMP support). Note that older Linux kernels have a 2GB filesize limit by default. If you have such a kernel and a need for files larger than 2GB, get the Large File Support (LFS) patch for the ext2 file system. Other file systems such as ReiserFS and XFS do not have this 2GB limitation.

Before using MySQL in production, we advise you to test it on your intended platform.

Other tips:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.
- Avoid external locking for `MyISAM` tables. Since MySQL 4.0, the default has been for external locking to be disabled on all systems. The `--external-locking` [422] and `--skip-external-locking` [439] options explicitly enable and disable external locking.

Note that disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems it is mandatory to disable external locking because it does not work, anyway.

The only case in which you cannot disable external locking is when you run multiple MySQL servers (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally *not* recommended, except when using MySQL Cluster.

**Note**

MySQL Cluster is currently not supported in MySQL 5.6. Users wishing to upgrade a MySQL Cluster from MySQL 5.0 or 5.1 should instead migrate to MySQL Cluster NDB 7.0 or 7.1; these are based on MySQL 5.1 but contain the latest improvements and fixes for [NDB](#).

The [LOCK TABLES](#) and [UNLOCK TABLES](#) statements use internal locking, so you can use them even if external locking is disabled.

## 8.11.2. Tuning Server Parameters

You can determine the default buffer sizes used by the `mysqld` server using this command:

```
shell> mysqld --verbose --help
```

This command produces a list of all `mysqld` options and configurable system variables. The output includes the default variable values and looks something like this:

```

abort-slave-event-count          0
allow-suspicious-udfs           FALSE
archive                          ON
auto-increment-increment        1
auto-increment-offset           1
autocommit                       TRUE
automatic-sp-privileges         TRUE
back-log                         80
basedir                          /home/jon/bin/mysql-5.6/

For a `mysqld` server that is currently running, you can see the current values of its system variables by connecting to it and issuing this statement:

```
mysql> SHOW VARIABLES;
```

You can also see some statistical and status indicators for a running server by issuing this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also can be obtained using `mysqladmin`:

```
shell> mysqladmin variables
shell> mysqladmin extended-status
```

For a full description of all system and status variables, see [Section 5.1.4, “Server System Variables”](#), and [Section 5.1.6, “Server Status Variables”](#).

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally you get better performance by giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` [492] and `table_open_cache` [551]. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations.

- If you have at least 256MB of memory and many tables and want maximum performance with a moderate number of clients, use something like this:

```
shell> mysqld_safe --key_buffer_size=64M --table_open_cache=256 \  
--sort_buffer_size=4M --read_buffer_size=1M &
```

- If you have only 128MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:

```
shell> mysqld_safe --key_buffer_size=16M --sort_buffer_size=1M
```

If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

- With little memory and lots of connections, use something like this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K \  
--read_buffer_size=100K &
```

Or even this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K \  
--table_open_cache=32 --read_buffer_size=8K \  
--net_buffer_length=1K &
```

If you are performing `GROUP BY` or `ORDER BY` operations on tables that are much larger than your available memory, increase the value of `read_rnd_buffer_size` [533] to speed up the reading of rows following sorting operations.

You can make use of the example option files included with your MySQL distribution; see [Section 5.1.2, “Server Configuration Defaults”](#).

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file.

To see the effects of a parameter change, do something like this:

```
shell> mysqld --key_buffer_size=32M --verbose --help
```

The variable values are listed near the end of the output. Make sure that the `--verbose` [447] and `--help` [413] options are last. Otherwise, the effect of any options listed after them on the command line are not reflected in the output.

For information on tuning the `InnoDB` storage engine, see [Section 14.2.4.1, “InnoDB Performance Tuning Tips”](#).

### 8.11.3. Optimizing Disk I/O

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.
- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
  - Using symbolic links

This means that, for `MyISAM` tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the

seek and read times better, assuming that the disk is not used for other purposes as well. See [Section 8.11.3.1, “Using Symbolic Links”](#).

- **Striping**

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the  $N$ -th block on the  $(N \bmod \text{number\_of\_disks})$  disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See [Section 8.12.3, “Using Your Own Benchmarks”](#).

The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need  $2 \times N$  drives to hold  $N$  drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.
- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID  $N$  disk. RAID  $N$  can be a problem if you have many writes, due to the time required to update the parity bits.
- On Linux, you can get much better performance by using `hdparm` to configure your disk's interface. (Up to 100% under load is not uncommon.) The following `hdparm` options should be quite good for MySQL, and probably for many other applications:

```
hdparm -m 16 -d 1
```

Note that performance and reliability when using this command depend on your hardware, so we strongly suggest that you test your system thoroughly after using `hdparm`. Please consult the `hdparm` manual page for more information. If `hdparm` is not used wisely, file system corruption may result, so back up everything before experimenting!

- You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

### 8.11.3.1. Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

For `InnoDB` tables, use the `DATA DIRECTORY` clause on the `CREATE TABLE` statement instead of symbolic links, as explained in [Section 5.4.1.2, “Specifying the Location of a Tablespace”](#). This new feature is a supported, cross-platform technique.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink `MyISAM` tables only as a last resort.

To determine the location of your data directory, use this statement:

```
SHOW VARIABLES LIKE 'datadir';
```

### 8.11.3.1.1. Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a soft link to it from the MySQL data directory.

```
shell> mkdir /dr1/databases/test
shell> ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
shell> cd /path/to/datadir
shell> ln -s db1 db2
```

The result is that, or any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

### 8.11.3.1.2. Using Symbolic Links for MyISAM Tables on Unix

Symlinks are fully supported only for `MyISAM` tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links. For `InnoDB` tables, use the alternative technique explained in [Section 5.4.1.2, “Specifying the Location of a Tablespace”](#) instead.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`.) To determine whether your system supports symbolic links, check the value of the `have_symlink` [\[487\]](#) system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

The handling of symbolic links for `MyISAM` tables works as follows:

- In the data directory, you always have the table format (`.frm`) file, the data (`.MYD`) file, and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.
- You can symlink the data file and the index file independently to different directories.
- To instruct a running MySQL server to perform the symlinking, use the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See [Section 13.1.14, “CREATE TABLE Syntax”](#). Alternatively, if `mysqld` is not running, symlinking can be accomplished manually using `ln -s` from the command line.

#### Note

The path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL `data` directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

#### Note

When you drop a table that is using symlinks, *both the symlink and the file to which the symlink points are dropped*. This is an extremely good reason

not to run `mysqld` as the system `root` or permit system users to have write access to MySQL database directories.

- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you are not using symlinks, start `mysqld` with the `--skip-symbolic-links` [441] option to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.
- As indicated previously, only the data and index files can be symbolic links. The `.frm` file must *never* be a symbolic link. Attempting to do this (for example, to make one table name a synonym for another) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

```
shell> cd /path/to/datadir/db1
shell> ln -s tbl1.frm tbl2.frm
shell> ln -s tbl1.MYD tbl2.MYD
shell> ln -s tbl1.MYI tbl2.MYI
```

Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

- The query cache is “fooled” (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).
- `ALTER` statements on `tbl2` fail.

### 8.11.3.1.3. Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named `mydb` at `D:\data\mydb`. To do this, create a symbolic link in the MySQL data directory that points to `D:\data\mydb`. However, before creating the symbolic link, make sure that the `D:\data\mydb` directory exists by creating it if necessary. If you already have a database directory named `mydb` in the data directory, move it to `D:\data`. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.

The procedure for creating the database symbolic link depends on your version of Windows.

Windows Vista, Windows Server 2008, or newer have native symbolic link support, so you can create a symlink using the `mklink` command. This command requires administrative privileges.

1. Change location into the data directory:

```
C:\> cd \path\to\datadir
```

2. In the data directory, create a symlink named `mydb` that points to the location of the database directory:

```
C:\> mklink /d mydb D:\data\mydb
```

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

Alternatively, on any version of Windows supported by MySQL, you can create a symbolic link to a MySQL database by creating a `.sym` file in the data directory that contains the path to the destination directory. The file should be named `db_name.sym`, where `db_name` is the database name.

Support for database symbolic links on Windows using `.sym` files is enabled by default. If you do not need `.sym` file symbolic links, you can disable support for them by starting `mysqld` with the `--skip-symbolic-links` [441] option. To determine whether your system supports `.sym` file symbolic links, check the value of the `have_symlink` [487] system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

To create a `.sym` file symlink, use this procedure:

1. Change location into the data directory:

```
C:\> cd \path\to\datadir
```

2. In the data directory, create a text file named `mydb.sym` that contains this path name: `D:\data\mydb\`

#### Note

The path name to the new database and tables should be absolute. If you specify a relative path, the location will be relative to the `mydb.sym` file.

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

#### Note

Because support for `.sym` files is redundant with native symlink support available using `mklink`, use of `.sym` files is deprecated as of MySQL 5.6.9 and support for them will be removed in a future MySQL release.

The following limitations apply to the use of `.sym` files for database symbolic linking on Windows. These limitations do not apply for symlinks created using `mklink`.

- The symbolic link is not used if a directory with the same name as the database exists in the MySQL data directory.
- The `--innodb_file_per_table` [1718] option cannot be used.
- If you run `mysqld` as a service, you cannot use a mapped drive to a remote server as the destination of the symbolic link. As a workaround, you can use the full path (`\\servername\path\`).

## 8.11.4. Optimizing Memory Use

### 8.11.4.1. How MySQL Uses Memory

The following list indicates some of the ways that the `mysqld` server uses memory. Where applicable, the name of the system variable relevant to the memory use is given:

- All threads share the `MyISAM` key buffer; its size is determined by the `key_buffer_size` [492] variable. Other buffers used by the server are allocated as needed. See [Section 8.11.2, “Tuning Server Parameters”](#).
- Each thread that is used to manage client connections uses some thread-specific space. The following list indicates these and which variables control their size:

- A stack (variable `thread_stack` [556])
- A connection buffer (variable `net_buffer_length` [515])
- A result buffer (variable `net_buffer_length` [515])

The connection buffer and result buffer each begin with a size equal to `net_buffer_length` [515] bytes, but are dynamically enlarged up to `max_allowed_packet` [502] bytes as needed. The result buffer shrinks to `net_buffer_length` [515] bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.
- The `myisam_use_mmap` [514] system variable can be set to 1 to enable memory-mapping for all `MyISAM` tables.
- Each request that performs a sequential scan of a table allocates a *read buffer* (variable `read_buffer_size` [532]).
- When reading rows in an arbitrary sequence (for example, following a sort), a *random-read buffer* (variable `read_rnd_buffer_size` [533]) may be allocated to avoid disk seeks.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain `BLOB` columns are stored on disk.

If an internal in-memory temporary table becomes too large, MySQL handles this automatically by changing the table from in-memory to on-disk format, to be handled by the `MyISAM` storage engine. You can increase the permissible temporary table size as described in [Section 8.4.3.3, “How MySQL Uses Internal Temporary Tables”](#).

- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See [Section C.5.4.4, “Where MySQL Stores Temporary Files”](#).
- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, so the normal slow memory allocation and freeing is avoided. Memory is allocated only for unexpectedly large strings.
- For each `MyISAM` table that is opened, the index file is opened once; the data file is opened once for each concurrently running thread. For each concurrent thread, a table structure, column structures for each column, and a buffer of size  $3 * N$  are allocated (where  $N$  is the maximum row length, not counting `BLOB` columns). A `BLOB` column requires five to eight bytes plus the length of the `BLOB` data. The `MyISAM` storage engine maintains one extra row buffer for internal use.
- For each table having `BLOB` columns, a buffer is enlarged dynamically to read in larger `BLOB` values. If you scan a table, a buffer as large as the largest `BLOB` value is allocated.
- Handler structures for all in-use tables are saved in a cache and managed as a FIFO. The initial cache size is taken from the value of the `table_open_cache` [551] system variable. If a table has been used by two running threads at the same time, the cache contains two entries for the table. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).
- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.

- The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

#### 8.11.4.2. Enabling Large Page Support

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` [440] or `--skip-super-large-pages` [440] option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the `Documentation/vm/hugetlbpage.txt` file of your Linux sources.

The kernel for some recent systems such as Red Hat Enterprise Linux appear to have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      0
HugePages_Free:       0
HugePages_Rsvd:       0
HugePages_Surp:       0
Hugepagesize:         4096 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the `hugetlbpage.txt` file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```
# Set the number of pages to be used.
# Each page is normally 2MB, so a value of 20 = 40MB.
# This command actually allocates memory, so this much
# memory must be available.
```

```
echo 20 > /proc/sys/vm/nr_hugepages

# Set the group number that is permitted to access this
# memory (102 in this case). The mysql user must be a
# member of this group.
echo 102 > /proc/sys/vm/hugetlb_shm_group

# Increase the amount of shmem permitted per segment
# (12G in this case).
echo 1560281088 > /proc/sys/kernel/shmmax

# Increase total amount of shared memory. The value
# is the number of pages. At 4KB/page, 4194304 = 16GB.
echo 4194304 > /proc/sys/kernel/shmall
```

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:       0
HugePages_Surp:       0
Hugepagesize:         4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an “unlimited” value for the memlock limit. This can be done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:

```
ulimit -l unlimited
```

Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to `unlimited` before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in MySQL is disabled by default. To enable it, start the server with the `--large-pages [425]` option. For example, you can use the following lines in your server's `my.cnf` file:

```
[mysqld]
large-pages
```

With this option, `InnoDB` uses large pages automatically for its buffer pool and additional memory pool. If `InnoDB` cannot do this, it falls back to use of traditional memory and writes a warning to the error log: `Warning: Using conventional memory pool`

To verify that large pages are being used, check `/proc/meminfo` again:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:       2
HugePages_Surp:       0
Hugepagesize:         4096 kB
```

## 8.11.5. Optimizing Network Use

### 8.11.5.1. How MySQL Uses Threads for Client Connections

Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread

handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

As of MySQL 5.6.10, commercial distributions of MySQL 5.6 include a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. It implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. See [Section 8.11.6, “The Thread Pool Plugin”](#).

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See [Section 5.1.4, “Server System Variables”](#), and [Section 5.1.6, “Server Status Variables”](#).)

The thread cache has a size determined by the `thread_cache_size` [552] system variable. The default value is 0 (no caching), which causes a thread to be set up for each new connection and disposed of when the connection terminates. Set `thread_cache_size` [552] to *N* to enable *N* inactive connection threads to be cached. `thread_cache_size` [552] can be set at server startup or changed while the server runs. A connection thread becomes inactive when the client connection with which it was associated terminates.

To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, monitor the `Threads_cached` [601] and `Threads_created` [601] status variables.

You can set `max_connections` [503] at server startup or at runtime to control the maximum number of clients that can connect simultaneously.

When the thread stack is too small, this limits the complexity of the SQL statements which the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of *N* bytes for each thread, start the server with `--thread_stack=N` [556].

### 8.11.5.2. DNS Lookup Optimization and the Host Cache

The MySQL server maintains a host cache in memory that contains information about clients: IP address, host name, and error information. The server uses this cache for nonlocal TCP connections. It does not use the cache for TCP connections established using a loopback interface address (`127.0.0.1` or `:::1`), or for connections established using a Unix socket file, named pipe, or shared memory.

For each new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If not, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information

about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The `host_cache` Performance Schema table exposes the contents of the host cache so that it can be examined using `SELECT` statements. This may help you diagnose the causes of connection problems. See [Section 20.9.9.1, “The `host\_cache` Table”](#).

The server handles entries in the host cache like this:

1. When the first TCP client connection reaches the server from a given IP address, a new entry is created to record the client IP, host name, and client lookup validation flag. Initially, the host name is set to `NULL` and the flag is false. This entry is also used for subsequent client connections from the same originating IP.
2. If the validation flag for the client IP entry is false, the server attempts an IP-to-host name DNS resolution. If that is successful, the host name is updated with the resolved host name and the validation flag is set to true. If resolution is unsuccessful, the action taken depends on whether the error is permanent or transient. For permanent failures, the host name remains `NULL` and the validation flag is set to true. For transient failures, the host name and validation flag remain unchanged. (Another DNS resolution attempt occurs the next time a client connects from this IP.)
3. If an error occurs while processing an incoming client connection from a given IP address, the server updates the corresponding error counters in the entry for that IP. For a description of the errors recorded, see [Section 20.9.9.1, “The `host\_cache` Table”](#).

The server performs host name resolution using the thread-safe `gethostbyaddr_r()` and `gethostbyname_r()` calls if the operating system supports them. Otherwise, the thread performing the lookup locks a mutex and calls `gethostbyaddr()` and `gethostbyname()` instead. In this case, no other thread can resolve host names that are not in the host cache until the thread holding the mutex lock releases it.

The server uses the host cache for several purposes:

- By caching the results of IP-to-host name lookups, the server avoids doing a DNS lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.
- The cache contains information about errors that occur during the connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The `max_connect_errors` [502] system variable determines the number of permitted errors before blocking occurs. See [Section C.5.2.6, “Host ‘`host\_name`’ is blocked”](#).

To unblock blocked hosts, flush the host cache by issuing a `FLUSH HOSTS` statement or executing a `mysqladmin flush-hosts` command.

It is possible for a blocked host to become unblocked even without `FLUSH HOSTS` if activity from other hosts has occurred since the last connection attempt from the blocked host. This can occur because the server discards the least recently used cache entry to make room for a new entry if the cache is full when a connection arrives from a client IP not in the cache. If the discarded entry is for a blocked host, that host becomes unblocked.

The host cache is enabled by default. To disable it, set the `host_cache_size` [487] system variable to 0, either at server startup or at runtime.

To disable DNS host name lookups, start the server with the `--skip-name-resolve` [440] option. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used.

If you have a very slow DNS and many hosts, you might be able to improve performance either by disabling DNS lookups with `--skip-name-resolve` [440] or by increasing the value of `host_cache_size` [487] to make the host cache larger.

To disallow TCP/IP connections entirely, start the server with the `--skip-networking` [440] option.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). For information about these errors, check the `Connection_errors_xxx` [587] status variables (see Section 5.1.6, “Server Status Variables”).

## 8.11.6. The Thread Pool Plugin

### Note

MySQL Thread Pool is a commercial extension. To learn more about commercial products (MySQL Enterprise Edition), see <http://www.mysql.com/products/>.

As of MySQL 5.6.10, commercial distributions of MySQL 5.6 include MySQL Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the one thread per connection model:

- Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.
- With too many threads executing in parallel, context switching overhead is high. This also presents a challenging task to the operating system scheduler. The thread pool controls the number of active threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.
- Too many transactions executing in parallel increases resource contention. In `InnoDB`, this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

The thread pool plugin is a commercial feature. It is not included in MySQL community distributions.

On Windows, the thread pool plugin requires Windows Vista or newer. On Linux, the plugin requires kernel 2.6.9 or newer.

## Additional Resources

[Section B.14, “MySQL 5.6 FAQ: MySQL Enterprise Scalability Thread Pool”](#)

### 8.11.6.1. Thread Pool Components and Installation

The thread pool feature comprises these components:

- A plugin library object file contains a plugin for the thread pool code and plugins for several `INFORMATION_SCHEMA` tables.

For a detailed description of how the thread pool works, see [Section 8.11.6.2, “Thread Pool Operation”](#).

The `INFORMATION_SCHEMA` tables are named `TP_THREAD_STATE`, `TP_THREAD_GROUP_STATE`, and `TP_THREAD_GROUP_STATS`. These tables provide information about thread pool operation. For more information, see [Section 19.31, “Thread Pool `INFORMATION\_SCHEMA` Tables”](#).

- Several system variables are related to the thread pool. The `thread_handling` [553] system variable has a value of `loaded-dynamically` when the server successfully loads the thread pool plugin.

The other related variables are implemented by the thread pool plugin; they are not available unless it is enabled:

- `thread_pool_algorithm` [554]: The concurrency algorithm to use for scheduling.
- `thread_pool_high_priority_connection` [554]: How to schedule statement execution for a session.
- `thread_pool_prio_kickup_timer` [555]: How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.
- `thread_pool_max_unused_threads` [555]: How many sleeping threads to permit.
- `thread_pool_size` [556]: The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.
- `thread_pool_stall_limit` [556]: The time before an executing statement is considered to be stalled.

If any variable implemented by the plugin is set to an illegal value at startup, plugin initialization fails and the plugin does not load.

For information about setting thread pool parameters, see [Section 8.11.6.3, “Thread Pool Tuning”](#).

- The Performance Schema exposes information about the thread pool and may be used to investigate operational performance. For more information, see [Chapter 20, MySQL Performance Schema](#).

To be usable by the server, the thread pool library object file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` [525] system variable). To enable thread pool capability, load the plugins to be used by starting the server with the `--plugin-load` [435] option. For example, if you name just the plugin object file, the server loads all plugins that it contains (that is, the thread pool plugin and all the `INFORMATION_SCHEMA` tables). To do this, put these lines in your `my.cnf` file:

```
[mysqld]
plugin-load=thread_pool.so
```

If object files have a suffix different from `.so` on your system, substitute the correct suffix (for example, `.dll` on Windows).

If necessary, set the value of the `plugin_dir` [525] system variable to tell the server the location of the plugin directory.

If desired, you can load individual plugins from the library file. To load the thread pool plugin but not the `INFORMATION_SCHEMA` tables, use an option like this:

```
[mysqld]
plugin-load=thread_pool=thread_pool.so
```

To load the thread pool plugin and only the `TP_THREAD_STATE INFORMATION_SCHEMA` table, use an option like this:

```
[mysqld]
plugin-load=thread_pool=thread_pool.so;TP_THREAD_STATE=thread_pool.so
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

If the server loads the thread plugin successfully, it sets the `thread_handling` system variable to `dynamically-loaded`. If the plugin fails to load, the server writes a message to the error log.

### 8.11.6.2. Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

The number of thread groups is configurable using the `thread_pool_size` [556] system variable. The default number of groups is 16. For guidelines on setting this variable, see [Section 8.11.6.3, “Thread Pool Tuning”](#).

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that the thread executes all statements from the connection.

The thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance. The algorithm works in the following manner:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:
  - Immediate execution occurs if the statement is the only one received and no statements are queued or currently executing.
  - Queuing occurs if the statement cannot begin executing immediately.
- If immediate execution occurs, execution is performed by the listener thread. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

By using the listening thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` [556] system variable determines the meaning of “finishes quickly” in the previous item. The default time before threads are considered stalled is 60ms but can be set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.
- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute. If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there

is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication master, a thread that is sending binary log events to a slave effectively runs forever.

- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.
- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` [554] system variable, which causes all queued statements for a session to go into the high-priority queue.

Statements for a nontransactional storage engine, or a transactional engine if `autocommit` [464] is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for `InnoDB` and `MyISAM` tables, the thread pool prioritizes those for `InnoDB` over those for `MyISAM` unless `autocommit` [464] is enabled. With `autocommit` [464] enabled, all statements will be low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.
- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` [555] system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms or 100 per second will be moved from the low-priority queue to the high-priority queue.
- The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.
- While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

- One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even though the first thread is still executing.
- One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.
- One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for the statement to be considered stalled, the group permits another thread to begin executing another statement.

The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

- Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.
- Binary log dump threads that read the binary log and send it to slaves. This is a kind of long-running “statement” that runs for a very long time, and that should not prevent other statements from executing.
- Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement's execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of `max_connections` [503] and `thread_pool_size` [556]. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

### 8.11.6.3. Thread Pool Tuning

This section provides guidelines on setting thread pool system variables for best performance, measured using a metric such as transactions per second.

`thread_pool_size` [556] is the most important parameter controlling thread pool performance. It can be set only at server startup. Our experience in testing the thread pool indicates the following:

- If the primary storage engine is `InnoDB`, the optimal `thread_pool_size` [556] setting is likely to be between 16 and 36, with the most common optimal values tending to be from 24 to 36. We have not seen any situation where the setting has been optimal beyond 36. There may be special cases where a value smaller than 16 is optimal.

For workloads such as DBT2 and Sysbench, the optimum for `InnoDB` seems to be usually around 36. For very write-intensive workloads, the optimal setting can sometimes be lower.

- If the primary storage engine is `MyISAM`, the `thread_pool_size` [556] setting should be fairly low. We tend to get optimal performance for values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

Another system variable, `thread_pool_stall_limit` [556], is important for handling of blocked and long-running statements. If all calls that block the MySQL Server are reported to the thread pool, it would always know when execution threads are blocked. However, this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout, the length of which can be tuned using the `thread_pool_stall_limit` [556] system variable. This parameter ensures that the server does not become completely blocked. The value of `thread_pool_stall_limit` [556] has an upper limit of 6 seconds to prevent the risk of a deadlocked server.

`thread_pool_stall_limit` [556] also enables the thread pool to handle long-running statements. If a long-running statement was permitted to block a thread group, all other connections assigned to the group would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of `thread_pool_stall_limit` [556] should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the `thread_pool_stall_limit` [556] parameter too high means that long-

running statements will block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set `thread_pool_stall_limit` [556] to 10 (meaning 100ms). The default value of 60ms is okay for servers that primarily execute very simple statements.

The `thread_pool_stall_limit` [556] parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the `TP_THREAD_GROUP_STATS` table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM information_schema.TP_THREAD_GROUP_STATS;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of `thread_pool_stall_limit` [556].

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing? Suppose that the following conditions apply:

- There are 200 statements queued in the low-priority queue.
- There are 10 statements queued in the high-priority queue.
- `thread_pool_prio_kickup_timer` [555] is set to 10000 (10 seconds).
- `thread_pool_stall_limit` [556] is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements will be moved to the high-priority queue because it will always already contain statements awaiting execution. After 10 seconds, the new statement is eligible to be moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those will become stalled and it will take 1 second for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it will take 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

## 8.12. Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a “workload”) works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.
- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.

- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.
- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The two most important features to try with each workload are the [MySQL query cache](#), and the [adaptive hash index](#) for [InnoDB](#) tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

### 8.12.1. Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` [1266] function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count, expression)` [1266]. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+-----+
| BENCHMARK(1000000,1+1) |
+-----+
|                          0 |
+-----+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` [1266] is an excellent tool for finding out if some function is a problem for your queries.

### 8.12.2. The MySQL Benchmark Suite

This benchmark suite is meant to tell any user what operations a given SQL implementation performs well or poorly. You can get a good idea for how the benchmarks work by looking at the code and results in the `sql-bench` directory in any MySQL source distribution.

Note that this benchmark is single-threaded, so it measures the minimum time for the operations performed. We plan to add multi-threaded tests to the benchmark suite in the future.

To use the benchmark suite, the following requirements must be satisfied:

- The benchmark suite is provided with MySQL source distributions. You can either download a released distribution from <http://dev.mysql.com/downloads/>, or use the current development source tree. (See [Section 2.9.3, “Installing MySQL from a Development Source Tree”](#).)
- The benchmark scripts are written in Perl and use the Perl DBI module to access database servers, so DBI must be installed. You also need the server-specific DBD drivers for each of the servers you want to test. For example, to test MySQL, PostgreSQL, and DB2, you must have the `DBD::mysql`, `DBD::Pg`, and `DBD::DB2` modules installed. See [Section 2.13, “Perl Installation Notes”](#).

After you obtain a MySQL source distribution, you can find the benchmark suite located in its `sql-bench` directory. To run the benchmark tests, build MySQL, and then change location into the `sql-bench` directory and execute the `run-all-tests` script:

```
shell> cd sql-bench
shell> perl run-all-tests --server=server_name
```

`server_name` should be the name of one of the supported servers. To get a list of all options and supported servers, invoke this command:

```
shell> perl run-all-tests --help
```

The `crash-me` script also is located in the `sql-bench` directory. `crash-me` tries to determine what features a database system supports and what its capabilities and limitations are by actually running queries. For example, it determines:

- What data types are supported
- How many indexes are supported
- What functions are supported
- How big a query can be
- How big a `VARCHAR` column can be

For more information about benchmark results, visit <http://www.mysql.com/why-mysql/benchmarks/>.

### 8.12.3. Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

For examples of portable benchmark programs, look at those in the MySQL benchmark suite. See [Section 8.12.2, “The MySQL Benchmark Suite”](#). You can take any program from this suite and modify it for your own needs. By doing this, you can try different solutions to your problem and test which really is fastest for you.

Another free benchmark suite is the Open Source Database Benchmark, available at <http://osdb.sourceforge.net/>.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See [Section 4.5.7, “mysqlslap — Load Emulation Client”](#).
- You can also try benchmarking packages such as SysBench and DBT2, available at <http://sourceforge.net/projects/sysbench/>, and <http://osldb.sourceforge.net/#dbt2>.

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

### 8.12.4. Measuring Performance with `performance_schema`

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See [Chapter 20, \*MySQL Performance Schema\*](#) for details.

### 8.12.5. Examining Thread Information

When you are attempting to ascertain what your MySQL server is doing, it can be helpful to examine the process list, which is the set of threads currently executing within the server. Process list information is available from these sources:

- The `SHOW [FULL] PROCESSLIST` statement: [Section 13.7.5.30, “SHOW PROCESSLIST Syntax”](#)
- The `SHOW PROFILE` statement: [Section 13.7.5.32, “SHOW PROFILES Syntax”](#)
- The `INFORMATION_SCHEMA.PROCESSLIST` table: [Section 19.16, “The INFORMATION\\_SCHEMA PROCESSLIST Table”](#)
- The `mysqladmin processlist` command: [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)
- The `performance_schema.threads` table: [Section 20.9.9, “Performance Schema Miscellaneous Tables”](#)

Access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

You can always view information about your own threads. To view information about threads being executed for other accounts, you must have the `PROCESS [755]` privilege.

Each process list entry contains several pieces of information:

- `Id` is the connection identifier for the client associated with the thread.
- `User` and `Host` indicate the account associated with the thread.
- `db` is the default database for the thread, or `NULL` if none is selected.
- `Command` and `State` indicate what the thread is doing.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- `Time` indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a thread running on a slave that is processing events from the master, the thread time is set to the time found in the events and thus reflects current time on the master and not the slave.
- `Info` contains the text of the statement being executed by the thread, or `NULL` if it is not executing one. By default, this value contains only the first 100 characters of the statement. To see the complete statements, use `SHOW FULL PROCESSLIST`.

The following sections list the possible `Command` values, and `State` values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

### 8.12.5.1. Thread Command Values

A thread can have any of the following `Command` values:

- `Binlog Dump`
- `Change user`

This is a thread on a master server for sending binary log contents to a slave server.

The thread is executing a change-user operation.

- `Close stmt`  
The thread is closing a prepared statement.
- `Connect`  
A replication slave is connected to its master.
- `Connect Out`  
A replication slave is connecting to its master.
- `Create DB`  
The thread is executing a create-database operation.
- `Daemon`  
This thread is internal to the server, not a thread that services a client connection.
- `Debug`  
The thread is generating debugging information.
- `Delayed insert`  
The thread is a delayed-insert handler.
- `Drop DB`  
The thread is executing a drop-database operation.
- `Error`
- `Execute`  
The thread is executing a prepared statement.
- `Fetch`  
The thread is fetching the results from executing a prepared statement.
- `Field List`  
The thread is retrieving information for table columns.
- `Init DB`  
The thread is selecting a default database.
- `Kill`  
The thread is killing another thread.
- `Long Data`  
The thread is retrieving long data in the result of executing a prepared statement.
- `Ping`  
The thread is handling a server-ping request.
- `Prepare`  
The thread is preparing a prepared statement.

- `Processlist`  
The thread is producing information about server threads.
- `Query`  
The thread is executing a statement.
- `Quit`  
The thread is terminating.
- `Refresh`  
The thread is flushing table, logs, or caches, or resetting status variable or replication server information.
- `Register Slave`  
The thread is registering a slave server.
- `Reset stmt`  
The thread is resetting a prepared statement.
- `Set option`  
The thread is setting or resetting a client statement-execution option.
- `Shutdown`  
The thread is shutting down the server.
- `Sleep`  
The thread is waiting for the client to send a new statement to it.
- `Statistics`  
The thread is producing server-status information.
- `Table Dump`  
The thread is sending table contents to a slave server.
- `Time`  
Unused.

### 8.12.5.2. General Thread States

The following list describes thread `State` values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- `After create`  
This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.
- `altering table`  
The server is in the process of executing an in-place `ALTER TABLE`.

- `Analyzing`

The thread is calculating a `MyISAM` table key distributions (for example, for `ANALYZE TABLE`).

- `checking permissions`

The thread is checking whether the server has the required privileges to execute the statement.

- `Checking table`

The thread is performing a table check operation.

- `cleaning up`

The thread has processed one command and is preparing to free memory and reset certain state variables.

- `closing tables`

The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

- `committing alter table to storage engine`

The server has finished an in-place `ALTER TABLE` and is committing the result.

- `converting HEAP to MyISAM`

The thread is converting an internal temporary table from a `MEMORY` table to an on-disk `MyISAM` table.

- `copy to tmp table`

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

- `Copying to group table`

If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- `Copying to tmp table`

The server is copying to a temporary table in memory.

- `Copying to tmp table on disk`

The server is copying to a temporary table on disk. The temporary result set has become too large (see [Section 8.4.3.3, "How MySQL Uses Internal Temporary Tables"](#)). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- `Creating index`

The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- `Creating sort index`

The thread is processing a `SELECT` that is resolved using an internal temporary table.

- `creating table`

The thread is creating a table. This includes creation of temporary tables.

- `Creating tmp table`

The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation will be `Copying to tmp table on disk`.

- `deleting from main table`

The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- `deleting from reference tables`

The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `discard_or_import_tablespace`

The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- `end`

This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

- `executing`

The thread has begun executing a statement.

- `Execution of init_command`

The thread is executing statements in the value of the `init_command` system variable.

- `freeing items`

The thread has executed a command. Some freeing of items done during this state involves the query cache. This state is usually followed by `cleaning up`.

- `Flushing tables`

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables.

- `FULLTEXT initialization`

The server is preparing to perform a natural-language full-text search.

- `init`

This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log, the `InnoDB` log, and some query cache cleanup operations.

For the `end` state, the following operations could be happening:

- Removing query cache entries after data in a table is changed
- Writing an event to the binary log
- Freeing memory buffers, including for blobs
- `Killed`

Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time

for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- `logging slow query`

The thread is writing a statement to the slow-query log.

- `NULL`

This state is used for the `SHOW PROCESSLIST` state.

- `login`

The initial state for a connection thread until the client has been authenticated successfully.

- `manage keys`

The server is enabling or disabling a table index.

- `Opening tables, Opening table`

The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` [551] value is large enough.

- `optimizing`

The server is performing initial optimizations for a query.

- `preparing`

This state occurs during query optimization.

- `preparing for alter table`

The server is preparing to execute an in-place `ALTER TABLE`.

- `Purging old relay logs`

The thread is removing unneeded relay log files.

- `query end`

This state occurs after processing a query but before the `freeing items` state.

- `Reading from net`

The server is reading a packet from the network.

- `Removing duplicates`

The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `removing tmp table`

The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- `rename`

The thread is renaming a table.

- `rename result table`

The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- `Reopen tables`

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

The repair code is using a sort to create indexes.

- `Repair done`

The thread has completed a multi-threaded repair for a `MyISAM` table.

- `Repair with keycache`

The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Rolling back`

The thread is rolling back a transaction.

- `Saving state`

For `MyISAM` table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- `Searching rows for update`

The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- `Sending data`

The thread is reading and processing rows for a `SELECT` statement, and sending data to the client. Because operations occurring during this state tend to perform large amounts of disk access (reads), it is often the longest-running state over the lifetime of a given query.

- `setup`

The thread is beginning an `ALTER TABLE` operation.

- `Sorting for group`

The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

The thread is doing a sort to satisfy a `ORDER BY`.

- `Sorting index`

The thread is sorting index pages for more efficient access during a `MyISAM` table optimization operation.

- `Sorting result`

For a `SELECT` statement, this is similar to `Creating sort index`, but for nontemporary tables.

- `statistics`

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

- `System lock`

The thread is going to request or is waiting for an internal or external system lock for the table. If this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same `MyISAM` tables, you can disable external system locks with the `--skip-external-locking` [439] option. However, external locking is disabled by default, so it is likely that this option will have no effect. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `update`

The thread is getting ready to start updating the table.

- `Updating`

The thread is searching for rows to update and is updating them.

- `updating main table`

The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- `updating reference tables`

The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- `User lock`

The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` [1275] call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `User sleep`

The thread has invoked a `SLEEP()` [1280] call.

- `Waiting for commit lock`

`FLUSH TABLES WITH READ LOCK`) is waiting for a commit lock.

- `Waiting for global read lock`

`FLUSH TABLES WITH READ LOCK`) is waiting for a global read lock.

- `Waiting for tables,Waiting for table flush`

The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for lock_type lock`

The server is waiting to acquire a lock, where `lock_type` indicates the type of lock:

- `Waiting for event metadata lock`
- `Waiting for global read lock`
- `Waiting for schema metadata lock`
- `Waiting for stored function metadata lock`
- `Waiting for stored procedure metadata lock`
- `Waiting for table level lock`
- `Waiting for table metadata lock`
- `Waiting for trigger metadata lock`
- `Waiting on cond`

A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- `Writing to net`

The server is writing a packet to the network.

### 8.12.5.3. Delayed-Insert Thread States

These thread states are associated with processing for `DELAYED` inserts (see [Section 13.2.5.2, “INSERT DELAYED Syntax”](#)). Some states are associated with connection threads that process `INSERT DELAYED` statements from clients. Other states are associated with delayed-insert handler threads that insert the rows. There is a delayed-insert handler thread for each table for which `INSERT DELAYED` statements are issued.

States associated with a connection thread that processes an `INSERT DELAYED` statement from the client:

- `allocating local table`

The thread is preparing to feed rows to the delayed-insert handler thread.

- `Creating delayed handler`

The thread is creating a handler for `DELAYED` inserts.

- `got handler lock`

This occurs before the `allocating local table` state and after the `waiting for handler lock` state, when the connection thread gets access to the delayed-insert handler thread.

- `got old table`

This occurs after the `waiting for handler open` state. The delayed-insert handler thread has signaled that it has ended its initialization phase, which includes opening the table for delayed inserts.

- `storing row into queue`

The thread is adding a new row to the list of rows that the delayed-insert handler thread must insert.

- `waiting for delay_list`

This occurs during the initialization phase when the thread is trying to find the delayed-insert handler thread for the table, and before attempting to gain access to the list of delayed-insert threads.

- `waiting for handler insert`

An `INSERT DELAYED` handler has processed all pending inserts and is waiting for new ones.

- `waiting for handler lock`

This occurs before the `allocating local table` state when the connection thread waits for access to the delayed-insert handler thread.

- `waiting for handler open`

This occurs after the `Creating delayed handler` state and before the `got old table` state. The delayed-insert handler thread has just been started, and the connection thread is waiting for it to initialize.

States associated with a delayed-insert handler thread that inserts the rows:

- `insert`

The state that occurs just before inserting rows into the table.

- `reschedule`

After inserting a number of rows, the delayed-insert thread sleeps to let other threads do work.

- `upgrading lock`

A delayed-insert handler is trying to get a lock for the table to insert rows.

- `Waiting for INSERT`

A delayed-insert handler is waiting for a connection thread to add rows to the queue (see `storing row into queue`).

#### 8.12.5.4. Query Cache Thread States

These thread states are associated with the query cache (see [Section 8.9.3, “The MySQL Query Cache”](#)).

- `checking privileges on cached query`

The server is checking whether the user has privileges to access a cached query result.

- `checking query cache for query`

The server is checking whether the current query is present in the query cache.

- `invalidating query cache entries`

Query cache entries are being marked invalid because the underlying tables have changed.

- `sending cached result to client`

The server is taking the result of a query from the query cache and sending it to the client.

- `storing result in query cache`

The server is storing the result of a query in the query cache.

- `Waiting for query cache lock`

This state occurs while a session is waiting to take the query cache lock. This can happen for any statement that needs to perform some query cache operation, such as an `INSERT` or `DELETE` that

invalidates the query cache, a `SELECT` that looks for a cached entry, `RESET QUERY CACHE`, and so forth.

### 8.12.5.5. Replication Master Thread States

The following list shows the most common states you may see in the `State` column for the master's `Binlog Dump` thread. If you see no `Binlog Dump` threads on a master server, this means that replication is not running—that is, that no slaves are currently connected.

- `Sending binlog event to slave`

Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.

- `Finished reading one binlog; switching to next binlog`

The thread has finished reading a binary log file and is opening the next one to send to the slave.

- `Master has sent all binlog to slave; waiting for binlog to be updated`

The thread has read all outstanding updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.

- `Waiting to finalize termination`

A very brief state that occurs as the thread is stopping.

### 8.12.5.6. Replication Slave I/O Thread States

The following list shows the most common states you see in the `State` column for a slave server I/O thread. This state also appears in the `Slave_IO_State` column displayed by `SHOW SLAVE STATUS`, so you can get a good view of what is happening by using that statement.

- `Waiting for master update`

The initial state before `Connecting to master`.

- `Connecting to master`

The thread is attempting to connect to the master.

- `Checking master version`

A state that occurs very briefly, after the connection to the master is established.

- `Registering slave on master`

A state that occurs very briefly after the connection to the master is established.

- `Requesting binlog dump`

A state that occurs very briefly, after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log file name and position.

- `Waiting to reconnect after a failed binlog dump request`

If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement.

- `Reconnecting after a failed binlog dump request`

The thread is trying to reconnect to the master.

- `Waiting for master to send event`

The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_net_timeout` [1993] seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- `Queueing master event to the relay log`

The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Waiting to reconnect after a failed master event read`

An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement (default 60) before attempting to reconnect.

- `Reconnecting after a failed master event read`

The thread is trying to reconnect to the master. When connection is established again, the state becomes `Waiting for master to send event`.

- `Waiting for the slave SQL thread to free enough relay log space`

You are using a nonzero `relay_log_space_limit` [534] value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- `Waiting for slave mutex on exit`

A state that occurs briefly as the thread is stopping.

### 8.12.5.7. Replication Slave SQL Thread States

The following list shows the most common states you may see in the `State` column for a slave server SQL thread:

- `Waiting for the next event in relay log`

The initial state before `Reading event from the relay log`.

- `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

- `Making temp file`

The thread is executing a `LOAD DATA INFILE` statement and is creating a temporary file containing the data from which the slave will read rows.

- `Slave has read all relay log; waiting for the slave I/O thread to update it`

The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- `Waiting for slave mutex on exit`

A very brief state that occurs as the thread is stopping.

- `Waiting until MASTER_DELAY seconds after master executed event`

The SQL thread has read an event but is waiting for the slave delay to lapse. This delay is set with the `MASTER_DELAY` option of `CHANGE MASTER TO`.

The `State` column for the I/O thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and is executing it.

### 8.12.5.8. Replication Slave Connection Thread States

These thread states occur on a replication slave but are associated with connection threads, not with the I/O or SQL threads.

- `Changing master`

The thread is processing a `CHANGE MASTER TO` statement.

- `Killing slave`

The thread is processing a `STOP SLAVE` statement.

- `Opening master dump table`

This state occurs after `Creating table from master dump`.

- `Reading master dump table data`

This state occurs after `Opening master dump table`.

- `Rebuilding the index on master dump table`

This state occurs after `Reading master dump table data`.

### 8.12.5.9. Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

- `Clearing`

The scheduler thread or a thread that was executing an event is terminating and is about to end.

- `Initialized`

The scheduler thread or a thread that will execute an event has been initialized.

- `Waiting for next activation`

The scheduler has a nonempty event queue but the next activation is in the future.

- `Waiting for scheduler to stop`

The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

- `Waiting on empty queue`

The scheduler's event queue is empty and it is sleeping.

## 8.13. Internal Details of MySQL Optimizations

This background information helps you to understand some of the terms you see in the `EXPLAIN` plan output. If you are rewriting queries to make them more efficient, or writing your own application logic for lookups, joining, or sorting, use this information to determine which optimizations you write yourself and which you can rely on MySQL to perform.

## 8.13.1. Range Optimization

The [range \[899\]](#) access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections give a detailed description of how intervals are extracted from the [WHERE](#) clause.

### 8.13.1.1. The Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the [WHERE](#) clause, so we speak of *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both [BTREE](#) and [HASH](#) indexes, comparison of a key part with a constant value is a range condition when using the [= \[1166\]](#), [<=> \[1167\]](#), [IN\(\) \[1169\]](#), [IS NULL \[1168\]](#), or [IS NOT NULL \[1168\]](#) operators.
- Additionally, for [BTREE](#) indexes, comparison of a key part with a constant value is a range condition when using the [> \[1167\]](#), [< \[1167\]](#), [>= \[1167\]](#), [<= \[1167\]](#), [BETWEEN \[1168\]](#), [!= \[1167\]](#), or [<> \[1167\]](#) operators, or [LIKE \[1190\]](#) comparisons if the argument to [LIKE \[1190\]](#) is a constant string that does not start with a wildcard character.
- For all types of indexes, multiple range conditions combined with [OR \[1172\]](#) or [AND \[1171\]](#) form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a [const \[898\]](#) or [system \[898\]](#) table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the [WHERE](#) clause:

```
SELECT * FROM t1
  WHERE key_col > 1
     AND key_col < 10;

SELECT * FROM t1
  WHERE key_col = 1
     OR key_col IN (15,18,20);

SELECT * FROM t1
  WHERE key_col LIKE 'ab%'
     OR key_col BETWEEN 'bar' AND 'foo';
```

Note that some nonconstant values may be converted to constants during the constant propagation phase.

MySQL tries to extract range conditions from the [WHERE](#) clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where [key1](#) is an indexed column and [nonkey](#) is not indexed:

```
SELECT * FROM t1 WHERE
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
```

```
(key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Having replaced them with `TRUE`, we get:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

- `(key1 LIKE 'abcde%' OR TRUE)` is always true
- `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants, we get:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants, we obtain:

```
(key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
(key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND` [1171]/`OR` [1172] constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

Currently, MySQL does not support merging multiple ranges for the `range` [899] access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

### 8.13.1.2. The Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

<code>key_part1</code>	<code>key_part2</code>	<code>key_part3</code>
NULL	1	'abc'
NULL	1	'xyz'
NULL	2	'foo'
1	1	'abc'
1	1	'xyz'
1	2	'abc'

```
2      1      'aaa'
```

The condition `key_part1 = 1` defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For [HASH](#) indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, `const1`, `const2`, ... are constants, `cmp` is one of the `=` [1166], `<=>` [1167], or `IS NULL` [1168] comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part [HASH](#) index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

For the definition of what is considered to be a constant, see [Section 8.13.1.1, “The Range Access Method for Single-Part Indexes”](#).

- For a [BTREE](#) index, an interval might be usable for conditions combined with `AND` [1171], where each condition compares a key part with a constant value using `=` [1166], `<=>` [1167], `IS NULL` [1168], `>` [1167], `<` [1167], `>=` [1167], `<=` [1167], `!=` [1167], `<>` [1167], `BETWEEN` [1168], or `LIKE 'pattern'` [1190] (where `'pattern'` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` [1167] or `!=` [1167] is used).

The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is `=` [1166], `<=>` [1167], or `IS NULL` [1168]. If the operator is `>` [1167], `<` [1167], `>=` [1167], `<=` [1167], `!=` [1167], `<>` [1167], `BETWEEN` [1168], or `LIKE` [1190], the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses `=` [1166] from the first comparison. It also uses `>=` [1167] from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:

```
('foo',10,-inf) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)
```

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with `OR` [1172], they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with `AND` [1171], they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

```
(key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
```

The intervals are:

```
(1,-inf) < (key_part1,key_part2) < (1,2)
(5,-inf) < (key_part1,key_part2)
```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The `key_len` column in the `EXPLAIN` output indicates the maximum length of the key prefix used.

In some cases, `key_len` may indicate that a key part was used, but that might be not what you would expect. Suppose that `key_part1` and `key_part2` can be `NULL`. Then the `key_len` column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

Section 8.13.1.1, “The Range Access Method for Single-Part Indexes”, describes how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index. Analogous steps are performed for range conditions on multiple-part indexes.

### 8.13.1.3. Equality Range Optimization of Many-Valued Comparisons

Consider these expressions, where `col_name` is an indexed column:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

Each expression is true if `col_name` is equal to any of several values. These comparisons are equality range comparisons (where the “range” is a single value). The optimizer estimates the cost of reading qualifying rows for equality range comparisons as follows:

- If there is a unique index on `col_name`, the row estimate for each range is 1 because at most one row can have the given value.
- Otherwise, the optimizer can estimate the row count for each range using dives into the index or index statistics.

With index dives, the optimizer makes a dive at each end of a range and uses the number of rows in the range as the estimate. For example, the expression `col_name IN (10, 20, 30)` has three equality ranges and the optimizer makes two dives per range to generate a row estimate. Each pair of dives yields an estimate of the number of rows that have the given value.

Index dives provide accurate row estimates, but as the number of comparison values in the expression increases, the optimizer takes longer to generate a row estimate. Use of index statistics is less accurate than index dives but permits faster row estimation for large value lists.

The `eq_range_index_dive_limit` [479] system variable enables you to configure the number of values at which the optimizer switches from one row estimation strategy to the other. To disable use of statistics and always use index dives, set `eq_range_index_dive_limit` [479] to 0. To permit use of index dives for comparisons of up to *N* equality ranges, set `eq_range_index_dive_limit` [479] to *N* + 1.

`eq_range_index_dive_limit` [479] is available as of MySQL 5.6.5. Before 5.6.5, the optimizer uses index dives, which is equivalent to `eq_range_index_dive_limit=0` [479].

To update table index statistics for best estimates, use `ANALYZE TABLE`.

## 8.13.2. Index Merge Optimization

The *Index Merge* method is used to retrieve rows with several [range \[899\]](#) scans and to merge their results into one. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans. This access method merges index scans from a single table; it does not merge scans across multiple tables.

In `EXPLAIN` output, the Index Merge method appears as `index_merge [899]` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

Examples:

```
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;

SELECT * FROM tbl_name
  WHERE (key1 = 10 OR key2 = 20) AND non_key=30;

SELECT * FROM t1, t2
  WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
     AND t2.key1=t1.some_col;

SELECT * FROM t1, t2
  WHERE t1.key1=1
     AND (t2.key1=t1.some_col OR t2.key2=t1.some_col2);
```

The Index Merge method has several access algorithms (seen in the `Extra` field of `EXPLAIN` output):

- `Using intersect(...)`
- `Using union(...)`
- `Using sort_union(...)`

The following sections describe these methods in greater detail.

#### Note

The Index Merge optimization algorithm has the following known deficiencies:

- If your query has a complex `WHERE` clause with deep `AND [1171]/OR [1172]` nesting and MySQL doesn't choose the optimal plan, try distributing terms using the following identity laws:

```
(x AND y) OR z = (x OR z) AND (y OR z)
(x OR y) AND z = (x AND z) OR (y AND z)
```

- Index Merge is not applicable to full-text indexes. We plan to extend it to cover these in a future MySQL release.
- Before MySQL 5.6.6, if a range scan is possible on some key, the optimizer will not consider using Index Merge Union or Index Merge Sort-Union algorithms. For example, consider this query:

```
SELECT * FROM t1 WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
```

For this query, two plans are possible:

- An Index Merge scan using the `(goodkey1 < 10 OR goodkey2 < 20)` condition.
- A range scan using the `badkey < 30` condition.

However, the optimizer considers only the second plan.

The choice between different possible variants of the Index Merge access method and other access methods is based on cost estimates of various available options.

### 8.13.2.1. The Index Merge Intersection Access Algorithm

This access algorithm can be employed when a `WHERE` clause was converted to several range conditions on different keys combined with `AND` [1171], and each condition is one of the following:

- In this form, where the index has exactly  $N$  parts (that is, all index parts are covered):

```
key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
```

- Any range condition over a primary key of an `InnoDB` table.

Examples:

```
SELECT * FROM innodb_table WHERE primary_key < 10 AND key_coll=20;
```

```
SELECT * FROM tbl_name
WHERE (key1_part1=1 AND key1_part2=2) AND key2=2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (`EXPLAIN` output contains `Using index` in `Extra` field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1=1 AND key2=1;
```

If the used indexes don't cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over a primary key of an `InnoDB` table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

### 8.13.2.2. The Index Merge Union Access Algorithm

The applicability criteria for this algorithm are similar to those for the Index Merge method intersection algorithm. The algorithm can be employed when the table's `WHERE` clause was converted to several range conditions on different keys combined with `OR` [1172], and each condition is one of the following:

- In this form, where the index has exactly  $N$  parts (that is, all index parts are covered):

```
key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
```

- Any range condition over a primary key of an `InnoDB` table.
- A condition for which the Index Merge method intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1 WHERE key1=1 OR key2=2 OR key3=3;
```

```
SELECT * FROM innodb_table WHERE (key1=1 AND key2=2) OR
(key3='foo' AND key4='bar') AND key5=5;
```

### 8.13.2.3. The Index Merge Sort-Union Access Algorithm

This access algorithm is employed when the `WHERE` clause was converted to several range conditions combined by `OR` [1172], but for which the Index Merge method union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name WHERE key_coll < 10 OR key_coll2 < 20;
```

```
SELECT * FROM tbl_name
WHERE (key_coll > 10 OR key_coll2 = 20) AND nonkey_coll=30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

### 8.13.3. Engine Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the [NDB](#) storage engine.

**Note**

The [NDB](#) storage engine is currently not available in MySQL 5.6. If you are interested in using MySQL Cluster, see [MySQL Cluster NDB 7.2](#), which provides information about MySQL Cluster NDB 7.2, which is based on MySQL 5.5 but contains the latest improvements and fixes for [NDB](#).

For MySQL Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL Server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that a MySQL Cluster table is defined as follows:

```
CREATE TABLE t1 (
  a INT,
  b INT,
  KEY(a)
) ENGINE=NDB;
```

Condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```
SELECT a, b FROM t1 WHERE b = 10;
```

The use of condition pushdown can be seen in the output of [EXPLAIN](#):

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: t1
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
         ref: NULL
        rows: 10
     Extra: Using where with pushed condition
```

However, condition pushdown *cannot* be used with either of these two queries:

```
SELECT a,b FROM t1 WHERE a = 10;
SELECT a,b FROM t1 WHERE b + 1 = 10;
```

Condition pushdown is not applicable to the first query because an index exists on column [a](#). (An index access method would be more efficient and so would be chosen in preference to condition pushdown.) Condition pushdown cannot be employed for the second query because the comparison involving the nonindexed column [b](#) is indirect. (However, condition pushdown could be applied if you were to reduce  $b + 1 = 10$  to  $b = 9$  in the [WHERE](#) clause.)

Condition pushdown may also be employed when an indexed column is compared with a constant using a  $>$  or  $<$  operator:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2\G
***** 1. row *****
      id: 1
```

```

select_type: SIMPLE
  table: t1
  type: range
possible_keys: a
  key: a
  key_len: 5
  ref: NULL
  rows: 2
Extra: Using where with pushed condition

```

Other supported comparisons for condition pushdown include the following:

- `column [NOT] LIKE pattern`

`pattern` must be a string literal containing the pattern to be matched; for syntax, see [Section 12.5.1, “String Comparison Functions”](#).

- `column IS [NOT] NULL`
- `column IN (value_list)`

Each item in the `value_list` must be a constant, literal value.

- `column BETWEEN constant1 AND constant2`

`constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Engine condition pushdown is enabled by default. To disable it at server startup, set the `optimizer_switch [520]` system variable. For example, in a `my.cnf` file, use these lines:

```

[mysqld]
optimizer_switch=engine_condition_pushdown=off

```

At runtime, enable condition pushdown like this:

```

SET optimizer_switch='engine_condition_pushdown=off';

```

**Limitations.** Engine condition pushdown is subject to the following limitations:

- Condition pushdown is supported only by the [NDB](#) storage engine.
- Columns may be compared with constants only; however, this includes expressions which evaluate to constant values.
- Columns used in comparisons cannot be of any of the [BLOB](#) or [TEXT](#) types.
- A string value to be compared with a column must use the same collation as the column.
- Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use [EXPLAIN EXTENDED](#) to determine which conditions are actually pushed down.

## 8.13.4. Index Condition Pushdown Optimization

Index Condition Pushdown (ICP) is an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the [WHERE](#) condition for the rows. With ICP enabled, and if parts of the [WHERE](#) condition can be evaluated by using only fields from the index, the MySQL server pushes this part of the [WHERE](#) condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is the row read from the table. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine.

Index Condition Pushdown optimization is used for the [range \[899\]](#), [ref \[898\]](#), [eq\\_ref \[898\]](#), and [ref\\_or\\_null \[899\]](#) access methods when there is a need to access full table rows. This strategy can be used for [InnoDB](#) and [MyISAM](#) tables.

To see how this optimization works, consider first how an index scan proceeds when Index Condition Pushdown is not used:

1. Get the next row, first by reading the index tuple, and then by using the index tuple to locate and read the full table row.
2. Test the part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

When Index Condition Pushdown is used, the scan proceeds like this instead:

1. Get the next row's index tuple (but not the full table row).
2. Test the part of the `WHERE` condition that applies to this table and can be checked using only index columns. If the condition is not satisfied, proceed to the index tuple for the next row.
3. If the condition is satisfied, use the index tuple to locate and read the full table row.
4. Test the remaining part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

When Index Condition Pushdown is used, the `Extra` column in `EXPLAIN` output shows `Using index condition`. It will not show `Index only` because that does not apply when full table rows must be read.

Suppose that we have a table containing information about people and their addresses and that the table has an index defined as `INDEX (zipcode, lastname, firstname)`. If we know a person's `zipcode` value but are not sure about the last name, we can search like this:

```
SELECT * FROM people
WHERE zipcode='95054'
AND lastname LIKE '%etrunia%'
AND address LIKE '%Main Street%';
```

MySQL can use the index to scan through people with `zipcode='95054'`. The second part (`lastname LIKE '%etrunia%'`) cannot be used to limit the number of rows that must be scanned, so without Index Condition Pushdown, this query must retrieve full table rows for all the people who have `zipcode='95054'`.

With Index Condition Pushdown, MySQL will check the `lastname LIKE '%etrunia%'` part before reading the full table row. This avoids reading full rows corresponding to all index tuples that do not match the `lastname` condition.

Index Condition Pushdown is enabled by default; it can be controlled with the [optimizer\\_switch \[520\]](#) system variable by setting the `index_condition_pushdown` flag. See [Section 8.8.5.2, "Controlling Switchable Optimizations"](#).

## 8.13.5. Use of Index Extensions

[InnoDB](#) automatically extends each secondary index by appending the primary key columns to it. Consider this table definition:

```
CREATE TABLE t1 (
  i1 INT NOT NULL DEFAULT 0,
  i2 INT NOT NULL DEFAULT 0,
  d DATE DEFAULT NULL,
  PRIMARY KEY (i1, i2),
  INDEX k_d (d)
```

```
) ENGINE = InnoDB;
```

This table defines the primary key on columns (*i1*, *i2*). It also defines a secondary index *k\_d* on column (*d*), but internally *InnoDB* extends this index and treats it as columns (*d*, *i1*, *i2*).

Before MySQL 5.6.9, the optimizer does not take into account the primary key columns of the extended secondary index when determining how and whether to use that index. As of 5.6.9, the optimizer takes the primary key columns into account, which can result in more efficient query execution plans and better performance.

The optimizer can use extended secondary indexes for *ref*, *range*, and *index\_merge* index access, for loose index scans, for join and sorting optimization, and for *MIN()* [1284]/*MAX()* [1284] optimization.

The following example shows how execution plans are affected by whether the optimizer uses extended secondary indexes. Suppose that *t1* is populated with these rows:

```
INSERT INTO t1 VALUES
(1, 1, '1998-01-01'), (1, 2, '1999-01-01'),
(1, 3, '2000-01-01'), (1, 4, '2001-01-01'),
(1, 5, '2002-01-01'), (2, 1, '1998-01-01'),
(2, 2, '1999-01-01'), (2, 3, '2000-01-01'),
(2, 4, '2001-01-01'), (2, 5, '2002-01-01'),
(3, 1, '1998-01-01'), (3, 2, '1999-01-01'),
(3, 3, '2000-01-01'), (3, 4, '2001-01-01'),
(3, 5, '2002-01-01'), (4, 1, '1998-01-01'),
(4, 2, '1999-01-01'), (4, 3, '2000-01-01'),
(4, 4, '2001-01-01'), (4, 5, '2002-01-01'),
(5, 1, '1998-01-01'), (5, 2, '1999-01-01'),
(5, 3, '2000-01-01'), (5, 4, '2001-01-01'),
(5, 5, '2002-01-01');
```

Now consider this query:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'
```

The optimizer cannot use the primary key in this case because that comprises columns (*i1*, *i2*) and the query does not refer to *i2*. Instead, the optimizer can use the secondary index *k\_d* on (*d*), and the execution plan depends on whether the extended index is used.

When the optimizer does not consider index extensions, it treats the index *k\_d* as only (*d*). *EXPLAIN* for the query produces this result:

```
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
       type: ref
possible_keys: PRIMARY,k_d
         key: k_d
      key_len: 4
         ref: const
        rows: 5
      Extra: Using where; Using index
```

When the optimizer takes index extensions into account, it treats *k\_d* as (*d*, *i1*, *i2*). In this case, it can use the leftmost index prefix (*d*, *i1*) to produce a better execution plan:

```
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
       type: ref
possible_keys: PRIMARY,k_d
         key: k_d
```

```

key_len: 8
  ref: const,const
  rows: 1
  Extra: Using index

```

In both cases, `key` indicates that the optimizer will use secondary index `k_d` but the `EXPLAIN` output shows these improvements from using the extended index:

- `key_len` goes from 4 bytes to 8 bytes, indicating that key lookups use columns `d` and `i1`, not just `d`.
- The `ref` value changes from `const` to `const,const` because the key lookup uses two key parts, not one.
- The `rows` count decreases from 5 to 1, indicating that `InnoDB` should need to examine fewer rows to produce the result.
- The `Extra` value changes from `Using where; Using index` to `Using index`. This means that rows can be read using only the index, without consulting columns in the data row.

Differences in optimizer behavior for use of extended indexes can also be seen with `SHOW STATUS`:

```

FLUSH TABLE t1;
FLUSH STATUS;
SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01';
SHOW STATUS LIKE 'handler_read%'

```

The preceding statements include `FLUSH TABLE` and `FLUSH STATUS` to flush the table cache and clear the status counters.

Without index extensions, `SHOW STATUS` produces this result:

```

+-----+-----+
| Variable_name | Value |
+-----+-----+
| Handler_read_first | 0 |
| Handler_read_key | 1 |
| Handler_read_last | 0 |
| Handler_read_next | 5 |
| Handler_read_prev | 0 |
| Handler_read_rnd | 0 |
| Handler_read_rnd_next | 0 |
+-----+-----+

```

With index extensions, `SHOW STATUS` produces this result. The `Handler_read_next` [589] value decreases from 5 to 1, indicating more efficient use of the index:

```

+-----+-----+
| Variable_name | Value |
+-----+-----+
| Handler_read_first | 0 |
| Handler_read_key | 1 |
| Handler_read_last | 0 |
| Handler_read_next | 1 |
| Handler_read_prev | 0 |
| Handler_read_rnd | 0 |
| Handler_read_rnd_next | 0 |
+-----+-----+

```

The `use_index_extensions` flag of the `optimizer_switch` [520] system variable permits control over whether the optimizer takes the primary key columns into account when determining how to use an `InnoDB` table's secondary indexes. By default, `use_index_extensions` is enabled. To check whether disabling use of index extensions will improve performance, use this statement:

```

SET optimizer_switch = 'use_index_extensions=off';

```

Use of index extensions by the optimizer is subject to the usual limits on the number of key parts in an index (16) and the maximum key length (3072 bytes).

### 8.13.6. IS NULL Optimization

MySQL can perform the same optimization on `col_name IS NULL` [1168] that it can use for `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for `NULL` with `IS NULL` [1168].

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;

SELECT * FROM tbl_name WHERE key_col <=> NULL;

SELECT * FROM tbl_name
WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` [1168] condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway; for example, if it comes from a table on the right side of a `LEFT JOIN`.

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` [899] when this optimization is used.

This optimization can handle one `IS NULL` [1168] for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;

SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;

SELECT * FROM t1, t2
WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;

SELECT * FROM t1, t2
WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);

SELECT * FROM t1, t2
WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` [899] works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

Note that the optimization can handle only one `IS NULL` [1168] level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```
SELECT * FROM t1, t2
WHERE (t1.a=t2.a AND t2.a IS NULL)
OR (t1.b=t2.b AND t2.b IS NULL);
```

### 8.13.7. LEFT JOIN and RIGHT JOIN Optimization

MySQL implements an `A LEFT JOIN B join_condition` as follows:

- Table `B` is set to depend on table `A` and all tables on which `A` depends.
- Table `A` is set to depend on all tables (except `B`) that are used in the `LEFT JOIN` condition.
- The `LEFT JOIN` condition is used to decide how to retrieve rows from table `B`. (In other words, any condition in the `WHERE` clause is not used.)

- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependence, MySQL issues an error.
- All standard `WHERE` optimizations are performed.
- If there is a row in `A` that matches the `WHERE` clause, but there is no row in `B` that matches the `ON` condition, an extra `B` row is generated with all columns set to `NULL`.
- If you use `LEFT JOIN` to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the `WHERE` part, where `col_name` is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

The implementation of `RIGHT JOIN` is analogous to that of `LEFT JOIN` with the roles of the tables reversed.

The join optimizer calculates the order in which tables should be joined. The table read order forced by `LEFT JOIN` or `STRAIGHT_JOIN` helps the join optimizer do its work much more quickly, because there are fewer table permutations to check. Note that this means that if you do a query of the following type, MySQL does a full scan on `b` because the `LEFT JOIN` forces it to be read before `d`:

```
SELECT *
FROM a JOIN b LEFT JOIN c ON (c.key=a.key)
LEFT JOIN d ON (d.key=a.key)
WHERE b.key=d.key;
```

The fix in this case is reverse the order in which `a` and `b` are listed in the `FROM` clause:

```
SELECT *
FROM b JOIN a LEFT JOIN c ON (c.key=a.key)
LEFT JOIN d ON (d.key=a.key)
WHERE b.key=d.key;
```

For a `LEFT JOIN`, if the `WHERE` condition is always false for the generated `NULL` row, the `LEFT JOIN` is changed to a normal join. For example, the `WHERE` clause would be false in the following query if `t2.column1` were `NULL`:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to a normal join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

This can be made faster because MySQL can use table `t2` before table `t1` if doing so would result in a better query plan. To provide a hint about the table join order, use `STRAIGHT_JOIN`. (See [Section 13.2.9, "SELECT Syntax"](#).)

### 8.13.8. Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

#### Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables `t1`, `t2`, and `t3` is to be executed using the following join types:

Table	Join Type
t1	range
t2	ref

t3      ALL

If a simple NLJ algorithm is used, the join is processed like this:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    for each row in t3 {
      if row satisfies join conditions,
        send to client
    }
  }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

### Block Nested-Loop Join Algorithm

A Block Nested-Loop (BNL) join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. This reduces the number of times the inner table must be read by an order of magnitude.

MySQL uses join buffering under these conditions:

- The `join_buffer_size` [490] system variable determines the size of each join buffer.
- Join buffering can be used when the join is of type `ALL` [900] or `index` [899] (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or `range` [899]. In MySQL 5.6, use of buffering is extended to be applicable to outer joins, as described in [Section 8.13.12, “Block Nested-Loop and Batched Key Access Joins”](#).
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.
- A join buffer is never allocated for the first nonconst table, even if it would be of type `ALL` [900] or `index` [899].
- A join buffer is allocated prior to executing the join and freed after the query is done.
- Only columns of interest to the join are stored in the join buffer, not whole rows.

For the example join described previously for the NLJ algorithm (without buffering), the join is done as follows using join buffering:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    store used columns from t1, t2 in join buffer
    if buffer is full {
      for each row in t3 {
        for each t1, t2 combination in join buffer {
          if row satisfies join conditions,
            send to client
        }
      }
      empty buffer
    }
  }
}

if buffer is not empty {
  for each row in t3 {
    for each t1, t2 combination in join buffer {
      if row satisfies join conditions,
        send to client
    }
  }
}
```

```
}
}
```

If  $S$  is the size of each stored  $t_1$ ,  $t_2$  combination is the join buffer and  $C$  is the number of combinations in the buffer, the number of times table  $t_3$  is scanned is:

```
(S * C) / join_buffer_size + 1
```

The number of  $t_3$  scans decreases as the value of `join_buffer_size` [490] increases, up to the point when `join_buffer_size` [490] is large enough to hold all previous row combinations. At that point, there is no speed to be gained by making it larger.

### 8.13.9. Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in [Section 13.2.9.2, “JOIN Syntax”](#).

The syntax of *table\_factor* is extended in comparison with the SQL Standard. The latter accepts only *table\_reference*, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of *table\_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause; `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. After removing parentheses and grouping operations to the left, the join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
      ON t1.a=t2.a
```

transforms into the expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
      ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables  $t_1$ ,  $t_2$ , and  $t_3$  have the following state:

- Table  $t_1$  contains rows (1), (2)
- Table  $t_2$  contains row (1,101)
- Table  $t_3$  contains row (101)

In this case, the first expression returns a result set including the rows (1,1,101,101), (2,NULL,NULL,NULL), whereas the second expression returns the rows (1,1,101,101), (2,NULL,NULL,101):

```
mysql> SELECT *
-> FROM t1
-> LEFT JOIN
-> (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
-> ON t1.a=t2.a;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
```

```

+-----+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | NULL |
+-----+-----+-----+-----+

mysql> SELECT *
-> FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
-> LEFT JOIN t3
-> ON t2.b=t3.b OR t2.b IS NULL;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | 101 |
+-----+-----+-----+-----+

```

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3.
```

For the given table states, the two expressions return different sets of rows:

```

mysql> SELECT *
-> FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | NULL |
+-----+-----+-----+-----+

mysql> SELECT *
-> FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | 101 |
+-----+-----+-----+-----+

```

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

is equivalent to this expression:

```
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

for any tables `t1, t2, t3` and any condition `P` over attributes `t2.b` and `t3.b`.

Whenever the order of execution of the join operations in a join expression (*join\_table*) is not from left to right, we talk about nested joins. Consider the following queries:

```

SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
WHERE t1.a > 1

SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a

```

```
WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

The nested join is formed in the first query with a left join operation, whereas in the second query it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. (In our extended syntax the parentheses in `(t2, t3)` of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` would play the role of the left and right delimiters for the expression `(t2,t3)`.)

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed. You can remove parentheses and evaluate left to right (or, in fact, you can evaluate the tables in any order).
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall by what algorithmic schema the nested-loop join executes a query. Suppose that we have a join query over 3 tables `T1, T2, T3` of the form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
           INNER JOIN T3 ON P2(T2,T3)
WHERE P(T1,T2,T3).
```

Here, `P1(T1,T2)` and `P2(T2,T3)` are some join conditions (on expressions), whereas `P(t1,t2,t3)` is a condition over columns of tables `T1, T2, T3`.

The nested-loop join algorithm would execute this query in the following manner:

```
FOR each row t1 in T1 {
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

The notation `t1 || t2 || t3` means “a row constructed by concatenating the columns of rows `t1`, `t2`, and `t3`.” In some of the following examples, `NULL` where a row name appears means that `NULL` is used for each column of that row. For example, `t1 || t2 || NULL` means “a row constructed by concatenating the columns of rows `t1` and `t2`, and `NULL` for each column of `t3`.”

Now let's consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN
           (T2 LEFT JOIN T3 ON P2(T2,T3))
           ON P1(T1,T2)
WHERE P(T1,T2,T3).
```

For this query, we modify the nested-loop pattern to get:

```

FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
      f1=TRUE;
    }
    IF (!f2) {
      IF P(t1,t2,NULL) {
        t:=t1||t2||NULL; OUTPUT t;
      }
      f1=TRUE;
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}

```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by **NULL** values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In our example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

Note that for the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```

FOR each row t3 in T3 {
  FOR each row t2 in T2 such that P2(t2,t3) {
    FOR each row t1 in T1 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}

```

For the queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer will evaluate two different nestings:

```

SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)

```

The nestings are these:

```

FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t1,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
}

```

```

IF (!f1) {
  IF P(t1,NULL,NULL) {
    t:=t1||NULL||NULL; OUTPUT t;
  }
}
}

```

and:

```

FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t3 in T3 such that P2(t1,t3) {
    FOR each row t2 in T2 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}

```

In both nestings, **T1** must be processed in the outer loop because it is used in an outer join. **T2** and **T3** are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, **T2** and **T3** can be processed in either order.

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our **WHERE** condition  $P(T1, T2, T3)$  can be represented by a conjunctive formula:

```
P(T1,T2,T2) = C1(T1) AND C2(T2) AND C3(T3).
```

In this case, MySQL actually uses the following nested-loop schema for the execution of the query with inner joins:

```

FOR each row t1 in T1 such that C1(t1) {
  FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
    FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}

```

You see that each of the conjuncts  $C1(T1)$ ,  $C2(T2)$ ,  $C3(T3)$  are pushed out of the most inner loop to the most outer loop where it can be evaluated. If  $C1(T1)$  is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table **T1** passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the **WHERE** condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we have to introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

For our example with outer joins with:

```
P(T1,T2,T3)=C1(T1) AND C(T2) AND C3(T3)
```

the nested-loop schema using guarded pushed-down conditions looks like this:

```

FOR each row t1 in T1 such that C1(t1) {
  BOOL f1:=FALSE;
  FOR each row t2 in T2
    such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3
      such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
        IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
          t:=t1||t2||t3; OUTPUT t;
        }
        f2=TRUE;
        f1=TRUE;
      }
    }
  IF (!f2) {
    IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
      t:=t1||t2||NULL; OUTPUT t;
    }
    f1=TRUE;
  }
}
IF (!f1 && P(t1,NULL,NULL)) {
  t:=t1||NULL||NULL; OUTPUT t;
}
}

```

In general, pushed-down predicates can be extracted from join conditions such as `P1(T1,T2)` and `P(T2,T3)`. In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Note that access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the `WHERE` condition. (We could use conditional key access in this case, but this technique is not employed yet in MySQL 5.6.)

### 8.13.10. Outer Join Simplification

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer joins operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed according to the following rule:

```

(T1, ...) RIGHT JOIN (T2,...) ON P(T1,...,T2,...) =
(T2, ...) LEFT JOIN (T1,...) ON P(T1,...,T2,...)

```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1,T2)` are replaced by the list `T1,T2,P(T1,T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for join queries with outer join operation, it takes into consideration only the plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer options are limited because only such plans enables us to execute queries with outer joins operations by the nested loop schema.

Suppose that we have a query of the form:

```

SELECT * T1 LEFT JOIN T2 ON P1(T1,T2)
WHERE P(T1,T2) AND R(T2)

```

with `R(T2)` narrowing greatly the number of matching rows from table `T2`. If we executed the query as it is, the optimizer would have no other choice besides to access table `T1` before table `T2` that may lead to a very inefficient execution plan.

Fortunately, MySQL converts such a query into a query without an outer join operation if the `WHERE` condition is null-rejected. A condition is called null-rejected for an outer join operation if it evaluates to `FALSE` or to `UNKNOWN` for any `NULL`-complemented row built for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected:

```
T2.B IS NOT NULL,
T2.B > 3,
T2.C <= T1.C,
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected:

```
T2.B IS NULL,
T1.B < 3 OR T2.B IS NOT NULL,
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple. A condition is null-rejected in the following cases:

- If it is of the form `A IS NOT NULL`, where `A` is an attribute of any of the inner tables
- If it is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`
- If it is a conjunction containing a null-rejected condition as a conjunct
- If it is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
           LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

the `WHERE` condition is null-rejected for the second outer join operation but is not null-rejected for the first one.

If the `WHERE` condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, the preceding query is replaced with the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
           INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

For the original query, the optimizer would evaluate plans compatible with only one access order `T1, T2, T3`. For the replacing query, it additionally considers the access sequence `T3, T1, T2`.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
           LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

will be first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
           INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
```

```
WHERE T3.C > 0 AND T3.B=T2.B
```

Now the remaining outer join operation can be replaced by an inner join, too, because the condition `T3.B=T2.B` is null-rejected and we get a query without outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes we succeed in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
      (T2 LEFT JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A
WHERE T3.C > 0
```

is converted to:

```
SELECT * FROM T1 LEFT JOIN
      (T2 INNER JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A
WHERE T3.C > 0,
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
      (T2,T3)
      ON (T2.A=T1.A AND T3.B=T2.B)
WHERE T3.C > 0.
```

When trying to convert an embedded outer join operation in a query, we must take into account the join condition for the embedding outer join together with the `WHERE` condition. In the query:

```
SELECT * FROM T1 LEFT JOIN
      (T2 LEFT JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A AND T3.C=T1.C
WHERE T3.D > 0 OR T1.D > 0
```

the `WHERE` condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join `T2.A=T1.A AND T3.C=T1.C` is null-rejected. So the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
      (T2, T3)
      ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
WHERE T3.D > 0 OR T1.D > 0
```

### 8.13.11. Multi-Range Read Optimization

Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data.

The Multi-Range Read optimization provides these benefits:

- MRR enables data rows to be accessed sequentially rather than in random order, based on index tuples. The server obtains a set of index tuples that satisfy the query conditions, sorts them according to data row ID order, and uses the sorted tuples to retrieve data rows in order. This makes data access more efficient and less expensive.
- MRR enables batch processing of requests for key access for operations that require access to data rows through index tuples, such as range index scans and equi-joins that use an index for the join

attribute. MRR iterates over a sequence of index ranges to obtain qualifying index tuples. As these results accumulate, they are used to access the corresponding data rows. It is not necessary to acquire all index tuples before starting to read data rows.

The following scenarios illustrate when MRR optimization can be advantageous:

Scenario A: MRR can be used for [InnoDB](#) and [MyISAM](#) tables for index range scans and equi-join operations.

1. A portion of the index tuples are accumulated in a buffer.
2. The tuples in the buffer are sorted by their data row ID.
3. Data rows are accessed according to the sorted index tuple sequence.

Scenario B: MRR can be used for [NDB](#) tables for multiple-range index scans or when performing an equi-join by an attribute.

1. A portion of ranges, possibly single-key ranges, is accumulated in a buffer on the central node where the query is submitted.
2. The ranges are sent to the execution nodes that access data rows.
3. The accessed rows are packed into packages and sent back to the central node.
4. The received packages with data rows are placed in a buffer.
5. Data rows are read from the buffer.

When MRR is used, the [Extra](#) column in [EXPLAIN](#) output shows [Using MRR](#).

[InnoDB](#) and [MyISAM](#) do not use MRR if full table rows need not be accessed to produce the query result. This is the case if results can be produced entirely on the basis on information in the index tuples (through a [covering index](#)); MRR provides no benefit.

Example query for which MRR can be used, assuming that there is an index on [\(key\\_part1, key\\_part2\)](#):

```
SELECT * FROM t
WHERE key_part1 >= 1000 AND key_part1 < 2000
AND key_part2 = 10000;
```

The index consists of tuples of [\(key\\_part1, key\\_part2\)](#) values, ordered first by [key\\_part1](#) and then by [key\\_part2](#).

Without MRR, an index scan covers all index tuples for the [key\\_part1](#) range from 1000 up to 2000, regardless of the [key\\_part2](#) value in these tuples. The scan does extra work to the extent that tuples in the range contain [key\\_part2](#) values other than 10000.

With MRR, the scan is broken up into multiple ranges, each for a single value of [key\\_part1](#) (1000, 1001, ..., 1999). Each of these scans need look only for tuples with [key\\_part2](#) = 10000. If the index contains many tuples for which [key\\_part2](#) is not 10000, MRR results in many fewer index tuples being read.

To express this using interval notation, the non-MRR scan must examine the index range [\[ {1000, 10000}, {2000, MIN\\_INT} \)](#), which may include many tuples other than those for which [key\\_part2](#) = 10000. The MRR scan examines multiple single-point intervals [\[ {1000, 10000} \]](#), ..., [\[ {1999, 10000} \]](#), which includes only tuples with [key\\_part2](#) = 10000.

Two [optimizer\\_switch \[520\]](#) system variable flags provide an interface to the use of MRR optimization. The [mrr](#) flag controls whether MRR is enabled. If [mrr](#) is enabled ([on](#)), the [mrr\\_cost\\_based](#) flag controls whether the optimizer attempts to make a cost-based choice between

using and not using MRR (`on`) or uses MRR whenever possible (`off`). By default, `mrr` is `on` and `mrr_cost_based` is `off` (use MRR whenever possible). See [Section 8.8.5.2, “Controlling Switchable Optimizations”](#).

For MRR, a storage engine uses the value of the `read_rnd_buffer_size` [533] system variable as a guideline for how much memory it can allocate for its buffer. The engine uses up to `read_rnd_buffer_size` [533] bytes and determines the number of ranges to process in a single pass.

## 8.13.12. Block Nested-Loop and Batched Key Access Joins

In MySQL 5.6, a Batched Key Access (BKA) Join algorithm is available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semi-join operations, including nested outer joins. Benefits of BKA include improved join performance due to more efficient table scanning. Also, the Block Nested-Loop (BNL) Join algorithm previously used only for inner joins is extended and can be employed for outer join and semi-join operations, including nested outer joins.

The following sections discuss the join buffer management that underlies the extension of the original BNL algorithm, the extended BNL algorithm, and the BKA algorithm. For information about semi-join strategies, see [Section 8.13.16.1, “Optimizing Subqueries with Semi-Join Transformations”](#)

### 8.13.12.1. Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms

In MySQL 5.6, MySQL Server can employ join buffers to execute not only inner joins without index access to the inner table, but also outer joins and semi-joins that appear after subquery flattening. Moreover, a join buffer can be effectively used when there is an index access to the inner table.

The join buffer management code slightly more efficiently utilizes join buffer space when storing the values of the interesting row columns: No additional bytes are allocated in buffers for a row column if its value is `NULL`, and the minimum number of bytes is allocated for any value of the `VARCHAR` type.

The code supports two types of buffers, regular and incremental. Suppose that join buffer `B1` is employed to join tables `t1` and `t2` and the result of this operation is joined with table `t3` using join buffer `B2`:

- A regular join buffer contains columns from each join operand. If `B2` is a regular join buffer, each row `r` put into `B2` is composed of the columns of a row `r1` from `B1` and the interesting columns of a matching row `r2` from table `t2`.
- An incremental join buffer contains only columns from rows of the table produced by the second join operand. That is, it is incremental to a row from the first operand buffer. If `B2` is an incremental join buffer, it contains the interesting columns of the row `r2` together with a link to the row `r1` from `B1`.

Incremental join buffers are always incremental relative to a join buffer from an earlier join operation, so the buffer from the first join operation is always a regular buffer. In the example just given, the buffer `B1` used to join tables `t1` and `t2` must be a regular buffer.

Each row of the incremental buffer used for a join operation contains only the interesting columns of a row from the table to be joined. These columns are augmented with a reference to the interesting columns of the matched row from the table produced by the first join operand. Several rows in the incremental buffer can refer to the same row `r` whose columns are stored in the previous join buffers insofar as all these rows match row `r`.

Incremental buffers enable less frequent copying of columns from buffers used for previous join operations. This provides a savings in buffer space because in the general case a row produced by the first join operand can be matched by several rows produced by the second join operand. It is unnecessary to make several copies of a row from the first operand. Incremental buffers also provide a savings in processing time due to the reduction in copying time.

As of MySQL 5.6.3, the `block_nested_loop` and `batched_key_access` flags of the `optimizer_switch` [520] system variable control how the optimizer uses the Block Nested-Loop and Batched Key Access join algorithms. By default, `block_nested_loop` is `on` and `batched_key_access` is `off`. See [Section 8.8.5.2, “Controlling Switchable Optimizations”](#).

Before MySQL 5.6.3, the `optimizer_join_cache_level` [519] system variable controls join buffer management. For the possible values of this variable and their meanings, see the description in [Section 5.1.4, “Server System Variables”](#).

For information about semi-join strategies, see [Section 8.13.16.1, “Optimizing Subqueries with Semi-Join Transformations”](#)

### 8.13.12.2. Block Nested-Loop Algorithm for Outer Joins and Semi-Joins

In MySQL 5.6, the original implementation of the BNL algorithm is extended to support outer join and semi-join operations.

When these operations are executed with a join buffer, each row put into the buffer is supplied with a match flag.

If an outer join operation is executed using a join buffer, each row of the table produced by the second operand is checked for a match against each row in the join buffer. When a match is found, a new extended row is formed (the original row plus columns from the second operand) and sent for further extensions by the remaining join operations. In addition, the match flag of the matched row in the buffer is enabled. After all rows of the table to be joined have been examined, the join buffer is scanned. Each row from the buffer that does not have its match flag enabled is extended by `NULL` complements (`NULL` values for each column in the second operand) and sent for further extensions by the remaining join operations.

As of MySQL 5.6.3, the `block_nested_loop` flag of the `optimizer_switch` [520] system variable controls how the optimizer uses the Block Nested-Loop algorithm. By default, `block_nested_loop` is `on`. See [Section 8.8.5.2, “Controlling Switchable Optimizations”](#).

Before MySQL 5.6.3, the `optimizer_join_cache_level` [519] system variable controls join buffer management. For the possible values of this variable and their meanings, see the description in [Section 5.1.4, “Server System Variables”](#).

In `EXPLAIN` output, use of BNL for a table is signified when the `Extra` value contains `Using join buffer (Block Nested Loop)` and the `type` value is `ALL` [900], `index` [899], or `range` [899].

For information about semi-join strategies, see [Section 8.13.16.1, “Optimizing Subqueries with Semi-Join Transformations”](#)

### 8.13.12.3. Batched Key Access Joins

MySQL 5.6.3 implements a method of joining tables called the Batched Key Access (BKA) join algorithm. BKA can be applied when there is an index access to the table produced by the second join operand. Like the BNL join algorithm, the BKA join algorithm employs a join buffer to accumulate the interesting columns of the rows produced by the first operand of the join operation. Then the BKA algorithm builds keys to access the table to be joined for all rows in the buffer and submits these keys in a batch to the database engine for index lookups. The keys are submitted to the engine through the Multi-Range Read (MRR) interface (see [Section 8.13.11, “Multi-Range Read Optimization”](#)). After submission of the keys, the MRR engine functions perform lookups in the index in an optimal way, fetching the rows of the joined table found by these keys, and starts feeding the BKA join algorithm with matching rows. Each matching row is coupled with a reference to a row in the join buffer.

For BKA to be used, the `batched_key_access` flag of the `optimizer_switch` [520] system variable must be set to `on`. BKA uses MRR, so the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used. The following setting enables BKA:

```
mysql> SET optimizer_switch='mrr=on,mrr_cost_based=off,batched_key_access=on';
```

There are two scenarios by which MRR functions execute:

- The first scenario is used for conventional disk-based storage engines such as [InnoDB](#) and [MyISAM](#). For these engines, usually the keys for all rows from the join buffer are submitted to the MRR interface at once. Engine-specific MRR functions perform index lookups for the submitted keys, get row IDs (or primary keys) from them, and then fetch rows for all these selected row IDs one by one by request from BKA algorithm. Every row is returned with an association reference that enables access to the matched row in the join buffer. The rows are fetched by the MRR functions in an optimal way: They are fetched in the row ID (primary key) order. This improves performance because reads are in disk order rather than random order.
- The second scenario is used for remote storage engines such as [NDB](#). A package of keys for a portion of rows from the join buffer, together with their associations, is sent by a MySQL Server (SQL node) to MySQL Cluster data nodes. In return, the SQL node receives a package (or several packages) of matching rows coupled with corresponding associations. The BKA join algorithm takes these rows and builds new joined rows. Then a new set of keys is sent to the data nodes and the rows from the returned packages are used to build new joined rows. The process continues until the last keys from the join buffer are sent to the data nodes, and the SQL node has received and joined all rows matching these keys. This improves performance because fewer key-bearing packages sent by the SQL node to the data nodes means fewer round trips between it and the data nodes to perform the join operation.

With the first scenario, a portion of the join buffer is reserved to store row IDs (primary keys) selected by index lookups and passed as a parameter to the MRR functions.

There is no special buffer to store keys built for rows from the join buffer. Instead, a function that builds the key for the next row in the buffer is passed as a parameter to the MRR functions.

In [EXPLAIN](#) output, use of BKA for a table is signified when the [Extra](#) value contains [Using join buffer \(Batched Key Access\)](#) and the [type](#) value is [ref \[898\]](#) or [eq\\_ref \[898\]](#).

### 8.13.13. ORDER BY Optimization

In some cases, MySQL can use an index to satisfy an [ORDER BY](#) clause without doing any extra sorting.

The index can also be used even if the [ORDER BY](#) does not match the index exactly, as long as all of the unused portions of the index and all the extra [ORDER BY](#) columns are constants in the [WHERE](#) clause. The following queries use the index to resolve the [ORDER BY](#) part:

```
SELECT * FROM t1
  ORDER BY key_part1,key_part2,... ;

SELECT * FROM t1
  WHERE key_part1 = constant
  ORDER BY key_part2;

SELECT * FROM t1
  ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
  WHERE key_part1 = 1
  ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
  WHERE key_part1 > constant
  ORDER BY key_part1 ASC;

SELECT * FROM t1
  WHERE key_part1 < constant
  ORDER BY key_part1 DESC;
```

```
SELECT * FROM t1
WHERE key_part1 = constant1 AND key_part2 > constant2
ORDER BY key_part2;
```

In some cases, MySQL *cannot* use indexes to resolve the `ORDER BY`, although it still uses indexes to find the rows that match the `WHERE` clause. These cases include the following:

- You use `ORDER BY` on different keys:

```
SELECT * FROM t1 ORDER BY key1, key2;
```

- You use `ORDER BY` on nonconsecutive parts of a key:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key_part2;
```

- You mix `ASC` and `DESC`:

```
SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;
```

- The key used to fetch the rows is not the same as the one used in the `ORDER BY`:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
```

- You use `ORDER BY` with an expression that includes terms other than the key column name:

```
SELECT * FROM t1 ORDER BY ABS(key);
SELECT * FROM t1 ORDER BY -key;
```

- You are joining many tables, and the columns in the `ORDER BY` are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that does not have a `const [898]` join type.)
- You have different `ORDER BY` and `GROUP BY` expressions.
- You index only a prefix of a column named in the `ORDER BY` clause. In this case, the index cannot be used to fully resolve the sort order. For example, if you have a `CHAR(20)` column, but index only the first 10 bytes, the index cannot distinguish values past the 10th byte and a `filesort` will be needed.
- The type of table index used does not store rows in order. For example, this is true for a `HASH` index in a `MEMORY` table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column `t1.a` is indexed. In this statement, the name of the column in the select list is `a`. It refers to `t1.a`, so for the reference to `a` in the `ORDER BY`, the index can be used:

```
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also `a`, but it is the alias name. It refers to `ABS(a)`, so for the reference to `a` in the `ORDER BY`, the index cannot be used:

```
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the `ORDER BY` refers to a name that is not the name of a column in the select list. But there is a column in `t1` named `a`, so the `ORDER BY` uses that, and the index can be used. (The resulting sort order may be completely different from the order for `ABS(a)`, of course.)

```
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

By default, MySQL sorts all `GROUP BY col1, col2, ...` queries as if you specified `ORDER BY col1, col2, ...` in the query as well. If you include an `ORDER BY` clause explicitly that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs. If a query includes `GROUP BY` but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying `ORDER BY NULL`. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```

Relying on implicit `GROUP BY` sorting in MySQL 5.6 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

With `EXPLAIN SELECT ... ORDER BY`, you can check whether MySQL can use indexes to resolve the query. It cannot if you see `Using filesort` in the `Extra` column. See [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#). `Filesort` uses a fixed-length row-storage format similar to that used by the `MEMORY` storage engine. Variable-length types such as `VARCHAR` are stored using a fixed length.

MySQL has two `filesort` algorithms for sorting and retrieving results. The original method uses only the `ORDER BY` columns. The modified method uses not just the `ORDER BY` columns, but all the columns used in the query.

The optimizer selects which `filesort` algorithm to use. It normally uses the modified algorithm except when `BLOB` or `TEXT` columns are involved, in which case it uses the original algorithm.

The original `filesort` algorithm works as follows:

1. Read all rows according to key or by table scanning. Rows that do not match the `WHERE` clause are skipped.
2. For each row, store a pair of values in a buffer (the sort key and the row pointer). The size of the buffer is the value of the `sort_buffer_size` [542] system variable.
3. When the buffer gets full, run a `qsort` (quicksort) on it and store the result in a temporary file. Save a pointer to the sorted block. (If all pairs fit into the sort buffer, no temporary file is created.)
4. Repeat the preceding steps until all rows have been read.
5. Do a multi-merge of up to `MERGEBUFF` (7) regions to one block in another temporary file. Repeat until all blocks from the first file are in the second file.
6. Repeat the following until there are fewer than `MERGEBUFF2` (15) blocks left.
7. On the last multi-merge, only the pointer to the row (the last part of the sort key) is written to a result file.
8. Read the rows in sorted order by using the row pointers in the result file. To optimize this, we read in a big block of row pointers, sort them, and use them to read the rows in sorted order into a row buffer. The size of the buffer is the value of the `read_rnd_buffer_size` [533] system variable. The code for this step is in the `sql/records.cc` source file.

One problem with this approach is that it reads rows twice: One time when evaluating the `WHERE` clause, and again after sorting the pair values. And even if the rows were accessed successively the first time (for example, if a table scan is done), the second time they are accessed randomly. (The sort keys are ordered, but the row positions are not.)

The modified `filesort` algorithm incorporates an optimization such that it records not only the sort key value and row position, but also the columns required for the query. This avoids reading the rows twice. The modified `filesort` algorithm works like this:

1. Read the rows that match the `WHERE` clause.
2. For each row, record a tuple of values consisting of the sort key value and row position, and also the columns required for the query.
3. Sort the tuples by sort key value

- Retrieve the rows in sorted order, but read the required columns directly from the sorted tuples rather than by accessing the table a second time.

Using the modified `filesort` algorithm, the tuples are longer than the pairs used in the original method, and fewer of them fit in the sort buffer (the size of which is given by `sort_buffer_size` [542]). As a result, it is possible for the extra I/O to make the modified approach slower, not faster. To avoid a slowdown, the optimization is used only if the total size of the extra columns in the sort tuple does not exceed the value of the `max_length_for_sort_data` [506] system variable. (A symptom of setting the value of this variable too high is a combination of high disk activity and low CPU activity.)

For slow queries for which `filesort` is not used, try lowering `max_length_for_sort_data` [506] to a value that is appropriate to trigger a `filesort`.

If you want to increase `ORDER BY` speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, you can try the following strategies:

- Increase the size of the `sort_buffer_size` [542] variable.
- Increase the size of the `read_rnd_buffer_size` [533] variable.
- Use less RAM per row by declaring columns only as large as they need to be to hold the values stored in them. For example, `CHAR(16)` is better than `CHAR(200)` if values never exceed 16 characters.
- Change `tmpdir` [559] to point to a dedicated file system with large amounts of free space. Also, this option accepts several paths that are used in round-robin fashion, so you can use this feature to spread the load across several directories. Paths should be separated by colon characters (":") on Unix and semicolon characters(";") on Windows. The paths should be for directories in file systems that are located on different *physical* disks, not different partitions on the same disk.

If an index is not used for `ORDER BY` but a `LIMIT` clause is also present, the optimizer may be able to avoid using a merge file and sort the rows in memory. For details, see [Section 8.2.1.3, "Optimizing LIMIT Queries"](#).

## 8.13.14. GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and to avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (for example, this is a `BTREE` index and not a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query through index access, as detailed in the following sections. In the first method, the grouping operation is applied together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

In MySQL, `GROUP BY` is used for sorting, so the server may also apply `ORDER BY` optimizations to grouping. See [Section 8.13.13, "ORDER BY Optimization"](#).

### 8.13.14.1. Loose Index Scan

The most efficient way to process `GROUP BY` is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, `BTREE`). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all `WHERE` conditions. This access method considers only

a fraction of the keys in an index, so it is called a *loose index scan*. When there is no `WHERE` clause, a loose index scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the `WHERE` clause contains range predicates (see the discussion of the [range \[899\]](#) join type in [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#)), a loose index scan looks up the first key of each group that satisfies the range conditions, and again reads the least possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The `GROUP BY` names only columns that form a leftmost prefix of the index and no other columns. (If, instead of `GROUP BY`, the query has a `DISTINCT` clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table `t1` has an index on `(c1, c2, c3)`, loose index scan is applicable if the query has `GROUP BY c1, c2,`. It is not applicable if the query has `GROUP BY c2, c3` (the columns are not a leftmost prefix) or `GROUP BY c1, c2, c4` (`c4` is not in the index).
- The only aggregate functions used in the select list (if any) are `MIN()` [1284] and `MAX()` [1284], and all of them refer to the same column. The column must be in the index and must follow the columns in the `GROUP BY`.
- Any other parts of the index than those from the `GROUP BY` referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of `MIN()` [1284] or `MAX()` [1284] functions.
- For columns in the index, full column values must be indexed, not just a prefix. For example, with `c1 VARCHAR(20)`, `INDEX (c1(10))`, the index cannot be used for loose index scan.

If loose index scan is applicable to a query, the `EXPLAIN` output shows `Using index for group-by` in the `Extra` column.

Assume that there is an index `idx(c1, c2, c3)` on table `t1(c1, c2, c3, c4)`. The loose index scan access method can be used for the following queries:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than `MIN()` [1284] or `MAX()` [1284]:

```
SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
```

- The columns in the `GROUP BY` clause do not form a leftmost prefix of the index:

```
SELECT c1, c2 FROM t1 GROUP BY c2, c3;
```

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant:

```
SELECT c1, c3 FROM t1 GROUP BY c1, c2;
```

Were the query to include `WHERE c3 = const`, loose index scan could be used.

The loose index scan access method can be applied to other forms of aggregate function references in the select list, in addition to the `MIN()` [1284] and `MAX()` [1284] references already supported:

- `AVG(DISTINCT)` [1282], `SUM(DISTINCT)` [1285], and `COUNT(DISTINCT)` [1283] are supported. `AVG(DISTINCT)` [1282] and `SUM(DISTINCT)` [1285] take a single argument. `COUNT(DISTINCT)` [1283] can have more than one column argument.

- There must be no `GROUP BY` or `DISTINCT` clause in the query.
- The loose scan limitations described earlier still apply.

Assume that there is an index `idx(c1, c2, c3)` on table `t1(c1, c2, c3, c4)`. The loose index scan access method can be used for the following queries:

```
SELECT COUNT(DISTINCT c1), SUM(DISTINCT c1) FROM t1;
SELECT COUNT(DISTINCT c1, c2), COUNT(DISTINCT c2, c1) FROM t1;
```

Loose index scan is not applicable for the following queries:

```
SELECT DISTINCT COUNT(DISTINCT c1) FROM t1;
SELECT COUNT(DISTINCT c1) FROM t1 GROUP BY c1;
```

### 8.13.14.2. Tight Index Scan

A tight index scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a loose index scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, we term it a *tight index scan*. With a tight index scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there is a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If we require sorting of the `GROUP BY` result, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index `idx(c1, c2, c3)` on table `t1(c1, c2, c3, c4)`. The following queries do not work with the loose index scan access method described earlier, but still work with the tight index scan access method.

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

```
SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

```
SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
```

### 8.13.15. DISTINCT Optimization

`DISTINCT` combined with `ORDER BY` needs a temporary table in many cases.

Because `DISTINCT` may use `GROUP BY`, learn how MySQL works with columns in `ORDER BY` or `HAVING` clauses that are not part of the selected columns. See [Section 12.17.3, “MySQL Extensions to GROUP BY”](#).

In most cases, a `DISTINCT` clause can be considered as a special case of `GROUP BY`. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;
```

```
SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see [Section 8.13.14, “GROUP BY Optimization”](#).

When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

## 8.13.16. Subquery Optimization

The MySQL query optimizer has different strategies available to evaluate subqueries. For `IN` (or `=ANY`) subqueries, the optimizer has these choices:

- Semi-join
- Materialization
- `EXISTS` strategy

For `NOT IN` (or `<>ANY`) subqueries, the optimizer has these choices:

- Materialization
- `EXISTS` strategy

The following sections provide more information about these optimization strategies.

### 8.13.16.1. Optimizing Subqueries with Semi-Join Transformations

As of MySQL 5.6.5, the optimizer uses semi-join strategies to improve subquery execution, as described in this section.

For an inner join between two tables, the join returns a row from one table as many times as there are matches in the other table. But for some questions, the only information that matters is whether there is a match, not the number of matches. Suppose that there are tables named `class` and `roster` that list classes in a course curriculum and class rosters (students enrolled in each class), respectively. To list the classes that actually have students enrolled, you could use this join:

```
SELECT class.class_num, class.class_name
FROM class INNER JOIN roster
WHERE class.class_num = roster.class_num;
```

However, the result lists each class once for each enrolled student. For the question being asked, this is unnecessary duplication of information.

Assuming that `class_num` is a primary key in the `class` table, duplicate suppression could be achieved by using `SELECT DISTINCT`, but it is inefficient to generate all matching rows first only to eliminate duplicates later.

The same duplicate-free result can be obtained by using a subquery:

```
SELECT class_num, class_name
FROM class
```

```
WHERE class_num IN (SELECT class_num FROM roster);
```

Here, the optimizer can recognize that the `IN` clause requires the subquery to return only one instance of each class number from the `roster` table. In this case, the query can be executed as a *semi-join*—that is, an operation that returns only one instance of each row in `class` that is matched by rows in `roster`.

Before MySQL 5.6.6, the outer query specification was limited to simple table scans or inner joins using comma syntax, and view references were not possible. As of 5.6.6, outer join and inner join syntax is permitted in the outer query specification, and the restriction that table references must be base tables has been lifted.

In MySQL, a subquery must satisfy these criteria to be handled as a semi-join:

- It must be an `IN` (or `=ANY`) subquery that appears at the top level of the `WHERE` or `ON` clause, possibly as a term in an `AND` expression. For example:

```
SELECT ...
FROM ot1, ...
WHERE (oe1, ...) IN (SELECT ie1, ... FROM it1, ... WHERE ...);
```

Here, `ot_i` and `it_i` represent tables in the outer and inner parts of the query, and `oe_i` and `ie_i` represent expressions that refer to columns in the outer and inner tables.

- It must be a single `SELECT` without `UNION` constructs.
- It must not contain a `GROUP BY` or `HAVING` clause or aggregate functions.
- It must not have `ORDER BY` with `LIMIT`.
- The number of outer and inner tables together must be less than the maximum number of tables permitted in a join.

The subquery may be correlated or uncorrelated. `DISTINCT` is permitted, as is `LIMIT` unless `ORDER BY` is also used.

If a subquery meets the preceding criteria, MySQL converts it to a semi-join and makes a cost-based choice from these strategies:

- Convert the subquery to a join, or use table pullout and run the query as an inner join between subquery tables and outer tables. Table pullout pulls a table out from the subquery to the outer query.
- Duplicate Weedout: Run the semi-join as if it was a join and remove duplicate records using a temporary table.
- FirstMatch: When scanning the inner tables for row combinations and there are multiple instances of a given value group, choose one rather than returning them all. This "shortcuts" scanning and eliminates production of unnecessary rows.
- LooseScan: Scan a subquery table using an index that enables a single value to be chosen from each subquery's value group.
- Materialize the subquery into a temporary table with an index and use the temporary table to perform a join. The index is used to remove duplicates. The index might also be used later for lookups when joining the temporary table with the outer tables; if not, the table is scanned.

Each of these strategies except Duplicate Weedout can be enabled or disabled using the `optimizer_switch` [520] system variable. The `semijoin` flag controls whether semi-joins are used. If it is set to `on`, the `firstmatch`, `loosescan`, and `materialization` flags enable finer control over the permitted semi-join strategies. These flags are `on` by default. See [Section 8.8.5.2, "Controlling Switchable Optimizations"](#).

The use of semi-join strategies is indicated in `EXPLAIN` output as follows:

- Semi-joined tables show up in the outer select. `EXPLAIN EXTENDED` plus `SHOW WARNINGS` shows the rewritten query, which displays the semi-join structure. From this you can get an idea about which tables were pulled out of the semi-join. If a subquery was converted to a semi-join, you will see that the subquery predicate is gone and its tables and `WHERE` clause were merged into the outer query join list and `WHERE` clause.
- Temporary table use for Duplicate Weedout is indicated by `Start temporary` and `End temporary` in the `Extra` column. Tables that were not pulled out and are in the range of `EXPLAIN` output rows covered by `Start temporary` and `End temporary` will have their `rowid` in the temporary table.
- `FirstMatch(tbl_name)` in the `Extra` column indicates join shortcutting.
- `LooseScan(m..n)` in the `Extra` column indicates use of the LooseScan strategy. `m` and `n` are key part numbers.
- As of MySQL 5.6.7, temporary table use for materialization is indicated by rows with a `select_type` value of `MATERIALIZED` and rows with a `table` value of `<subqueryN>`.

Before MySQL 5.6.7, temporary table use for materialization is indicated in the `Extra` column by `Materialize` if a single table is used, or by `Start materialize` and `End materialize` if multiple tables are used. If `Scan` is present, no temporary table index is used for table reads. Otherwise, an index lookup is used.

### 8.13.16.2. Optimizing Subqueries with Subquery Materialization

As of MySQL 5.6.5, the optimizer uses subquery materialization as a strategy that enables more efficient subquery processing.

If materialization is not used, the optimizer sometimes rewrites a noncorrelated subquery as a correlated subquery. For example, the following `IN` subquery is noncorrelated (`where_condition` involves only columns from `t2` and not `t1`):

```
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

The optimizer might rewrite this as an `EXISTS` correlated subquery:

```
SELECT * FROM t1
WHERE EXISTS (SELECT t2.b FROM t2 WHERE where_condition AND t1.a=t2.b);
```

Subquery materialization using a temporary table avoids such rewrites and makes it possible to execute the subquery only once rather than once per row of the outer query. Materialization speeds up query execution by generating a subquery result as a temporary table, normally in memory. The first time MySQL needs the subquery result, it materializes that result into a temporary table. Any subsequent time the result is needed, MySQL refers again to the temporary table. The table is indexed with a hash index to make lookups fast and inexpensive. The index is unique, which makes the table smaller because it has no duplicates.

Subquery materialization attempts to use an in-memory temporary table when possible, falling back to on-disk storage if the table becomes too large. See [Section 8.4.3.3, “How MySQL Uses Internal Temporary Tables”](#).

For subquery materialization to be used in MySQL, the `materialization` flag of the `optimizer_switch` [520] system variable must be `on`. Materialization then applies to subquery predicates that appear anywhere (in the select list, `WHERE`, `ON`, `GROUP BY`, `HAVING`, or `ORDER BY`), for predicates that fall into any of these use cases:

- The predicate has this form, when no outer expression `oe_i` or inner expression `ie_i` is nullable. `N` can be 1 or larger.

```
(oe_1, oe_2, ..., oe_N) [NOT] IN (SELECT ie_1, ie_2, ..., ie_N ...)
```

- The predicate has this form, when there is a single outer expression *oe* and inner expression *ie*. The expressions can be nullable.

```
oe [NOT] IN (SELECT ie ...)
```

- The predicate is `IN` or `NOT IN` and a result of `UNKNOWN (NULL)` has the same meaning as a result of `FALSE`.

The following examples illustrate how the requirement for equivalence of `UNKNOWN` and `FALSE` predicate evaluation affects whether subquery materialization can be used. Assume that *where\_condition* involves columns only from *t2* and not *t1* so that the subquery is noncorrelated.

This query is subject to materialization:

```
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

Here, it does not matter whether the `IN` predicate returns `UNKNOWN` or `FALSE`. Either way, the row from *t1* is not included in the query result.

An example where subquery materialization will not be used is the following query, where *t2.b* is a nullable column.

```
SELECT * FROM t1
WHERE (t1.a,t1.b) NOT IN (SELECT t2.a,t2.b FROM t2
                        WHERE where_condition);
```

Use of `EXPLAIN` with a query can give some indication of whether the optimizer uses subquery materialization. Compared to query execution that does not use materialization, *select\_type* may change from `DEPENDENT SUBQUERY` to `SUBQUERY`. This indicates that, for a subquery that would be executed once per outer row, materialization enables the subquery to be executed just once. In addition, for `EXPLAIN EXTENDED`, the text displayed by a following `SHOW WARNINGS` will include `materialize materialize` and `materialized-subquery (materialized subselect` before MySQL 5.6.6).

### 8.13.16.3. Optimizing Subqueries in the `FROM` Clause (Derived Tables)

As of MySQL 5.6.3, the optimizer more efficiently handles subqueries in the `FROM` clause (that is, derived tables):

- Materialization of subqueries in the `FROM` clause is postponed until their contents are needed during query execution, which improves performance:
  - Previously, subqueries in the `FROM` clause were materialized for `EXPLAIN SELECT` statements. This resulted in partial `SELECT` execution, even though the purpose of `EXPLAIN` is to obtain query plan information, not to execute the query. This materialization no longer occurs, so `EXPLAIN` is faster for such queries.
  - For non-`EXPLAIN` queries, delay of materialization may result in not having to do it at all. Consider a query that joins the result of a subquery in the `FROM` clause to another table: If the optimizer processes that other table first and finds that it returns no rows, the join need not be carried out further and the optimizer can completely skip materializing the subquery.
- During query execution, the optimizer may add an index to a derived table to speed up row retrieval from it.

Consider the following `EXPLAIN` statement, for which a subquery appears in the `FROM` clause of a `SELECT` query:

```
EXPLAIN SELECT * FROM (SELECT * FROM t1);
```

The optimizer avoids materializing the subquery by delaying it until the result is needed during `SELECT` execution. In this case, the query is not executed, so the result is never needed.

Even for queries that are executed, delay of subquery materialization may permit the optimizer to avoid materialization entirely. Consider the following query, which joins the result of a subquery in the `FROM` clause to another table:

```
SELECT * FROM t1
JOIN (SELECT t2.f1 FROM t2) AS derived_t2 ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

If the optimization processes `t1` first and the `WHERE` clause produces an empty result, the join must necessarily be empty and the subquery need not be materialized.

In the worst case (derived tables are materialized), query execution will take the same time as before MySQL 5.6.3 because no additional work is done. In the best case (derived tables are not materialized), query execution will be quicker by the time needed to perform materialization.

For cases when materialization is required for a subquery in the `FROM` clause, the optimizer may speed up access to the result by adding an index to the materialized table. If such an index would permit [ref \[898\]](#) access to the table, it can greatly reduce amount of data that must be read during query execution. Consider the following query:

```
SELECT * FROM t1
JOIN (SELECT * FROM t2) AS derived_t2 ON t1.f1=derived_t2.f1;
```

The optimizer constructs an index over column `f1` from `derived_t2` if doing so would permit the use of [ref \[898\]](#) access for the lowest cost execution plan. After adding the index, the optimizer can treat the materialized derived table the same as a usual table with an index, and it benefits similarly from the generated index. The overhead of index creation is negligible compared to the cost of query execution without the index. If [ref \[898\]](#) access would result in higher cost than some other access method, no index is created and the optimizer loses nothing.

#### 8.13.16.4. Optimizing Subqueries with `EXISTS` Strategy

Certain optimizations are applicable to comparisons that use the `IN` operator to test subquery results (or that use `=ANY`, which is equivalent). This section discusses these optimizations, particularly with regard to the challenges that `NULL` values present. The last part of the discussion includes suggestions on what you can do to help the optimizer.

Consider the following subquery comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression `outer_expr`, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression `inner_expr` is equal to `outer_expr`. This is done by pushing down an appropriate equality into the subquery's `WHERE` clause. That is, the comparison is converted to this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

After the conversion, MySQL can use the pushed-down equality to limit the number of rows that it must examine when evaluating the subquery.

More generally, a comparison of `N` values to a subquery that returns `N`-value rows is subject to the same conversion. If `oe_i` and `ie_i` represent corresponding outer and inner expression values, this subquery comparison:

```
(oe_1, ..., oe_N) IN
(SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

Becomes:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
      AND oe_1 = ie_1
      AND ...
      AND oe_N = ie_N)
```

The following discussion assumes a single pair of outer and inner expression values for simplicity.

The conversion just described has its limitations. It is valid only if we ignore possible `NULL` values. That is, the “pushdown” strategy works as long as both of these two conditions are true:

- `outer_expr` and `inner_expr` cannot be `NULL`.
- You do not need to distinguish `NULL` from `FALSE` subquery results. (If the subquery is a part of an `OR` [1172] or `AND` [1171] expression in the `WHERE` clause, MySQL assumes that you do not care.)

When either or both of those conditions do not hold, optimization is more complex.

Suppose that `outer_expr` is known to be a non-`NULL` value but the subquery does not produce a row such that `outer_expr = inner_expr`. Then `outer_expr IN (SELECT ...)` evaluates as follows:

- `NULL`, if the `SELECT` produces any row where `inner_expr` is `NULL`
- `FALSE`, if the `SELECT` produces only non-`NULL` values or produces nothing

In this situation, the approach of looking for rows with `outer_expr = inner_expr` is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where `inner_expr` is `NULL`. Roughly speaking, the subquery can be converted to:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND
      (outer_expr=inner_expr OR inner_expr IS NULL))
```

The need to evaluate the extra `IS NULL` [1168] condition is why MySQL has the `ref_or_null` [899] access method:

```
mysql> EXPLAIN
-> SELECT outer_expr IN (SELECT t2.maybe_null_key
->                        FROM t2, t3 WHERE ...)
-> FROM t1;
***** 1. row *****
      id: 1
      select_type: PRIMARY
      table: t1
...
***** 2. row *****
      id: 2
      select_type: DEPENDENT SUBQUERY
      table: t2
      type: ref_or_null
possible_keys: maybe_null_key
      key: maybe_null_key
      key_len: 5
      ref: func
      rows: 2
      Extra: Using where; Using index
...

```

The `unique_subquery` [899] and `index_subquery` [899] subquery-specific access methods also have “or `NULL`” variants. However, they are not visible in `EXPLAIN` output, so you must use `EXPLAIN EXTENDED` followed by `SHOW WARNINGS` (note the `checking NULL` in the warning message):

```
mysql> EXPLAIN EXTENDED
-> SELECT outer_expr IN (SELECT maybe_null_key FROM t2) FROM t1\G
***** 1. row *****
      id: 1

```

```

select_type: PRIMARY
table: t1
...
***** 2. row *****
      id: 2
select_type: DEPENDENT SUBQUERY
table: t2
type: index_subquery
possible_keys: maybe_null_key
key: maybe_null_key
key_len: 5
ref: func
rows: 2
Extra: Using index

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: select (`test`.`t1`.`outer_expr`,
              ((`test`.`t1`.`outer_expr`) in t2 on
              maybe_null_key checking NULL)) AS `outer_expr` IN (SELECT
              maybe_null_key FROM t2)` from `test`.`t1`

```

The additional `OR ... IS NULL` condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when `outer_expr` can be `NULL`. According to the SQL interpretation of `NULL` as “unknown value,” `NULL IN (SELECT inner_expr ...)` should evaluate to:

- `NULL`, if the `SELECT` produces any rows
- `FALSE`, if the `SELECT` produces no rows

For proper evaluation, it is necessary to be able to check whether the `SELECT` has produced any rows at all, so `outer_expr = inner_expr` cannot be pushed down into the subquery. This is a problem, because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of `outer_expr`.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that `outer_expr` might be `NULL`.

If `outer_expr` is `NULL`, to evaluate the following expression, it is necessary to run the `SELECT` to determine whether it produces any rows:

```
NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

It is necessary to run the original `SELECT` here, without any pushed-down equalities of the kind mentioned earlier.

On the other hand, when `outer_expr` is not `NULL`, it is absolutely essential that this comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

be converted to this expression that uses a pushed-down condition:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

Without this conversion, subqueries will be slow. To solve the dilemma of whether to push down or not push down conditions into the subquery, the conditions are wrapped in “trigger” functions. Thus, an expression of the following form:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

is converted into:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
      AND trigcond(outer_expr=inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

and converts it to this expression:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
      AND trigcond(oe_1=ie_1)
      AND ...
      AND trigcond(oe_N=ie_N)
    )
```

Each `trigcond(X)` is a special function that evaluates to the following values:

- `X` when the “linked” outer expression `oe_i` is not `NULL`
- `TRUE` when the “linked” outer expression `oe_i` is `NULL`

Note that trigger functions are *not* triggers of the kind that you create with `CREATE TRIGGER`.

Equalities that are wrapped into `trigcond()` functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any `trigcond(X)` to be an unknown function and ignore it. At the moment, triggered equalities can be used by those optimizations:

- Reference optimizations: `trigcond(X=Y [OR Y IS NULL])` can be used to construct `ref` [898], `eq_ref` [898], or `ref_or_null` [899] table accesses.
- Index lookup-based subquery execution engines: `trigcond(X=Y)` can be used to construct `unique_subquery` [899] or `index_subquery` [899] accesses.
- Table-condition generator: If the subquery is a join of several tables, the triggered condition will be checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In `EXPLAIN` output, the fallback shows up as `Full scan on NULL key` in the `Extra` column:

```
mysql> EXPLAIN SELECT t1.col1,
-> t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1\G
***** 1. row *****
      id: 1
      select_type: PRIMARY
      table: t1
      ...
***** 2. row *****
      id: 2
      select_type: DEPENDENT SUBQUERY
      table: t2
      type: index_subquery
possible_keys: key1
      key: key1
      key_len: 5
      ref: func
      rows: 2
      Extra: Using where; Full scan on NULL key
```

If you run `EXPLAIN EXTENDED` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
***** 1. row *****
Level: Note
Code: 1003
```

```

Message: select `test`.`t1`.`col1` AS `col1`,
<in_optimizer>(`test`.`t1`.`col1`,
<exists>(<index_lookup>(<cache>(`test`.`t1`.`col1`) in t2
on key1 checking NULL
where (`test`.`t2`.`col2` = `test`.`t1`.`col2`) having
trigcond(<is_not_null_test>(`test`.`t2`.`key1`)))) AS
`t1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)`
from `test`.`t1`

```

The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy was to improve compliance and not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` will be particularly slow because the join optimizer does not optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these tips:

- Declare a column as `NOT NULL` if it really is. (This also helps other aspects of the optimizer by simplifying condition testing for the column.)
- If you do not need to distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

```
outer_expr IN (SELECT inner_expr FROM ...)
```

with this expression:

```
(outer_expr IS NOT NULL) AND (outer_expr IN (SELECT inner_expr FROM ...))
```

Then `NULL IN (SELECT ...)` will never be evaluated because MySQL stops evaluating `AND [1171]` parts as soon as the expression result is clear.

The `subquery_materialization_cost_based` enables control over the choice between subquery materialization and `IN -> EXISTS` subquery transformation. See [Section 8.8.5.2, "Controlling Switchable Optimizations"](#).

This chapter discusses the rules for writing the following elements of [SQL](#) statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Reserved words
- User-defined and system variables
- Comments

## 9.1. Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal values, boolean values, and `NULL`. The section also covers the various nuances and “gotchas” that you may run into when dealing with these basic types in MySQL.

### 9.1.1. String Literals

A string is a sequence of bytes or characters, enclosed within either single quote (“’”) or double quote (“””) characters. Examples:

```
'a string'
"another string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
```

If the [ANSI\\_QUOTES \[603\]](#) SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A *binary string* is a string of bytes that has no character set or collation. A *nonbinary string* is a string of characters that has a character set and collation. For both types of strings, comparisons are based on

the numeric values of the string unit. For binary strings, the unit is the byte. For nonbinary strings the unit is the character and some character sets support multi-byte characters. Character value ordering is a function of the string collation.

String literals may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For more information about these forms of string syntax, see [Section 10.1.3.5, “Character String Literal Character Set and Collation”](#), and [Section 10.1.3.6, “National Character Set”](#).

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` [604] SQL mode is enabled. Each of these sequences begins with a backslash (“\”), known as the *escape character*. MySQL recognizes the escape sequences shown in [Table 9.1, “Special Character Escape Sequences”](#). For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, “\x” is just “x”. These sequences are case sensitive. For example, “\b” is interpreted as a backspace, but “\B” is interpreted as “B”. Escape processing is done according to the character set indicated by the `character_set_connection` [467] system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in [Section 10.1.3.5, “Character String Literal Character Set and Collation”](#).

**Table 9.1. Special Character Escape Sequences**

Escape Sequence	Character Represented by Sequence
\0	An ASCII NUL (0x00) character.
\'	A single quote (“'”) character.
\"	A double quote (“””) character.
\b	A backspace character.
\n	A newline (linefeed) character.
\r	A carriage return character.
\t	A tab character.
\z	ASCII 26 (Control+Z). See note following the table.
\\	A backslash (“\”) character.
\%	A “%” character. See note following the table.
\_	A “_” character. See note following the table.

The ASCII 26 character can be encoded as “\z” to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The “\%” and “\\_” sequences are used to search for literal instances of “%” and “\_” in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the `LIKE` [1190] operator in [Section 12.5.1, “String Comparison Functions”](#). If you use “\%” or “\\_” outside of pattern-matching contexts, they evaluate to the strings “\%” and “\\_”, not to “%” and “\_”.

There are several ways to include quote characters within a string:

- A “'” inside a string quoted with “'” may be written as “''”.
- A “”” inside a string quoted with “”” may be written as “"""”.
- Precede the quote character by an escape character (“\”).
- A “'” inside a string quoted with “”” needs no special treatment and need not be doubled or escaped. In the same way, “”” inside a string quoted with “'” needs no special treatment.

The following `SELECT` statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', '"hello"', '"hello"', 'hel'lo', '\hello';
+-----+-----+-----+-----+-----+
| hello | "hello" | '"hello"' | hel'lo | \hello |
+-----+-----+-----+-----+-----+

mysql> SELECT "hello", "'hello'", "'hello'", "hel"lo", "\"hello";
+-----+-----+-----+-----+-----+
| hello | 'hello' | "'hello'" | hel"lo | "\"hello" |
+-----+-----+-----+-----+-----+

mysql> SELECT 'This\nIs\nFour\nLines';
+-----+
| This
| Is
| Four
| Lines |
+-----+

mysql> SELECT 'disappearing\ backslash';
+-----+
| disappearing backslash |
+-----+
```

If you want to insert binary data into a string column (such as a `BLOB` column), you should represent certain characters by escape sequences. Backslash (“\”) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape `NUL` or Control+Z. The `mysql` client truncates quoted strings containing `NUL` characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see [Table 9.1, “Special Character Escape Sequences”](#).

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string()` C API function to escape characters. See [Section 21.8.6.54, “mysql\\_real\\_escape\\_string\(\)”](#). Within SQL statements that construct other SQL statements, you can use the `QUOTE()` [1183] function. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See [Section 21.10, “MySQL Perl API”](#). Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

## 9.1.2. Number Literals

Integers are represented as a sequence of digits. Floats use “.” as a decimal separator. Either type of number may be preceded by “-” or “+” to indicate a negative or positive value, respectively

Examples of valid integers:

```
1221
```

```
0
-32
```

Examples of valid floating-point numbers:

```
294.42
-32032.6809e+10
148.00
```

An integer may be used in a floating-point context; it is interpreted as the equivalent floating-point number.

### 9.1.3. Date and Time Literals

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of '2015-07-21', '20150721', and 20150721 as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, consult these sections:

- [Section 11.1.2, “Date and Time Type Overview”](#)
- [Section 11.3, “Date and Time Types”](#)

**Standard SQL and ODBC Date and Time Literals.** Standard SQL permits temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes those constructions and also the corresponding ODBC syntax:

```
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

Before MySQL 5.6.4, MySQL ignores the type keyword and each of the preceding constructions produces the string value 'str', with a type of `VARCHAR`.

As of 5.6.4, MySQL uses the type keyword and these constructions produce `DATE`, `TIME`, and `DATETIME` values, respectively, including a trailing fractional seconds part if specified. The `TIMESTAMP` syntax produces a `DATETIME` value in MySQL because `DATETIME` has a range that more closely corresponds to the standard SQL `TIMESTAMP` type, which has a year range from 0001 to 9999. (The MySQL `TIMESTAMP` year range is 1970 to 2038.)

**String and Numeric Literals in Date and Time Context.** MySQL recognizes `DATE` values in these formats:

- As a string in either 'YYYY-MM-DD' or 'YY-MM-DD' format. A “relaxed” syntax is permitted: Any punctuation character may be used as the delimiter between date parts. For example, '2012-12-31', '2012/12/31', '2012^12^31', and '2012@12@31' are equivalent.
- As a string with no delimiters in either 'YYYYMMDD' or 'YYMMDD' format, provided that the string makes sense as a date. For example, '20070523' and '070523' are interpreted as '2007-05-23', but '071332' is illegal (it has nonsensical month and day parts) and becomes '0000-00-00'.
- As a number in either YYYYMMDD or YYMMDD format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as '1983-09-05'.

MySQL recognizes `DATETIME` and `TIMESTAMP` values in these formats:

- As a string in either 'YYYY-MM-DD HH:MM:SS' or 'YY-MM-DD HH:MM:SS' format. A “relaxed” syntax is permitted here, too: Any punctuation character may be used as the delimiter between

date parts or time parts. For example, `'2012-12-31 11:30:45'`, `'2012^12^31 11+30+45'`, `'2012/12/31 11*30*45'`, and `'2012@12@31 11^30^45'` are equivalent.

- As a string with no delimiters in either `'YYYYMMDDHHMMSS'` or `'YYMMDDHHMMSS'` format, provided that the string makes sense as a date. For example, `'20070523091528'` and `'070523091528'` are interpreted as `'2007-05-23 09:15:28'`, but `'071122129015'` is illegal (it has a nonsensical minute part) and becomes `'0000-00-00 00:00:00'`.
- As a number in either `YYYYMMDDHHMMSS` or `YYMMDDHHMMSS` format, provided that the number makes sense as a date. For example, `19830905132800` and `830905132800` are interpreted as `'1983-09-05 13:28:00'`.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. For information about fractional seconds support in MySQL, see [Section 11.3.6, “Fractional Seconds in Time Values”](#).

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

- Year values in the range `70-99` are converted to `1970-1999`.
- Year values in the range `00-69` are converted to `2000-2069`.

See also [Section 11.3.8, “Two-Digit Years in Dates”](#).

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. `'2015-6-9'` is the same as `'2015-06-09'`. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. `'2015-10-30 1:2:3'` is the same as `'2015-10-30 01:02:03'`.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYMMDD` or `YYYYMMDDHHMMSS` format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in `YYMMDD` or `YYMMDDHHMMSS` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify `'9903'`, thinking that represents March, 1999, MySQL converts it to the “zero” date value. This occurs because the year and month values are `99` and `03`, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value `'1999-03-00'`, use `'990300'`.

MySQL recognizes `TIME` values in these formats:

- As a string in `'D HH:MM:SS'` format. You can also use one of the following “relaxed” syntaxes: `'HH:MM:SS'`, `'HH:MM'`, `'D HH:MM'`, `'D HH'`, or `'SS'`. Here `D` represents days and can have a value from 0 to 34.
- As a string with no delimiters in `'HHMMSS'` format, provided that it makes sense as a time. For example, `'101112'` is understood as `'10:11:12'`, but `'109712'` is illegal (it has a nonsensical minute part) and becomes `'00:00:00'`.
- As a number in `HHMMSS` format, provided that it makes sense as a time. For example, `101112` is understood as `'10:11:12'`. The following alternative formats are also understood: `SS`, `MMSS`, or `HHMMSS`.

A trailing fractional seconds part is recognized in the `'D HH:MM:SS.fraction'`, `'HH:MM:SS.fraction'`, `'HHMMSS.fraction'`, and `HHMMSS.fraction` time formats, where

`fraction` is the fractional part in up to microseconds (6 digits) precision. For information about fractional seconds support in MySQL, see [Section 11.3.6, “Fractional Seconds in Time Values”](#).

For `TIME` values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. `'8:3:2'` is the same as `'08:03:02'`.

## 9.1.4. Hexadecimal Literals

MySQL supports hexadecimal values, written using `X'val'`, `x'val'`, or `0xval` format, where `val` contains hexadecimal digits (`0..9, A..F`). Lettercase of the digits does not matter. For values written using `X'val'` or `x'val'` format, `val` must contain an even number of digits. For values written using `0xval` syntax, values that contain an odd number of digits are treated as having an extra leading 0. For example, `0x0a` and `0xaaa` are interpreted as `0x0a` and `0x0aaa`.

In numeric contexts, hexadecimal values act like integers (64-bit precision). In string contexts, they act like binary strings, where each pair of hex digits is converted to a character:

```
mysql> SELECT X'4D7953514C';
      -> 'MySQL'
mysql> SELECT 0x0a+0;
      -> 10
mysql> SELECT 0x5061756c;
      -> 'Paul'
```

The default type of a hexadecimal value is a string. If you want to ensure that the value is treated as a number, you can use `CAST(... AS UNSIGNED)` [\[1245\]](#):

```
mysql> SELECT 0x41, CAST(0x41 AS UNSIGNED);
      -> 'A', 65
```

The `X'hexstring'` syntax is based on standard SQL. The `0x` syntax is based on ODBC. Hexadecimal strings are often used by ODBC to supply values for `BLOB` columns.

You can convert a string or a number to a string in hexadecimal format with the `HEX()` [\[1180\]](#) function:

```
mysql> SELECT HEX('cat');
      -> '636174'
mysql> SELECT 0x636174;
      -> 'cat'
```

## 9.1.5. Boolean Literals

The constants `TRUE` and `FALSE` evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
      -> 1, 1, 0, 0
```

## 9.1.6. Bit-Field Literals

Bit-field values can be written using `b'value'` or `0bvalue` notation. `value` is a binary value written using zeros and ones.

Bit-field notation is convenient for specifying values to be assigned to `BIT` columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values are returned as binary values. To display them in printable form, add 0 or use a conversion function such as `BIN()` [\[1177\]](#). High-order 0 bits are not displayed in the converted value.

```
mysql> SELECT b+0, BIN(b+0), OCT(b+0), HEX(b+0) FROM t;
```

b+0	BIN(b+0)	OCT(b+0)	HEX(b+0)
255	11111111	377	FF
10	1010	12	A
5	101	5	5

Bit values assigned to user variables are treated as binary strings. To assign a bit value as a number to a user variable, use `CAST( ) [1245]` or `+0`:

```
mysql> SET @v1 = 0b1000001;
mysql> SET @v2 = CAST(0b1000001 AS UNSIGNED), @v3 = 0b1000001+0;
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A | 65 | 65 |
+-----+-----+-----+
```

### 9.1.7. NULL Values

The `NULL` value means “no data.” `NULL` can be written in any lettercase. A synonym is `\N` (case sensitive).

For text file import or export operations performed with `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

Be aware that the `NULL` value is different from values such as `0` for numeric types or the empty string for string types. For more information, see [Section C.5.5.3, “Problems with NULL Values”](#).

## 9.2. Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. [Section 9.2.2, “Identifier Case Sensitivity”](#), describes which types of identifiers are case sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you *must* quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at [Section 9.3, “Reserved Words”](#).

Identifiers are converted to Unicode internally. They may contain these characters:

- Permitted characters in unquoted identifiers:
  - ASCII: [0-9,a-z,A-Z\$\_] (basic Latin letters, digits 0-9, dollar, underscore)
  - Extended: U+0080 .. U+FFFF
- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
  - ASCII: U+0001 .. U+007F
  - Extended: U+0080 .. U+FFFF
- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.
- Identifiers may begin with a digit but unless quoted may not consist solely of digits.
- Database, table, and column names cannot end with space characters.

The identifier quote character is the backtick (“`”):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the [ANSI\\_QUOTES \[603\]](#) SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The [ANSI\\_QUOTES \[603\]](#) mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in [Section 5.1.7, “Server SQL Modes”](#).

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b` that contains a column named `c"d`:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
| one | two |
+-----+-----+
| 1 | 2 |
+-----+-----+
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with *Me* or *MeN*, where *M* and *N* are integers. For example, avoid using `1e` as an identifier, because an expression such as `1e+3` is ambiguous. Depending on context, it might be interpreted as the expression `1e + 3` or as the number `1e+3`.

Be careful when using `MD5()` [\[1263\]](#) to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See [Section 9.4, “User-Defined Variables”](#), for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#). If you have databases or tables from an older version of MySQL that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#`. For information about referring to such names or converting them to the newer encoding, see that section.

The following table describes the maximum length for each type of identifier.

Identifier	Maximum Length (characters)
Database	64
Table	64
Column	64
Index	64
Constraint	64

Identifier	Maximum Length (characters)
Stored Procedure or Function	64
Trigger	64
View	64
Event	64
Tablespace	64
Server	64
Log File Group	64
Alias	256 (see exception following table)
Compound Statement Label	16

Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that are stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multi-byte characters without reducing the number of characters permitted for values stored in these columns, something not true prior to MySQL 4.1. As indicated earlier, the permissible Unicode characters are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted.

### 9.2.1. Identifier Qualifiers

MySQL permits names that consist of a single identifier or multiple identifiers. The components of a multiple-part name must be separated by period (“.”) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which the final identifier is interpreted.

In MySQL, you can refer to a table column using any of the following forms.

Column Reference	Meaning
<code>col_name</code>	The column <code>col_name</code> from whichever table used in the statement contains a column of that name.
<code>tbl_name.col_name</code>	The column <code>col_name</code> from table <code>tbl_name</code> of the default database.
<code>db_name.tbl_name.col_name</code>	The column <code>col_name</code> from table <code>tbl_name</code> of the database <code>db_name</code> .

The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.

If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write ``my-table`.`my-column``, not ``my-table.my-column``.

A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference in a statement unless the reference would be ambiguous. Suppose that tables `t1` and `t2` each contain a column `c`, and you retrieve `c` in a `SELECT` statement that uses both `t1` and `t2`. In this case, `c` is ambiguous because it is not unique among the tables used in the statement. You must qualify it with a table name as `t1.c` or `t2.c` to indicate which table you mean. Similarly, to retrieve from a table `t` in database `db1` and from a table `t` in database `db2` in the same statement, you must refer to columns in those tables as `db1.t.col_name` and `db2.t.col_name`.

The syntax `.tbl_name` means the table `tbl_name` in the default database. This syntax is accepted for ODBC compatibility because some ODBC programs prefix table names with a “.” character.

## 9.2.2. Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case sensitive in Windows, but are case sensitive in most varieties of Unix. One notable exception is Mac OS X, which is Unix-based but uses a default file system type (HFS+) that is not case sensitive. However, Mac OS X also supports UFS volumes, which are case sensitive just as on any Unix. See [Section 1.8.4, “MySQL Extensions to Standard SQL”](#). The `lower_case_table_names` [501] system variable also affects how the server handles identifier case sensitivity, as described later in this section.

### Note

Although database, table, and trigger names are not case sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, and event names are not case sensitive on any platform, nor are column aliases.

However, names of logfile groups are case sensitive. This differs from standard SQL.

By default, table aliases are case sensitive on Unix, but not so on Windows or Mac OS X. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
-> WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` [501] system variable, which you can set when starting `mysqld`. `lower_case_table_names` [501] can take the values shown in the following table. This variable does *not* affect case sensitivity of trigger identifiers. On Unix, the default value of `lower_case_table_names` [501] is 0. On Windows the default value is 1. On Mac OS X, the default value is 2.

Value	Meaning
0	Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case sensitive. You should <i>not</i> set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or Mac OS X). If you force this variable to 0 with <code>--lower-case-table-names=0</code> [501] on a case-insensitive file system and access <code>MyISAM</code> tablename using different lettercases, index corruption may result.
1	Table names are stored in lowercase on disk and name comparisons are not case sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.
2	Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. This works <i>only</i> on file systems that are not case sensitive! <code>InnoDB</code> table names are stored in lowercase, as for <code>lower_case_table_names=1</code> .

If you are using MySQL on only one platform, you do not normally have to change the `lower_case_table_names` [501] variable from its default value. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- Use `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.
- Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

**Exception:** If you are using InnoDB tables and you are trying to avoid these data transfer problems, you should set `lower_case_table_names` [501] to 1 on all platforms to force names to be converted to lowercase.

If you plan to set the `lower_case_table_names` [501] system variable to 1 on Unix, you must first convert your old database and table names to lowercase before stopping `mysqld` and restarting it with the new variable setting. To do this for an individual table, use `RENAME TABLE`:

```
RENAME TABLE T1 TO t1;
```

To convert one or more entire databases, dump them before setting `lower_case_table_names` [501], then drop the databases, and reload them after setting `lower_case_table_names` [501]:

1. Use `mysqldump` to dump each database:

```
mysqldump --databases db1 > db1.sql
mysqldump --databases db2 > db2.sql
...
```

Do this for each database that must be recreated.

2. Use `DROP DATABASE` to drop each database.
3. Stop the server, set `lower_case_table_names` [501], and restart the server.
4. Reload the dump file for each database. Because `lower_case_table_names` [501] is set, each database and table name will be converted to lowercase as it is recreated:

```
mysql < db1.sql
mysql < db2.sql
...
```

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see [Section 10.1.7.9, “Collation and INFORMATION\\_SCHEMA Searches”](#).

### 9.2.3. Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and each table by one or more files in the appropriate database directory. For the table format files (`.FRM`), the data is always stored in this structure and location.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the same location as the [FRM](#) files, or the information may be stored in a separate file. [InnoDB](#) data is stored in the InnoDB data files. If you are using tablespaces with [InnoDB](#), then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NUL (0x00). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters ([a..zA..Z](#)), digits ([0..9](#)) and underscore ([\\_](#)) are encoded as is. Consequently, their case sensitivity directly depends on file system features.
- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

Code Range	Pattern	Number	Used	Unused	Blocks
00C0..017F	[@][0..4][g..z]	5*20= 100	97	3	Latin-1 Supplement + Latin Extended-A
0370..03FF	[@][5..9][g..z]	5*20= 100	88	12	Greek and Coptic
0400..052F	[@][g..z][0..6]	20*7= 140	137	3	Cyrillic + Cyrillic Supplement
0530..058F	[@][g..z][7..8]	20*2= 40	38	2	Armenian
2160..217F	[@][g..z][9]	20*1= 20	16	4	Number Forms
0180..02AF	[@][g..z][a..k]	20*11=220	203	17	Latin Extended-B + IPA Extensions
1E00..1EFF	[@][g..z][l..r]	20*7= 140	136	4	Latin Extended Additional
1F00..1FFF	[@][g..z][s..z]	20*8= 160	144	16	Greek Extended
.... ....	[@][a..f][g..z]	6*20= 120	0	120	RESERVED
24B6..24E9	[@][@][a..z]	26	26	0	Enclosed Alphanumerics
FF21..FF5A	[@][a..z][@]	26	26	0	Halfwidth and Fullwidth forms

One of the bytes in the sequence encodes lettercase. For example: [LATIN CAPITAL LETTER A WITH GRAVE](#) is encoded as @0G, whereas [LATIN SMALL LETTER A WITH GRAVE](#) is encoded as @0g. Here the third byte (G or g) indicates lettercase. (On a case-insensitive file system, both letters will be treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore ([\\_](#)), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hex digits [a..f](#):

```
0x003F -> @003f
0xFFFF -> @ffff
```

The hexadecimal values correspond to character values in the [ucs2](#) double-byte character set.

On Windows, some names such as [nul](#), [prn](#), and [aux](#) are encoded by appending @@@ to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

If you have databases or tables from a version of MySQL older than 5.1.6 that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#` in the output from `INFORMATION_SCHEMA` tables or `SHOW` statements. For example, if you have a table named `a@b` and its name encoding has not been updated, `SHOW TABLES` displays it like this:

```
mysql> SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| #mysql50#a@b   |
+-----+
```

To refer to such a name for which the encoding has not been updated, you must supply the `#mysql50#` prefix:

```
mysql> SHOW COLUMNS FROM `a@b`;
ERROR 1146 (42S02): Table 'test.a@b' doesn't exist

mysql> SHOW COLUMNS FROM `#mysql50#a@b`;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| i     | int(11)| YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

To update old names to eliminate the need to use the special prefix to refer to them, re-encode them with `mysqlcheck`. The following command updates all names to the new encoding:

```
shell> mysqlcheck --check-upgrade --fix-db-names --fix-table-names --all-databases
```

To check only specific databases or tables, omit `--all-databases` [276] and provide the appropriate database or table arguments. For information about `mysqlcheck` invocation syntax, see [Section 4.5.3](#), “`mysqlcheck` — A Table Maintenance Program”.

#### Note

The `#mysql50#` prefix is intended only to be used internally by the server. You should not create databases or tables with names that use this prefix.

Also, `mysqlcheck` cannot fix names that contain literal instances of the `@` character that is used for encoding special characters. If you have databases or tables that contain this character, use `mysqldump` to dump them before upgrading to MySQL 5.1.6 or later, and then reload the dump file after upgrading.

## 9.2.4. Function Name Parsing and Resolution

MySQL 5.6 supports built-in (native) functions, user-defined functions (UDFs), and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

### Built-In Function Name Parsing

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` [604] SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following “(” parenthesis character.
- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such name. The exact list of function names for which following whitespace determines their interpretation are those listed in the `sql_functions[]` array of the `sql/lex.h` source file. Before MySQL 5.1, these are rather numerous (about 200), so you may find it easiest to treat the no-whitespace requirement as applying to all function calls. In MySQL 5.1 and later, parser improvements reduce to about 30 the number of affected function names.

For functions not listed in the `sql_functions[]` array, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. `ASCII` is one such name. However, for these nonaffected function names, interpretation may vary in expression context: `func_name ()` is interpreted as a built-in function if there is one with the given name; if not, `func_name ()` is interpreted as a user-defined function or stored function if one exists with that name.

The `IGNORE_SPACE` [604] SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- With `IGNORE_SPACE` [604] disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'
```

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```
CREATE TABLE count (i INT);
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

- With `IGNORE_SPACE` [604] enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```
SELECT COUNT(*) FROM mytable;
SELECT COUNT (*) FROM mytable;
```

However, enabling `IGNORE_SPACE` [604] also has the side effect that the parser treats the affected function names as reserved words (see Section 9.3, “Reserved Words”). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with `IGNORE_SPACE` [604] enabled, both of the following statements fail with a syntax error because the parser interprets `count` as a reserved word:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

To use the function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

To enable the `IGNORE_SPACE` [604] SQL mode, use this statement:

```
SET sql_mode = 'IGNORE_SPACE';
```

`IGNORE_SPACE` [604] is also enabled by certain other composite modes such as `ANSI` [608] that include it in their value:

```
SET sql_mode = 'ANSI';
```

Check [Section 5.1.7, “Server SQL Modes”](#), to see which composite modes enable `IGNORE_SPACE` [604].

To minimize the dependency of SQL code on the `IGNORE_SPACE` [604] setting, use these guidelines:

- Avoid creating UDFs or stored functions that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use `count` (one of the affected function names affected by `IGNORE_SPACE` [604]), so they fail with or without whitespace following the name if `IGNORE_SPACE` [604] is enabled:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

If you must use a function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

The number of function names affected by `IGNORE_SPACE` [604] was reduced significantly in MySQL 5.1.13, from about 200 to about 30. As of MySQL 5.1.13, only the following functions are still affected by the `IGNORE_SPACE` [604] setting.

ADDDATE	BIT_AND	BIT_OR	BIT_XOR
CAST	COUNT	CURDATE	CURTIME
DATE_ADD	DATE_SUB	EXTRACT	GROUP_CONCAT
MAX	MID	MIN	NOW
POSITION	SESSION_USER	STD	STDDEV
STDDEV_POP	STDDEV_SAMP	SUBDATE	SUBSTR
SUBSTRING	SUM	SYSDATE	SYSTEM_USER
TRIM	VARIANCE	VAR_POP	VAR_SAMP

For earlier versions of MySQL, check the contents of the `sql_functions[]` array in the `sql/lex.h` source file to see which functions are affected by `IGNORE_SPACE` [604].

**Incompatibility warning:** The change in MySQL 5.1.13 that reduces the number of function names affected by `IGNORE_SPACE` [604] improves the consistency of parser operation. However, it also introduces the possibility of incompatibility for old SQL code that relies on the following conditions:

- `IGNORE_SPACE` [604] is disabled.
- The presence or absence of whitespace following a function name is used to distinguish between a built-in function and stored function that have the same name, such as `PI()` [1205] versus `PI ( )`.

For functions that are no longer affected by `IGNORE_SPACE` [604] as of MySQL 5.1.13, that strategy no longer works. Either of the following approaches can be used if you have code that is subject to the preceding incompatibility:

- If a stored function has a name that conflicts with a built-in function, refer to the stored function with a schema name qualifier, regardless of whether whitespace is present. For example, write `schema_name.PI()` or `schema_name.PI ()`.
- Alternatively, rename the stored function to use a nonconflicting name and change invocations of the function to use the new name.

### Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:

- Built-in functions and user-defined functions

An error occurs if you try to create a UDF with the same name as a built-in function.

- Built-in functions and stored functions

It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named `PI` in the `test` schema, you invoke it as `test.PI()` because the server resolves `PI()` [1205] as a reference to the built-in function. The server creates a warning if the stored function name collides with a built-in function name. The warning can be displayed with `SHOW WARNINGS`.

- User-defined functions and stored functions

User-defined functions and stored functions share the same namespace, so you cannot create a UDF and a stored function with the same name.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

- If you have already created a user-defined function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name.
- If a new version of MySQL implements a built-in function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change calls to the function so that they use a schema qualifier (that is, use `schema_name.func_name()` syntax).

## 9.3. Reserved Words

Certain words such as `SELECT`, `DELETE`, or `BIGINT` are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Reserved words are permitted as identifiers if you quote them as described in [Section 9.2, “Schema Object Names”](#):

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'
```

```
mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following “(” character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further detail on recognition of function names, see [Section 9.2.4, “Function Name Parsing and Resolution”](#).

The words in the following table are explicitly reserved in MySQL 5.6. In addition, `_FILENAME` is reserved. At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the words in the table are forbidden by standard SQL as column or table names (for example, `GROUP`). A few are reserved because MySQL needs them and uses a `yacc` parser. A reserved word can be used as an identifier if you quote it.

For a more detailed list of reserved words, including differences between versions, see [Reserved Words in MySQL 5.6](#).

**Table 9.2. Reserved Words in MySQL 5.6.11**

MySQL permits some keywords to be used as unquoted identifiers because many people previously used them. Examples are those in the following list:

- ACTION
- BIT
- DATE
- ENUM
- NO
- TEXT
- TIME
- TIMESTAMP

## 9.4. User-Defined Variables

You can store a value in a user-defined variable in one statement and then refer to it later in another statement. This enables you to pass values from one statement to another. *User-defined variables are session-specific.* That is, a user variable defined by one client cannot be seen or used by other clients. All variables for a given client session are automatically freed when that client exits.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumeric characters, “.”, “\_”, and “\$”. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var``).

User variable names are not case sensitive in MySQL 5.0 and up.

One way to set a user-defined variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `= [1173]` or `:= [1172]` can be used as the assignment operator.

You can also assign a value to a user variable in statements other than `SET`. In this case, the assignment operator must be `:= [1172]` and not `= [1173]` because the latter is treated as the comparison operator `= [1166]` in non-`SET` statements:

```
mysql> SET @t1=1, @t2=2, @t3:=4;
mysql> SELECT @t1, @t2, @t3, @t4 := @t1+@t2+@t3;
+-----+-----+-----+-----+

```

```

| @t1 | @t2 | @t3 | @t4 := @t1+@t2+@t3 |
+-----+-----+-----+-----+
| 1 | 2 | 4 | 7 |
+-----+-----+-----+

```

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Bit values assigned to user variables are treated as binary strings. To assign a bit value as a number to a user variable, use `CAST() [1245]` or `+0`:

```

mysql> SET @v1 = b'1000001';
mysql> SET @v2 = CAST(b'1000001' AS UNSIGNED), @v3 = b'1000001'+0;
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A | 65 | 65 |
+-----+-----+-----+

```

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of `NULL` and a type of string.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE N LINES` clause of a `LOAD DATA` statement.

As a general rule, you should never assign a value to a user variable and read the value within the same statement. You might get the results you expect, but this is not guaranteed. The order of evaluation for expressions involving user variables is undefined and may change based on the elements contained within a given statement; in addition, this order is not guaranteed to be the same between releases of the MySQL Server. In `SELECT @a, @a:=@a+1, ...`, you might think that MySQL will evaluate `@a` first and then do an assignment second. However, changing the statement (for example, by adding a `GROUP BY`, `HAVING`, or `ORDER BY` clause) may cause MySQL to select an execution plan with a different order of evaluation.

Another issue with assigning a value to a variable and reading the value within the same statement is that the default result type of a variable is based on its type at the start of the statement. The following example illustrates this:

```

mysql> SET @a='test';
mysql> SELECT @a,(@a:=20) FROM tbl_name;

```

For this `SELECT` statement, MySQL reports to the client that column one is a string and converts all accesses of `@a` to strings, even though `@a` is set to a number for the second row. After the `SELECT` statement executes, `@a` is regarded as a number for the next statement.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to `0`, `0.0`, or `' '` to define its type before you use it.

In a `SELECT` statement, each select expression is evaluated only when sent to the client. This means that in a `HAVING`, `GROUP BY`, or `ORDER BY` clause, referring to a variable that is assigned a value in the select expression list does *not* work as expected:

```
mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
```

The reference to `b` in the `HAVING` clause refers to an alias for an expression in the select list that uses `@aa`. This does not work as expected: `@aa` contains the value of `id` from the previous selected row, not from the current row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as `SELECT`. This is true even if the variable is quoted, as shown in the following example:

```
mysql> SELECT c1 FROM t;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| c1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "`c1`";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| `c1` |
+-----+
1 row in set (0.00 sec)
```

An exception to this principle that user variables cannot be used to provide identifiers is that if you are constructing a string for use as a prepared statement to be executed later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

```
mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)
```

```
mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)
```

See [Section 13.5, “SQL Syntax for Prepared Statements”](#), for more information.

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```
<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");

    if( mysqli_connect_errno() )
        die("Connection failed: %s\n", mysqli_connect_error());

    $col = "c1";

    $query = "SELECT $col FROM t";

    $result = $mysqli->query($query);

    while($row = $result->fetch_assoc())
    {
        echo "<p>" . $row["$col"] . "</p>\n";
    }

    $result->close();

    $mysqli->close();
?>
```

Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

## 9.5. Expression Syntax

The following rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. See the notes after the grammar for additional information about some of the terms. Operator precedence is given in [Section 12.3.1, “Operator Precedence”](#).

```
expr:
    expr OR expr
  | expr || expr
  | expr XOR expr
  | expr AND expr
  | expr && expr
  | NOT expr
  | ! expr
  | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
  | boolean_primary

boolean_primary:
    boolean_primary IS [NOT] NULL
  | boolean_primary <=> predicate
  | boolean_primary comparison_operator predicate
  | boolean_primary comparison_operator {ALL | ANY} (subquery)
  | predicate

comparison_operator: = | >= | > | <= | < | <> | !=

predicate:
    bit_expr [NOT] IN (subquery)
  | bit_expr [NOT] IN (expr [, expr] ...)
  | bit_expr [NOT] BETWEEN bit_expr AND predicate
  | bit_expr SOUNDS LIKE bit_expr
  | bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]
  | bit_expr [NOT] REGEXP bit_expr
  | bit_expr
```

```

bit_expr:
  bit_expr | bit_expr
  | bit_expr & bit_expr
  | bit_expr << bit_expr
  | bit_expr >> bit_expr
  | bit_expr + bit_expr
  | bit_expr - bit_expr
  | bit_expr * bit_expr
  | bit_expr / bit_expr
  | bit_expr DIV bit_expr
  | bit_expr MOD bit_expr
  | bit_expr % bit_expr
  | bit_expr ^ bit_expr
  | bit_expr + interval_expr
  | bit_expr - interval_expr
  | simple_expr

simple_expr:
  literal
  | identifier
  | function_call
  | simple_expr COLLATE collation_name
  | param_marker
  | variable
  | simple_expr || simple_expr
  | + simple_expr
  | - simple_expr
  | ~ simple_expr
  | ! simple_expr
  | BINARY simple_expr
  | (expr [, expr] ...)
  | ROW (expr, expr [, expr] ...)
  | (subquery)
  | EXISTS (subquery)
  | {identifier expr}
  | match_expr
  | case_expr
  | interval_expr

```

**Notes:**

For literal value syntax, see [Section 9.1, “Literal Values”](#).

For identifier syntax, see [Section 9.2, “Schema Object Names”](#).

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: [Section 9.4, “User-Defined Variables”](#)
- System variables: [Section 5.1.5, “Using System Variables”](#)
- Local variables: [Section 13.6.4.1, “Local Variable DECLARE Syntax”](#)
- Parameters: [Section 13.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#)

*param\_marker* is '?' as used in prepared statements for placeholders. See [Section 13.5.1, “PREPARE Syntax”](#).

(*subquery*) indicates a subquery that returns a single value; that is, a scalar subquery. See [Section 13.2.10.1, “The Subquery as Scalar Operand”](#).

{*identifier expr*} is ODBC escape syntax and is accepted for ODBC compatibility. The value is *expr*. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

*match\_expr* indicates a `MATCH [1229]` expression. See [Section 12.9, “Full-Text Search Functions”](#).

*case\_expr* indicates a `CASE [1174]` expression. See [Section 12.4, “Control Flow Functions”](#).

*interval\_expr* represents a time interval. The syntax is `INTERVAL expr unit`, where *unit* is a specifier such as `HOUR`, `DAY`, or `WEEK`. For the full list of *unit* specifiers, see the description of the `DATE_ADD()` [1213] function in Section 12.7, “Date and Time Functions”.

The meaning of some operators depends on the SQL mode:

- By default, `||` [1172] is a logical `OR` [1172] operator. With `PIPES_AS_CONCAT` [607] enabled, `||` [1172] is string concatenation, with a precedence between `^` [1258] and the unary operators.
- By default, `!` [1171] has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` [603] enabled, `!` [1171] and `NOT` have the same precedence.

See Section 5.1.7, “Server SQL Modes”.

## 9.6. Comment Syntax

MySQL Server supports three comment styles:

- From a “#” character to the end of the line.
- From a “-- ” sequence to the end of the line. In MySQL, the “-- ” (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.8.5.5, “‘--’ as the Start of a Comment”.
- From a `/*` sequence to the following `*/` sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```
mysql> SELECT 1+1;      # This comment continues to the end of line
mysql> SELECT 1+1;      -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;
```

Nested comments are not supported. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the “!” character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.)

Comments in this format, `/*!12345 ... */`, are not stored on the server. If this format is used to comment stored routines, the comments will not be retained on the server.

The use of short-form `mysql` commands such as `\C` within multi-line `/* ... */` comments is not supported.

---

10.7. MySQL Server Locale Support .....	1107

This chapter covers issues of globalization, which includes internationalization (MySQL's capabilities for adapting to local use) and localization (selecting particular local conventions):

- MySQL support for character sets in SQL statements.
- How to configure the server to support different character sets.
- Selecting the language for error messages.
- How to set the server's time zone and enable per-connection time zone support.
- Selecting the locale for day and month names.

## 10.1. Character Set Support

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. You can specify character sets at the server, database, table, and column level. MySQL supports the use of character sets for the [MyISAM](#), [MEMORY](#), and [InnoDB](#) storage engines.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see [Section 10.1.5, “Configuring the Character Set and Collation for Applications”](#), and [Section 10.1.4, “Connection Character Sets and Collations”](#).

### 10.1.1. Character Sets and Collations in General

A *character set* is a set of symbols and encodings. A *collation* is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: “A”, “B”, “a”, “b”. We give each letter a number: “A” = 0, “B” = 1, “a” = 2, “b” = 3. The letter “A” is a symbol, the number 0 is the **encoding** for “A”, and the combination of all four letters and their encodings is a **character set**.

Suppose that we want to compare two string values, “A” and “B”. The simplest way to do this is to look at the encodings: 0 for “A” and 1 for “B”. Because 0 is less than 1, we say “A” is less than “B”. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a *binary* collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters “a” and “b” as equivalent to “A” and “B”; (2) then compare the encodings. We call this a *case-insensitive* collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just “A” and “B” but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German “ö”), and for multiple-character mappings (such as the rule that “ö” = “oe” in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

In these respects, MySQL is far ahead of most other database management systems. However, to use these features effectively, you need to know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

## 10.1.2. Character Sets and Collations in MySQL

The MySQL server can support multiple character sets. To list the available character sets, use the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see [Section 10.1.14, “Character Sets and Collations That MySQL Supports”](#).

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8    | DEC West European | dec8_swedish_ci | 1 |
| cp850   | DOS West European | cp850_general_ci | 1 |
| hp8     | HP West European | hp8_english_ci | 1 |
| koi8r   | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| swe7    | 7bit Swedish | swe7_swedish_ci | 1 |
| ascii   | US ASCII | ascii_general_ci | 1 |
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| hebrew  | ISO 8859-8 Hebrew | hebrew_general_ci | 1 |
| tis620  | TIS620 Thai | tis620_thai_ci | 1 |
| euckr   | EUC-KR Korean | euckr_korean_ci | 2 |
| koi8u   | KOI8-U Ukrainian | koi8u_general_ci | 1 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci | 2 |
| greek   | ISO 8859-7 Greek | greek_general_ci | 1 |
| cp1250  | Windows Central European | cp1250_general_ci | 1 |
| gbk     | GBK Simplified Chinese | gbk_chinese_ci | 2 |
| latin5  | ISO 8859-9 Turkish | latin5_turkish_ci | 1 |
...

```

Any given character set always has at least one collation. It may have several collations. To list the collations for a character set, use the `SHOW COLLATION` statement. For example, to see the collations for the `latin1` (cp1252 West European) character set, use this statement to find those collation names that begin with `latin1`:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_german1_ci | latin1 | 5 | | | 0 |
| latin1_swedish_ci | latin1 | 8 | Yes | Yes | 1 |
| latin1_danish_ci | latin1 | 15 | | | 0 |
| latin1_german2_ci | latin1 | 31 | | Yes | 2 |
| latin1_bin | latin1 | 47 | | Yes | 1 |
| latin1_general_ci | latin1 | 48 | | | 0 |
| latin1_general_cs | latin1 | 49 | | | 0 |
| latin1_spanish_ci | latin1 | 94 | | | 0 |
+-----+-----+-----+-----+-----+-----+

```

The `latin1` collations have the following meanings.

Collation	Meaning
<code>latin1_german1_ci</code>	German DIN-1
<code>latin1_swedish_ci</code>	Swedish/Finnish
<code>latin1_danish_ci</code>	Danish/Norwegian
<code>latin1_german2_ci</code>	German DIN-2
<code>latin1_bin</code>	Binary according to <code>latin1</code> encoding
<code>latin1_general_ci</code>	Multilingual (Western European)
<code>latin1_general_cs</code>	Multilingual (ISO Western European), case sensitive
<code>latin1_spanish_ci</code>	Modern Spanish

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has one collation that is the *default collation*. For example, the default collation for `latin1` is `latin1_swedish_ci`. The output for `SHOW CHARACTER SET` indicates which collation is the default for each displayed character set.
- There is a convention for collation names: They start with the name of the character set with which they are associated, they usually include a language name, and they end with `_ci` (case insensitive), `_cs` (case sensitive), or `_bin` (binary).

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

[Collation-Charts.Org](http://Collation-Charts.Org) is a useful site for information that shows how one collation compares to another.

### 10.1.3. Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see [Section 10.1.4, “Connection Character Sets and Collations”](#).

#### 10.1.3.1. Server Character Set and Collation

MySQL Server has a server character set and a server collation. These can be set at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` [417] for the character set. Along with it, you can add `--collation-server` [417] for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=latin1` [417]. If you specify only a character set (for example, `latin1`) but not a collation, that is the same as saying `--character-set-server=latin1` [417] `--collation-server=latin1_swedish_ci` [417] because `latin1_swedish_ci` is the default collation for `latin1`. Therefore, the following three commands all have the same effect:

```
shell> mysqld
shell> mysqld --character-set-server=latin1
shell> mysqld --character-set-server=latin1 \
--collation-server=latin1_swedish_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the `DEFAULT_CHARSET` [134] and `DEFAULT_COLLATION` [134] options for `CMake`. For example:

```
shell> cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```
shell> cmake . -DDEFAULT_CHARSET=latin1 \
-DDEFAULT_COLLATION=latin1_german1_ci
```

Both `mysqld` and `CMake` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in `CREATE DATABASE` statements. They have no other purpose.

The current server character set and collation can be determined from the values of the `character_set_server` [468] and `collation_server` [470] system variables. These variables can be changed at runtime.

### 10.1.3.2. Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

All database options are stored in a text file named `db.opt` that can be found in the database directory.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.
- If `CHARACTER SET X` is specified without `COLLATE`, character set `X` and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with `Y` and collation `Y` are used.
- Otherwise, the server character set and server collation are used.

The database character set and collation are used as default values for table definitions if the table character set and collation are not specified in `CREATE TABLE` statements. The database character set also is used by `LOAD DATA INFILE`. The character set and collation have no other purposes.

The character set and collation for the default database can be determined from the values of the `character_set_database` [468] and `collation_database` [469] system variables. The server sets these variables whenever the default database changes. If there is no default

database, the variables have the same value as the corresponding server-level system variables, `character_set_server` [468] and `collation_server` [470].

### 10.1.3.3. Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]]

ALTER TABLE tbl_name
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.
- If `CHARACTER SET X` is specified without `COLLATE`, character set `X` and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with `Y` and collation `Y` are used.
- Otherwise, the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

### 10.1.3.4. Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, or `TEXT`) has a column character set and a column collation. Column definition syntax for `CREATE TABLE` and `ALTER TABLE` has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
  [CHARACTER SET charset_name]
  [COLLATE collation_name]
```

These clauses can also be used for `ENUM` and `SET` columns:

```
col_name {ENUM | SET} (val_list)
  [CHARACTER SET charset_name]
  [COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
(
  col1 VARCHAR(5)
  CHARACTER SET latin1
  COLLATE latin1_german1_ci
);

ALTER TABLE t1 MODIFY
col1 VARCHAR(5)
CHARACTER SET latin1
```

```
COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.

```
CREATE TABLE t1
(
  coll CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set `utf8` and collation `utf8_unicode_ci`.

- If `CHARACTER SET X` is specified without `COLLATE`, character set `X` and its default collation are used.

```
CREATE TABLE t1
(
  coll CHAR(10) CHARACTER SET utf8
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set `utf8` and the default collation for `utf8`, which is `utf8_general_ci`. To see the default collation for each character set, use the `SHOW COLLATION` statement.

- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with `Y` and collation `Y` are used.

```
CREATE TABLE t1
(
  coll CHAR(10) COLLATE utf8_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation `utf8_polish_ci` and the character set is the one associated with the collation, which is `utf8`.

- Otherwise, the table character set and collation are used.

```
CREATE TABLE t1
(
  coll CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation are specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

### 10.1.3.5. Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

A character string literal may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT 'string';
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

For the simple statement `SELECT 'string'`, the string has the character set and collation defined by the `character_set_connection` [467] and `collation_connection` [469] system variables.

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that is about to follow uses character set *X*.” Because this has confused people in the past, we emphasize that an introducer does not change the string to the introducer character set like `CONVERT()` [1245] would do. It does not change the string's value, although padding may occur. The introducer is just a signal. An introducer is also legal before standard hex literal and numeric hex literal notation (`x'literal'` and `0xnnnn`), or before bit-field literal notation (`b'literal'` and `0bnnnn`).

Examples:

```
SELECT _latin1 x'AABBCC';
SELECT _latin1 0xAABBCC;
SELECT _latin1 b'1100011';
SELECT _latin1 0b1100011;
```

MySQL determines a literal's character set and collation in the following manner:

- If both `_X` and `COLLATE Y` are specified, character set *X* and collation *Y* are used.
- If `_X` is specified but `COLLATE` is not specified, character set *X* and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- Otherwise, the character set and collation given by the `character_set_connection` [467] and `collation_connection` [469] system variables are used.

Examples:

- A string with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
```

- A string with `latin1` character set and its default collation (that is, `latin1_swedish_ci`):

```
SELECT _latin1'Müller';
```

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

An introducer indicates the character set for the following string, but does not change now how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection` [467].

The following examples show that escape processing occurs using `character_set_connection` [467] even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection` [467], as discussed in Section 10.1.4, “Connection Character Sets and Collations”), and display the resulting strings using the `HEX()` [1180] function so that the exact string contents can be seen.

Example 1:

```
mysql> SET NAMES latin1;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+-----+-----+
| HEX('à\n') | HEX(_sjis'à\n') |
+-----+-----+
| E00A      | E00A              |
```

```
+-----+-----+
1 row in set (0.00 sec)
```

Here, “à” (hex value `E0`) is followed by “\n”, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` [467] value of `latin1` to produce a literal newline (hex value `0A`). This happens even for the second string. That is, the introducer of `_sjis` does not affect the parser's escape processing.

Example 2:

```
mysql> SET NAMES sjis;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
+-----+-----+
| HEX('à\n') | HEX(_latin1'à\n') |
+-----+-----+
| E05C6E     | E05C6E             |
+-----+-----+
1 row in set (0.04 sec)
```

Here, `character_set_connection` [467] is `sjis`, a character set in which the sequence of “à” followed by “\” (hex values `05` and `5C`) is a valid multi-byte character. Hence, the first two bytes of the string are interpreted as a single `sjis` character, and the “\” is not interpreted as an escape character. The following “n” (hex value `6E`) is not interpreted as part of an escape sequence. This is true even for the second string; the introducer of `_latin1` does not affect escape processing.

### 10.1.3.6. National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL 5.6 uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information on upgrading character sets to MySQL 5.6 from versions prior to 4.1, see the *MySQL 3.23, 4.0, 4.1 Reference Manual*.

### 10.1.3.7. Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

#### Example 1: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

### Example 2: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

### Example 3: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

### Example 4: Database, Table, and Column Definition

```
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
  c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

## 10.1.3.8. Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

## 10.1.4. Connection Character Sets and Collations

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The server character set and collation are the values of the `character_set_server` [468] and `collation_server` [470] system variables.
- The character set and collation of the default database are the values of the `character_set_database` [468] and `collation_database` [469] system variables.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has connection-related character set and collation system variables.

A “connection” is what you make when you connect to the server. The client sends SQL statements, such as queries, over the connection to the server. The server sends responses, such as result sets or error messages, over the connection back to the client. This leads to several questions about character set and collation handling for client connections, each of which can be answered in terms of system variables:

- What character set is the statement in when it leaves the client?

The server takes the `character_set_client` [467] system variable to be the character set in which statements are sent by the client.

- What character set should the server translate a statement to after receiving it?

For this, the server uses the `character_set_connection` [467] and `collation_connection` [469] system variables. It converts statements sent by the client from `character_set_client` [467] to `character_set_connection` [467] (except for string literals that have an introducer such as `_latin1` or `_utf8`). `collation_connection` [469] is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` [469] does not matter because columns have their own collation, which has a higher collation precedence.

- What character set should the server translate to before shipping result sets or error messages back to the client?

The `character_set_results` [468] system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, and result metadata such as column names and error messages.

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings *for each connection to the server*.

Two statements affect the connection-related character set variables as a group:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

`SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement.)

A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET character_set_connection = charset_name;
```

Setting `character_set_connection` [467] to `charset_name` also implicitly sets `collation_connection` [469] to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation, use the optional `COLLATE` clause:

```
SET NAMES 'charset_name' COLLATE 'collation_name'
```

- `SET CHARACTER SET charset_name`

`SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` [467] and `collation_connection` [469] to `character_set_database` [468] and `collation_database` [469]. A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
```

```
SET character_set_results = charset_name ;
SET collation_connection = @@collation_database ;
```

Setting `collation_connection` [469] also implicitly sets `character_set_connection` [467] to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` [467] explicitly.

**Note**

`ucs2`, `utf16`, `utf16le`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES` or `SET CHARACTER SET`.

The MySQL client programs `mysql`, `mysqladmin`, `mysqlcheck`, `mysqlimport`, and `mysqlshow` determine the default character set to use as follows:

- In the absence of other information, the programs use the compiled-in default character set, usually `latin1`.
- The programs can autodetect which character set to use based on the operating system setting, such as the value of the `LANG` or `LC_ALL` locale environment variable on Unix systems or the code page setting on Windows systems. For systems on which the locale is available from the OS, the client uses it to set the default character set rather than using the compiled-in default. For example, setting `LANG` to `ru_RU.KOI8-R` causes the `koi8r` character set to be used. Thus, users can configure the locale in their environment for use by MySQL clients.

The OS character set is mapped to the closest MySQL character set if there is no exact match. If the client does not support the matching character set, it uses the compiled-in default. For example, `ucs2` is not supported as a connection character set.

C applications can use character set autodetection based on the OS setting by invoking `mysql_options()` as follows before connecting to the server:

```
mysql_options(mysql,
              MYSQL_SET_CHARSET_NAME,
              MYSQL_AUTODETECT_CHARSET_NAME) ;
```

- The programs support a `--default-character-set` [249] option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

When a client connects to the server, it sends the name of the character set that it wants to use. The server uses the name to set the `character_set_client` [467], `character_set_results` [468], and `character_set_connection` [467] system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

With the `mysql` client, to use a character set different from the default, you could explicitly execute `SET NAMES` every time you start up. To accomplish the same result more easily, add the `--default-character-set` [249] option setting to your `mysql` command line or in your option file. For example, the following option file setting changes the three connection-related character set variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

If you are using the `mysql` client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```
mysql> charset utf8
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that `mysql` uses when it reconnects after the connection has dropped.

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET latin1` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy if there are characters that are not in both character sets.

If you want the server to perform no conversion of result sets or error messages, set `character_set_results` [468] to `NULL` or `binary`:

```
SET character_set_results = NULL;
```

To see the values of the character set and collation system variables that apply to your connection, use these statements:

```
SHOW VARIABLES LIKE 'character_set%';
SHOW VARIABLES LIKE 'collation%';
```

You must also consider the environment within which your MySQL applications execute. See [Section 10.1.5, “Configuring the Character Set and Collation for Applications”](#).

For more information about character sets and error messages, see [Section 10.1.6, “Character Set for Error Messages”](#).

## 10.1.5. Configuring the Character Set and Collation for Applications

For applications that store data using the default MySQL character set and collation (`latin1`, `latin1_swedish_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might require `utf8`, whereas applications that use another database might require `sjis`.
- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.
- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the `utf8` character set and `utf8_general_ci` collation.

**Specify character settings per database.** To create a database such that its tables will use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```
CREATE DATABASE mydb
  DEFAULT CHARACTER SET utf8
  DEFAULT COLLATE utf8_general_ci;
```

Tables created in the database will use `utf8` and `utf8_general_ci` by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'utf8'` statement after connecting. The statement can be used regardless of connection method: The `mysql` client, PHP scripts, and so forth.

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, for connections made using `mysql`, you can specify the `--default-character-set=utf8` [249] command-line option to achieve the same effect as `SET NAMES 'utf8'`.

For more information about configuring client connections, see [Section 10.1.4, “Connection Character Sets and Collations”](#).

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)

**Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` [417] and `--collation-server` [417] options. For example, to specify the options in an option file, include these lines:

```
[mysqld]
character-set-server=utf8
collation-server=utf8_general_ci
```

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'utf8'"` [489] option to cause `SET NAMES` to be executed automatically for each client that connects. However, this will yield inconsistent results because the `init_connect` [489] value is not executed for users who have the `SUPER` [756] privilege.

**Specify character settings at MySQL configuration time.** To select a character set and collation when you configure and build MySQL from source, use the `DEFAULT_CHARSET` [134] and `DEFAULT_COLLATION` [134] options for CMake:

```
shell> cmake . -DDEFAULT_CHARSET=utf8 \
-DDEFAULT_COLLATION=utf8_general_ci
```

The resulting server uses `utf8` and `utf8_general_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` [417] and `--collation-server` [417] to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. If you will send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

## 10.1.6. Character Set for Error Messages

This section describes how the server uses character sets for constructing error messages and returning them to clients. For information about the language of error messages (rather than the character set), see [Section 10.2, “Setting the Error Message Language”](#).

In MySQL 5.6, the server constructs error messages using UTF-8 and returns them to clients in the character set specified by the `character_set_results` [468] system variable.

The server constructs error messages as follows:

- The message template uses UTF-8.
- Parameters in the message template are replaced with values that apply to a specific error occurrence:
  - Identifiers such as table or column names use UTF-8 internally so they are copied as is.
  - Character (nonbinary) string values are converted from their character set to UTF-8.
  - Binary string values are copied as is for bytes in the range `0x20` to `0x7E`, and using `\x` hex encoding for bytes outside that range. For example, if a duplicate-key error occurs for an attempt to insert `0x41CF9F` into a `VARBINARY` unique column, the resulting error message uses UTF-8 with some bytes hex encoded:

```
Duplicate entry 'A\xC3\x9F' for key 1
```

To return a message to the client after it has been constructed, the server converts it from UTF-8 to the character set specified by the `character_set_results` [468] system variable. If `character_set_results` [468] has a value of `NULL` or `binary`, no conversion occurs. No conversion occurs if the variable value is `utf8`, either, because that matches the original error message character set.

For characters that cannot be represented in `character_set_results` [468], some encoding may occur during the conversion. The encoding uses Unicode code point values:

- Characters in the Basic Multilingual Plane (BMP) range (`0x0000` to `0xFFFF`) are written using `\nnnn` notation.
- Characters outside the BMP range (`0x01000` to `0x10FFFF`) are written using `\+nnnnnnn` notation.

Clients can set `character_set_results` [468] to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as `SET NAMES`. For more information about `character_set_results` [468], see [Section 10.1.4, "Connection Character Sets and Collations"](#).

The encoding that occurs during the conversion to `character_set_results` [468] before returning error messages to clients can result in different message content compared to earlier versions (before MySQL 5.5). For example, if an error occurs for an attempt to drop a table named `^` (KATAKANA LETTER PE) and `character_set_results` [468] is a character set such as `latin1` that does not contain that character, the resulting message sent to the client has an encoded table name:

```
ERROR 1051 (42S02): Unknown table '\30DA'
```

Before MySQL 5.5, the name is not encoded:

```
ERROR 1051 (42S02): Unknown table '^'
```

## 10.1.7. Collation Issues

The following sections discuss various aspects of character set collations.

### 10.1.7.1. Collation Names

MySQL collation names follow these rules:

- A name ending in `_ci` indicates a case-insensitive collation.

- A name ending in `_cs` indicates a case-sensitive collation.
- A name ending in `_bin` indicates a binary collation. Character comparisons are based on character binary code values.
- Unicode collation names may include a version number to indicate the version of the Unicode Collation Algorithm (UCA) on which the collation is based. UCA-based collations without a version number in the name use the version-4.0.0 UCA weight keys: <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>. A collation name such as `utf8_unicode_520_ci` is based on UCA 5.2.0 weight keys: <http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>.

### 10.1.7.2. Using `COLLATE` in SQL Statements

With the `COLLATE` clause, you can override whatever the default collation is for a comparison. `COLLATE` may be used in various parts of SQL statements. Here are some examples:

- With `ORDER BY`:

```
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With `AS`:

```
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
ORDER BY k1;
```

- With `GROUP BY`:

```
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With `DISTINCT`:

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With `WHERE`:

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```
SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With `HAVING`:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

### 10.1.7.3. `COLLATE` Clause Precedence

The `COLLATE` clause has high precedence (higher than `||` [1172]), so the following two expressions are equivalent:

```
x || y COLLATE z
```

```
x || (y COLLATE z)
```

#### 10.1.7.4. Collations Must Be for the Right Character Set

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

#### 10.1.7.5. Collation of Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `charset_name`:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, with multiple operands, there can be ambiguity. For example:

```
SELECT x FROM T WHERE x = 'Y';
```

Should the comparison use the collation of the column `x`, or of the string literal `'Y'`? Both `x` and `'Y'` have collations, so which collation takes precedence?

Standard SQL resolves such questions using what used to be called “coercibility” rules. MySQL assigns coercibility values as follows:

- An explicit `COLLATE` clause has a coercibility of 0. (Not coercible at all.)
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` [1273] or `VERSION()` [1273]) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 5.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:

```
SELECT CONCAT(utf8_column, latin1_column) FROM t1;
```

It returns a result that has a character set of `utf8` and the same collation as `utf8_column`. Values of `latin1_column` are automatically converted to `utf8` before concatenating.

- For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix

nonbinary and binary strings evaluate the operands as binary strings, except that it is for collations rather than data types.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

Examples:

Comparison	Collation Used
<code>column1 = 'A'</code>	Use collation of <code>column1</code>
<code>column1 = 'A' COLLATE x</code>	Use collation of <code>'A' COLLATE x</code>
<code>column1 COLLATE x = 'A' COLLATE y</code>	Error

The `COERCIBILITY()` [1266] function can be used to determine the coercibility of a string expression:

```
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
```

See [Section 12.14, “Information Functions”](#).

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument `1` in the expression `CONCAT(1, 'abc')` [1178], the result is a character (nonbinary) string that has a character set and collation determined by the `character_set_connection` [467] and `collation_connection` [469] system variables. See [Section 12.2, “Type Conversion in Expression Evaluation”](#).

### 10.1.7.6. The `_bin` and `binary` Collations

This section describes how `_bin` collations for nonbinary strings differ from the `binary` “collation” for binary strings.

Nonbinary strings (as stored in the `CHAR`, `VARCHAR`, and `TEXT` data types) have a character set and collation. A given character set can have several collations, each of which defines a particular sorting and comparison order for the characters in the set. One of these is the binary collation for the character set, indicated by a `_bin` suffix in the collation name. For example, `latin1` and `utf8` have binary collations named `latin1_bin` and `utf8_bin`.

Binary strings (as stored in the `BINARY`, `VARBINARY`, and `BLOB` data types) have no character set or collation in the sense that nonbinary strings do. (Applied to a binary string, the `CHARSET()` and `COLLATION()` functions both return a value of `binary`.) Binary strings are sequences of bytes and the numeric values of those bytes determine sort order.

The `_bin` collations differ from the `binary` collation in several respects.

**The unit for sorting and comparison.** Binary strings are sequences of bytes. Sorting and comparison is always based on numeric byte values. Nonbinary strings are sequences of characters, which might be multi-byte. Collations for nonbinary strings define an ordering of the character values for sorting and comparison. For the `_bin` collation, this ordering is based solely on binary code values of the characters (which is similar to ordering for binary strings except that a `_bin` collation must take into account that a character might contain multiple bytes). For other collations, character ordering might take additional factors such as lettercase into account.

**Character set conversion.** A nonbinary string has a character set and is converted to another character set in many cases, even when the string has a `_bin` collation:

- When assigning column values from another column that has a different character set:

```
UPDATE t1 SET utf8_bin_column=latin1_column;
INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
```

- When assigning column values for `INSERT` or `UPDATE` using a string literal:

```
SET NAMES latin1;
INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
```

- When sending results from the server to a client:

```
SET NAMES latin1;
SELECT utf8_bin_column FROM t2;
```

For binary string columns, no conversion occurs. For the preceding cases, the string value is copied byte-wise.

**Lettercase conversion.** Collations provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for `_bin` collations that ignore lettercase for ordering:

```
mysql> SET NAMES latin1 COLLATE latin1_bin;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT LOWER('aA'), UPPER('zZ');
+-----+-----+
| LOWER('aA') | UPPER('zZ') |
+-----+-----+
| aa          | ZZ          |
+-----+-----+
1 row in set (0.13 sec)
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must be converted to a nonbinary string:

```
mysql> SET NAMES binary;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING latin1));
+-----+-----+
| LOWER('aA') | LOWER(CONVERT('aA' USING latin1)) |
+-----+-----+
| aA          | aa          |
+-----+-----+
1 row in set (0.00 sec)
```

**Trailing space handling in comparisons.** Nonbinary strings have `PADSPACE` behavior for all collations, including `_bin` collations. Trailing spaces are insignificant in comparisons:

```
mysql> SET NAMES utf8 COLLATE utf8_bin;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
| 1          |
+-----+
1 row in set (0.00 sec)
```

For binary strings, all characters are significant in comparisons, including trailing spaces:

```
mysql> SET NAMES binary;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
```

```

+-----+
|          0 |
+-----+
1 row in set (0.00 sec)

```

**Trailing space handling for inserts and retrievals.** `CHAR(N)` columns store nonbinary strings. Values shorter than `N` characters are extended with spaces on insertion. For retrieval, trailing spaces are removed.

`BINARY(N)` columns store binary strings. Values shorter than `N` bytes are extended with `0x00` bytes on insertion. For retrieval, nothing is removed; a value of the declared length is always returned.

```

mysql> CREATE TABLE t1 (
->   a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin,
->   b BINARY(10)
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t1 VALUES ('a','a');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(a), HEX(b) FROM t1;
+-----+-----+
| HEX(a) | HEX(b) |
+-----+-----+
| 61     | 61000000000000000000 |
+-----+-----+
1 row in set (0.04 sec)

```

### 10.1.7.7. The `BINARY` Operator

The `BINARY` [1244] operator casts the string following it to a binary string. This is an easy way to force a comparison to be done byte by byte rather than character by character. `BINARY` [1244] also causes trailing spaces to be significant.

```

mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0

```

`BINARY str` is shorthand for `CAST(str AS BINARY)` [1245].

The `BINARY` attribute in character column definitions has a different effect. A character column defined with the `BINARY` attribute is assigned the binary collation of the column character set. Every character set has a binary collation. For example, the binary collation for the `latin1` character set is `latin1_bin`, so if the table default character set is `latin1`, these two column definitions are equivalent:

```

CHAR(10) BINARY
CHAR(10) CHARACTER SET latin1 COLLATE latin1_bin

```

The effect of `BINARY` as a column attribute differs from its effect prior to MySQL 4.1. Formerly, `BINARY` resulted in a column that was treated as a binary string. A binary string is a string of bytes that has no character set or collation, which differs from a nonbinary character string that has a binary collation. For both types of strings, comparisons are based on the numeric values of the string unit, but for nonbinary strings the unit is the character and some character sets support multi-byte characters. Section 11.4.2, “The `BINARY` and `VARBINARY` Types”.

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as a binary data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

### 10.1.7.8. Examples of the Effect of Collation

#### Example 1: Sorting German Umlauts

Suppose that column `X` in table `T` has these `latin1` column values:

```
Muffler
Müller
MX Systems
MySQL
```

Suppose also that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use `ORDER BY` with different collations.

<code>latin1_swedish_ci</code>	<code>latin1_german1_ci</code>	<code>latin1_german2_ci</code>
Muffler	Muffler	Müller
MX Systems	Müller	Muffler
Müller	MX Systems	MX Systems
MySQL	MySQL	MySQL

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the `SELECT` using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

#### Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (
  ->   c CHAR(10)
  -> ) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (
  ->   c CHAR(10)
  -> ) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (
  ->   c CHAR(10)
  -> ) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
```

```
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an `A = Ä` equality, and one has no such equality (`latin1_german2_ci`). For that reason, you'll get these results in comparisons:

```
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+-----+
| c     |
+-----+
| Bar   |
| Bär   |
+-----+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+-----+
| c     |
+-----+
| Bär   |
+-----+
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+-----+
| c     |
+-----+
| Bar   |
| Bär   |
+-----+
```

This is not a bug but rather a consequence of the sorting properties of `latin1_german1_ci` and `utf8_unicode_ci` (the sorting shown is done according to the German DIN 5007 standard).

### 10.1.7.9. Collation and `INFORMATION_SCHEMA` Searches

String columns in `INFORMATION_SCHEMA` tables have a collation of `utf8_general_ci`, which is case insensitive. However, searches in `INFORMATION_SCHEMA` string columns are also affected by file system case sensitivity. For values that correspond to objects that are represented in the file system, such as names of databases and tables, searches may be case sensitive if the file system is case sensitive. This section describes how to work around this issue if necessary; see also Bug #34921.

Suppose that a query searches the `SCHEMATA.SCHEMA_NAME` column for the `test` database. On Linux, file systems are case sensitive, so comparisons of `SCHEMATA.SCHEMA_NAME` with `'test'` match, but comparisons with `'TEST'` do not:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
-> WHERE SCHEMA_NAME = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+
1 row in set (0.01 sec)

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
-> WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)
```

On Windows or Mac OS X where file systems are not case sensitive, comparisons match both `'test'` and `'TEST'`:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
-> WHERE SCHEMA_NAME = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+
1 row in set (0.00 sec)

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
-> WHERE SCHEMA_NAME = 'TEST';
```

```

+-----+
| SCHEMA_NAME |
+-----+
| TEST        |
+-----+
1 row in set (0.00 sec)

```

The value of the `lower_case_table_names` [501] system variable makes no difference in this context.

This behavior occurs because the `utf8_general_ci` collation is not used for `INFORMATION_SCHEMA` queries when searching the file system for database objects. It is a result of optimizations implemented for `INFORMATION_SCHEMA` searches in MySQL. For information about these optimizations, see [Section 8.2.4, “Optimizing INFORMATION\\_SCHEMA Queries”](#).

Searches in `INFORMATION_SCHEMA` string columns for values that refer to `INFORMATION_SCHEMA` itself do use the `utf8_general_ci` collation because `INFORMATION_SCHEMA` is a “virtual” database and is not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match `'information_schema'` or `'INFORMATION_SCHEMA'` regardless of platform:

```

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      -> WHERE SCHEMA_NAME = 'information_schema';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+
1 row in set (0.00 sec)

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      -> WHERE SCHEMA_NAME = 'INFORMATION_SCHEMA';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+
1 row in set (0.00 sec)

```

If the result of a string operation on an `INFORMATION_SCHEMA` column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation ([Section 10.1.7.2, “Using COLLATE in SQL Statements”](#)). For example, to perform a case-insensitive search, use `COLLATE` with the `INFORMATION_SCHEMA` column name:

```

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      -> WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+
1 row in set (0.00 sec)

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      -> WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'TEST';
| SCHEMA_NAME |
+-----+
| test        |
+-----+
1 row in set (0.00 sec)

```

You can also use the `UPPER()` [1187] or `LOWER()` [1182] function:

```

WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'

```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named

`city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly:

```
WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'
```

The first of those comparisons (with `utf8_bin`) is case sensitive; the others are not.

## 10.1.8. String Repertoire

The *repertoire* of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only characters in the Unicode range `U+0000` to `U+007F`.
- **UNICODE**: The expression can contain characters in the Unicode range `U+0000` to `U+FFFF`.

The **ASCII** range is a subset of **UNICODE** range, so a string with **ASCII** repertoire can be converted safely without loss of information to the character set of any string with **UNICODE** repertoire or to a character set that is a superset of **ASCII**. (All MySQL character sets are supersets of **ASCII** with the exception of `swe7`, which reuses some punctuation characters for Swedish accented characters.) The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an “illegal mix of collations” error.

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for string constants depends on string content:

```
SET NAMES utf8; SELECT 'abc';
SELECT _utf8'def';
SELECT N'MySQL';
```

Although the character set is `utf8` in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is **ASCII** rather than **UNICODE**.

- Columns having the `ascii` character set have **ASCII** repertoire because of their character set. In the following table, `c1` has **ASCII** repertoire:

```
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
```

The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

```
CREATE TABLE t1 (
  c1 CHAR(1) CHARACTER SET latin1,
  c2 CHAR(1) CHARACTER SET ascii
);
INSERT INTO t1 VALUES ('a','b');
SELECT CONCAT(c1,c2) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset (`ascii` to `latin1`) conversion can occur and a result is returned:

```
+-----+
| CONCAT(c1,c2) |
+-----+
```

```
| ab |
+-----+
```

- Functions with one string argument inherit the repertoire of their argument. The result of `UPPER(_utf8'abc')` [1187] has `ASCII` repertoire because its argument has `ASCII` repertoire.
- For functions that return a string but do not have string arguments and use `character_set_connection` [467] as the result character set, the result repertoire is `ASCII` if `character_set_connection` [467] is `ascii`, and `UNICODE` otherwise:

```
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

```
+-----+
| CONCAT(FORMAT(a, 4), b) |
+-----+
| 1.0000b                |
+-----+
```

- Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire (`UNICODE` is wider than `ASCII`). Consider the following `CONCAT()` [1178] calls:

```
CONCAT(_ucs2 0x0041, _ucs2 0x0042)
CONCAT(_ucs2 0x0041, _ucs2 0x00C2)
```

For the first call, the repertoire is `ASCII` because both arguments are within the range of the `ascii` character set. For the second call, the repertoire is `UNICODE` because the second argument is outside the `ascii` character set range.

- The repertoire for function return values is determined based only on the repertoire of the arguments that affect the result's character set and collation.

```
IF(column1 < column2, 'smaller', 'greater')
```

The result repertoire is `ASCII` because the two string arguments (the second argument and the third argument) both have `ASCII` repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

## 10.1.9. Operations Affected by Character Set Support

This section describes operations that take character set information into account.

### 10.1.9.1. Result Strings

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` [1187] returns a string whose character string and collation are the same as that of `X`. The same applies for `INSTR()` [1181], `LCASE()` [1181], `LOWER()` [1182], `LTRIM()` [1182], `MID()` [1183],

`REPEAT()` [1183], `REPLACE()` [1183], `REVERSE()` [1184], `RIGHT()` [1184], `RPAD()` [1184], `RTRIM()` [1184], `SOUNDEX()` [1184], `SUBSTRING()` [1185], `TRIM()` [1186], `UCASE()` [1186], and `UPPER()` [1187].

Note: The `REPLACE()` [1183] function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has no character set or collation. This can be checked by using the `CHARSET()` [1266] and `COLLATION()` [1267] functions, both of which return `binary` to indicate that their argument is a binary string:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+-----+-----+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+-----+-----+
| binary              | binary                 |
+-----+-----+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE X` occurs, use `X`.
- If explicit `COLLATE X` and `COLLATE Y` occur, raise an error.
- Otherwise, if all collations are `X`, use `X`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION, ||` [1172], `CONCAT()` [1178], `ELT()` [1179], `GREATEST()` [1169], `IF()` [1174], and `LEAST()` [1170].

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` [467] and `collation_connection` [469] system variables. This applies only to `CAST()` [1245], `CONV()` [1203], `FORMAT()` [1180], `HEX()` [1180], and `SPACE()` [1185].

If you are uncertain about the character set or collation of the result returned by a string function, you can use the `CHARSET()` [1266] or `COLLATION()` [1267] function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+-----+-----+-----+
| USER()          | CHARSET(USER()) | COLLATION(USER()) |
+-----+-----+-----+
| test@localhost | utf8            | utf8_general_ci  |
+-----+-----+-----+
```

### 10.1.9.2. `CONVERT()` and `CAST()`

`CONVERT()` [1245] provides a way to convert data between different character sets. The syntax is:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8table (utf8column)
  SELECT CONVERT(latin1field USING utf8) FROM latin1table;
```

`CONVERT(... USING ...)` [1245] is implemented according to the standard SQL specification.

You may also use `CAST()` [1245] to convert a string to a different character set. The syntax is:

```
CAST(character_string AS character_data_type CHARACTER SET charset_name)
```

Example:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8);
```

If you use `CAST()` [1245] without specifying `CHARACTER SET`, the resulting character set and collation are defined by the `character_set_connection` [467] and `collation_connection` [469] system variables. If you use `CAST()` [1245] with `CHARACTER SET X`, the resulting character set and collation are `X` and the default collation of `X`.

You may not use a `COLLATE` clause inside a `CONVERT()` [1245] or `CAST()` [1245] call, but you may use it outside. For example, `CAST(... COLLATE ...)` [1245] is illegal, but `CAST(...)  
COLLATE ...` [1245] is legal:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

### 10.1.9.3. SHOW Statements and INFORMATION\_SCHEMA

Several `SHOW` statements provide additional character set information. These include `SHOW CHARACTER SET`, `SHOW COLLATION`, `SHOW CREATE DATABASE`, `SHOW CREATE TABLE` and `SHOW COLUMNS`. These statements are described here briefly. For more information, see [Section 13.7.5, “SHOW Syntax”](#).

`INFORMATION_SCHEMA` has several tables that contain information similar to that displayed by the `SHOW` statements. For example, the `CHARACTER_SETS` and `COLLATIONS` tables contain the information displayed by `SHOW CHARACTER SET` and `SHOW COLLATION`. See [Chapter 19, INFORMATION\\_SCHEMA Tables](#).

The `SHOW CHARACTER SET` statement shows all available character sets. It takes an optional `LIKE` [1190] clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

Charset	Description	Default collation	Maxlen
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

The output from `SHOW COLLATION` includes all available character sets. It takes an optional `LIKE` [1190] clause that indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	0
latin1_danish_ci	latin1	15			0
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	0
latin1_general_ci	latin1	48			0
latin1_general_cs	latin1	49			0
latin1_spanish_ci	latin1	94			0

`SHOW CREATE DATABASE` displays the `CREATE DATABASE` statement that creates a given database:

```
mysql> SHOW CREATE DATABASE test;
```

Database	Create Database
test	CREATE DATABASE test

Before MySQL 5.5	MySQL 5.5 and up
All Unicode 3.0 characters	All Unicode 5.0 and 6.0 characters
No supplementary characters	With supplementary characters
<code>ucs2</code> character set, BMP only	No change
<code>utf8</code> character set for up to three bytes, BMP only	No change
	New <code>utf8mb4</code> character set for up to four bytes, BMP or supplemental
	New <code>utf16</code> character set, BMP or supplemental
	New <code>utf16le</code> character set, BMP or supplemental (5.6.1 and up)
	New <code>utf32</code> character set, BMP or supplemental

These changes are upward compatible. If you want to use the new character sets, there are potential incompatibility issues for your applications; see [Section 10.1.11, “Upgrading from Previous to Current Unicode Support”](#). That section also describes how to convert tables from `utf8` to the (4-byte) `utf8mb4` character set, and what constraints may apply in doing so.

MySQL 5.6 supports these Unicode character sets:

- `ucs2`, the UCS-2 encoding of the Unicode character set using 16 bits per character.
- `utf16`, the UTF-16 encoding for the Unicode character set; like `ucs2` but with an extension for supplementary characters.
- `utf16le`, the UTF-16LE encoding for the Unicode character set; like `utf16` but little-endian rather than big-endian.
- `utf32`, the UTF-32 encoding for the Unicode character set using 32 bits per character.
- `utf8`, a UTF-8 encoding of the Unicode character set using one to three bytes per character.
- `utf8mb4`, a UTF-8 encoding of the Unicode character set using one to four bytes per character.

`ucs2` and `utf8` support BMP characters. `utf8mb4`, `utf16`, `utf16le`, and `utf32` support BMP and supplementary characters.

A similar set of collations is available for most Unicode character sets. For example, each has a Danish collation, the names of which are `ucs2_danish_ci`, `utf16_danish_ci`, `utf32_danish_ci`, `utf8_danish_ci`, and `utf8mb4_danish_ci`. The exception is `utf16le`, which has only two collations. All Unicode collations are listed at [Section 10.1.14.1, “Unicode Character Sets”](#), which also describes collation properties for supplementary characters.

Note that although many of the supplementary characters come from East Asian languages, what MySQL 5.6 adds is support for more Japanese and Chinese characters in Unicode character sets, not support for new Japanese and Chinese character sets.

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values will need to be performed when transferring data between those systems and MySQL. The implementation of UTF-16LE is little-endian.

MySQL uses no BOM for UTF-8 values.

Client applications that need to communicate with the server using Unicode should set the client character set accordingly; for example, by issuing a `SET NAMES 'utf8'` statement. `ucs2`, `utf16`,

`utf16le`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES` or `SET CHARACTER SET`. (See [Section 10.1.4, “Connection Character Sets and Collations”](#).)

The following sections provide additional detail on the Unicode character sets in MySQL.

### 10.1.10.1. The `ucs2` Character Set (UCS-2 Unicode Encoding)

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: `LATIN CAPITAL LETTER A` has the code `0x0041` and it is stored as a 2-byte sequence: `0x00 0x41`. `CYRILLIC SMALL LETTER YERU` (Unicode `0x044B`) is stored as a 2-byte sequence: `0x04 0x4B`. For Unicode characters and their codes, please refer to the [Unicode Home Page](#).

In MySQL, the `ucs2` character set is a fixed-length 16-bit encoding for Unicode BMP characters.

### 10.1.10.2. The `utf16` Character Set (UTF-16 Unicode Encoding)

The `utf16` character set is the `ucs2` character set with an extension that enables encoding of supplementary characters:

- For a BMP character, `utf16` and `ucs2` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf16` has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than `0xffff`, take 10 bits and add them to `0xd800` and put them in the first 16-bit word, take 10 more bits and add them to `0xdc00` and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between `0xd800` and `0xdbff`, and the last 16 bits are a number between `0xdc00` and `0xdfff`. Examples are in [Section 15.5 Surrogates Area](#) of the Unicode 4.0 document.

Because `utf16` supports surrogates and `ucs2` does not, there is a validity check that applies only in `utf16`: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:

```
INSERT INTO t (ucs2_column) VALUES (0xd800); /* legal */
INSERT INTO t (utf16_column)VALUES (0xd800); /* illegal */
```

There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like `0xffff`). For example, since `U+F8FF` is the Apple Logo, this is legal:

```
INSERT INTO t (utf16_column)VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a `utf16` column or index is only half of the maximum length for a `ucs2` column or index. For example, in MySQL 5.6, the maximum length of a `MEMORY` table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for `ucs2` and `utf16` columns:

```
CREATE TABLE tf (s1 VARCHAR(1536) CHARACTER SET ucs2) ENGINE=MEMORY;
CREATE INDEX i ON tf (s1);
CREATE TABLE tg (s1 VARCHAR(768) CHARACTER SET utf16) ENGINE=MEMORY;
CREATE INDEX i ON tg (s1);
```

### 10.1.10.3. The `utf16le` Character Set (UTF-16LE Unicode Encoding)

This is the same as `utf16` but is little-endian rather than big-endian.

### 10.1.10.4. The `utf32` Character Set (UTF-32 Unicode Encoding)

The `utf32` character set is fixed length (like `ucs2` and unlike `utf16`). `utf32` uses 32 bits for every character, unlike `ucs2` (which uses 16 bits for every character), and unlike `utf16` (which uses 16 bits for some characters and 32 bits for others).

`utf32` takes twice as much space as `ucs2` and more space than `utf16`, but `utf32` has the same advantage as `ucs2` that it is predictable for storage: The required number of bytes for `utf32` equals the number of characters times 4. Also, unlike `utf16`, there are no tricks for encoding in `utf32`, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a `utf8mb4` value given the `utf32` code value:

```
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32,
                  utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for `utf32`: No code value may be greater than `0x10ffff`. For example, this is illegal:

```
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

### 10.1.10.5. The `utf8` Character Set (3-Byte UTF-8 Unicode Encoding)

UTF-8 (Unicode Transformation Format with 8-bit units) is an alternative way to store Unicode data. It is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. (An older standard for UTF-8 encoding, RFC 2279, describes UTF-8 sequences that take from one to six bytes. RFC 3629 renders RFC 2279 obsolete; for this reason, sequences with five and six bytes are no longer used.)

The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

The `utf8` character set is the same in MySQL 5.6 as before 5.6 and has exactly the same characteristics:

- No support for supplementary characters (BMP characters only).
- A maximum of three bytes per multi-byte character.

Exactly the same set of characters is available in `utf8` as in `ucs2`. That is, they have the same repertoire.

### 10.1.10.6. The `utf8mb3` “Character Set” (Alias for `utf8`)

In a future version of MySQL, it is possible that `utf8` will become the 4-byte `utf8`, and that users who want to indicate 3-byte `utf8` will have to say `utf8mb3`. To avoid some future problems which might occur with replication when master and slave servers have different MySQL versions, it is possible for users to specify `utf8mb3` in `CHARACTER SET` clauses, and `utf8mb3_collation_substring` in `COLLATE` clauses, where `collation_substring` is `bin`, `czech_ci`, `danish_ci`, `esperanto_ci`, `estonian_ci`, and so forth. For example:

```
CREATE TABLE t (s1 CHAR(1) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8) COLLATE utf8_czech_ci;
```

MySQL immediately converts instances of `utf8mb3` in an alias to `utf8`, so in statements such as `SHOW CREATE TABLE` or `SELECT CHARACTER_SET_NAME FROM INFORMATION_SCHEMA.COLUMNS` or `SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLUMNS`, users will see the true name, `utf8` or `utf8_collation_substring`.

The `utf8mb3` alias is valid only in `CHARACTER SET` clauses, and in certain other places. For example, these are legal:

```
mysql> --character-set-server=utf8mb3
SET NAMES 'utf8mb3'; /* and other SET statements that have similar effect */
SELECT _utf8mb3 'a';
```

There is no `utf8mb3` alias to the corresponding `utf8` collation for collation names that include a version number (for example, `utf8_unicode_520_ci`) to indicate the Unicode Collation Algorithm version on which the collation is based.

### 10.1.10.7. The `utf8mb4` Character Set (4-Byte UTF-8 Unicode Encoding)

The character set named `utf8` uses a maximum of three bytes per character and contains only BMP characters. The `utf8mb4` character set uses a maximum of four bytes per character supports supplemental characters:

- For a BMP character, `utf8` and `utf8mb4` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8` cannot store the character at all, while `utf8mb4` requires four bytes to store it. Since `utf8` cannot store the character at all, you do not have any supplementary characters in `utf8` columns and you need not worry about converting characters or losing data when upgrading `utf8` data from older versions of MySQL.

`utf8mb4` is a superset of `utf8`, so for an operation such as the following concatenation, the result has character set `utf8mb4` and the collation of `utf8mb4_col`:

```
SELECT CONCAT(utf8_col, utf8mb4_col);
```

Similarly, the following comparison in the `WHERE` clause works according to the collation of `utf8mb_col`:

```
SELECT * FROM utf8_tbl, utf8mb4_tbl
WHERE utf8_tbl.utf8_col = utf8mb4_tbl.utf8mb4_col;
```

#### Tip

To save space with UTF-8, use `VARCHAR` instead of `CHAR`. Otherwise, MySQL must reserve three (or four) bytes for each character in a `CHAR CHARACTER SET utf8` (or `utf8mb4`) column because that is the maximum possible length. For example, MySQL must reserve 40 bytes for a `CHAR(10) CHARACTER SET utf8mb4` column.

### 10.1.11. Upgrading from Previous to Current Unicode Support

This section describes issues pertaining to Unicode support that you may face when upgrading to MySQL 5.6 from an older MySQL release. It also provides guidelines for downgrading from MySQL 5.6 to an older release.

In most respects, upgrading to MySQL 5.6 should present few problems with regard to Unicode usage, although there are some potential areas of incompatibility. These are the primary areas of concern:

- For the variable-length character data types ([VARCHAR](#) and the [TEXT](#) types), the maximum length in characters is less for [utf8mb4](#) columns than for [utf8](#) columns.
- For all character data types ([CHAR](#), [VARCHAR](#), and the [TEXT](#) types), the maximum number of characters that can be indexed is less for [utf8mb4](#) columns than for [utf8](#) columns.

Consequently, if you want to upgrade tables from [utf8](#) to [utf8mb4](#) to take advantage of supplementary-character support, it may be necessary to change some column or index definitions.

Tables can be converted from [utf8](#) to [utf8mb4](#) by using [ALTER TABLE](#). Suppose that a table was originally defined as follows:

```
CREATE TABLE t1 (
  col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci NOT NULL,
  col2 CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL
) CHARACTER SET utf8;
```

The following statement converts [t1](#) to use [utf8mb4](#):

```
ALTER TABLE t1
  DEFAULT CHARACTER SET utf8mb4,
  MODIFY col1 CHAR(10)
  CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,
  MODIFY col2 CHAR(10)
  CHARACTER SET utf8mb4 COLLATE utf8mb4_bin NOT NULL;
```

In terms of table content, conversion from [utf8](#) to [utf8mb4](#) presents no problems:

- For a BMP character, [utf8](#) and [utf8mb4](#) have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, [utf8](#) cannot store the character at all, while [utf8mb4](#) requires four bytes to store it. Since [utf8](#) cannot store the character at all, you do not have any supplementary characters in [utf8](#) columns and you need not worry about converting characters or losing data when upgrading [utf8](#) data from older versions of MySQL.

In terms of table structure, the catch when converting from [utf8](#) to [utf8mb4](#) is that the maximum length of a column or index key is unchanged in terms of *bytes*. Therefore, it is smaller in terms of *characters* because the maximum length of a character is four bytes instead of three. For the [CHAR](#), [VARCHAR](#), and [TEXT](#) data types, watch for these things when converting your MySQL tables:

- Check all definitions of [utf8](#) columns and make sure they will not exceed the maximum length for the storage engine.
- Check all indexes on [utf8](#) columns and make sure they will not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use [utf8](#) rather than [utf8mb4](#).

Here are some examples where structural changes may be needed:

- A [TINYTEXT](#) column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a [TINYTEXT](#) column that uses [utf8](#) but must be able to contain more than 63 characters. You cannot convert it to [utf8mb4](#) unless you also change the data type to a longer type such as [TEXT](#).

Similarly, a very long [VARCHAR](#) column may need to be changed to one of the longer [TEXT](#) types if you want to convert it from [utf8](#) to [utf8mb4](#).

- [InnoDB](#) has a maximum index length of 767 bytes, so for [utf8](#) or [utf8mb4](#) columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have [utf8](#) columns with indexes longer than 191 characters, you will need to index a smaller number of characters. In an [InnoDB](#) table, these column and index definitions are legal:

```
coll VARCHAR(500) CHARACTER SET utf8, INDEX (coll(255))
```

To use `utf8mb4` instead, the index must be smaller:

```
coll VARCHAR(500) CHARACTER SET utf8mb4, INDEX (coll(191))
```

The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from `utf8` to `utf8mb4` without problems. You can do this by using `ALTER TABLE` as described earlier in this section after upgrading in place to 5.6.

The following items summarize other potential areas of incompatibility:

- Performance of 4-byte UTF-8 (`utf8mb4`) is slower than for 3-byte UTF-8 (`utf8`). If you do not want to incur this penalty, continue to use `utf8`.
- `SET NAMES 'utf8mb4'` causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them.
- Applications cannot send `utf16`, `utf16le`, or `utf32` character data to an older server that does not understand them.
- For replication, if the character sets that support supplementary characters are going to be used on the master, all slaves must understand them as well. If you attempt to replicate from a MySQL 5.6 master to an older slave, `utf8` data will be seen as `utf8` by the slave and should replicate correctly. But you cannot send `utf8mb4`, `utf16`, `utf16le`, or `utf32` data.

Also, keep in mind the general principle that if a table has different definitions on the master and slave, this can lead to unexpected results. For example, the differences in limitations on index key length makes it risky to use `utf8` on the master and `utf8mb4` on the slave.

If you have upgraded to MySQL 5.6, and then decide to downgrade back to an older release, these considerations apply:

- `ucs2` and `utf8` data should present no problems.
- Any definitions that refer to the `utf8mb4`, `utf16`, `utf16le`, or `utf32` character sets will not be recognized by the older server.
- For object definitions that refer to the `utf8mb4` character set, you can dump them with `mysqldump` in MySQL 5.6, edit the dump file to change instances of `utf8mb4` to `utf8`, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server will see `utf8` in the dump file object definitions and create new objects that use the (3-byte) `utf8` character set.

## 10.1.12. UTF-8 for Metadata

*Metadata* is “the data about the data.” Anything that *describes* the database—as opposed to being the *contents* of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from `SHOW` are metadata. This is also true of the contents of tables in `INFORMATION_SCHEMA` because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the `SHOW` statements nor `SELECT` statements for tables in `INFORMATION_SCHEMA` would work properly because different rows in the same column of the results of these operations would be in different character sets.

- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the `USER()` [1273], `CURRENT_USER()` [1267], `SESSION_USER()` [1273], `SYSTEM_USER()` [1273], `DATABASE()` [1268], and `VERSION()` [1273] functions have the UTF-8 character set by default.

The server sets the `character_set_system` [469] system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_system | utf8 |
+-----+-----+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` [469] character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` [468] system variable, which has a default value of `latin1`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` [468] and other related system variables. (See Section 10.1.4, “Connection Character Sets and Collations”.) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If `character_set_results` [468] is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system` [469]).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` [1273] function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` [1273] are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see Section 10.1.7.5, “Collation of Expressions”.

### 10.1.13. Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you're converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.
- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `coll` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `coll` contains binary data representing characters in the `greek` character set, you can convert it as follows:

```
ALTER TABLE t MODIFY coll VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of `BINARY(50)`, you could convert it to `CHAR(50)`, but the resulting values will be padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the `TRIM()` [1186] function:

```
UPDATE t SET coll = TRIM(TRAILING 0x00 FROM coll);
```

Suppose that table `t` has a nonbinary column named `coll` defined as `CHAR(50) CHARACTER SET latin1` but you want to convert it to use `utf8` so that you can store values from many languages. The following statement accomplishes this:

```
ALTER TABLE t MODIFY coll CHAR(50) CHARACTER SET utf8;
```

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server's default character set. For example, an application might have stored `sjis` values in a column, even though MySQL's default character set was `latin1`. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server's default character set was `latin1` and `coll` is defined as `CHAR(50)` but its contents are `sjis` values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```
ALTER TABLE t MODIFY coll BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```
ALTER TABLE t MODIFY coll CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as `INSERT` or `UPDATE` after an upgrade to MySQL 4.1 or later. In that case, MySQL would store new values in the column using `latin1`, and the column will contain a mix of `sjis` and `latin1` values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with `ALTER TABLE`. For example, if you specified `NOT NULL` and an explicit `DEFAULT` value, you should also provide them in the `ALTER TABLE` statement. Otherwise, the resulting column definition will not include those attributes.

## 10.1.14. Character Sets and Collations That MySQL Supports

MySQL supports 70+ collations for 30+ character sets. This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

You can always list the available character sets and their default collations with the `SHOW CHARACTER SET` statement:

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation
big5	Big5 Traditional Chinese	big5_chinese_ci
dec8	DEC West European	dec8_swedish_ci
cp850	DOS West European	cp850_general_ci
hp8	HP West European	hp8_english_ci
koi8r	KOI8-R Relcom Russian	koi8r_general_ci
latin1	cp1252 West European	latin1_swedish_ci
latin2	ISO 8859-2 Central European	latin2_general_ci
swe7	7bit Swedish	swe7_swedish_ci
ascii	US ASCII	ascii_general_ci
ujis	EUC-JP Japanese	ujis_japanese_ci
sjis	Shift-JIS Japanese	sjis_japanese_ci
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci
tis620	TIS620 Thai	tis620_thai_ci
euckr	EUC-KR Korean	euckr_korean_ci
koi8u	KOI8-U Ukrainian	koi8u_general_ci
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci
greek	ISO 8859-7 Greek	greek_general_ci
cp1250	Windows Central European	cp1250_general_ci
gbk	GBK Simplified Chinese	gbk_chinese_ci
latin5	ISO 8859-9 Turkish	latin5_turkish_ci
armscii8	ARMSCII-8 Armenian	armscii8_general_ci
utf8	UTF-8 Unicode	utf8_general_ci
ucs2	UCS-2 Unicode	ucs2_general_ci
cp866	DOS Russian	cp866_general_ci
keybcs2	DOS Kamenicky Czech-Slovak	keybcs2_general_ci
macce	Mac Central European	macce_general_ci
macroman	Mac West European	macroman_general_ci
cp852	DOS Central European	cp852_general_ci
latin7	ISO 8859-13 Baltic	latin7_general_ci
utf8mb4	UTF-8 Unicode	utf8mb4_general_ci
cp1251	Windows Cyrillic	cp1251_general_ci
utf16	UTF-16 Unicode	utf16_general_ci
utf16le	UTF-16LE Unicode	utf16le_general_ci
cp1256	Windows Arabic	cp1256_general_ci
cp1257	Windows Baltic	cp1257_general_ci
utf32	UTF-32 Unicode	utf32_general_ci
binary	Binary pseudo charset	binary
geostd8	GEOSTD8 Georgian	geostd8_general_ci
cp932	SJIS for Windows Japanese	cp932_japanese_ci
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

[Collation-Charts.Org](http://Collation-Charts.Org) is a useful site for information that shows how one collation compares to another.

### 10.1.14.1. Unicode Character Sets

MySQL 5.6 supports these Unicode character sets:

- `ucs2`, the UCS-2 encoding of the Unicode character set using 16 bits per character.
- `utf16`, the UTF-16 encoding for the Unicode character set; like `ucs2` but with an extension for supplementary characters.
- `utf16le`, the UTF-16LE encoding for the Unicode character set; like `utf16` but little-endian rather than big-endian.
- `utf32`, the UTF-32 encoding for the Unicode character set using 32 bits per character.

- `utf8`, a UTF-8 encoding of the Unicode character set using one to three bytes per character.
- `utf8mb4`, a UTF-8 encoding of the Unicode character set using one to four bytes per character.

`ucs2` and `utf8` support Basic Multilingual Plane (BMP) characters. `utf8mb4`, `utf16`, `utf16le`, and `utf32` support BMP and supplementary characters. `utf16le` was added in MySQL 5.6.1.

You can store text in about 650 languages using these character sets. This section lists the collations available for each Unicode character set and describes their differentiating properties. For general information about the character sets, see [Section 10.1.10, “Unicode Support”](#).

A similar set of collations is available for most Unicode character sets. These are shown in the following list, where `xxx` represents the character set name. For example, `xxx_danish_ci` represents the Danish collations, the specific names of which are `ucs2_danish_ci`, `utf16_danish_ci`, `utf32_danish_ci`, `utf8_danish_ci`, and `utf8mb4_danish_ci`.

Collation support for `utf16le` is more limited. The only collations available are `utf16le_general_ci` and `utf16le_bin`. These are similar to `utf16_general_ci` and `utf16_bin`.

Unicode collation names may also include a version number (for example, `xxx_unicode_520_ci`) to indicate the Unicode Collation Algorithm version on which the collation is based, as described later in this section. For such collations, there is no `utf8mb3` alias to the corresponding `utf8` collation. See [Section 10.1.10.6, “The `utf8mb3` “Character Set” \(Alias for `utf8`\)”](#).

- `xxx_bin`
- `xxx_croatian_ci`
- `xxx_czech_ci`
- `xxx_danish_ci`
- `xxx_esperanto_ci`
- `xxx_estonian_ci`
- `xxx_general_ci` (default)
- `xxx_german2_ci`
- `xxx_general_mysql500_ci`
- `xxx_hungarian_ci`
- `xxx_icelandic_ci`
- `xxx_latvian_ci`
- `xxx_lithuanian_ci`
- `xxx_persian_ci`
- `xxx_polish_ci`
- `xxx_roman_ci`
- `xxx_romanian_ci`
- `xxx_sinhala_ci`
- `xxx_slovak_ci`
- `xxx_slovenian_ci`

- `xxx_spanish_ci`
- `xxx_spanish2_ci`
- `xxx_swedish_ci`
- `xxx_turkish_ci`
- `xxx_unicode_ci`
- `xxx_vietnamese_ci`

MySQL implements the `xxx_unicode_ci` collations according to the Unicode Collation Algorithm (UCA) described at <http://www.unicode.org/reports/tr10/>. The collation uses the version-4.0.0 UCA weight keys: <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>. Currently, the `xxx_unicode_ci` collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported yet. Also, combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo.

MySQL implements language-specific Unicode collations only if the ordering with `xxx_unicode_ci` does not work well for a language. Language-specific collations are UCA-based. They are derived from `xxx_unicode_ci` with additional language tailoring rules.

Collations based on UCA versions later than 4.0.0 include the version in the collation name. Thus, `xxx_unicode_520_ci` collations are based on UCA 5.2.0 weight keys: <http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>.

`LOWER()` [1182] and `UPPER()` [1187] perform case folding according to the collation of their argument. A character that has uppercase and lowercase versions only in a Unicode version more recent than 4.0.0 will be converted by these functions only if the argument has a collation that uses a recent enough UCA version.

For any Unicode character set, operations performed using the `xxx_general_ci` collation are faster than those for the `xxx_unicode_ci` collation. For example, comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. The reason for this is that `utf8_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, in German and some other languages “ß” is equal to “ss”. `utf8_unicode_ci` also supports contractions and ignorable characters. `utf8_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci` (for the effect this has in comparisons or when doing searches, see [Section 10.1.7.8, “Examples of the Effect of Collation”](#)):

```
Ä = A
Ö = O
Ü = U
```

A difference between the collations is that this is true for `utf8_general_ci`:

```
ß = s
```

Whereas this is true for `utf8_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):

```
ß = ss
```

MySQL implements language-specific collations for the `utf8` character set only if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German dictionary order and French, so there is no need to create special `utf8` collations.

`utf8_general_ci` also is satisfactory for both German and French, except that “ß” is equal to “s”, and not to “ss”. If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8_unicode_ci` because it is more accurate.

If you require German DIN-2 (phone book) ordering, use the `utf8_german2_ci` collation, which compares the following sets of characters equal:

```

Ä = Æ = AE
Ö = Œ = OE
Ü = UE
ß = ss

```

`utf8_german2_ci` is similar to `latin1_german2_ci`, but the latter does not compare “Æ” equal to “AE” or “Œ” equal to “OE”. There is no `utf8_german_ci` corresponding to `latin1_german_ci` for German dictionary order because `utf8_general_ci` suffices.

`xxx_swedish_ci` includes Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

```

Û = Y < Ö

```

The `xxx_spanish_ci` and `xxx_spanish2_ci` collations correspond to modern Spanish and traditional Spanish, respectively. In both collations, “ñ” (n-tilde) is a separate letter between “n” and “o”. In addition, for traditional Spanish, “ch” is a separate letter between “c” and “d”, and “ll” is a separate letter between “l” and “m”.

In the `xxx_roman_ci` collations, I and J compare as equal, and U and V compare as equal.

The `xxx_croatian_ci` collations are tailored for these Croatian letters: Č, Ć, DŽ, Đ, Lj, Nj, Š, Ž.

For all Unicode collations except the “binary” (`xxx_bin`) collations, MySQL performs a table lookup to find a character’s collating weight. This weight can be displayed using the `WEIGHT_STRING()` [1187] function. (See Section 12.5, “String Functions”.) If a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

- For BMP characters in general collations (`xxx_general_ci`), weight = code point.
- For BMP characters in UCA collations (for example, `xxx_unicode_ci` and language-specific collations), the following algorithm applies:

```

if (code >= 0x3400 && code <= 0x4DB5)
    base= 0xFB80; /* CJK Ideograph Extension */
else if (code >= 0x4E00 && code <= 0x9FA5)
    base= 0xFB40; /* CJK Ideograph */
else
    base= 0xFBC0; /* All other characters */
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;

```

The result is a sequence of two collating elements, `aaaa` followed by `bbbb`. For example:

```

mysql> SELECT HEX(WEIGHT_STRING(ucs2 0x04CF COLLATE ucs2_unicode_ci));
+-----+
| HEX(WEIGHT_STRING(ucs2 0x04CF COLLATE ucs2_unicode_ci)) |
+-----+
| FBC084CF |
+-----+

```

Thus, `U+04cf` **CYRILLIC SMALL LETTER PALOCHKA** is, with all UCA 4.0.0 collations, greater than `U+04c0` **CYRILLIC LETTER PALOCHKA**. With UCA 5.2.0 collations, all palochkas sort together.

- For supplementary characters in general collations, the weight is the weight for `0xffff` **REPLACEMENT CHARACTER**. For supplementary characters in UCA 4.0.0 collations, their collating

weight is `0xffffd`. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and `COUNT(DISTINCT)`:

```
CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0xffffd); /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;
```

The result is 2 because in the MySQL `xxx_unicode_ci` collations, the replacement character has a weight of `0x0dc6`, whereas Deseret Bee and Deseret Tee both have a weight of `0xffffd`. (Were the `utf32_general_ci` collation used instead, the result would be 1 because all three characters have a weight of `0xffffd` in that collation.)

An example with cuneiform characters and `WEIGHT_STRING()` [1187]:

```
/*
The four characters in the INSERT string are
00000041 # LATIN CAPITAL LETTER A
0001218F # CUNEIFORM SIGN KAB
000121A7 # CUNEIFORM SIGN KISH
00000042 # LATIN CAPITAL LETTER B
*/
CREATE TABLE t (s1 CHAR(4) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0x000000410001218f000121a700000042);
SELECT HEX(WEIGHT_STRING(s1)) FROM t;
```

The result is:

```
0E33 FFFD FFFD 0E4A
```

`0E33` and `0E4A` are primary weights as in [UCA 4.0.0](#). `FFFD` is the weight for KAB and also for KISH.

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to cause trouble. These characters are very rare, so it will be very rare that a multi-character string consists entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted by MySQL's rule and secondarily by code point value, it is easy:

```
ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin
```

- For supplementary characters based on UCA versions later than 4.0.0 (for example, `xxx_unicode_520_ci`), supplementary characters do not necessarily all have the same collation weight. Some have explicit weights from the UCA `allkeys.txt` file. Others have weights calculated from this algorithm:

```
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
```

### The `utf16_bin` Collation

There is a difference between “ordering by the character's code value” and “ordering by the character's binary representation,” a difference that appears only with `utf16_bin`, because of surrogates.

Suppose that `utf16_bin` (the binary collation for `utf16`) was a binary comparison “byte by byte” rather than “character by character.” If that were so, the order of characters in `utf16_bin` would differ from the order in `utf8_bin`. For example, the following chart shows two rare characters. The first character is in the range `E000-FFFF`, so it is greater than a surrogate but less than a supplementary. The second character is a supplementary.

Code point	Character	utf8	utf16
0FF9D	HALFWIDTH KATAKANA LETTER N	EF BE 9D	FF 9D
10384	UGARITIC LETTER DELTA	F0 90 8E 84	D8 00 DF 84

The two characters in the chart are in order by code point value because `0xff9d < 0x10384`. And they are in order by `utf8` value because `0xef < 0xf0`. But they are not in order by `utf16` value, if we use byte-by-byte comparison, because `0xff > 0xd8`.

So MySQL's `utf16_bin` collation is not “byte by byte.” It is “by code point.” When MySQL sees a supplementary-character encoding in `utf16`, it converts to the character's code-point value, and then compares. Therefore, `utf8_bin` and `utf16_bin` are the same ordering. This is consistent with the SQL:2008 standard requirement for a UCS\_BASIC collation: “UCS\_BASIC is a collation in which the ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted. It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS\_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer.”

If the character set is `ucs2`, comparison is byte-by-byte, but `ucs2` strings should not contain surrogates, anyway.

The `xxx_general_mysql500_ci` collations were added in MySQL 5.6.5. They preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24. For more information, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), and [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

For additional information about Unicode collations in MySQL, see [Collation-Charts.Org](#) (`utf8`).

#### 10.1.14.2. West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
  - `ascii_bin`
  - `ascii_general_ci` (default)
- `cp850` (DOS West European) collations:
  - `cp850_bin`
  - `cp850_general_ci` (default)
- `dec8` (DEC Western European) collations:
  - `dec8_bin`
  - `dec8_swedish_ci` (default)
- `hp8` (HP Western European) collations:
  - `hp8_bin`
  - `hp8_english_ci` (default)
- `latin1` (cp1252 West European) collations:
  - `latin1_bin`
  - `latin1_danish_ci`
  - `latin1_general_ci`
  - `latin1_general_cs`

- `latin1_german1_ci`
- `latin1_german2_ci`
- `latin1_spanish_ci`
- `latin1_swedish_ci` (default)

`latin1` is the default character set. MySQL's `latin1` is the same as the Windows `cp1252` character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) `latin1`, except that IANA `latin1` treats the code points between `0x80` and `0x9f` as “undefined,” whereas `cp1252`, and therefore MySQL's `latin1`, assign characters for those positions. For example, `0x80` is the Euro sign. For the “undefined” entries in `cp1252`, MySQL translates `0x81` to Unicode `0x0081`, `0x8d` to `0x008d`, `0x8f` to `0x008f`, `0x90` to `0x0090`, and `0x9d` to `0x009d`.

The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for *Deutsches Institut für Normung* (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see [Section 10.1.7.8, “Examples of the Effect of Collation”](#).

- `latin1_german1_ci` (dictionary) rules:

```

Ä = A
Ö = O
Û = U
ß = s

```

- `latin1_german2_ci` (phone-book) rules:

```

Ä = AE
Ö = OE
Û = UE
ß = ss

```

In the `latin1_spanish_ci` collation, “ñ” (n-tilde) is a separate letter between “n” and “o”.

- `macroman` (Mac West European) collations:
  - `macroman_bin`
  - `macroman_general_ci` (default)
- `swe7` (7bit Swedish) collations:
  - `swe7_bin`
  - `swe7_swedish_ci` (default)

For additional information about Western European collations in MySQL, see [Collation-Charts.Org](#) ([ascii](#), [cp850](#), [dec8](#), [hp8](#), [latin1](#), [macroman](#), [swe7](#)).

### 10.1.14.3. Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- `cp1250` (Windows Central European) collations:

- `cp1250_bin`
- `cp1250_croatian_ci`
- `cp1250_czech_cs`
- `cp1250_general_ci` (default)
- `cp1250_polish_ci`
- `cp852` (DOS Central European) collations:
  - `cp852_bin`
  - `cp852_general_ci` (default)
- `keybcs2` (DOS Kamenicky Czech-Slovak) collations:
  - `keybcs2_bin`
  - `keybcs2_general_ci` (default)
- `latin2` (ISO 8859-2 Central European) collations:
  - `latin2_bin`
  - `latin2_croatian_ci`
  - `latin2_czech_cs`
  - `latin2_general_ci` (default)
  - `latin2_hungarian_ci`
- `macce` (Mac Central European) collations:
  - `macce_bin`
  - `macce_general_ci` (default)

For additional information about Central European collations in MySQL, see [Collation-Charts.Org](http://Collation-Charts.Org) ([cp1250](#), [cp852](#), [keybcs2](#), [latin2](#), [macce](#)).

#### 10.1.14.4. South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMScii-8 Armenian) collations:
  - `armscii8_bin`
  - `armscii8_general_ci` (default)
- `cp1256` (Windows Arabic) collations:
  - `cp1256_bin`
  - `cp1256_general_ci` (default)
- `geostd8` (GEOSTD8 Georgian) collations:
  - `geostd8_bin`

- `geostd8_general_ci` (default)
- `greek` (ISO 8859-7 Greek) collations:
  - `greek_bin`
  - `greek_general_ci` (default)
- `hebrew` (ISO 8859-8 Hebrew) collations:
  - `hebrew_bin`
  - `hebrew_general_ci` (default)
- `latin5` (ISO 8859-9 Turkish) collations:
  - `latin5_bin`
  - `latin5_turkish_ci` (default)

For additional information about South European and Middle Eastern collations in MySQL, see Collation-Charts.Org ([armscii8](#), [cp1256](#), [geostd8](#), [greek](#), [hebrew](#), [latin5](#)).

#### 10.1.14.5. Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:
  - `cp1257_bin`
  - `cp1257_general_ci` (default)
  - `cp1257_lithuanian_ci`
- `latin7` (ISO 8859-13 Baltic) collations:
  - `latin7_bin`
  - `latin7_estonian_cs`
  - `latin7_general_ci` (default)
  - `latin7_general_cs`

For additional information about Baltic collations in MySQL, see Collation-Charts.Org ([cp1257](#), [latin7](#)).

#### 10.1.14.6. Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- `cp1251` (Windows Cyrillic) collations:
  - `cp1251_bin`
  - `cp1251_bulgarian_ci`
  - `cp1251_general_ci` (default)
  - `cp1251_general_cs`
  - `cp1251_ukrainian_ci`

- `cp866` (DOS Russian) collations:
  - `cp866_bin`
  - `cp866_general_ci` (default)
- `koi8r` (KOI8-R Relcom Russian) collations:
  - `koi8r_bin`
  - `koi8r_general_ci` (default)
- `koi8u` (KOI8-U Ukrainian) collations:
  - `koi8u_bin`
  - `koi8u_general_ci` (default)

For additional information about Cyrillic collations in MySQL, see [Collation-Charts.Org](http://Collation-Charts.Org) ([cp1251](#), [cp866](#), [koi8r](#), [koi8u](#)). ).

### 10.1.14.7. Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See [Section 10.1.14.7.1, “The `cp932` Character Set”](#), for additional information about the `cp932` and `sjis` character sets.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see [Section B.11, “MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”](#).

- `big5` (Big5 Traditional Chinese) collations:
  - `big5_bin`
  - `big5_chinese_ci` (default)
- `cp932` (SJIS for Windows Japanese) collations:
  - `cp932_bin`
  - `cp932_japanese_ci` (default)
- `ucjpm` (UJIS for Windows Japanese) collations:
  - `ucjpm_bin`
  - `ucjpm_japanese_ci` (default)
- `euckr` (EUC-KR Korean) collations:
  - `euckr_bin`
  - `euckr_korean_ci` (default)
- `gb2312` (GB2312 Simplified Chinese) collations:
  - `gb2312_bin`
  - `gb2312_chinese_ci` (default)
- `gbk` (GBK Simplified Chinese) collations:
  - `gbk_bin`

- `gbk_chinese_ci` (default)
- `sjis` (Shift-JIS Japanese) collations:
  - `sjis_bin`
  - `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
  - `tis620_bin`
  - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
  - `ujis_bin`
  - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

For additional information about Asian collations in MySQL, see Collation-Charts.Org ([big5](#), [cp932](#), [eucjpm](#), [euckr](#), [gb2312](#), [gbk](#), [sjis](#), [tis620](#), [ujis](#)).

#### 10.1.14.7.1. The `cp932` Character Set

##### Why is `cp932` needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See <http://www.iana.org/assignments/character-sets>.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

##### How does `cp932` differ from `sjis`?

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
- Some `cp932` characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to `cp932`, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See <http://support.microsoft.com/kb/170559/EN-US/>.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
- If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at <http://www.microsoft.com/globaldev/reference/dbcs/932.htm> provides information about the Unicode values of `cp932` characters. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (`ucs2`) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters:

[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_87.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_87.htm)

- NEC selected—IBM extended characters:

[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_ED.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_ED.htm)  
[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_EE.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_EE.htm)

- IBM selected characters:

[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_FA.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_FA.htm)  
[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_FB.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_FB.htm)  
[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_FC.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_FC.htm)

- `cp932` supports conversion of user-defined characters in combination with `eucajpms`, and solves the problems with `sjis/ujis` conversion. For details, please refer to <http://www.opengroup.org/jp/jvc/cde/sjis-euc-e.html>.

For some characters, conversion to and from `ucs2` is different for `sjis` and `cp932`. The following tables illustrate these differences.

Conversion to `ucs2`:

<code>sjis/cp932</code> Value	<code>sjis</code> -> <code>ucs2</code> Conversion	<code>cp932</code> -> <code>ucs2</code> Conversion
5C	005C	005C
7E	007E	007E
815C	2015	2015
815F	005C	FF3C
8160	301C	FF5E
8161	2016	2225

<b>sjis/cp932 Value</b>	<b>sjis -&gt; ucs2 Conversion</b>	<b>cp932 -&gt; ucs2 Conversion</b>
817C	2212	FF0D
8191	00A2	FFE0
8192	00A3	FFE1
81CA	00AC	FFE2

Conversion from `ucs2`:

<b>ucs2 value</b>	<b>ucs2 -&gt; sjis Conversion</b>	<b>ucs2 -&gt; cp932 Conversion</b>
005C	815F	5C
007E	7E	7E
00A2	8191	3F
00A3	8192	3F
00AC	81CA	3F
2015	815C	815C
2016	8161	3F
2212	817C	3F
2225	3F	8161
301C	8160	3F
FF0D	3F	817C
FF3C	3F	815F
FF5E	3F	8160
FFE0	3F	8191
FFE1	3F	8192
FFE2	3F	81CA

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` [416] (or `--skip-character-set-client-handshake` [416]) has an important effect. See Section 5.1.3, “Server Command Options”.

## 10.2. Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can also be displayed in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish.

You can select which language the server uses for error messages using the instructions in this section.

In MySQL 5.6, the server searches for the error message file in two locations:

- It tries to find the file in a directory constructed from two system variable values, `lc_messages_dir` [495] and `lc_messages` [495], with the latter converted to a language name. Suppose that you start the server using this command:

```
shell> mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR
```

In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `/usr/share/mysql/french` directory.

- If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` [495] value and uses only the `lc_messages_dir` [495] value as the location in which to look.

The `lc_messages_dir` [495] system variable has only a global value and is read only. `lc_messages` [495] has global and session values and can be modified at runtime, so the error message language can be changed while the server is running, and individual clients each can have a different error message language by changing their session `lc_messages` [495] value to a different locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

```
mysql> SET lc_messages = 'en_US';
```

By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

For information about changing the character set for error messages (rather than the language), see [Section 10.1.6, “Character Set for Error Messages”](#).

You can change the content of the error messages produced by the server using the instructions in the MySQL Internals manual, available at [MySQL Internals: Error Messages](#). If you do change the content of error messages, remember to repeat your changes after each upgrade to a newer version of MySQL.

## 10.3. Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need special string collating routines for sorting and does not need multi-byte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, `MYSET` represents the name of the character set that you want to add.

1. Add a `<charset>` element for `MYSET` to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the `latin1` `<charset>` element follows:

```
<charset name="latin1">
  <family>Western</family>
  <description>cp1252 West European</description>
  ...
  <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
    <flag>primary</flag>
    <flag>compiled</flag>
  </collation>
  <collation name="latin1_danish_ci" id="15" order="Danish"/>
  ...
  <collation name="latin1_bin" id="47" order="Binary">
    <flag>binary</flag>
    <flag>compiled</flag>
  </collation>
  ...
</charset>
```

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of `general_ci` (general, case insensitive). It is possible for the binary collation to be the

default collation, but usually they are different. The default collation should have a [primary](#) flag. The binary collation should have a [binary](#) flag.

You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:

```
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multi-byte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See [Section 10.3.1, “Character Definition Arrays”](#).
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See [Section 10.3.1, “Character Definition Arrays”](#).
  - For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
  - If the character set requires string collating functions, see [Section 10.3.2, “String Collating Support for Complex Character Sets”](#).
  - If the character set requires multi-byte character support, see [Section 10.3.3, “Multi-Byte Character Support for Complex Character Sets”](#).
3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.

- a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```
#ifdef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```
#ifdef HAVE_CHARSET_MYSET
add_compiled_collation(&my_charset_MYSET_general_ci);
```

```
add_compiled_collation(&my_charset_MYSET_bin);
#endif
```

- b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.
  - c. Edit `cmake/character_sets.cmake`:
    - i. Add `MYSET` to the value of with `CHARSETS_AVAILABLE` in alphabetic order.
    - ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, or CMake will not recognize `-DDEFAULT_CHARSET=MYSET` [134].
4. Reconfigure, recompile, and test.

### 10.3.1. Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparisons and sorts, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[ ]`, `to_lower_MYSET[ ]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*.c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling EOF.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```
#define _MY_U 01 /* Upper case */
#define _MY_L 02 /* Lower case */
#define _MY_NMR 04 /* Numeral (digit) */
#define _MY_SPC 010 /* Spacing character */
#define _MY_PNT 020 /* Punctuation */
#define _MY_CTR 040 /* Control character */
#define _MY_B 0100 /* Blank */
#define _MY_X 0200 /* hexadecimal digit */
```

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (`_MY_U`) as well as a hexadecimal digit (`_MY_X`), so its `ctype` value should be defined like this:

```
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
lower['A'] should contain 'a'
```

```
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in [Section 10.3.2, “String Collating Support for Complex Character Sets”](#).

### 10.3.2. String Collating Support for Complex Character Sets

For a simple character set named *MYSET*, sorting rules are specified in the *MYSET.xml* configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the *ctype-MYSET.c* source file in the *strings* directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the *ctype-\*.c* files in the *strings* directory, such as the files for the *big5*, *czech*, *gbk*, *sjis*, and *tis160* character sets. Take a look at the *MY\_COLLATION\_HANDLER* structures to see how they are used. See also the *CHARSET\_INFO.txt* file in the *strings* directory for additional information.

### 10.3.3. Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named *MYSET* that includes multi-byte characters, you must use multi-byte character functions in the *ctype-MYSET.c* source file in the *strings* directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the *ctype-\*.c* files in the *strings* directory, such as the files for the *euc\_kr*, *gb2312*, *gbk*, *sjis*, and *ujis* character sets. Take a look at the *MY\_CHARSET\_HANDLER* structures to see how they are used. See also the *CHARSET\_INFO.txt* file in the *strings* directory for additional information.

## 10.4. Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

The `WEIGHT_STRING()` [1187] function can be used to see the weights for the characters in a string. The value that it returns to indicate weights is a binary string, so it is convenient to use `HEX(WEIGHT_STRING(str))` to display the weights in printable form. The following example shows that weights do not differ for lettercase for the letters in `'AaBb'` if it is a nonbinary case-insensitive string, but do differ if it is a binary string:

```
mysql> SELECT HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci));
+-----+
| HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci)) |
+-----+
| 41414242                                             |
+-----+
mysql> SELECT HEX(WEIGHT_STRING(BINARY 'AaBb'));
+-----+
| HEX(WEIGHT_STRING(BINARY 'AaBb')) |
+-----+
| 41614262                                             |
+-----+
```

MySQL supports several collation implementations, as discussed in [Section 10.4.1, “Collation Implementation Types”](#). Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (`xxx_bin`) collations.

The following sections describe how to add collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the collation is present.

The instructions here cover only collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in [Section 10.3, “Adding a Character Set”](#). However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add data structures, functions, and configuration information for the new collation.

#### Note

If you modify an existing collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. For further information, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).

### 10.4.1. Collation Implementation Types

MySQL implements several types of collations:

#### Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. `latin1_swedish_ci` is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX(WEIGHT_STRING('a')), HEX(WEIGHT_STRING('A'));
+-----+-----+

```

```

| HEX(WEIGHT_STRING('a')) | HEX(WEIGHT_STRING('A')) |
+-----+-----+
| 41 | 41 |
+-----+-----+
1 row in set (0.01 sec)

mysql> SELECT 'a' = 'A';
+-----+
| 'a' = 'A' |
+-----+
| 1 |
+-----+
1 row in set (0.12 sec)

```

For implementation instructions, see [Section 10.4.3, “Adding a Simple Collation to an 8-Bit Character Set”](#).

### Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in [Section 10.3, “Adding a Character Set”](#).

### Collations for non-Unicode multi-byte character sets

For this type of collation, 8-bit (single-byte) and multi-byte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of 0x41.) For multi-byte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. `sjis_japanese_ci` is an example of this kind of collation. The multi-byte character 'ぢ' has a character code of 0x82C0, and the weight is also 0x82C0.

```

mysql> CREATE TABLE t1
  -> (c1 VARCHAR(2) CHARACTER SET sjis COLLATE sjis_japanese_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x82C0);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1 | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a | 61 | 41 |
| A | 41 | 41 |
| ぢ | 82C0 | 82C0 |
+-----+-----+-----+
3 rows in set (0.00 sec)

```

- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. `gbk_chinese_ci` is an example of this kind of collation. The multi-byte character '臙' has a character code of 0x81B0 but a weight of 0xC286.

```

mysql> CREATE TABLE t1
  -> (c1 VARCHAR(2) CHARACTER SET gbk COLLATE gbk_chinese_ci);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x81B0);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1 | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a | 61 | 41 |
| A | 41 | 41 |

```

```
| 膳      | 81B0      | C286      |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

For implementation instructions, see [Section 10.3, “Adding a Character Set”](#).

### Collations for Unicode multi-byte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case insensitive and accent insensitive. `utf8_general_ci` is an example: `'a'`, `'A'`, `'À'`, and `'á'` each have different character codes but all have a weight of `0x0041` and compare as equal.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1
-> (c1 CHAR(1) CHARACTER SET UTF8 COLLATE utf8_general_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),('À'),('á');
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1    | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a     | 61      | 0041                    |
| A     | 41      | 0041                    |
| À     | C380    | 0041                    |
| á     | C3A1    | 0041                    |
+-----+-----+-----+
4 rows in set (0.00 sec)
```

UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits).
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: `'a'` has a weight of `0x0E33`.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_unicode_ci';
Query OK, 0 rows affected (0.05 sec)

mysql> SELECT HEX('a'), HEX(WEIGHT_STRING('a'));
+-----+-----+
| HEX('a') | HEX(WEIGHT_STRING('a')) |
+-----+-----+
| 61      | 0E33                     |
+-----+-----+
1 row in set (0.02 sec)
```

- A character may have many weights. This is an expansion. Example: The German letter `'ß'` (SZ ligature, or SHARP S) has a weight of `0x0FEA0FEA`.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_unicode_ci';
Query OK, 0 rows affected (0.11 sec)

mysql> SELECT HEX('ß'), HEX(WEIGHT_STRING('ß'));
+-----+-----+
| HEX('ß') | HEX(WEIGHT_STRING('ß')) |
+-----+-----+
| C39F    | 0FEA0FEA                 |
+-----+-----+
```

```
1 row in set (0.00 sec)
```

- Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0x0EE2.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_czech_ci';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT HEX('ch'), HEX(WEIGHT_STRING('ch'));
+-----+-----+
| HEX('ch') | HEX(WEIGHT_STRING('ch')) |
+-----+-----+
| 6368      | 0EE2                      |
+-----+-----+
1 row in set (0.00 sec)
```

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see [Section 10.3, “Adding a Character Set”](#). For a UCA collation, see [Section 10.4.4, “Adding a UCA Collation to a Unicode Character Set”](#).

### Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

## 10.4.2. Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. The range of IDs from 1024 to 2047 is reserved for user-defined collations. The collation ID that you choose will appear in these contexts:

- The `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table.
- The `Id` column of `SHOW COLLATION` output.
- The `charsetnr` member of the `MYSQL_FIELD` C API data structure.
- The `number` member of the `MY_CHARSET_INFO` data structure returned by the `mysql_get_character_set_info()` C API function.

To determine the largest currently used ID, issue the following statement:

```
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
+-----+
| MAX(ID) |
+-----+
|      210 |
+-----+
```

To display a list of all currently used IDs, issue this statement:

```
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
+-----+
| ID |
+-----+
|  1 |
|  2 |
| ... |
| 52 |
| 53 |
| 57 |
| 58 |
| ... |
| 98 |
| 99 |
+-----+
```

```
| 128 |
| 129 |
| ... |
| 210 |
+-----+
```

### Warning

Before MySQL 5.5, which provides for a range of user-defined collation IDs, you must choose an ID in the range from 1 to 254. In this case, if you upgrade MySQL, you may find that the collation ID you choose has been assigned to a collation included in the new MySQL distribution. In this case, you will need to choose a new value for your own collation.

In addition, before upgrading, you should save the configuration files that you change. If you upgrade in place, the process will replace the your modified files.

## 10.4.3. Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the `<collation>` elements associated with a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in [Section 10.4.2, “Choosing a Collation ID”](#). The following steps use an ID of 1024.
2. Modify the `Index.xml` and `latin1.xml` configuration files. These files will be located in the directory named by the `character_sets_dir` [469] system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+
| Variable_name | Value |
+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. For example:

```
<charset name="latin1">
...
  <collation name="latin1_test_ci" id="1024"/>
...
</charset>
```

4. In the `latin1.xml` configuration file, add a `<collation>` element that names the collation and that contains a `<map>` element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the `<map>` element must be a number in hexadecimal format.

```
<collation name="latin1_test_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
```

```

41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5C D7 5C 55 55 55 59 59 DE DF
41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5C F7 5C 55 55 55 59 59 DE FF
</map>
</collation>

```

- Restart the server and use this statement to verify that the collation is present:

```

mysql> SHOW COLLATION LIKE 'latin1_test_ci';
+-----+-----+-----+-----+-----+-----+
| Collation      | Charset | Id    | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_test_ci | latin1  | 1024  |         |          | 1       |
+-----+-----+-----+-----+-----+-----+

```

### 10.4.4. Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at <http://www.unicode.org/reports/tr35/>. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined. It is not possible to create user-defined UCA collations for `utf16le`; there is no `utf16le_unicode_ci` collation that would serve as the basis for such collations.

**Table 10.1. MySQL Character Sets Available for User-Defined UCA Collations**

Character Set	Base Collation
<code>utf8</code>	<code>utf8_unicode_ci</code>
<code>ucs2</code>	<code>ucs2_unicode_ci</code>
<code>utf16</code>	<code>utf16_unicode_ci</code>
<code>utf32</code>	<code>utf32_unicode_ci</code>

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

#### 10.4.4.1. Defining a UCA Collation using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see [Section 10.4.4.2, “LDML Syntax Supported in MySQL”](#).

The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

```

+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567

```

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

- Choose a collation ID, as shown in [Section 10.4.2, “Choosing a Collation ID”](#). The following steps use an ID of 1029.

- To modify the `Index.xml` configuration file. This file will be located in the directory named by the `character_sets_dir` [469] system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

- Choose a name for the collation and list it in the `Index.xml` file. In addition, you'll need to provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

```
<charset name="utf8">
...
  <collation name="utf8_phone_ci" id="1029">
    <rules>
      <reset>\u0000</reset>
      <i>\u0020</i> <!-- space -->
      <i>\u0028</i> <!-- left parenthesis -->
      <i>\u0029</i> <!-- right parenthesis -->
      <i>\u002B</i> <!-- plus -->
      <i>\u002D</i> <!-- hyphen -->
    </rules>
  </collation>
...
</charset>
```

- If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.
- Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION LIKE 'utf8_phone_ci';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| utf8_phone_ci | utf8 | 1029 | | | 8 |
+-----+-----+-----+-----+-----+-----+
```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```
mysql> CREATE TABLE phonebook (
->   name VARCHAR(64),
->   phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)
```

Run some queries to see whether the ignored punctuation characters are in fact ignored for sorting and comparisons:

```
mysql> SELECT * FROM phonebook ORDER BY phone;
+-----+-----+
| name | phone                |
+-----+-----+
| Sanja | +380 (912) 8008005 |
| Bar   | +7-912-800-80-01 |
| Svoj  | +7 912 800 80 02 |
| Ramil | (7912) 800 80 03 |
| Hf    | +7 (912) 800 80 04 |
+-----+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+-----+-----+
| name | phone                |
+-----+-----+
| Bar   | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+-----+-----+
| name | phone                |
+-----+-----+
| Bar   | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+-----+-----+
| name | phone                |
+-----+-----+
| Bar   | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)
```

#### 10.4.4.2. LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at <http://www.unicode.org/reports/tr35/>, which should be consulted for further information. MySQL recognizes a large enough subset of the syntax that, in many cases, it is possible to download a collation definition from the Unicode Common Locale Data Repository and paste the relevant part (that is, the part between the `<rules>` and `</rules>` tags) into the MySQL `Index.xml` file. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file. See [Section 10.4.4.3, “Diagnostics During `Index.xml` Parsing”](#).

##### Character Representation

Characters named in LDML rules can be written literally or in `\unnnn` format, where `nnnn` is the hexadecimal Unicode code point value. For example, `A` and `á` can be written literally or as `\u0041` and `\u00E1`. Within hexadecimal values, the digits `A` through `F` are not case sensitive; `\u00E1` and `\u00e1` are equivalent. For UCA 4.0.0 collations, hexadecimal notation can be used only for characters in the Basic Multilingual Plane, not for characters outside the BMP range of `0000` to `FFFF`. For UCA 5.2.0 collations, hexadecimal notation can be used for any character.

The `Index.xml` file itself should be written using UTF-8 encoding.

##### Syntax Rules

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

- A `<reset>` rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter 'A':

```
<reset>A</reset>
<reset>\u0041</reset>
```

- The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:
  - Use primary differences to distinguish separate letters.
  - Use secondary differences to distinguish accent variations.
  - Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the 'G' character:

```
<p>G</p>
<p>\u0047</p>
```

- The `<i>` shift rule indicates that one character sorts identically to another. The following rules cause 'b' to sort the same as 'a':

```
<reset>a</reset>
<i>b</i>
```

- Abbreviated shift syntax specifies multiple shift rules using a single pair of tags. The following table shows the correspondence between abbreviated syntax rules and the equivalent nonabbreviated rules.

**Table 10.2. Abbreviated Shift Syntax**

Abbreviated Syntax	Nonabbreviated Syntax
<code>&lt;pc&gt;xyz&lt;/pc&gt;</code>	<code>&lt;p&gt;x&lt;/p&gt;&lt;p&gt;y&lt;/p&gt;&lt;p&gt;z&lt;/p&gt;</code>
<code>&lt;sc&gt;xyz&lt;/sc&gt;</code>	<code>&lt;s&gt;x&lt;/s&gt;&lt;s&gt;y&lt;/s&gt;&lt;s&gt;z&lt;/s&gt;</code>
<code>&lt;tc&gt;xyz&lt;/tc&gt;</code>	<code>&lt;t&gt;x&lt;/t&gt;&lt;t&gt;y&lt;/t&gt;&lt;t&gt;z&lt;/t&gt;</code>
<code>&lt;ic&gt;xyz&lt;/ic&gt;</code>	<code>&lt;i&gt;x&lt;/i&gt;&lt;i&gt;y&lt;/i&gt;&lt;i&gt;z&lt;/i&gt;</code>

- An expansion is a reset rule that establishes an anchor point for a multiple-character sequence. MySQL supports expansions 2 to 6 characters long. The following rules put 'z' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
<p>z</p>
```

- A contraction is a shift rule that sorts a multiple-character sequence. MySQL supports contractions 2 to 6 characters long. The following rules put the sequence of three characters 'xyz' greater at the primary level than 'a':

```
<reset>a</reset>
<p>xyz</p>
```

- Long expansions and long contractions can be used together. These rules put the sequence of three characters 'xyz' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
```

```
<p>xyz</p>
```

- Normal expansion syntax uses `<x>` plus `<extend>` elements to specify an expansion. The following rules put the character 'k' greater at the secondary level than the sequence 'ch'. That is, 'k' behaves as if it expands to a character after 'c' followed by 'h':

```
<reset>c</reset>
<x><s>k</s><extend>h</extend></x>
```

This syntax permits long sequences. These rules sort the sequence 'ccs' greater at the tertiary level than the sequence 'cscs':

```
<reset>cs</reset>
<x><t>ccs</t><extend>cs</extend></x>
```

The LDML specification describes normal expansion syntax as “tricky.” See that specification for details.

- Previous context syntax uses `<x>` plus `<context>` elements to specify that the context before a character affects how it sorts. The following rules put '-' greater at the secondary level than 'a', but only when '-' occurs after 'b':

```
<reset>a</reset>
<x><context>b</context><s>-</s></x>
```

- Previous context syntax can include the `<extend>` element. These rules put 'def' greater at the primary level than 'aghi', but only when 'def' comes after 'abc':

```
<reset>a</reset>
<x><context>abc</context><p>def</p><extend>ghi</extend></x>
```

- Reset rules permit a `before` attribute. Normally, shift rules after a reset rule indicate characters that sort after the reset character. Shift rules after a reset rule that has the `before` attribute indicate characters that sort before the reset character. The following rules put the character 'b' immediately before 'a' at the primary level:

```
<reset before="primary">a</reset>
<p>b</p>
```

Permissible `before` attribute values specify the sort level by name or the equivalent numeric value:

```
<reset before="primary">
<reset before="1">

<reset before="secondary">
<reset before="2">

<reset before="tertiary">
<reset before="3">
```

- A reset rule can name a logical reset position rather than a literal character:

```
<first_tertiary_ignorable/>
<last_tertiary_ignorable/>
<first_secondary_ignorable/>
<last_secondary_ignorable/>
<first_primary_ignorable/>
<last_primary_ignorable/>
<first_variable/>
<last_variable/>
<first_non_ignorable/>
<last_non_ignorable/>
<first_trailing/>
<last_trailing/>
```

These rules put 'z' greater at the primary level than nonignorable characters that have a Default Unicode Collation Element Table (DUCET) entry and that are not CJK:

```
<reset><last_non_ignorable/></reset>
<p>z</p>
```

Logical positions have the code points shown in the following table.

**Table 10.3. Logical Reset Position Code Points**

Logical Position	Unicode 4.0.0 Code Point	Unicode 5.2.0 Code Point
<code>&lt;first_non_ignorable/&gt;</code>	U+02D0	U+02D0
<code>&lt;last_non_ignorable/&gt;</code>	U+A48C	U+1342E
<code>&lt;first_primary_ignorable/&gt;</code>	U+0332	U+0332
<code>&lt;last_primary_ignorable/&gt;</code>	U+20EA	U+101FD
<code>&lt;first_secondary_ignorable/&gt;</code>	U+0000	U+0000
<code>&lt;last_secondary_ignorable/&gt;</code>	U+FE73	U+FE73
<code>&lt;first_tertiary_ignorable/&gt;</code>	U+0000	U+0000
<code>&lt;last_tertiary_ignorable/&gt;</code>	U+FE73	U+FE73
<code>&lt;first_trailing/&gt;</code>	U+0000	U+0000
<code>&lt;last_trailing/&gt;</code>	U+0000	U+0000
<code>&lt;first_variable/&gt;</code>	U+0009	U+0009
<code>&lt;last_variable/&gt;</code>	U+2183	U+1D371

- The `<collation>` element permits a `shift-after-method` attribute that affects character weight calculation for shift rules. The attribute has these permitted values:
  - `simple`: Calculate character weights as for reset rules that do not have a `before` attribute. This is the default if the attribute is not given.
  - `expand`: Use expansions for shifts after reset rules.

Suppose that '0' and '1' have weights of 0E29 and 0E2A and we want to put all basic Latin letters between '0' and '1':

```
<reset>0</reset>
<pc>abcdefghijklmnopqrstuvwxyz</pc>
```

For simple shift mode, weights are calculated as follows:

```
'a' has weight 0E29+1
'b' has weight 0E29+2
'c' has weight 0E29+3
...
```

However, there are not enough vacant positions to put 26 characters between '0' and '1'. The result is that digits and letters are intermixed.

To solve this, use `shift-after-method="expand"`. Then weights are calculated like this:

```
'a' has weight [0E29][233D+1]
'b' has weight [0E29][233D+2]
'c' has weight [0E29][233D+3]
...
```

233D is the UCA 4.0.0 weight for character 0xA48C, which is the last nonignorable character (a sort of the greatest character in the collation, excluding CJK). UCA 5.2.0 is similar but uses 3ACA, for character 0x1342E.

In MySQL 5.6, an extension to LDML rules permits the `<collation>` element to include an optional `version` attribute in `<collation>` tags to indicate the UCA version on which the collation is based. If the `version` attribute is omitted, its default value is 4.0.0. For example, this specification indicates a collation that is based on UCA 5.2.0:

```
<collation id="nnn" name="utf8_xxx_ci" version="5.2.0">
...
</collation>
```

#### 10.4.4.3. Diagnostics During `Index.xml` Parsing

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file:

- Unknown tags are written to the error log. For example, the following message results if a collation definition contains a `<aaa>` tag:

```
[Warning] Buffered warning: Unknown LDML tag:
'charsets/charset/collation/rules/aaa'
```

- If collation initialization is not possible, the server reports an “Unknown collation” error, and also generates warnings explaining the problems, such as in the previous example. In other cases, when a collation description is generally correct but contains some unknown tags, the collation is initialized and is available for use. The unknown parts are ignored, but a warning is generated in the error log.
- Problems with collations generate warnings that clients can display with `SHOW WARNINGS`. Suppose that a reset rule contains an expansion longer than the maximum supported length of 6 characters:

```
<reset>abcdefghi</reset>
<i>x</i>
```

An attempt to use the collation produces warnings:

```
mysql> SELECT _utf8'test' COLLATE utf8_test_ci;
ERROR 1273 (HY000): Unknown collation: 'utf8_test_ci'
mysql> SHOW WARNINGS;
```

Level	Code	Message
Error	1273	Unknown collation: 'utf8_test_ci'
Warning	1273	Expansion is too long at 'abcdefghi=x'

## 10.5. Character Set Configuration

You can change the default server character set and collation with the `--character-set-server` [417] and `--collation-server` [417] options when you start the server. The collation must be a legal collation for the default character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.) See [Section 5.1.3, “Server Command Options”](#).

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- Your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory). This can be fixed by using the `--character-sets-dir` option when you run the program in question. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets

[client]
character-sets-dir="C:/Program Files/MySQL/MySQL Server 5.6/share/charsets"
```

- The character set is a complex character set that cannot be loaded dynamically. In this case, you must recompile the program with support for the character set.

For Unicode character sets, you can define collations without recompiling by using LDML notation. See [Section 10.4.4, “Adding a UCA Collation to a Unicode Character Set”](#).

- The character set is a dynamic character set, but you do not have a configuration file for it. In this case, you should install the configuration file for the character set from a new MySQL distribution.
- If your character set index file does not contain the name for the character set, your program displays an error message. The file is named `Index.xml` and the message is:

```
Character set 'charset_name' is not a compiled character set and is not
specified in the '/usr/share/mysql/charsets/Index.xml' file
```

To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` [469] differs from `character_set_server` [468] or `character_set_client` [467], and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=system_character_set` [249]—that is, setting the client character set to match the system character set—should fix the problem.

For MyISAM tables, you can check the character set name and number for a table with `myisamchk -dvv tbl_name`.

## 10.6. MySQL Server Time Zone Support

The MySQL server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` [550] system variable. The value does not change thereafter.

You can set the system time zone for MySQL Server at startup with the `--timezone=timezone_name` [229] option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`. The permissible values for `--timezone` [229] or `TZ` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server's current time zone. The global `time_zone` [557] system variable indicates the time zone the server currently is operating in. The initial value for `time_zone` [557] is 'SYSTEM', which indicates that the server time zone is the same as the system time zone.

The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone=timezone` [420] option on the command line, or you can use the following line in an option file:

```
default-time-zone='timezone'
```

If you have the `SUPER` [756] privilege, you can set the global server time zone value at runtime with this statement:

```
mysql> SET GLOBAL time_zone = timezone;
```

- Per-connection time zones. Each client that connects has its own time zone setting, given by the session `time_zone` [557] variable. Initially, the session variable takes its value from the global `time_zone` [557] variable, but the client can change its own time zone with this statement:

```
mysql> SET time_zone = timezone;
```

The current session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` [1220] or `CURTIME()` [1213], and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the current time zone to UTC for storage, and from UTC to the current time zone for retrieval.

The current time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` [1227] or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current values of the global and client-specific time zones can be retrieved like this:

```
mysql> SELECT @@global.time_zone, @@session.time_zone;
```

`timezone` values can be given in several formats, none of which are case sensitive:

- The value `'SYSTEM'` indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as `'+10:00'` or `'-6:00'`.
- The value can be given as a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, or `'MET'`. Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated.

The MySQL installation procedure creates the time zone tables in the `mysql` database, but does not load them. You must do so manually using the following instructions. (If you are upgrading to MySQL 4.1.3 or later from an earlier version, you can create the tables by upgrading your `mysql` database. Use the instructions in [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#). After creating the tables, you can load them.)

#### Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. For example, the rules for Daylight Saving Time in the United States, Mexico, and parts of Canada changed in 2007. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See the notes at the end of this section.

If your system has its own `zoneinfo` database (the set of files describing time zones), you should use the `mysql_tzinfo_to_sql` program for filling the time zone tables. Examples of such systems are Linux, FreeBSD, Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a `zoneinfo` database, you can use the downloadable package described later in this section.

The `mysql_tzinfo_to_sql` program is used to load the time zone tables. On the command line, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or to generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone needs to account for leap seconds, initialize the leap second information like this, where `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

- After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

If your system is one that has no zoneinfo database (for example, Windows or HP-UX), you can use the package of pre-built time zone tables that is available for download at the MySQL Developer Zone:

<http://dev.mysql.com/downloads/timezones.html>

This time zone package contains `.frm`, `.MYD`, and `.MYI` files for the `MyISAM` time zone tables. These tables should be part of the `mysql` database, so you should place the files in the `mysql` subdirectory of your MySQL server's data directory. The server should be stopped while you do this and restarted afterward.

#### Warning

Do not use the downloadable package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

For information about time zone settings in replication setup, please see [Section 16.4.1, “Replication Features and Issues”](#).

## 10.6.1. Staying Current with Time Zone Changes

As mentioned earlier, when the time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are two factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the Web site for your operating system vendor for an update that addresses the time changes.
- If you replace the system's `/etc/localtime` timezone file with a version that uses rules differing from those in effect at `mysqld` startup, you should restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.
- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date. If your system has its own zoneinfo database, you should reload the MySQL time zone tables whenever the zoneinfo database is updated, using the instructions given earlier in this section. For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace your current time zone tables. `mysqld` caches time zone information that it looks up, so after replacing

the time zone tables, you should restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+-----+
| COUNT(*) |
+-----+
|         0 |
+-----+
```

A count of zero indicates that the table is empty. In this case, no one can be using named time zones, and you don't need to update the tables. A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, you should be sure to reload your time zone tables so that anyone who uses named time zones will get correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses these two queries:

```
SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you would see an incorrect result like this:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 02:00:00 |
+-----+
```

After updating the tables, you should see the correct result:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+
```

## 10.6.2. Time Zone Leap Second Support

Leap second values are returned with a time part that ends with `:59:59`. This means that a function such as `NOW()` [1220] can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with `:59:60` or `:59:61` are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with `'YYYY-MM-DD hh:mm:ss'` values. The following example demonstrates this. It changes the local time zone to UTC so there is no difference between internal values (which are in UTC) and displayed values (which have time zone correction applied).

```
mysql> CREATE TABLE t1 (
->   a INT,
->   ts TIMESTAMP DEFAULT NOW(),
->   PRIMARY KEY (ts)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> -- change to UTC
mysql> SET time_zone = '+00:00';
Query OK, 0 rows affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:59'
mysql> SET timestamp = 1230767999;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:60'
mysql> SET timestamp = 1230768000;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (2);
Query OK, 1 row affected (0.00 sec)

mysql> -- values differ internally but display the same
mysql> SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;
+-----+-----+-----+
| a    | ts                | UNIX_TIMESTAMP(ts) |
+-----+-----+-----+
| 1    | 2008-12-31 23:59:59 | 1230767999         |
| 2    | 2008-12-31 23:59:59 | 1230768000         |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> -- only the non-leap value matches
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';
+-----+-----+
| a    | ts                |
+-----+-----+
| 1    | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)

mysql> -- the leap value with seconds=60 is invalid
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';
Empty set, 2 warnings (0.00 sec)
```

To work around this, you can use a comparison based on the UTC value actually stored in column, which has the leap second correction applied:

```
mysql> -- selecting using UNIX_TIMESTAMP value return leap value
mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
+-----+-----+
| a    | ts                |
+-----+-----+
| 2    | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)
```

## 10.7. MySQL Server Locale Support

The locale indicated by the `lc_time_names` [495] system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()` [1215], `DAYNAME()` [1217], and `MONTHNAME()` [1220] functions.

`lc_time_names` [495] does not affect the `STR_TO_DATE()` [1221] or `GET_FORMAT()` [1218] function.

The `lc_time_names` [495] value does not affect the result from `FORMAT()` [1180], but this function takes an optional third parameter that enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` [495] system variable.

Locale names have language and region subtags listed by IANA (<http://www.iana.org/assignments/language-subtag-registry>) such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting, but you can set the value at server startup or set the `GLOBAL` value if you have the `SUPER` [756] privilege. Any client can examine the value of `lc_time_names` [495] or set its `SESSION` value to affect the locale for its own connection.

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| en_US           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| Friday                | January                  |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| Friday Fri January Jan                    |
+-----+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| es_MX           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| viernes                | enero                    |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
```

```
| DATE_FORMAT('2010-01-01', '%W %a %M %b') |
+-----+
| viernes vie enero ene |
+-----+
1 row in set (0.00 sec)
```

The day or month name for each of the affected functions is converted from `utf8` to the character set indicated by the `character_set_connection` [467] system variable.

`lc_time_names` [495] may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

<code>ar_AE</code> : Arabic - United Arab Emirates	<code>ar_BH</code> : Arabic - Bahrain

11.5. Data Type Default Values .....	1146
11.6. Data Type Storage Requirements .....	1147
11.7. Choosing the Right Type for a Column .....	1151
11.8. Using Data Types from Other Database Engines .....	1151

MySQL supports a number of [SQL](#) data types in several categories: numeric types, date and time types, and string (character and byte) types. This chapter provides an overview of these data types, a more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overview is intentionally brief. The more detailed descriptions later in the chapter should be consulted for additional information about particular data types, such as the permissible formats in which you can specify values.

MySQL also supports extensions for handling spatial data. For information about these data types, see [Section 12.18, “Spatial Extensions”](#).

Data type descriptions use these conventions:

- *M* indicates the maximum display width for integer types. For floating-point and fixed-point types, *M* is the total number of digits that can be stored (the precision). For string types, *M* is the maximum length. The maximum permissible value of *M* depends on the data type.
- *D* applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than *M*–2.
- *fsp* applies to the `TIME`, `DATETIME`, and `TIMESTAMP` types and represents fractional seconds precision; that is, the number of digits following the decimal point for fractional parts of seconds. The *fsp* value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part.

If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Square brackets (“[” and “]”) indicate optional parts of type definitions.

## 11.1. Data Type Overview

### 11.1.1. Numeric Type Overview

A summary of the numeric data types follows. For additional information about properties and storage requirements of the numeric types, see [Section 11.2, “Numeric Types”](#), and [Section 11.6, “Data Type Storage Requirements”](#).

*M* indicates the maximum display width for integer types. The maximum display width is 255. Display width is unrelated to the range of values a type can contain, as described in [Section 11.2, “Numeric Types”](#). For floating-point and fixed-point types, *M* is the total number of digits that can be stored.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Numeric data types that permit the `UNSIGNED` attribute also permit `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

#### Warning

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION [605]` SQL mode is enabled. See [Section 12.10, “Cast Functions and Operators”](#).

- `BIT[ (M) ]`

A bit-field type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

- `TINYINT[ (M) ] [UNSIGNED] [ZEROFILL]`

A very small integer. The signed range is `-128` to `127`. The unsigned range is `0` to `255`.

- `BOOL`, `BOOLEAN`

These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Nonzero values are considered true:

```
mysql> SELECT IF(0, 'true', 'false');
+-----+
| IF(0, 'true', 'false') |
+-----+
| false                   |
+-----+

mysql> SELECT IF(1, 'true', 'false');
+-----+
| IF(1, 'true', 'false') |
+-----+
| true                   |
+-----+

mysql> SELECT IF(2, 'true', 'false');
+-----+
| IF(2, 'true', 'false') |
+-----+
```

```
+-----+
| true  |
+-----+
```

However, the values `TRUE` and `FALSE` are merely aliases for `1` and `0`, respectively, as shown here:

```
mysql> SELECT IF(0 = FALSE, 'true', 'false');
+-----+
| IF(0 = FALSE, 'true', 'false') |
+-----+
| true                            |
+-----+

mysql> SELECT IF(1 = TRUE, 'true', 'false');
+-----+
| IF(1 = TRUE, 'true', 'false')  |
+-----+
| true                            |
+-----+

mysql> SELECT IF(2 = TRUE, 'true', 'false');
+-----+
| IF(2 = TRUE, 'true', 'false')  |
+-----+
| false                           |
+-----+

mysql> SELECT IF(2 = FALSE, 'true', 'false');
+-----+
| IF(2 = FALSE, 'true', 'false') |
+-----+
| false                           |
+-----+
```

The last two statements display the results shown because `2` is equal to neither `1` nor `0`.

- `SMALLINT[(M)] [UNSIGNED] [ZEROFILL]`

A small integer. The signed range is `-32768` to `32767`. The unsigned range is `0` to `65535`.

- `MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]`

A medium-sized integer. The signed range is `-8388608` to `8388607`. The unsigned range is `0` to `16777215`.

- `INT[(M)] [UNSIGNED] [ZEROFILL]`

A normal-size integer. The signed range is `-2147483648` to `2147483647`. The unsigned range is `0` to `4294967295`.

- `INTEGER[(M)] [UNSIGNED] [ZEROFILL]`

This type is a synonym for `INT`.

- `BIGINT[(M)] [UNSIGNED] [ZEROFILL]`

A large integer. The signed range is `-9223372036854775808` to `9223372036854775807`. The unsigned range is `0` to `18446744073709551615`.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

Some things you should be aware of with respect to `BIGINT` columns:

- All arithmetic is done using signed `BIGINT` or `DOUBLE` values, so you should not use unsigned big integers larger than `9223372036854775807` (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

MySQL can handle `BIGINT` in the following cases:

- When using integers to store large unsigned values in a `BIGINT` column.
- In `MIN(col_name) [1284]` or `MAX(col_name) [1284]`, where `col_name` refers to a `BIGINT` column.
- When using operators (`+ [1200]`, `- [1200]`, `* [1200]`, and so on) where both operands are integers.
- You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The `- [1200]`, `+ [1200]`, and `* [1200]` operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than `9223372036854775807`.
- `DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]`

A packed “exact” fixed-point number. `M` is the total number of digits (the precision) and `D` is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the “-” sign are not counted in `M`. If `D` is 0, values have no decimal point or fractional part. The maximum number of digits (`M`) for `DECIMAL` is 65. The maximum number of supported decimals (`D`) is 30. If `D` is omitted, the default is 0. If `M` is omitted, the default is 10.

`UNSIGNED`, if specified, disallows negative values.

All basic calculations (`+`, `-`, `*`, `/`) with `DECIMAL` columns are done with a precision of 65 digits.

- `DEC[(M[,D])] [UNSIGNED] [ZEROFILL]`, `NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL]`, `FIXED[(M[,D])] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DECIMAL`. The `FIXED` synonym is available for compatibility with other database systems.

- `FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]`

A small (single-precision) floating-point number. Permissible values are `-3.402823466E+38` to `-1.175494351E-38`, 0, and `1.175494351E-38` to `3.402823466E+38`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

`M` is the total number of digits and `D` is the number of digits following the decimal point. If `M` and `D` are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

`UNSIGNED`, if specified, disallows negative values.

Using `FLOAT` might give you some unexpected problems because all calculations in MySQL are done with double precision. See [Section C.5.5.7, “Solving Problems with No Matching Rows”](#).

- `DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]`

A normal-size (double-precision) floating-point number. Permissible values are `-1.7976931348623157E+308` to `-2.2250738585072014E-308`, 0, and `2.2250738585072014E-308` to `1.7976931348623157E+308`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

$M$  is the total number of digits and  $D$  is the number of digits following the decimal point. If  $M$  and  $D$  are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

`UNSIGNED`, if specified, disallows negative values.

- `DOUBLE PRECISION[( $M$ , $D$ )] [UNSIGNED] [ZEROFILL], REAL[( $M$ , $D$ )] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DOUBLE`. Exception: If the `REAL_AS_FLOAT` [607] SQL mode is enabled, `REAL` is a synonym for `FLOAT` rather than `DOUBLE`.

- `FLOAT( $p$ ) [UNSIGNED] [ZEROFILL]`

A floating-point number.  $p$  represents the precision in bits, but MySQL uses this value only to determine whether to use `FLOAT` or `DOUBLE` for the resulting data type. If  $p$  is from 0 to 24, the data type becomes `FLOAT` with no  $M$  or  $D$  values. If  $p$  is from 25 to 53, the data type becomes `DOUBLE` with no  $M$  or  $D$  values. The range of the resulting column is the same as for the single-precision `FLOAT` or double-precision `DOUBLE` data types described earlier in this section.

`FLOAT( $p$ )` syntax is provided for ODBC compatibility.

## 11.1.2. Date and Time Type Overview

A summary of the temporal data types follows. For additional information about properties and storage requirements of the temporal types, see [Section 11.3, “Date and Time Types”](#), and [Section 11.6, “Data Type Storage Requirements”](#). For descriptions of functions that operate on temporal values, see [Section 12.7, “Date and Time Functions”](#).

For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

MySQL 5.6.4 and up permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. To define a column that includes a fractional seconds part, use the syntax `type_name( $fsp$ )`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and  $fsp$  is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

The  $fsp$  value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

MySQL 5.6.5 introduces expanded automatic initialization and updating of temporal types. Any `TIMESTAMP` column in a table can have these properties, rather than at most one column per table. In addition, these properties are now available for `DATETIME` columns.

The `YEAR(2)` data type has certain issues that you should consider before choosing to use it. As of MySQL 5.6.6, `YEAR(2)` is deprecated. `YEAR(2)` columns in existing tables are treated as before, but `YEAR(2)` in new or altered tables are converted to `YEAR(4)`. For more information, see [Section 11.3.4, “YEAR\(2\) Limitations and Migrating to YEAR\(4\)”](#).

- `DATE`

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays `DATE` values in 'YYYY-MM-DD' format, but permits assignment of values to `DATE` columns using either strings or numbers.

- `DATETIME[( $fsp$ )]`

A date and time combination. The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. MySQL displays `DATETIME` values in 'YYYY-MM-DD

`HH:MM:SS[.fraction]` format, but permits assignment of values to `DATETIME` columns using either strings or numbers.

As of MySQL 5.6.4, an optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

As of MySQL 5.6.5, automatic initialization and updating to the current date and time for `DATETIME` columns can be specified using `DEFAULT` and `ON UPDATE` column definition clauses, as described in [Section 11.3.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”](#).

- `TIMESTAMP[ (fsp) ]`

A timestamp. The range is `'1970-01-01 00:00:01.000000'` UTC to `'2038-01-19 03:14:07.999999'` UTC. `TIMESTAMP` values are stored as the number of seconds since the epoch (`'1970-01-01 00:00:00'` UTC). A `TIMESTAMP` cannot represent the value `'1970-01-01 00:00:00'` because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing `'0000-00-00 00:00:00'`, the “zero” `TIMESTAMP` value.

As of MySQL 5.6.4, an optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

The way the server handles `TIMESTAMP` definitions depends on the value of the `explicit_defaults_for_timestamp` [\[481\]](#) system variable (see [Section 5.1.4, “Server System Variables”](#)). By default, `explicit_defaults_for_timestamp` [\[481\]](#) is disabled and the server handles `TIMESTAMP` as follows:

Unless specified otherwise, the first `TIMESTAMP` column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes `TIMESTAMP` useful for recording the timestamp of an `INSERT` or `UPDATE` operation. You can also set any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

Automatic initialization and updating to the current date and time can be specified using `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` column definition clauses. By default, the first `TIMESTAMP` column has these properties, as previously noted. As of MySQL 5.6.5, any `TIMESTAMP` column in a table can be defined to have these properties. Before 5.6.5, at most one `TIMESTAMP` column per table can have them, but it is possible to suppress them for the first column and instead assign them to a different `TIMESTAMP` column. See [Section 11.3.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”](#).

If `explicit_defaults_for_timestamp` [\[481\]](#) is enabled, there is no automatic assignment of the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes to any `TIMESTAMP` column. They must be included explicitly in the column definition. Also, any `TIMESTAMP` not explicitly declared as `NOT NULL` permits `NULL` values.

`explicit_defaults_for_timestamp` [\[481\]](#) is available as of MySQL 5.6.6. Before 5.6.6, the server handles `TIMESTAMP` as discussed for `explicit_defaults_for_timestamp` [\[481\]](#) disabled. Those behaviors, while they remain the default, are nonstandard and are deprecated as of 5.6.6. For discussion regarding upgrading to an installation with `explicit_defaults_for_timestamp` [\[481\]](#) enabled, see [Section 2.11.1.1, “Upgrading from MySQL 5.5 to 5.6”](#).

- `TIME[ (fsp) ]`

A time. The range is `'-838:59:59.000000'` to `'838:59:59.000000'`. MySQL displays `TIME` values in `'HH:MM:SS[.fraction]'` format, but permits assignment of values to `TIME` columns using either strings or numbers.

As of MySQL 5.6.4, an optional *fsp* value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

- `YEAR[(2|4)]`

A year in two-digit or four-digit format. The default is four-digit format. `YEAR(2)` or `YEAR(4)` differ in display format, but have the same range of values. In four-digit format, values display as 1901 to 2155, and 0000. In two-digit format, values display as 70 to 69, representing years from 1970 to 2069. MySQL displays `YEAR` values in `YYYY` or `YY` format, but permits assignment of values to `YEAR` columns using either strings or numbers.

#### Note

The `YEAR(2)` data type has certain issues that you should consider before choosing to use it. As of MySQL 5.6.6, `YEAR(2)` is deprecated. `YEAR(2)` columns in existing tables are treated as before, but `YEAR(2)` in new or altered tables are converted to `YEAR(4)`. For more information, see [Section 11.3.4, “YEAR\(2\) Limitations and Migrating to YEAR\(4\)”](#).

For additional information about `YEAR` display format and interpretation of input values, see [Section 11.3.3, “The YEAR Type”](#).

The `SUM()` [1285] and `AVG()` [1282] aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;  
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

#### Note

The MySQL server can be run with the `MAXDB` [608] SQL mode enabled. In this case, `TIMESTAMP` is identical with `DATETIME`. If this mode is enabled at the time that a table is created, `TIMESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See [Section 5.1.7, “Server SQL Modes”](#).

## 11.1.3. String Type Overview

A summary of the string data types follows. For additional information about properties and storage requirements of the string types, see [Section 11.4, “String Types”](#), and [Section 11.6, “Data Type Storage Requirements”](#).

In some cases, MySQL may change a string column to a type different from that given in a `CREATE TABLE` or `ALTER TABLE` statement. See [Section 13.1.14.3, “Silent Column Specification Changes”](#).

MySQL interprets length specifications in character column definitions in character units. This applies to `CHAR`, `VARCHAR`, and the `TEXT` types.

Column definitions for many string data types can include attributes that specify the character set or collation of the column. These attributes apply to the `CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, and `SET` data types:

- The `CHARACTER SET` attribute specifies the character set, and the `COLLATE` attribute specifies a collation for the character set. For example:

```
CREATE TABLE t  
(  
  c1 VARCHAR(20) CHARACTER SET utf8,
```

```
c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named `c1` that has a character set of `utf8` with the default collation for that character set, and a column named `c2` that has a character set of `latin1` and a case-sensitive collation.

The rules for assigning the character set and collation when either or both of the `CHARACTER SET` and `COLLATE` attributes are missing are described in [Section 10.1.3.4, “Column Character Set and Collation”](#).

`CHARSET` is a synonym for `CHARACTER SET`.

- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

- The `ASCII` attribute is shorthand for `CHARACTER SET latin1`.
- The `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`.
- The `BINARY` attribute is shorthand for specifying the binary collation of the column character set. In this case, sorting and comparison are based on numeric character values.

Character column sorting and comparison are based on the character set assigned to the column. For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary collation or the `BINARY` attribute to cause sorting and comparison to use the underlying character code values rather than a lexical ordering.

[Section 10.1, “Character Set Support”](#), provides additional information about use of character sets in MySQL.

- `[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`

A fixed-length string that is always right-padded with spaces to the specified length when stored. *M* represents the column length in characters. The range of *M* is 0 to 255. If *M* is omitted, the length is 1.

#### Note

Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH [606]` SQL mode is enabled.

`CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL 4.1 and up uses `utf8` as this predefined character set. [Section 10.1.3.6, “National Character Set”](#).

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you have to be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `''` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A variable-length string. *M* represents the maximum column length in characters. The range of *M* is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters. See [Section E.10.4, “Limits on Table Column Count and Row Size”](#).

MySQL stores `VARCHAR` values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

#### Note

MySQL 5.6 follows the standard SQL specification, and does *not* remove trailing spaces from `VARCHAR` values.

`VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MySQL 4.1 and up uses `utf8` as this predefined character set. [Section 10.1.3.6, “National Character Set”](#). `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

- `BINARY(M)`

The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than nonbinary character strings. *M* represents the column length in bytes.

- `VARBINARY(M)`

The `VARBINARY` type is similar to the `VARCHAR` type, but stores binary byte strings rather than nonbinary character strings. *M* represents the maximum column length in bytes.

- `TINYBLOB`

A `BLOB` column with a maximum length of 255 ( $2^8 - 1$ ) bytes. Each `TINYBLOB` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 255 ( $2^8 - 1$ ) characters. The effective maximum length is less if the value contains multi-byte characters. Each `TINYTEXT` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `BLOB[ (M) ]`

A `BLOB` column with a maximum length of 65,535 ( $2^{16} - 1$ ) bytes. Each `BLOB` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length *M* can be given for this type. If this is done, MySQL creates the column as the smallest `BLOB` type large enough to hold values *M* bytes long.

- `TEXT[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 65,535 ( $2^{16} - 1$ ) characters. The effective maximum length is less if the value contains multi-byte characters. Each `TEXT` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length *M* can be given for this type. If this is done, MySQL creates the column as the smallest `TEXT` type large enough to hold values *M* characters long.

- `MEDIUMBLOB`

A `BLOB` column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) bytes. Each `MEDIUMBLOB` value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- `MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) characters. The effective maximum length is less if the value contains multi-byte characters. Each `MEDIUMTEXT` value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- `LOBLOB`

A `BLOB` column with a maximum length of 4,294,967,295 or 4GB ( $2^{32} - 1$ ) bytes. The effective maximum length of `LOBLOB` columns depends on the configured maximum packet size in the client/server protocol and available memory. Each `LOBLOB` value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- `LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 4,294,967,295 or 4GB ( $2^{32} - 1$ ) characters. The effective maximum length is less if the value contains multi-byte characters. The effective maximum length of `LONGTEXT` columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGTEXT` value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- `ENUM('value1', 'value2', ...) [CHARACTER SET charset_name] [COLLATE collation_name]`

An enumeration. A string object that can have only one value, chosen from the list of values `'value1', 'value2', ..., NULL` or the special `' '` error value. `ENUM` values are represented internally as integers.

An `ENUM` column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on these limits, see [Section E.10.5, "Limits Imposed by .frm File Structure"](#).

- `SET('value1', 'value2', ...) [CHARACTER SET charset_name] [COLLATE collation_name]`

A set. A string object that can have zero or more values, each of which must be chosen from the list of values `'value1', 'value2', ...`. `SET` values are represented internally as integers.

A `SET` column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on this limit, see [Section E.10.5, "Limits Imposed by .frm File Structure"](#).

## 11.2. Numeric Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (`INTEGER`, `SMALLINT`, `DECIMAL`, and `NUMERIC`), as well as the approximate numeric data types (`FLOAT`, `REAL`, and `DOUBLE PRECISION`). The keyword `INT` is a synonym for `INTEGER`, and

the keywords [DEC](#) and [FIXED](#) are synonyms for [DECIMAL](#). MySQL treats [DOUBLE](#) as a synonym for [DOUBLE PRECISION](#) (a nonstandard extension). MySQL also treats [REAL](#) as a synonym for [DOUBLE PRECISION](#) (a nonstandard variation), unless the [REAL\\_AS\\_FLOAT \[607\]](#) SQL mode is enabled.

The [BIT](#) data type stores bit-field values and is supported for [MyISAM](#), [MEMORY](#), [InnoDB](#), and [NDB](#) tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see [Section 11.2.6, “Out-of-Range and Overflow Handling”](#).

For information about numeric type storage requirements, see [Section 11.6, “Data Type Storage Requirements”](#).

The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see [Section 12.6.1, “Arithmetic Operators”](#).

### 11.2.1. Integer Types (Exact Value) - [INTEGER](#), [INT](#), [SMALLINT](#), [TINYINT](#), [MEDIUMINT](#), [BIGINT](#)

MySQL supports the SQL standard integer types [INTEGER](#) (or [INT](#)) and [SMALLINT](#). As an extension to the standard, MySQL also supports the integer types [TINYINT](#), [MEDIUMINT](#), and [BIGINT](#). The following table shows the required storage and range for each integer type.

Type	Storage (Bytes)	Minimum Value (Signed/Unsigned)	Maximum Value (Signed/Unsigned)
<a href="#">TINYINT</a>	1	-128 0	127 255
<a href="#">SMALLINT</a>	2	-32768 0	32767 65535
<a href="#">MEDIUMINT</a>	3	-8388608 0	8388607 16777215
<a href="#">INT</a>	4	-2147483648 0	2147483647 4294967295
<a href="#">BIGINT</a>	8	-9223372036854775808 0	9223372036854775807 18446744073709551615

### 11.2.2. Fixed-Point Types (Exact Value) - [DECIMAL](#), [NUMERIC](#)

The [DECIMAL](#) and [NUMERIC](#) types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, [NUMERIC](#) is implemented as [DECIMAL](#), so the following remarks about [DECIMAL](#) apply equally to [NUMERIC](#).

MySQL 5.6 stores [DECIMAL](#) values in binary format. See [Section 12.19, “Precision Math”](#).

In a [DECIMAL](#) column declaration, the precision and scale can be (and usually is) specified; for example:

```
salary DECIMAL(5,2)
```

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that `DECIMAL(5,2)` be able to store any value with five digits and two decimals, so values that can be stored in the `salary` column range from `-999.99` to `999.99`.

In standard SQL, the syntax `DECIMAL(M)` is equivalent to `DECIMAL(M,0)`. Similarly, the syntax `DECIMAL` is equivalent to `DECIMAL(M,0)`, where the implementation is permitted to decide the value of `M`. MySQL supports both of these variant forms of `DECIMAL` syntax. The default value of `M` is 10.

If the scale is 0, `DECIMAL` values contain no decimal point or fractional part.

The maximum number of digits for `DECIMAL` is 65, but the actual range for a given `DECIMAL` column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

### 11.2.3. Floating-Point Types (Approximate Value) - `FLOAT`, `DOUBLE`

The `FLOAT` and `DOUBLE` types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For `FLOAT`, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses. MySQL also supports this optional precision specification, but the precision value is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an 8-byte double-precision `DOUBLE` column.

MySQL permits a nonstandard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here, “`(M,D)`” means that values can be stored with up to `M` digits in total, of which `D` digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` will look like `-999.9999` when displayed. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see [Section C.5.5.8, “Problems with Floating-Point Values”](#)

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

### 11.2.4. Bit-Value Type - `BIT`

The `BIT` data type is used to store bit-field values. A type of `BIT(M)` enables storage of `M`-bit values. `M` can range from 1 to 64.

To specify bit values, `b'value'` notation can be used. `value` is a binary value written using zeros and ones. For example, `b'111'` and `b'1000000'` represent 7 and 128, respectively. See [Section 9.1.6, “Bit-Field Literals”](#).

If you assign a value to a `BIT(M)` column that is less than `M` bits long, the value is padded on the left with zeros. For example, assigning a value of `b'101'` to a `BIT(6)` column is, in effect, the same as assigning `b'000101'`.

### 11.2.5. Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, `INT(4)` specifies an `INT` with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces.

(That is, this width is present in the metadata returned with result sets. Whether it is used or not is up to the application.)

The display width does *not* constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as `SMALLINT(3)` has the usual `SMALLINT` range of `-32768` to `32767`, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) attribute `ZEROFILL`, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(4) ZEROFILL`, a value of `5` is retrieved as `0005`.

#### Note

The `ZEROFILL` attribute is ignored when a column is involved in expressions or `UNION` queries.

If you store values larger than the display width in an integer column that has the `ZEROFILL` attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

All integer types can have an optional (nonstandard) attribute `UNSIGNED`. Unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the column. For example, if an `INT` column is `UNSIGNED`, the size of the column's range is the same but its endpoints shift from `-2147483648` and `2147483647` up to `0` and `4294967295`.

Floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Integer or floating-point data types can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

## 11.2.6. Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.
- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the range and stores the resulting value instead.

When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range. If you store `256` into a `TINYINT` or `TINYINT UNSIGNED` column, MySQL stores `127` or `255`, respectively.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Column-assignment conversions that occur due to clipping when MySQL is not operating in strict mode are reported as warnings for `ALTER TABLE`, `LOAD DATA INFILE`, `UPDATE`, and multiple-row `INSERT`

statements. In strict mode, these statements fail, and some or all the values will not be inserted or changed, depending on whether the table is a transactional table and other factors. For details, see [Section 5.1.7, “Server SQL Modes”](#).

In MySQL 5.6, overflow during numeric expression evaluation results in an error. For example, the largest signed `BIGINT` value is 9223372036854775807, so the following expression produces an error:

```
mysql> SELECT 9223372036854775807 + 1;
ERROR 1690 (22003): BIGINT value is out of range in '(9223372036854775807 + 1)'
```

To enable the operation to succeed in this case, convert the value to unsigned;

```
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-----+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
+-----+
|                9223372036854775808 |
+-----+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because `DECIMAL` values have a larger range than integers:

```
mysql> SELECT 9223372036854775807.0 + 1;
+-----+
| 9223372036854775807.0 + 1 |
+-----+
|                9223372036854775808.0 |
+-----+
```

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. Prior to MySQL 5.5.5, if the result would otherwise have been negative, it becomes the maximum integer value:

```
mysql> SET sql_mode = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| 18446744073709551615 |
+-----+
```

As of MySQL 5.5.5, if the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` [\[605\]](#) SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
|                -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` [\[605\]](#) is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

## 11.3. Date and Time Types

The date and time types for representing temporal values are [DATE](#), [TIME](#), [DATETIME](#), [TIMESTAMP](#), and [YEAR](#). Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The [TIMESTAMP](#) type has special automatic updating behavior, described later. For temporal type storage requirements, see [Section 11.6, “Data Type Storage Requirements”](#).

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see [Section 9.1.3, “Date and Time Literals”](#). It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.
- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, `'98-09-04'`), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, `'09-04-98'`, `'04-09-98'`).
- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  - Year values in the range `70-99` are converted to `1970-1999`.
  - Year values in the range `00-69` are converted to `2000-2069`.

See also [Section 11.3.8, “Two-Digit Years in Dates”](#).

- Conversion of values from one temporal type to another occurs according to the rules in [Section 11.3.7, “Conversion Between Date and Time Types”](#).
- MySQL automatically converts a date or time value to a number if the value is used in a numeric context and vice versa.
- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range [TIME](#) values are clipped to the appropriate endpoint of the [TIME](#) range.
- By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See [Section 5.1.7, “Server SQL Modes”](#).) You can get MySQL to accept certain dates, such as `'2009-11-31'`, by enabling the [ALLOW\\_INVALID\\_DATES \[603\]](#) SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.
- MySQL permits you to store dates where the day or month and day are zero in a [DATE](#) or [DATETIME](#) column. This is extremely useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as `'2009-00-00'` or `'2009-01-00'`. If you store dates such as these, you should not expect to get correct results for functions such as [DATE\\_SUB\(\) \[1217\]](#) or [DATE\\_ADD\(\) \[1213\]](#) that require complete dates. To disallow zero month or day parts in dates, enable the [NO\\_ZERO\\_IN\\_DATE \[606\]](#) SQL mode.
- MySQL permits you to store a “zero” value of `'0000-00-00'` as a “dummy date.” This is in some cases more convenient than using [NULL](#) values, and uses less data and index space. To disallow `'0000-00-00'`, enable the [NO\\_ZERO\\_DATE \[606\]](#) SQL mode.
- “Zero” date or time values used through Connector/ODBC are converted automatically to [NULL](#) because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this

using the values `'0'` or `0`, which are easier to write. For temporal types that include a date part (`DATE`, `DATETIME`, and `TIMESTAMP`), use of these values produces warnings if the `NO_ZERO_DATE` [606] SQL mode is enabled.

Data Type	“Zero” Value
<code>DATE</code>	<code>'0000-00-00'</code>
<code>TIME</code>	<code>'00:00:00'</code>
<code>DATETIME</code>	<code>'0000-00-00 00:00:00'</code>
<code>TIMESTAMP</code>	<code>'0000-00-00 00:00:00'</code>
<code>YEAR</code>	<code>0000</code>

### 11.3.1. The `DATE`, `DATETIME`, and `TIMESTAMP` Types

The `DATE`, `DATETIME`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes `DATE`, `DATETIME`, and `TIMESTAMP` values in several formats, described in [Section 9.1.3, “Date and Time Literals”](#). For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The `DATE` type is used for values with a date part but no time part. MySQL retrieves and displays `DATE` values in `'YYYY-MM-DD'` format. The supported range is `'1000-01-01'` to `'9999-12-31'`.

The `DATETIME` type is used for values that contain both date and time parts. MySQL retrieves and displays `DATETIME` values in `'YYYY-MM-DD HH:MM:SS'` format. The supported range is `'1000-01-01 00:00:00'` to `'9999-12-31 23:59:59'`.

The `TIMESTAMP` data type is used for values that contain both date and time parts. `TIMESTAMP` has a range of `'1970-01-01 00:00:01'` UTC to `'2038-01-19 03:14:07'` UTC.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. In particular, as of MySQL 5.6.4, any fractional part in a value inserted into a `DATETIME` or `TIMESTAMP` column is stored rather than discarded. With the fractional part included, the format for these values is `'YYYY-MM-DD HH:MM:SS[.fraction]'`, the range for `DATETIME` values is `'1000-01-01 00:00:00.000000'` to `'9999-12-31 23:59:59.999999'`, and the range for `TIMESTAMP` values is `'1970-01-01 00:00:01.000000'` to `'2038-01-19 03:14:07.999999'`. For information about fractional seconds support in MySQL, see [Section 11.3.6, “Fractional Seconds in Time Values”](#).

The `TIMESTAMP` and (as of MySQL 5.6.5) `DATETIME` data types offer automatic initialization and updating to the current date and time. For more information, see [Section 11.3.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”](#).

MySQL converts `TIMESTAMP` values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as `DATETIME`.) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a `TIMESTAMP` value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` [557] system variable. For more information, see [Section 10.6, “MySQL Server Time Zone Support”](#).

Invalid `DATE`, `DATETIME`, or `TIMESTAMP` values are converted to the “zero” value of the appropriate type (`'0000-00-00'` or `'0000-00-00 00:00:00'`).

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as `'10:11:12'` might look like a time value because of the “:” delimiter, but is interpreted as the year `'2010-11-12'` if used in a date context. The value `'10:45:15'` is converted to `'0000-00-00'` because `'45'` is not a valid month.
- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES` [603]. See Section 5.1.7, “Server SQL Modes”, for more information.
- MySQL does not accept `TIMESTAMP` values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value `'0000-00-00 00:00:00'`.
- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  - Year values in the range `00-69` are converted to `2000-2069`.
  - Year values in the range `70-99` are converted to `1970-1999`.

See also Section 11.3.8, “Two-Digit Years in Dates”.

#### Note

The MySQL server can be run with the `MAXDB` [608] SQL mode enabled. In this case, `TIMESTAMP` is identical with `DATETIME`. If this mode is enabled at the time that a table is created, `TIMESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See Section 5.1.7, “Server SQL Modes”.

### 11.3.2. The `TIME` Type

MySQL retrieves and displays `TIME` values in `'HH:MM:SS'` format (or `'HHH:MM:SS'` format for large hours values). `TIME` values may range from `'-838:59:59'` to `'838:59:59'`. The hours part may be so large because the `TIME` type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes `TIME` values in several formats, some of which can include a trailing fractional seconds part in up to microseconds (6 digits) precision. See Section 9.1.3, “Date and Time Literals”. For information about fractional seconds support in MySQL, see Section 11.3.6, “Fractional Seconds in Time Values”. In particular, as of MySQL 5.6.4, any fractional part in a value inserted into a `TIME` column is stored rather than discarded. With the fractional part included, the range for `TIME` values is `'-838:59:59.000000'` to `'838:59:59.000000'`.

Be careful about assigning abbreviated values to a `TIME` column. MySQL interprets abbreviated `TIME` values with colons as time of the day. That is, `'11:12'` means `'11:12:00'`, not `'00:11:12'`. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o'clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`.

By default, values that lie outside the `TIME` range but are otherwise valid are clipped to the closest endpoint of the range. For example, `'-850:00:00'` and `'850:00:00'` are converted to `'-838:59:59'` and `'838:59:59'`. Invalid `TIME` values are converted to `'00:00:00'`. Note that

because '00:00:00' is itself a valid `TIME` value, there is no way to tell, from a value of '00:00:00' stored in a table, whether the original value was specified as '00:00:00' or whether it was invalid.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See [Section 5.1.7, “Server SQL Modes”](#).

### 11.3.3. The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR(4)` or `YEAR(2)` to specify a display width of four or two characters. The default is four characters if no width is given.

#### Note

The `YEAR(2)` data type has certain issues that you should consider before choosing to use it. Also, as of MySQL 5.6.6, `YEAR(2)` is deprecated. `YEAR(2)` columns in existing tables are treated as before, but `YEAR(2)` in new or altered tables are converted to `YEAR(4)`. For more information, see [Section 11.3.4, “YEAR\(2\) Limitations and Migrating to YEAR\(4\)”](#).

`YEAR(4)` and `YEAR(2)` differ in display format, but have the same range of values. For 4-digit format, MySQL displays `YEAR` values in `YYYY` format, with a range of 1901 to 2155, or 0000. For 2-digit format, MySQL displays only the last two (least significant) digits; for example, 70 (1970 or 2070) or 69 (2069).

You can specify input `YEAR` values in a variety of formats:

- As a 4-digit string in the range '1901' to '2155'.
- As a 4-digit number in the range 1901 to 2155.
- As a 1- or 2-digit string in the range '0' to '99'. Values in the ranges '0' to '69' and '70' to '99' are converted to `YEAR` values in the ranges 2000 to 2069 and 1970 to 1999.
- As a 1- or 2-digit number in the range 1 to 99. Values in the ranges 1 to 69 and 70 to 99 are converted to `YEAR` values in the ranges 2001 to 2069 and 1970 to 1999.

Inserting a numeric 0 has a different effect for `YEAR(2)` and `YEAR(4)`. For `YEAR(2)`, the result has a display value of 00 and an internal value of 2000. For `YEAR(4)`, the result has a display value of 0000 and an internal value of 0000. To specify zero for `YEAR(4)` and have it be interpreted as 2000, specify it as a string '0' or '00'.

- As the result of a function that returns a value that is acceptable in a `YEAR` context, such as `NOW()` [1220].

Invalid `YEAR` values are converted to 0000.

See also [Section 11.3.8, “Two-Digit Years in Dates”](#).

### 11.3.4. YEAR(2) Limitations and Migrating to YEAR(4)

Although the internal range of values for `YEAR(4)` and `YEAR(2)` is the same (1901 to 2155, and 0000), the display width for `YEAR(2)` makes that type inherently ambiguous because displayed values indicate only the last two digits of the internal values. The result can be a loss of information under certain circumstances. For this reason, consider avoiding `YEAR(2)` throughout your applications and using `YEAR(4)` wherever you need a `YEAR` data type. This section describes problems that can occur when using `YEAR(2)` and provides information about migrating existing `YEAR(2)` columns to `YEAR(4)`. Note that migration will become necessary at some point because support for `YEAR` data types with display values other than 4, most notably `YEAR(2)`, is reduced as of MySQL 5.6.6 and will be removed entirely in a future release.

## YEAR(2) Limitations

Issues with the YEAR(2) data type include ambiguity of displayed values, and possible loss of information when values are dumped and reloaded or converted to strings.

- Displayed YEAR(2) values can be ambiguous. It is possible for up to three YEAR(2) values that have different internal values to have the same displayed value, as the following example demonstrates:

```
mysql> CREATE TABLE t (y2 YEAR(2), y4 YEAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t (y2) VALUES(1912),(2012),(2112);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> UPDATE t SET y4 = y2;
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0

mysql> SELECT * FROM t;
+-----+-----+
| y2   | y4   |
+-----+-----+
| 12   | 1912 |
| 12   | 2012 |
| 12   | 2112 |
+-----+-----+
3 rows in set (0.00 sec)
```

- If you use `mysqldump` to dump the table created in the preceding item, the dump file represents all y2 values using the same 2-digit representation (12). If you reload the table from the dump file, all resulting rows have internal value 2012 and display value 12, thus losing the distinctions among them.
- Conversion of a YEAR(2) or YEAR(4) data value to string form uses the display width of the YEAR type. Suppose that YEAR(2) and YEAR(4) columns both contain the value 1970. Assigning each column to a string results in a value of '70' or '1970', respectively. That is, loss of information occurs for conversion from YEAR(2) to string.
- Values outside the range from 1970 to 2069 are stored incorrectly when inserted into a YEAR(2) column in a CSV table. For example, inserting 2111 results in a display value of 11 but an internal value of 2011.

To avoid these problems, use YEAR(4) rather than YEAR(2). Suggestions regarding migration strategies appear later in this section.

## Reduced YEAR(2) Support in MySQL 5.6

As of MySQL 5.6.6, support for YEAR(2) is diminished:

- YEAR(2) in column definitions for new tables is converted (with a warning) to YEAR(4):

```
mysql> CREATE TABLE t1 (y YEAR(2));
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1818
Message: YEAR(2) column type is deprecated. Creating YEAR(4) column instead.
1 row in set (0.00 sec)

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
Table: t1
Create Table: CREATE TABLE `t1` (
```

```
`y` year(4) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

- YEAR(2) in existing tables remains as YEAR(2) and is processed in queries as in older versions of MySQL. However, several programs or statements convert YEAR(2) to YEAR(4) automatically:
  - ALTER TABLE statements that result in a table rebuild.
  - REPAIR TABLE (which CHECK TABLE recommends you use if it finds that a table contains YEAR(2) columns).
  - mysql\_upgrade (which uses REPAIR TABLE).
  - Dumping with mysqldump and reloading the dump file. Unlike the conversions performed by the preceding three items, a dump and reload has the potential to change values.

A MySQL upgrade usually involves at least one of the last two items. However, with respect to YEAR(2), you should avoid dumping and reloading; as noted, that can change values.

## Migrating from YEAR(2) to YEAR(4)

Should you decide to convert YEAR(2) columns to YEAR(4), you can do so manually at any time without upgrading. Alternatively, you can upgrade to a version of MySQL with reduced support for YEAR(2) (MySQL 5.6.6 or later), then have MySQL convert YEAR(2) columns automatically. In the latter case, avoid upgrading by dumping and reloading your data because that can change data values. In addition, if you use replication, there are upgrade considerations you must take into account.

To convert YEAR(2) columns to YEAR(4) manually, use ALTER TABLE. Suppose that a table t1 has this definition:

```
CREATE TABLE t1 (ycol YEAR(2) NOT NULL DEFAULT '70');
```

Modify the column using ALTER TABLE as follows. Remember to include any column attributes such as NOT NULL or DEFAULT:

```
ALTER TABLE t1 MODIFY ycol YEAR(4) NOT NULL DEFAULT '1970';
```

The ALTER TABLE statement converts the table without changing YEAR(2) values. If the server is a replication master, the ALTER TABLE statement replicates to slaves and makes the corresponding table change on each one.

Another migration method is to perform a binary upgrade: Install MySQL 5.6.6 or later without dumping and reloading your data. Then run mysql\_upgrade, which uses REPAIR TABLE to convert YEAR(2) columns to YEAR(4) without changing data values. If the server is a replication master, the REPAIR TABLE statements replicate to slaves and make the corresponding table changes on each one, unless you invoke mysql\_upgrade with the --skip-write-binlog [244] option.

Upgrades to replication servers usually involve upgrading slaves to a newer version of MySQL, then upgrading the master. For example, if a master and slave both run MySQL 5.5, a typical upgrade sequence involves upgrading the slave to 5.6, then upgrading the master to 5.6. With regard to the different treatment of YEAR(2) as of MySQL 5.6.6, that upgrade sequence results in a problem: Suppose that the slave has been upgraded but not yet the master. Then creating a table containing a YEAR(2) column on the master results in a table containing a YEAR(4) column on the slave. Consequently, these operations will have a different result on the master and slave, if you use statement-based replication:

- Inserting numeric 0. The resulting value has an internal value of 2000 on the master but 0000 on the slave.
- Converting YEAR(2) to string. This operation uses the display value of YEAR(2) on the master but YEAR(4) on the slave.

To avoid such problems, use one of these strategies:

- Use row-based replication instead of statement-based replication.
- Modify all `YEAR(2)` columns on the master to `YEAR(4)` before upgrading. (Use `ALTER TABLE`, as described previously.) Then you can upgrade normally (slave first, then master) without introducing any `YEAR(2)` to `YEAR(4)` differences between the master and slave).

One migration method should be avoided: Do not dump your data with `mysqldump` and reload the dump file after upgrading. This has the potential to change `YEAR(2)` values, as described previously.

A migration from `YEAR(2)` to `YEAR(4)` should also involve examining application code for the possibility of changed behavior under conditions such as these:

- Code that expects selecting a `YEAR` column to produce exactly two digits.
- Code that does not account for different handling for inserts of numeric 0: Inserting 0 into `YEAR(2)` or `YEAR(4)` results in an internal value of 2000 or 0000, respectively.

### 11.3.5. Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`

#### Note

The following discussion applies under the assumption that the `explicit_defaults_for_timestamp` [481] system variable is disabled. If this variable is enabled, the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses that specify automatic initialization and updating are available, but are not assigned to any `TIMESTAMP` column unless explicitly included in the column definition.

As of MySQL 5.6.5, `TIMESTAMP` and `DATETIME` columns can be automatically initialized and updated to the current date and time (that is, the current timestamp). Before 5.6.5, this is true only for `TIMESTAMP`, and for at most one `TIMESTAMP` column per table. The following notes first describe automatic initialization and updating for MySQL 5.6.5 and up, then the differences for versions preceding 5.6.5.

For any `TIMESTAMP` or `DATETIME` column in a table, you can assign the current timestamp as the default value, the auto-update value, or both:

- An auto-initialized column is set to the current timestamp for inserted rows that specify no value for the column.
- An auto-updated column is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. An auto-updated column remains unchanged if all other columns are set to their current values. To prevent an auto-updated column from updating when other columns change, explicitly set it to its current value. To update an auto-updated column even when other columns do not change, explicitly set it to the value it should have (for example, set it to `CURRENT_TIMESTAMP` [1213]).

In addition, you can initialize or update any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

To specify automatic properties, use the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses in column definitions. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for `CURRENT_TIMESTAMP` [1213] have the same meaning as `CURRENT_TIMESTAMP` [1213]. These are `CURRENT_TIMESTAMP()` [1213], `NOW()` [1220], `LOCALTIME` [1219], `LOCALTIME()` [1219], `LOCALTIMESTAMP` [1219], and `LOCALTIMESTAMP()` [1219].

Use of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` is specific to `TIMESTAMP` and `DATETIME`. The `DEFAULT` clause also can be used to specify a constant (nonautomatic) default value; for example, `DEFAULT 0` or `DEFAULT '2000-01-01 00:00:00'`.

**Note**

The following examples that use `DEFAULT 0` do not work if the `NO_ZERO_DATE` [606] SQL mode is enabled because that mode causes “zero” date values (specified, for example, as `0 '0000-00-00 00:00:00'`) to be rejected. Be aware that the `TRADITIONAL` [609] SQL mode includes `NO_ZERO_DATE` [606].

`TIMESTAMP` or `DATETIME` column definitions can specify the current timestamp for both the default and auto-update values, for one but not the other, or for neither. Different columns can have different combinations of automatic properties. The following rules describe the possibilities:

- With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`, the column has the current timestamp for its default value and is automatically updated to the current timestamp.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
);
```

- With a `DEFAULT` clause but no `ON UPDATE CURRENT_TIMESTAMP` clause, the column has the given default value and is not automatically updated to the current timestamp.

The default depends on whether the `DEFAULT` clause specifies `CURRENT_TIMESTAMP` or a constant value. With `CURRENT_TIMESTAMP`, the default is the current timestamp.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
  dt DATETIME DEFAULT CURRENT_TIMESTAMP
);
```

With a constant, the default is the given value. In this case, the column has no automatic properties at all.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT 0,
  dt DATETIME DEFAULT 0
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause and a constant `DEFAULT` clause, the column is automatically updated to the current timestamp and has the given constant default value.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP,
  dt DATETIME DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause but no `DEFAULT` clause, the column is automatically updated to the current timestamp but does not have the current timestamp for its default value.

The default in this case is type dependent. `TIMESTAMP` has a default of 0 unless defined with the `NULL` attribute, in which case the default is `NULL`.

```
CREATE TABLE t1 (
  ts1 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,      -- default 0
  ts2 TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL
);
```

`DATETIME` has a default of `NULL` unless defined with the `NOT NULL` attribute, in which case the default is 0.

```
CREATE TABLE t1 (
  dt1 DATETIME ON UPDATE CURRENT_TIMESTAMP,      -- default NULL
  dt2 DATETIME NOT NULL ON UPDATE CURRENT_TIMESTAMP -- default 0
);
```

`TIMESTAMP` and `DATETIME` columns have no automatic properties unless they are specified explicitly, with this exception: By default, the *first* `TIMESTAMP` column has both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` if neither is specified explicitly. To suppress automatic properties for the first `TIMESTAMP` column, do either of the following:

- Define the column with a `DEFAULT` clause that specifies a constant default value.
- Specify the `NULL` attribute. This also causes the column to permit `NULL` values, which means that you cannot assign the current timestamp by setting the column to `NULL`. Assigning `NULL` sets the column to `NULL`.

Consider these table definitions:

```
CREATE TABLE t1 (
  ts1 TIMESTAMP DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t2 (
  ts1 TIMESTAMP NULL,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t3 (
  ts1 TIMESTAMP NULL DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
```

The tables have these properties:

- In each table definition, the first `TIMESTAMP` column has no automatic initialization or updating.
- The tables differ in how the `ts1` column handles `NULL` values. For `t1`, `ts1` is `NOT NULL` and assigning it a value of `NULL` sets it to the current timestamp. For `t2` and `t3`, `ts1` permits `NULL` and assigning it a value of `NULL` sets it to `NULL`.
- `t2` and `t3` differ in the default value for `ts1`. For `t2`, `ts1` is defined to permit `NULL`, so the default is also `NULL` in the absence of an explicit `DEFAULT` clause. For `t3`, `ts1` permits `NULL` but has an explicit default of 0.

If a `TIMESTAMP` or `DATETIME` column definition includes an explicit fractional seconds precision value anywhere, the same value must be used throughout the column definition. This is permitted:

```
CREATE TABLE t1 (
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6) ON UPDATE CURRENT_TIMESTAMP(6)
);
```

This is not permitted:

```
CREATE TABLE t1 (
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP(3)
);
```

## Automatic Timestamp Properties Before MySQL 5.6.5

Before MySQL 5.6.5, support for automatic initialization and updating is more limited:

- `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` cannot be used with `DATETIME` columns.
- `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` can be used with at most one `TIMESTAMP` column per table. It is not possible to have the current timestamp be the default value for one column and the auto-update value for another column.

You can choose whether to use these properties and which `TIMESTAMP` column should have them. It need not be the first one in a table that is automatically initialized or updated to the current timestamp. To specify automatic initialization or updating for a different `TIMESTAMP` column, you must suppress

the automatic properties for the first one, as previously described. Then, for the other `TIMESTAMP` column, the rules for the `DEFAULT` and `ON UPDATE` clauses are the same as for the first `TIMESTAMP` column, except that if you omit both clauses, no automatic initialization or updating occurs.

### TIMESTAMP Initialization and the NULL Attribute

By default, `TIMESTAMP` columns are `NOT NULL`, cannot contain `NULL` values, and assigning `NULL` assigns the current timestamp. To permit a `TIMESTAMP` column to contain `NULL`, explicitly declare it with the `NULL` attribute. In this case, the default value also becomes `NULL` unless overridden with a `DEFAULT` clause that specifies a different default value. `DEFAULT NULL` can be used to explicitly specify `NULL` as the default value. (For a `TIMESTAMP` column not declared with the `NULL` attribute, `DEFAULT NULL` is invalid.) If a `TIMESTAMP` column permits `NULL` values, assigning `NULL` sets it to `NULL`, not to the current timestamp.

The following table contains several `TIMESTAMP` columns that permit `NULL` values:

```
CREATE TABLE t
(
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
```

A `TIMESTAMP` column that permits `NULL` values does *not* take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP [1213]` and no value is specified for the column
- `CURRENT_TIMESTAMP [1213]` or any of its synonyms such as `NOW() [1220]` is explicitly inserted into the column

In other words, a `TIMESTAMP` column defined to permit `NULL` values auto-initializes only if its definition includes `DEFAULT CURRENT_TIMESTAMP`:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

If the `TIMESTAMP` column permits `NULL` values but its definition does not include `DEFAULT CURRENT_TIMESTAMP`, you must explicitly insert a value corresponding to the current date and time. Suppose that tables `t1` and `t2` have these definitions:

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
```

To set the `TIMESTAMP` column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

```
INSERT INTO t1 VALUES (NOW());
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
```

## 11.3.6. Fractional Seconds in Time Values

Before MySQL 5.6.4, the instances are limited in which a fractional seconds part is permitted in temporal values. A trailing fractional part is permissible in contexts such as literal values, and in the arguments to or return values from some temporal functions. Example:

```
mysql> SELECT MICROSECOND('2010-12-10 14:12:09.019473');
+-----+
| MICROSECOND('2010-12-10 14:12:09.019473') |
+-----+
|                                     19473 |
+-----+
```

However, when MySQL stores a value into a column of any temporal data type, it discards any fractional part and does not store it.

MySQL 5.6.4 and up expands fractional seconds support for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision:

- To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and `fsp` is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate. For example, `NOW()` [1220] with no argument returns the current date and time with no fractional part, but takes an optional argument from 0 to 6 to specify that the return value includes a fractional seconds part of that many digits.
- Syntax for temporal literals produces temporal values: `DATE 'str'`, `TIME 'str'`, and `TIMESTAMP 'str'`, and the ODBC-syntax equivalents. The resulting value includes a trailing fractional seconds part if specified. Previously, the temporal type keyword was ignored and these constructs produced the string value. See [Standard SQL and ODBC Date and Time Literals](#)

In some cases, previously accepted syntax may produce different results. The following items indicate where existing code may need to be changed to avoid problems:

- Some expressions produce results that differ from previous results. Examples: The `timestamp` system variable returns a value that includes a microseconds fractional part rather than an integer. Functions that return a result that includes the current time (such as `CURTIME()` [1213], `SYSDATE()` [1223], or `UTC_TIMESTAMP()` [1227]) interpret an argument as an `fsp` value and the return value includes a fractional seconds part of that many digits. Previously, these functions permitted an argument but ignored it.
- `TIME` values are converted to `DATETIME` by adding the time to the current date. (This means that the date part of the result differs from the current date if the time value is outside the range from `'00:00:00'` to `'23:59:59'`.) Previously, conversion of `TIME` values to `DATETIME` was unreliable. See [Section 11.3.7, "Conversion Between Date and Time Types"](#).
- `TIMESTAMP(N)` was permitted in old MySQL versions, but `N` was a display width rather than fractional seconds precision. Support for this behavior was removed in MySQL 5.5.3, so applications that are reasonably up to date should not be subject to this issue. Otherwise, code must be rewritten.

### 11.3.7. Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although `DATE`, `DATETIME`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. `TIMESTAMP` values cannot be earlier than 1970 UTC or later than `'2038-01-19 03:14:07'` UTC. This means that a date such as `'1968-01-01'`, while valid as a `DATE` or `DATETIME` value, is not valid as a `TIMESTAMP` value and is converted to 0.

Conversion of `DATE` values:

- Conversion to a `DATETIME` or `TIMESTAMP` value adds a time part of `'00:00:00'` because the `DATE` value contains no time information.
- Conversion to a `TIME` value is not useful; the result is `'00:00:00'`.

Conversion of `DATETIME` and `TIMESTAMP` values:

- Conversion to a `DATE` value discards the time part because the `DATE` type contains no time information.
- Conversion to a `TIME` value discards the date part because the `TIME` type contains no date information.

Conversion of `TIME` values to other temporal types is version specific:

- As of MySQL 5.6.4, the value of `CURRENT_DATE()` [1212] is used for the date part. The `TIME` is interpreted as elapsed time (not time of day) and added to the date. This means that the date part of the result differs from the current date if the time value is outside the range from `'00:00:00'` to `'23:59:59'`.

Suppose that the current date is `'2012-01-01'`. `TIME` values of `'12:00:00'`, `'24:00:00'`, and `'-12:00:00'`, when converted to `DATETIME` or `TIMESTAMP` values, result in `'2012-01-01 12:00:00'`, `'2012-01-02 00:00:00'`, and `'2011-12-31 12:00:00'`, respectively.

Conversion of `TIME` to `DATE` is similar but discards the time part from the result: `'2012-01-01'`, `'2012-01-02'`, and `'2011-12-31'`, respectively.

- Before 5.6.4, MySQL converts a time value to a date or date-and-time value by parsing the string value of the time as a date or date-and-time. This is unlikely to be useful. For example, `'23:12:31'` interpreted as a date becomes `'2032-12-31'`. Time values not valid as dates become `'0000-00-00'` or `NULL`.

Explicit conversion can be used to override implicit conversion. For example, in comparison of `DATE` and `DATETIME` values, the `DATE` value is coerced to the `DATETIME` type by adding a time part of `'00:00:00'`. To perform the comparison by ignoring the time part of the `DATETIME` value instead, use the `CAST()` [1245] function in the following way:

```
date_col = CAST(datetime_col AS DATE)
```

Conversion of `TIME` and `DATETIME` values to numeric form (for example, by adding `+0`) occurs as follows:

- As of MySQL 5.6.4, `TIME(N)` or `DATETIME(N)` is converted to integer when `N` is 0 (or omitted) and to a `DECIMAL` value with `N` decimal digits when `N` is greater than 0:

```
mysql> SELECT CURTIME(), CURTIME()+0, CURTIME(3)+0;
+-----+-----+-----+
| CURTIME() | CURTIME()+0 | CURTIME(3)+0 |
+-----+-----+-----+
| 09:28:00 |          92800 |      92800.887 |
+-----+-----+-----+
mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+-----+-----+-----+
| NOW() | NOW()+0 | NOW(3)+0 |
+-----+-----+-----+
| 2012-08-15 09:28:00 | 20120815092800 | 20120815092800.889 |
+-----+-----+-----+
```

- Before MySQL 5.6.4, the conversion results in a double-precision value with a microseconds part of `.000000`:

```
mysql> SELECT CURTIME(), CURTIME()+0;
+-----+-----+
| CURTIME() | CURTIME()+0 |
+-----+-----+
| 09:28:00 | 92800.000000 |
+-----+-----+
mysql> SELECT NOW(), NOW()+0;
+-----+-----+
| NOW() | NOW()+0 |
+-----+-----+
| 2012-08-15 09:28:00 | 20120815092800.000000 |
+-----+-----+
```

---

### 11.3.8. Two-Digit Years in Dates

Date values with two-digit years are ambiguous because the century is unknown. Such values must be interpreted into four-digit form because MySQL stores years internally using four digits.

For `DATETIME`, `DATE`, and `TIMESTAMP` types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range `00–69` are converted to `2000–2069`.
- Year values in the range `70–99` are converted to `1970–1999`.

For `YEAR`, the rules are the same, with this exception: A numeric `00` inserted into `YEAR(4)` results in `0000` rather than `2000`. To specify zero for `YEAR(4)` and have it be interpreted as `2000`, specify it as a string `'0'` or `'00'`.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing four-digit year values.

`ORDER BY` properly sorts `YEAR` values that have two-digit years.

Some functions like `MIN()` [1284] and `MAX()` [1284] convert a `YEAR` to a number. This means that a value with a two-digit year does not work properly with these functions. The fix in this case is to convert the `YEAR` to four-digit year format.

## 11.4. String Types

The string types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`. This section describes how these types work and how to use them in your queries. For string type storage requirements, see [Section 11.6, “Data Type Storage Requirements”](#).

### 11.4.1. The `CHAR` and `VARCHAR` Types

The `CHAR` and `VARCHAR` types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The `CHAR` and `VARCHAR` types are declared with a length that indicates the maximum number of characters you want to store. For example, `CHAR(30)` can hold up to 30 characters.

The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed unless the `PAD_CHAR_TO_FULL_LENGTH` [606] SQL mode is enabled.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See [Section E.10.4, “Limits on Table Column Count and Row Size”](#).

In contrast to `CHAR`, `VARCHAR` values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a `CHAR` or `VARCHAR` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

For VARCHAR columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For CHAR columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

VARCHAR values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between CHAR and VARCHAR by showing the result of storing various string values into CHAR(4) and VARCHAR(4) columns (assuming that the column uses a single-byte character set such as latin1).

Value	CHAR(4)	Storage Required	VARCHAR(4)	Storage Required
' '	'    '	4 bytes	' '	1 byte
'ab'	'ab  '	4 bytes	'ab'	3 bytes
'abcd'	'abcd'	4 bytes	'abcd'	5 bytes
'abcdefgh'	'abcd'	4 bytes	'abcd'	5 bytes

The values shown as stored in the last row of the table apply *only when not using strict mode*; if MySQL is running in strict mode, values that exceed the column length are *not stored*, and an error results.

If a given value is stored into the CHAR(4) and VARCHAR(4) columns, the values retrieved from the columns are not always the same because trailing spaces are removed from CHAR columns upon retrieval. The following example illustrates this difference:

```
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab ', 'ab ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('( ', v, ')'), CONCAT('( ', c, ')) FROM vc;
+-----+-----+
| CONCAT('( ', v, ')) | CONCAT('( ', c, ')) |
+-----+-----+
| (ab )              | (ab)                |
+-----+-----+
1 row in set (0.06 sec)
```

Values in CHAR and VARCHAR columns are sorted and compared according to the character set collation assigned to the column.

All MySQL collations are of type PADSPACE. This means that all CHAR, VARCHAR, and TEXT values in MySQL are compared without regard to any trailing spaces. “Comparison” in this context does not include the LIKE [1190] pattern-matching operator, for which trailing spaces are significant. For example:

```
mysql> CREATE TABLE names (myname CHAR(10));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO names VALUES ('Monty');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT myname = 'Monty', myname = 'Monty ' FROM names;
+-----+-----+
| myname = 'Monty' | myname = 'Monty ' |
+-----+-----+
| 1                | 1                  |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT myname LIKE 'Monty', myname LIKE 'Monty ' FROM names;
+-----+-----+
| myname LIKE 'Monty' | myname LIKE 'Monty ' |
+-----+-----+
```

```

+-----+-----+
|          1 |          0 |
+-----+-----+
1 row in set (0.00 sec)

```

This is true for all MySQL versions, and is not affected by the server SQL mode.

#### Note

For more information about MySQL character sets and collations, see [Section 10.1, “Character Set Support”](#).

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

## 11.4.2. The `BINARY` and `VARBINARY` Types

The `BINARY` and `VARBINARY` types are similar to `CHAR` and `VARCHAR`, except that they contain binary strings rather than nonbinary strings. That is, they contain byte strings rather than character strings. This means that they have no character set, and sorting and comparison are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for `BINARY` and `VARBINARY` as it is for `CHAR` and `VARCHAR`, except that the length for `BINARY` and `VARBINARY` is a length in bytes rather than in characters.

The `BINARY` and `VARBINARY` data types are distinct from the `CHAR BINARY` and `VARCHAR BINARY` data types. For the latter types, the `BINARY` attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary collation for the column character set to be used, and the column itself contains nonbinary character strings rather than binary byte strings. For example, `CHAR(5) BINARY` is treated as `CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin`, assuming that the default character set is `latin1`. This differs from `BINARY(5)`, which stores 5-byte binary strings that have no character set or collation. For information about differences between nonbinary string binary collations and binary strings, see [Section 10.1.7.6, “The `\_bin` and binary Collations”](#).

If strict SQL mode is not enabled and you assign a value to a `BINARY` or `VARBINARY` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For cases of truncation, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

When `BINARY` values are stored, they are right-padded with the pad value to the specified length. The pad value is `0x00` (the zero byte). Values are right-padded with `0x00` on insert, and no trailing bytes are removed on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

Example: For a `BINARY(3)` column, 'a ' becomes 'a \0' when inserted. 'a\0' becomes 'a \0\0' when inserted. Both inserted values remain unchanged when selected.

For `VARBINARY`, there is no padding on insert and no bytes are stripped on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad bytes will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a\0' causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the `BINARY` data type for storing binary data and you require that the value retrieved be exactly the same

as the value stored. The following example illustrates how 0x00-padding of BINARY values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+-----+-----+-----+
| HEX(c) | c = 'a' | c = 'a\0\0' |
+-----+-----+-----+
| 610000 | 0 | 1 |
+-----+-----+-----+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use VARBINARY or one of the BLOB data types instead.

### 11.4.3. The BLOB and TEXT Types

A BLOB is a binary large object that can hold a variable amount of data. The four BLOB types are TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB. These differ only in the maximum length of the values they can hold. The four TEXT types are TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT. These correspond to the four BLOB types and have the same maximum lengths and storage requirements. See [Section 11.6, “Data Type Storage Requirements”](#).

BLOB values are treated as binary strings (byte strings). They have no character set, and sorting and comparison are based on the numeric values of the bytes in column values. TEXT values are treated as nonbinary strings (character strings). They have a character set, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a BLOB or TEXT column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

Truncation of excess trailing spaces from values to be inserted into TEXT columns always generates a warning, regardless of the SQL mode.

For TEXT and BLOB columns, there is no padding on insert and no bytes are stripped on select.

If a TEXT column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for BLOB columns.

In most respects, you can regard a BLOB column as a VARBINARY column that can be as large as you like. Similarly, you can regard a TEXT column as a VARCHAR column. BLOB and TEXT differ from VARBINARY and VARCHAR in the following ways:

- For indexes on BLOB and TEXT columns, you must specify an index prefix length. For CHAR and VARCHAR, a prefix length is optional. See [Section 8.3.4, “Column Indexes”](#).
- BLOB and TEXT columns cannot have DEFAULT values.

If you use the BINARY attribute with a TEXT data type, the column is assigned the binary collation of the column character set.

LONG and LONG VARCHAR map to the MEDIUMTEXT data type. This is a compatibility feature.

MySQL Connector/ODBC defines BLOB values as LONGVARBINARY and TEXT values as LONGVARCHAR.

Because `BLOB` and `TEXT` values can be extremely long, you might encounter some constraints in using them:

- Only the first `max_sort_length` [508] bytes of the column are used when sorting. The default value of `max_sort_length` [508] is 1024. You can make more bytes significant in sorting or grouping by increasing the value of `max_sort_length` [508] at server startup or runtime. Any client can change the value of its session `max_sort_length` [508] variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
-> ORDER BY comment;
```

- Instances of `BLOB` or `TEXT` columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the `MEMORY` storage engine does not support those data types (see [Section 8.4.3.3, “How MySQL Uses Internal Temporary Tables”](#)). Use of disk incurs a performance penalty, so include `BLOB` or `TEXT` columns in the query result only if they are really needed. For example, avoid using `SELECT *`, which selects all columns.
- The maximum size of a `BLOB` or `TEXT` object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the `max_allowed_packet` [502] variable, but you must do so for both the server and your client program. For example, both `mysql` and `mysqldump` enable you to change the client-side `max_allowed_packet` [502] value. See [Section 8.11.2, “Tuning Server Parameters”](#), [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see [Section 11.6, “Data Type Storage Requirements”](#)

Each `BLOB` or `TEXT` value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in `BLOB` or `TEXT` columns. You may find MySQL's string handling functions useful for working with such data. See [Section 12.5, “String Functions”](#). For security and other reasons, it is usually preferable to do so using application code rather than giving application users the `FILE` [754] privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (<http://forums.mysql.com/>).

#### 11.4.4. The ENUM Type

An `ENUM` is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time. It has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See [Section 11.6, “Data Type Storage Requirements”](#) for the storage requirements for `ENUM` types.
- Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

- If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in [Section 11.4.4, “Limitations”](#).
- Using `ENUM` columns in `ORDER BY` clauses requires extra care, as explained in [Section 11.4.4, “Sorting”](#).

#### Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an `ENUM` column like this:

```
CREATE TABLE shirts (
  name VARCHAR(40),
  size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);
INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'),
('polo shirt','small');
SELECT name, size FROM shirts WHERE size = 'medium';
+-----+-----+
| name   | size   |
+-----+-----+
| t-shirt | medium |
+-----+-----+
UPDATE shirts SET size = 'small' WHERE size = 'large';
COMMIT;
```

Inserting 1 million rows into this table with a value of 'medium' would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string 'medium' in a VARCHAR column.

### Index Values for Enumeration Literals

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following SELECT statement to find rows into which invalid ENUM values were assigned:

```
mysql> SELECT * FROM tbl_name WHERE enum_col=0;
```

- The index of the NULL value is NULL.
- The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as ENUM('Mercury', 'Venus', 'Earth') can have any of the values shown here. The index of each value is also shown.

Value	Index
NULL	NULL
' '	0
'Mercury'	1
'Venus'	2
'Earth'	3

An ENUM column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its ENUM and SET columns considered as a group. For more information on these limits, see Section E.10.5, “Limits Imposed by .frm File Structure”.

If you retrieve an ENUM value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an ENUM column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

Functions such as SUM() [1285] or AVG() [1282] that expect a numeric argument cast the argument to a number if necessary. For ENUM values, the index number is used in the calculation.

### Handling of Enumeration Literals

Trailing spaces are automatically deleted from ENUM member values in the table definition when a table is created.

When retrieved, values stored into an `ENUM` column are displayed using the lettercase that was used in the column definition. Note that `ENUM` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an `ENUM` column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does *not* work with `LOAD DATA`, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an `ENUM` column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of `'0'`, `'1'`, and `'2'`, but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes `'1'` (the value with index 2). If you store `'2'`, it matches an enumeration value, so it is stored as `'2'`. If you store `'3'`, it does not match any enumeration value, so it is treated as an index and becomes `'2'` (the value with index 3).

```
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
+-----+
| numbers |
+-----+
| 1       |
| 2       |
| 2       |
+-----+
```

To determine all possible values for an `ENUM` column, use `SHOW COLUMNS FROM tbl_name LIKE 'enum_col'` and parse the `ENUM` definition in the `Type` column of the output.

In the C API, `ENUM` values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [Section 21.8.4, “C API Data Structures”](#).

## Empty or NULL Enumeration Values

An enumeration value can also be the empty string (`' '`) or `NULL` under certain circumstances:

- If you insert an invalid value into an `ENUM` (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a “normal” empty string by the fact that this string has the numeric value 0. See [Section 11.4.4, “Index Values for Enumeration Literals”](#) for details about the numeric indexes for the enumeration values.

If strict SQL mode is enabled, attempts to insert invalid `ENUM` values result in an error.

- If an `ENUM` column is declared to permit `NULL`, the `NULL` value is a valid value for the column, and the default value is `NULL`. If an `ENUM` column is declared `NOT NULL`, its default value is the first element of the list of permitted values.

## Sorting

`ENUM` values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, `'b'` sorts before `'a'` for `ENUM('b', 'a')`. The empty string sorts before nonempty strings, and `NULL` values sort before all other enumeration values.

To prevent unexpected results when using the `ORDER BY` clause on an `ENUM` column, use one of these techniques:

- Specify the `ENUM` list in alphabetic order.
- Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST(col AS CHAR)` or `ORDER BY CONCAT(col)`.

## Limitations

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does *not* work because the `CONCAT` function cannot be used to construct an enumeration value:

```
CREATE TABLE sizes (
  size ENUM('small', CONCAT('med','ium'), 'large')
);
```

You also cannot employ a user variable as an enumeration value. This pair of statements do *not* work:

```
SET @mysize = 'medium';

CREATE TABLE sizes (
  size ENUM('small', @mysize, 'large')
);
```

We strongly recommend that you do *not* use numbers as enumeration values, because it does not save on storage over the appropriate `TINYINT` or `SMALLINT` type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the `ENUM` values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See [Section 11.4.4, “Handling of Enumeration Literals”](#) to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

### 11.4.5. The SET Type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. `SET` column values that consist of multiple set members are specified with members separated by commas (`,`). A consequence of this is that `SET` member values should not themselves contain commas.

For example, a column specified as `SET('one', 'two') NOT NULL` can have any of these values:

```
' '
'one'
'two'
'one,two'
```

A `SET` column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on this limit, see [Section E.10.5, “Limits Imposed by .frm File Structure”](#).

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from `SET` member values in the table definition when a table is created.

When retrieved, values stored in a `SET` column are displayed using the lettercase that was used in the column definition. Note that `SET` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores `SET` values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a `SET` value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a `SET` column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a SET column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as SET('a','b','c','d'), the members have the following decimal and binary values.

SET Member	Decimal Value	Binary Value
'a'	1	0001
'b'	2	0010
'c'	4	0100
'd'	8	1000

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth SET value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one SET element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. For example, suppose that a column is specified as SET('a','b','c','d'):

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

Then all these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
+-----+
| col   |
+-----+
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
+-----+
5 rows in set (0.04 sec)
```

If you set a SET column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+-----+-----+-----+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+-----+
| col   |
+-----+
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
+-----+
```

```
+-----+
6 rows in set (0.01 sec)
```

If strict SQL mode is enabled, attempts to insert invalid `SET` values result in an error.

`SET` values are sorted numerically. `NULL` values sort before non-`NULL` `SET` values.

Functions such as `SUM()` [1285] or `AVG()` [1282] that expect a numeric argument cast the argument to a number if necessary. For `SET` values, the cast operation causes the numeric value to be used.

Normally, you search for `SET` values using the `FIND_IN_SET()` [1179] function or the `LIKE` [1190] operator:

```
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```

The first statement finds rows where `set_col` contains the `value` set member. The second is similar, but not the same: It finds rows where `set_col` contains `value` anywhere, even as a substring of another set member.

The following statements also are permitted:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to `'val1,val2'` returns different results than comparing values to `'val2,val1'`. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a `SET` column, use `SHOW COLUMNS FROM tbl_name LIKE set_col` and parse the `SET` definition in the `Type` column of the output.

In the C API, `SET` values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [Section 21.8.4, “C API Data Structures”](#).

## 11.5. Data Type Default Values

The `DEFAULT value` clause in a data type specification indicates a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` [1220] or `CURRENT_DATE` [1212]. The exception is that you can specify `CURRENT_TIMESTAMP` [1213] as the default for `TIMESTAMP` and `DATETIME` columns. See [Section 11.3.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”](#).

`BLOB` and `TEXT` columns cannot be assigned a default value.

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as the value, MySQL defines the column with no explicit `DEFAULT` clause. Exception: If the column is defined as part of a `PRIMARY KEY` but not explicitly as `NOT NULL`, MySQL creates it as a `NOT NULL` column (because `PRIMARY KEY` columns must be `NOT NULL`), but also assigns it a `DEFAULT` clause using the implicit default value. To prevent this, include an explicit `NOT NULL` in the definition of any `PRIMARY KEY` column.

For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.
- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` [1275] cannot produce a value:

```
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See [Section 5.1.7, “Server SQL Modes”](#).

For a given table, you can use the `SHOW CREATE TABLE` statement to see which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is `0`, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.
- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. This is also true for `TIMESTAMP` if the `explicit_defaults_for_timestamp` [481] system variable is enabled (see [Section 5.1.4, “Server System Variables”](#)). Otherwise, for the first `TIMESTAMP` column in a table, the default value is the current date and time. See [Section 11.3, “Date and Time Types”](#).
- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

## 11.6. Data Type Storage Requirements

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes `BLOB` or `TEXT` columns, which contribute only 9 to 12 bytes toward this size. For `BLOB` and `TEXT` data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the

corresponding types. For more information, see [Chapter 14, Storage Engines](#), and [Section E.10.4, “Limits on Table Column Count and Row Size”](#).

## InnoDB Tables

See [Section 14.2.3.12.7, “Physical Row Structure”](#) for information about storage requirements for InnoDB tables.

## NDBCLUSTER Tables

### Important

NDB tables use *4-byte alignment*; all NDB data storage is done in multiples of 4 bytes. Thus, a column value that would typically take 15 bytes requires 16 bytes in an NDB table. For example, in NDB tables, the `TINYINT`, `SMALLINT`, `MEDIUMINT`, and `INTEGER (INT)` column types each require 4 bytes storage per record due to the alignment factor.

Each `BIT(M)` column takes  $M$  bits of storage space. Although an individual `BIT` column is *not* 4-byte aligned, NDB reserves 4 bytes (32 bits) per row for the first 1-32 bits needed for `BIT` columns, then another 4 bytes for bits 33-64, and so on.

While a `NULL` itself does not require any storage space, NDB reserves 4 bytes per row if the table definition contains any columns defined as `NULL`, up to 32 `NULL` columns. (If a MySQL Cluster table is defined with more than 32 `NULL` columns up to 64 `NULL` columns, then 8 bytes per row are reserved.)

Every table using the NDB storage engine requires a primary key; if you do not define a primary key, a “hidden” primary key is created by NDB. This hidden primary key consumes 31-35 bytes per table record.

You can use the `ndb_size.pl` Perl script to estimate NDB storage requirements. It connects to a current MySQL (not MySQL Cluster) database and creates a report on how much space that database would require if it used the NDB storage engine. See [ndb\\_size.pl — NDBCLUSTER Size Requirement Estimator](#) for more information.

## Storage Requirements for Numeric Types

Data Type	Storage Required
<code>TINYINT</code>	1 byte
<code>SMALLINT</code>	2 bytes
<code>MEDIUMINT</code>	3 bytes
<code>INT, INTEGER</code>	4 bytes
<code>BIGINT</code>	8 bytes
<code>FLOAT(p)</code>	4 bytes if $0 \leq p \leq 24$ , 8 bytes if $25 \leq p \leq 53$
<code>FLOAT</code>	4 bytes
<code>DOUBLE [PRECISION], REAL</code>	8 bytes
<code>DECIMAL(M,D), NUMERIC(M,D)</code>	Varies; see following discussion
<code>BIT(M)</code>	approximately $(M+7)/8$ bytes

Values for `DECIMAL` (and `NUMERIC`) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4

## Storage Requirements for Date and Time Types

For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.

Data Type	Storage Required Before MySQL 5.6.4	Storage Required as of MySQL 5.6.4
<code>YEAR</code>	1 byte	1 byte
<code>DATE</code>	3 bytes	3 bytes
<code>TIME</code>	3 bytes	3 bytes + fractional seconds storage
<code>DATETIME</code>	8 bytes	5 bytes + fractional seconds storage
<code>TIMESTAMP</code>	4 bytes	4 bytes + fractional seconds storage

As of MySQL 5.6.4, storage for `YEAR` and `DATE` remains unchanged. However, `TIME`, `DATETIME`, and `TIMESTAMP` are represented differently. `DATETIME` is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

Fractional Seconds Precision	Storage Required
0	0 bytes
1, 2	1 byte
3, 4	2 bytes
5, 6	3 bytes

For example, `TIME(0)`, `TIME(2)`, `TIME(4)`, and `TIME(6)` use 3, 4, 5, and 6 bytes, respectively. `TIME` and `TIME(0)` are equivalent and require the same storage.

For details about internal representation of temporal values, see [MySQL Internals: Important Algorithms and Structures](#).

## Storage Requirements for String Types

In the following table, *M* represents the declared column length in characters for nonbinary string types and bytes for binary string types. *L* represents the actual length in bytes of a given string value.

Data Type	Storage Required
<code>CHAR(M)</code>	$M \times w$ bytes, $0 \leq M \leq 255$ , where <i>w</i> is the number of bytes required for the maximum-length character in the character set

Data Type	Storage Required
<code>BINARY(M)</code>	$M$ bytes, $0 \leq M \leq 255$
<code>VARCHAR(M)</code> , <code>VARBINARY(M)</code>	$L + 1$ bytes if column values require 0 – 255 bytes, $L + 2$ bytes if values may require more than 255 bytes
<code>TINYBLOB</code> , <code>TINYTEXT</code>	$L + 1$ bytes, where $L < 2^8$
<code>BLOB</code> , <code>TEXT</code>	$L + 2$ bytes, where $L < 2^{16}$
<code>MEDIUMBLOB</code> , <code>MEDIUMTEXT</code>	$L + 3$ bytes, where $L < 2^{24}$
<code>LONGBLOB</code> , <code>LONGTEXT</code>	$L + 4$ bytes, where $L < 2^{32}$
<code>ENUM('value1', 'value2', ...)</code>	1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)
<code>SET('value1', 'value2', ...)</code>	1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is  $L$  (the byte length of the string). For example, storage for a `MEDIUMTEXT` value requires  $L$  bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular `CHAR`, `VARCHAR`, or `TEXT` column value, you must take into account the character set used for that column and whether the value contains multi-byte characters. In particular, when using the `utf8` (or `utf8mb4`) Unicode character set, you must keep in mind that not all characters use the same number of bytes and can require up to three (four) bytes per character. For a breakdown of the storage used for different categories of `utf8` or `utf8mb4` characters, see [Section 10.1.10, “Unicode Support”](#).

`VARCHAR`, `VARBINARY`, and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multi-byte characters

For example, a `VARCHAR(255)` column can hold a string with a maximum length of 255 characters. Assuming that the column uses the `latin1` character set (one byte per character), the actual storage required is the length of the string ( $L$ ), plus one byte to record the length of the string. For the string `'abcd'`,  $L$  is 4 and the storage requirement is five bytes. If the same column is instead declared to use the `ucs2` double-byte character set, the storage requirement is 10 bytes: The length of `'abcd'` is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of *bytes* that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multi-byte characters, the effective maximum number of *characters* is less. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters. See [Section E.10.4, “Limits on Table Column Count and Row Size”](#).

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See [Section 11.4.4, “The ENUM Type”](#).

The size of a `SET` object is determined by the number of different set members. If the set size is  $N$ , the object occupies  $(N+7) / 8$  bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See [Section 11.4.5, “The SET Type”](#).

## 11.7. Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, -, \*, and /) with `DECIMAL` columns are done with precision of 65 decimal (base 10) digits. See [Section 11.1.1, “Numeric Type Overview”](#).

If accuracy is not too important or if speed is the highest priority, the `DOUBLE` type may be good enough. For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

`PROCEDURE ANALYSE` can be used to obtain suggestions for optimal column data types. For more information, see [Section 8.4.2.4, “Using PROCEDURE ANALYSE”](#).

## 11.8. Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

Other Vendor Type	MySQL Type
BOOL	TINYINT
BOOLEAN	TINYINT
CHARACTER VARYING(M)	VARCHAR(M)
FIXED	DECIMAL
FLOAT4	FLOAT
FLOAT8	DOUBLE
INT1	TINYINT
INT2	SMALLINT
INT3	MEDIUMINT
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | tinyint(1)   | YES  |     | NULL    |       |
```

```
| b      | double | YES | | NULL | |  
| c      | mediumtext | YES | | NULL | |  
| d      | decimal(10,0) | YES | | NULL | |  
+-----+-----+-----+-----+-----+  
4 rows in set (0.01 sec)
```

---

12.19.5. Precision Math Examples .....	1319

Expressions can be used at several points in `SQL` statements, such as in the `ORDER BY` or `HAVING` clauses of `SELECT` statements, in the `WHERE` clause of a `SELECT`, `DELETE`, or `UPDATE` statement,

or in `SET` statements. Expressions can be written using literal values, column values, `NULL`, built-in functions, stored functions, user-defined functions, and operators. This chapter describes the functions and operators that are permitted for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#), and [Section 22.3, “Adding New Functions to MySQL”](#). See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for a particular function or operator.

#### Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` [442] option. (See [Section 5.1.7, “Server SQL Modes”](#).) Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----+
| mod(29,9) |
+-----+
|         2 |
+-----+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
-> 2
```

## 12.1. Function and Operator Reference

Table 12.1. Functions/Operators

Name	Description
<a href="#">ABS()</a> [1202]	Return the absolute value
<a href="#">ACOS()</a> [1202]	Return the arc cosine
<a href="#">ADDDATE()</a> [1211]	Add time values (intervals) to a date value
<a href="#">ADDTIME()</a> [1212]	Add time
<a href="#">AES_DECRYPT()</a> [1260]	Decrypt using AES
<a href="#">AES_ENCRYPT()</a> [1260]	Encrypt using AES
<a href="#">AND, &amp;&amp;</a> [1171]	Logical AND
<a href="#">ASCII()</a> [1177]	Return numeric value of left-most character
<a href="#">ASIN()</a> [1202]	Return the arc sine
<a href="#">=</a> [1173]	Assign a value (as part of a <code>SET</code> statement, or as part of the <code>SET</code> clause in an <code>UPDATE</code> statement)
<a href="#">:=</a> [1172]	Assign a value
<a href="#">ATAN2()</a> , <a href="#">ATAN()</a> [1203]	Return the arc tangent of the two arguments
<a href="#">ATAN()</a> [1202]	Return the arc tangent

<b>Name</b>	<b>Description</b>
<a href="#">AVG ( ) [1282]</a>	Return the average value of the argument
<a href="#">BENCHMARK ( ) [1266]</a>	Repeatedly execute an expression
<a href="#">BETWEEN ... AND ... [1168]</a>	Check whether a value is within a range of values
<a href="#">BIN ( ) [1177]</a>	Return a string containing binary representation of a number
<a href="#">BINARY [1244]</a>	Cast a string to a binary string
<a href="#">BIT_AND ( ) [1282]</a>	Return bitwise and
<a href="#">BIT_COUNT ( ) [1259]</a>	Return the number of bits that are set
<a href="#">BIT_LENGTH ( ) [1177]</a>	Return length of argument in bits
<a href="#">BIT_OR ( ) [1282]</a>	Return bitwise or
<a href="#">BIT_XOR ( ) [1283]</a>	Return bitwise xor
<a href="#">&amp; [1258]</a>	Bitwise AND
<a href="#">~ [1259]</a>	Invert bits
<a href="#">  [1258]</a>	Bitwise OR
<a href="#">^ [1258]</a>	Bitwise XOR
<a href="#">CASE [1174]</a>	Case operator
<a href="#">CAST ( ) [1245]</a>	Cast a value as a certain type
<a href="#">CEIL ( ) [1203]</a>	Return the smallest integer value not less than the argument
<a href="#">CEILING ( ) [1203]</a>	Return the smallest integer value not less than the argument
<a href="#">CHAR_LENGTH ( ) [1178]</a>	Return number of characters in argument
<a href="#">CHAR ( ) [1177]</a>	Return the character for each integer passed
<a href="#">CHARACTER_LENGTH ( ) [1178]</a>	A synonym for CHAR_LENGTH()
<a href="#">CHARSET ( ) [1266]</a>	Return the character set of the argument
<a href="#">COALESCE ( ) [1169]</a>	Return the first non-NULL argument
<a href="#">COERCIBILITY ( ) [1266]</a>	Return the collation coercibility value of the string argument
<a href="#">COLLATION ( ) [1267]</a>	Return the collation of the string argument
<a href="#">COMPRESS ( ) [1261]</a>	Return result as a binary string
<a href="#">CONCAT_WS ( ) [1179]</a>	Return concatenate with separator
<a href="#">CONCAT ( ) [1178]</a>	Return concatenated string
<a href="#">CONNECTION_ID ( ) [1267]</a>	Return the connection ID (thread ID) for the connection
<a href="#">CONV ( ) [1203]</a>	Convert numbers between different number bases
<a href="#">CONVERT_TZ ( ) [1212]</a>	Convert from one timezone to another
<a href="#">CONVERT ( ) [1245]</a>	Cast a value as a certain type
<a href="#">COS ( ) [1203]</a>	Return the cosine
<a href="#">COT ( ) [1203]</a>	Return the cotangent
<a href="#">COUNT(DISTINCT) [1283]</a>	Return the count of a number of different values
<a href="#">COUNT ( ) [1283]</a>	Return a count of the number of rows returned
<a href="#">CRC32 ( ) [1203]</a>	Compute a cyclic redundancy check value
<a href="#">CURDATE ( ) [1212]</a>	Return the current date
<a href="#">CURRENT_DATE ( ), CURRENT_DATE [1212]</a>	Synonyms for CURDATE()

Name	Description
<code>CURRENT_TIME()</code> , <code>CURRENT_TIME</code> [1212]	Synonyms for <code>CURTIME()</code>
<code>CURRENT_TIMESTAMP()</code> , <code>CURRENT_TIMESTAMP</code> [1213]	Synonyms for <code>NOW()</code>
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code> [1267]	The authenticated user name and host name
<code>CURTIME()</code> [1213]	Return the current time
<code>DATABASE()</code> [1268]	Return the default (current) database name
<code>DATE_ADD()</code> [1213]	Add time values (intervals) to a date value
<code>DATE_FORMAT()</code> [1215]	Format date as specified
<code>DATE_SUB()</code> [1217]	Subtract a time value (interval) from a date
<code>DATE()</code> [1213]	Extract the date part of a date or datetime expression
<code>DATEDIFF()</code> [1213]	Subtract two dates
<code>DAY()</code> [1217]	Synonym for <code>DAYOFMONTH()</code>
<code>DAYNAME()</code> [1217]	Return the name of the weekday
<code>DAYOFMONTH()</code> [1217]	Return the day of the month (0-31)
<code>DAYOFWEEK()</code> [1217]	Return the weekday index of the argument
<code>DAYOFYEAR()</code> [1217]	Return the day of the year (1-366)
<code>DECODE()</code> [1261]	Decodes a string encrypted using <code>ENCODE()</code>
<code>DEFAULT()</code> [1275]	Return the default value for a table column
<code>DEGREES()</code> [1204]	Convert radians to degrees
<code>DES_DECRYPT()</code> [1261]	Decrypt a string
<code>DES_ENCRYPT()</code> [1262]	Encrypt a string
<code>DIV</code> [1201]	Integer division
<code>/</code> [1200]	Division operator
<code>ELT()</code> [1179]	Return string at index number
<code>ENCODE()</code> [1262]	Encode a string
<code>ENCRYPT()</code> [1262]	Encrypt a string
<code>&lt;=&gt;</code> [1167]	NULL-safe equal to operator
<code>=</code> [1166]	Equal operator
<code>EXP()</code> [1204]	Raise to the power of
<code>EXPORT_SET()</code> [1179]	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
<code>EXTRACT()</code> [1217]	Extract part of a date
<code>ExtractValue()</code> [1249]	Extracts a value from an XML string using XPath notation
<code>FIELD()</code> [1179]	Return the index (position) of the first argument in the subsequent arguments
<code>FIND_IN_SET()</code> [1179]	Return the index position of the first argument within the second argument
<code>FLOOR()</code> [1204]	Return the largest integer value not greater than the argument

Name	Description
<a href="#">FORMAT ( ) [1180]</a>	Return a number formatted to specified number of decimal places
<a href="#">FOUND_ROWS ( ) [1268]</a>	For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause
<a href="#">FROM_BASE64 ( ) [1180]</a>	Decode to a base-64 string and return result
<a href="#">FROM_DAYS ( ) [1218]</a>	Convert a day number to a date
<a href="#">FROM_UNIXTIME ( ) [1218]</a>	Format UNIX timestamp as a date
<a href="#">GET_FORMAT ( ) [1218]</a>	Return a date format string
<a href="#">GET_LOCK ( ) [1275]</a>	Get a named lock
<a href="#">&gt;= [1167]</a>	Greater than or equal operator
<a href="#">&gt; [1167]</a>	Greater than operator
<a href="#">GREATEST ( ) [1169]</a>	Return the largest argument
<a href="#">GROUP_CONCAT ( ) [1283]</a>	Return a concatenated string
<a href="#">GTID_SUBSET ( ) [1274]</a>	Return true if all GTIDs in subset are also in set; otherwise false.
<a href="#">GTID_SUBTRACT ( ) [1274]</a>	Return all GTIDs in set that are not in subset.
<a href="#">HEX ( ) [1180]</a>	Return a hexadecimal representation of a decimal or string value
<a href="#">HOUR ( ) [1219]</a>	Extract the hour
<a href="#">IF ( ) [1174]</a>	If/else construct
<a href="#">IFNULL ( ) [1175]</a>	Null if/else construct
<a href="#">IN ( ) [1169]</a>	Check whether a value is within a set of values
<a href="#">INET_ATON ( ) [1276]</a>	Return the numeric value of an IP address
<a href="#">INET_NTOA ( ) [1276]</a>	Return the IP address from a numeric value
<a href="#">INET6_ATON ( ) [1276]</a>	Return the numeric value of an IPv6 address
<a href="#">INET6_NTOA ( ) [1277]</a>	Return the IPv6 address from a numeric value
<a href="#">INSERT ( ) [1180]</a>	Insert a substring at the specified position up to the specified number of characters
<a href="#">INSTR ( ) [1181]</a>	Return the index of the first occurrence of substring
<a href="#">INTERVAL ( ) [1170]</a>	Return the index of the argument that is less than the first argument
<a href="#">IS_FREE_LOCK ( ) [1278]</a>	Checks whether the named lock is free
<a href="#">IS_IPV4_COMPAT ( ) [1278]</a>	Return true if argument is an IPv4-compatible address
<a href="#">IS_IPV4_MAPPED ( ) [1278]</a>	Return true if argument is an IPv4-mapped address
<a href="#">IS_IPV4 ( ) [1278]</a>	Return true if argument is an IPv4 address
<a href="#">IS_IPV6 ( ) [1279]</a>	Return true if argument is an IPv6 address
<a href="#">IS NOT NULL [1168]</a>	NOT NULL value test
<a href="#">IS NOT [1168]</a>	Test a value against a boolean
<a href="#">IS NULL [1168]</a>	NULL value test
<a href="#">IS_USED_LOCK ( ) [1279]</a>	Checks whether the named lock is in use. Return connection identifier if true.
<a href="#">IS [1167]</a>	Test a value against a boolean
<a href="#">ISNULL ( ) [1170]</a>	Test whether the argument is NULL

Name	Description
LAST_DAY [1219]	Return the last day of the month for the argument
LAST_INSERT_ID() [1269]	Value of the AUTOINCREMENT column for the last INSERT
LCASE() [1181]	Synonym for LOWER()
LEAST() [1170]	Return the smallest argument
<< [1258]	Left shift
LEFT() [1181]	Return the leftmost number of characters as specified
LENGTH() [1181]	Return the length of a string in bytes
<= [1167]	Less than or equal operator
< [1167]	Less than operator
LIKE [1190]	Simple pattern matching
LN() [1204]	Return the natural logarithm of the argument
LOAD_FILE() [1181]	Load the named file
LOCALTIME(), LOCALTIME [1219]	Synonym for NOW()
LOCALTIMESTAMP, LOCALTIMESTAMP() [1219]	Synonym for NOW()
LOCATE() [1181]	Return the position of the first occurrence of substring
LOG10() [1205]	Return the base-10 logarithm of the argument
LOG2() [1205]	Return the base-2 logarithm of the argument
LOG() [1204]	Return the natural logarithm of the first argument
LOWER() [1182]	Return the argument in lowercase
LPAD() [1182]	Return the string argument, left-padded with the specified string
LTRIM() [1182]	Remove leading spaces
MAKE_SET() [1182]	Return a set of comma-separated strings that have the corresponding bit in bits set
MAKEDATE() [1219]	Create a date from the year and day of year
MAKETIME [1219]	MAKETIME()
MASTER_POS_WAIT() [1279]	Block until the slave has read and applied all updates up to the specified position
MATCH [1229]	Perform full-text search
MAX() [1284]	Return the maximum value
MD5() [1263]	Calculate MD5 checksum
MICROSECOND() [1220]	Return the microseconds from argument
MID() [1183]	Return a substring starting from the specified position
MIN() [1284]	Return the minimum value
- [1200]	Minus operator
MINUTE() [1220]	Return the minute from the argument
MOD() [1205]	Return the remainder
% or MOD [1201]	Modulo operator
MONTH() [1220]	Return the month from the date passed
MONTHNAME() [1220]	Return the name of the month
NAME_CONST() [1279]	Causes the column to have the given name

Name	Description
NOT BETWEEN ... AND ... [1169]	Check whether a value is not within a range of values
!=, <> [1167]	Not equal operator
NOT IN() [1170]	Check whether a value is not within a set of values
NOT LIKE [1192]	Negation of simple pattern matching
NOT REGEXP [1193]	Negation of REGEXP
NOT, ! [1171]	Negates value
NOW() [1220]	Return the current date and time
NULLIF() [1175]	Return NULL if expr1 = expr2
OCT() [1183]	Return a string containing octal representation of a number
OCTET_LENGTH() [1183]	A synonym for LENGTH()
OLD_PASSWORD() [1263]	Return the value of the pre-4.1 implementation of PASSWORD
, OR [1172]	Logical OR
ORD() [1183]	Return character code for leftmost character of the argument
PASSWORD() [1263]	Calculate and return a password string
PERIOD_ADD() [1221]	Add a period to a year-month
PERIOD_DIFF() [1221]	Return the number of months between periods
PI() [1205]	Return the value of pi
+ [1200]	Addition operator
POSITION() [1183]	A synonym for LOCATE()
POW() [1206]	Return the argument raised to the specified power
POWER() [1206]	Return the argument raised to the specified power
PROCEDURE ANALYSE()	Analyze the results of a query
QUARTER() [1221]	Return the quarter from a date argument
QUOTE() [1183]	Escape the argument for use in an SQL statement
RADIANS() [1206]	Return argument converted to radians
RAND() [1206]	Return a random floating-point value
REGEXP [1193]	Pattern matching using regular expressions
RELEASE_LOCK() [1280]	Releases the named lock
REPEAT() [1183]	Repeat a string the specified number of times
REPLACE() [1183]	Replace occurrences of a specified string
REVERSE() [1184]	Reverse the characters in a string
>> [1258]	Right shift
RIGHT() [1184]	Return the specified rightmost number of characters
RLIKE [1193]	Synonym for REGEXP
ROUND() [1207]	Round the argument
ROW_COUNT() [1272]	The number of rows updated
RPAD() [1184]	Append string the specified number of times
RTRIM() [1184]	Remove trailing spaces
SCHEMA() [1273]	A synonym for DATABASE()
SEC_TO_TIME() [1221]	Converts seconds to 'HH:MM:SS' format

Name	Description
SECOND ( ) [1221]	Return the second (0-59)
SESSION_USER ( ) [1273]	Synonym for USER()
SHA1 ( ), SHA ( ) [1264]	Calculate an SHA-1 160-bit checksum
SHA2 ( ) [1264]	Calculate an SHA-2 checksum
SIGN ( ) [1208]	Return the sign of the argument
SIN ( ) [1208]	Return the sine of the argument
SLEEP ( ) [1280]	Sleep for a number of seconds
SOUNDEX ( ) [1184]	Return a soundex string
SOUNDS LIKE [1185]	Compare sounds
SPACE ( ) [1185]	Return a string of the specified number of spaces
SQL_THREAD_WAIT_AFTER_GTIDS ( ) [1221] (ObsOLETE Replaced by 5.6.9)	WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()
SQRT ( ) [1208]	Return the square root of the argument
STD ( ) [1284]	Return the population standard deviation
STDDEV_POP ( ) [1285]	Return the population standard deviation
STDDEV_SAMP ( ) [1285]	Return the sample standard deviation
STDDEV ( ) [1285]	Return the population standard deviation
STR_TO_DATE ( ) [1221]	Convert a string to a date
STRCMP ( ) [1192]	Compare two strings
SUBDATE ( ) [1222]	A synonym for DATE_SUB() when invoked with three arguments
SUBSTR ( ) [1185]	Return the substring as specified
SUBSTRING_INDEX ( ) [1185]	Return a substring from a string before the specified number of occurrences of the delimiter
SUBSTRING ( ) [1185]	Return the substring as specified
SUBTIME ( ) [1223]	Subtract times
SUM ( ) [1285]	Return the sum
SYSDATE ( ) [1223]	Return the time at which the function executes
SYSTEM_USER ( ) [1273]	Synonym for USER()
TAN ( ) [1208]	Return the tangent of the argument
TIME_FORMAT ( ) [1224]	Format as time
TIME_TO_SEC ( ) [1225]	Return the argument converted to seconds
TIME ( ) [1223]	Extract the time portion of the expression passed
TIMEDIFF ( ) [1223]	Subtract time
* [1200]	Multiplication operator
TIMESTAMP ( ) [1224]	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
TIMESTAMPADD ( ) [1224]	Add an interval to a datetime expression
TIMESTAMPDIFF ( ) [1224]	Subtract an interval from a datetime expression
TO_BASE64 ( ) [1186]	Return the argument converted to a base-64 string
TO_DAYS ( ) [1225]	Return the date argument converted to days

Name	Description
<a href="#">TO_SECONDS ( ) [1226]</a>	Return the date or datetime argument converted to seconds since Year 0
<a href="#">TRIM ( ) [1186]</a>	Remove leading and trailing spaces
<a href="#">TRUNCATE ( ) [1209]</a>	Truncate to specified number of decimal places
<a href="#">UCASE ( ) [1186]</a>	Synonym for UPPER()
<a href="#">- [1200]</a>	Change the sign of the argument
<a href="#">UNCOMPRESS ( ) [1265]</a>	Uncompress a string compressed
<a href="#">UNCOMPRESSED_LENGTH ( ) [1265]</a>	Return the length of a string before compression
<a href="#">UNHEX ( ) [1186]</a>	Return a string containing hex representation of a number
<a href="#">UNIX_TIMESTAMP ( ) [1226]</a>	Return a UNIX timestamp
<a href="#">UpdateXML ( ) [1251]</a>	Return replaced XML fragment
<a href="#">UPPER ( ) [1187]</a>	Convert to uppercase
<a href="#">USER ( ) [1273]</a>	The user name and host name provided by the client
<a href="#">UTC_DATE ( ) [1227]</a>	Return the current UTC date
<a href="#">UTC_TIME ( ) [1227]</a>	Return the current UTC time
<a href="#">UTC_TIMESTAMP ( ) [1227]</a>	Return the current UTC date and time
<a href="#">UUID_SHORT ( ) [1281]</a>	Return an integer-valued universal identifier
<a href="#">UUID ( ) [1280]</a>	Return a Universal Unique Identifier (UUID)
<a href="#">VALIDATE_PASSWORD_STRENGTH ( ) [1205]</a>	Determine strength of password
<a href="#">VALUES ( ) [1281]</a>	Defines the values to be used during an INSERT
<a href="#">VAR_POP ( ) [1285]</a>	Return the population standard variance
<a href="#">VAR_SAMP ( ) [1285]</a>	Return the sample variance
<a href="#">VARIANCE ( ) [1285]</a>	Return the population standard variance
<a href="#">VERSION ( ) [1273]</a>	Returns a string that indicates the MySQL server version
<a href="#">WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS ( ) [1274]</a>	Wait until the slave SQL thread has executed all the given GTIDs. Returns: the number of events that were executed (or NULL, if GTID mode is not enabled).
<a href="#">WEEK ( ) [1228]</a>	Return the week number
<a href="#">WEEKDAY ( ) [1228]</a>	Return the weekday index
<a href="#">WEEKOFYEAR ( ) [1229]</a>	Return the calendar week of the date (0-53)
<a href="#">WEIGHT_STRING ( ) [1187]</a>	Return the weight string for a string
<a href="#">XOR [1172]</a>	Logical XOR
<a href="#">YEAR ( ) [1229]</a>	Return the year
<a href="#">YEARWEEK ( ) [1229]</a>	Return the year and week

## 12.2. Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts numbers to strings as necessary, and vice versa.

```
mysql> SELECT 1+'1';
-> 2
mysql> SELECT CONCAT(2,' test');
-> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` [1245] function. Conversion occurs implicitly with the `CONCAT()` [1178] function because it expects string arguments.

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL`-safe `<=>` [1167] equality comparison operator. For `NULL <=> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. Note that this is not done for the arguments to `IN()` [1169]! To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using `BETWEEN` [1168] with date or time values, use `CAST()` [1245] to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a `DATETIME` value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as `DATETIME` values, use `CAST()` [1245] to explicitly convert the subquery value to `DATETIME`.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.
- In all other cases, the arguments are compared as floating-point (real) numbers.

For information about conversion of values from one temporal type to another, see [Section 11.3.7, “Conversion Between Date and Time Types”](#).

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If `str_col` is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value `1`, such as `'1'`, `' 1'`, or `'1a'`.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```
mysql> SELECT '18015376320243458' = 18015376320243458;
-> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
-> 0
```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```
mysql> SELECT '18015376320243459'+0.0;
-> 1.8015376320243e+16
```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` [1245] so that a value will not be converted implicitly to a float-point number:

```
mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
-> 1
```

For more information about floating-point comparisons, see [Section C.5.5.8, “Problems with Floating-Point Values”](#).

In MySQL 5.6, the server includes `dtoa`, a conversion library that provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT/DOUBLE`) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
- Conversion of numbers to string format with the best possible precision. The precision of `dtoa` is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from previous results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The `dtoa` library provides conversions with the following properties. `D` represents a value with a `DECIMAL` or string representation, and `F` represents a floating-point number in native binary (IEEE) format.

- `F -> D` conversion is done with the best possible precision, returning `D` as the shortest string that yields `F` when read back in and rounded to the nearest value in native binary format as specified by IEEE.
- `D -> F` conversion is done such that `F` is the nearest native binary number to the input decimal string `D`.

These properties imply that `F -> D -> F` conversions are lossless unless `F` is `-inf`, `+inf`, or `NaN`. The latter values are not supported because the SQL standard defines them as invalid values for `FLOAT` or `DOUBLE`.

For `D -> F -> D` conversions, a sufficient condition for losslessness is that `D` uses 15 or fewer digits of precision, is not a denormal value, `-inf`, `+inf`, or `NaN`. In some cases, the conversion is lossless even if `D` has more than 15 digits of precision, but this is not always the case.

In MySQL 5.6, implicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the `character_set_connection` [467] and

`collation_connection` [469] system variables. (These variables commonly are set with `SET NAMES`. For information about connection character sets, see [Section 10.1.4, “Connection Character Sets and Collations”](#).)

This means that such a conversion results in a character (nonbinary) string (a `CHAR`, `VARCHAR`, or `LONGTEXT` value), except in the case that the connection character set is set to `binary`. In that case, the conversion result is a binary string (a `BINARY`, `VARBINARY`, or `LONGBLOB` value).

## 12.3. Operators

**Table 12.2. Operators**

Name	Description
<code>AND</code> , <code>&amp;&amp;</code> [1171]	Logical AND
<code>=</code> [1173]	Assign a value (as part of a <code>SET</code> statement, or as part of the <code>SET</code> clause in an <code>UPDATE</code> statement)
<code>:=</code> [1172]	Assign a value
<code>BETWEEN ... AND ...</code> [1168]	Check whether a value is within a range of values
<code>BINARY</code> [1244]	Cast a string to a binary string
<code>&amp;</code> [1258]	Bitwise AND
<code>~</code> [1259]	Invert bits
<code> </code> [1258]	Bitwise OR
<code>^</code> [1258]	Bitwise XOR
<code>CASE</code> [1174]	Case operator
<code>DIV</code> [1201]	Integer division
<code>/</code> [1200]	Division operator
<code>&lt;=&gt;</code> [1167]	NULL-safe equal to operator
<code>=</code> [1166]	Equal operator
<code>&gt;=</code> [1167]	Greater than or equal operator
<code>&gt;</code> [1167]	Greater than operator
<code>IS NOT NULL</code> [1168]	NOT NULL value test
<code>IS NOT</code> [1168]	Test a value against a boolean
<code>IS NULL</code> [1168]	NULL value test
<code>IS</code> [1167]	Test a value against a boolean
<code>&lt;&lt;</code> [1258]	Left shift
<code>&lt;=</code> [1167]	Less than or equal operator
<code>&lt;</code> [1167]	Less than operator
<code>LIKE</code> [1190]	Simple pattern matching
<code>-</code> [1200]	Minus operator
<code>%</code> or <code>MOD</code> [1201]	Modulo operator
<code>NOT BETWEEN ... AND ...</code> [1169]	Check whether a value is not within a range of values
<code>!=</code> , <code>&lt;&gt;</code> [1167]	Not equal operator
<code>NOT LIKE</code> [1192]	Negation of simple pattern matching
<code>NOT REGEXP</code> [1193]	Negation of REGEXP
<code>NOT</code> , <code>!</code> [1171]	Negates value
<code>  </code> , <code>OR</code> [1172]	Logical OR

Name	Description
+ [1200]	Addition operator
REGEXP [1193]	Pattern matching using regular expressions
>> [1258]	Right shift
RLIKE [1193]	Synonym for REGEXP
SOUNDS LIKE [1185]	Compare sounds
* [1200]	Multiplication operator
- [1200]	Change the sign of the argument
XOR [1172]	Logical XOR

### 12.3.1. Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```

INTERVAL
BINARY, COLLATE
!
- (unary minus), ~ (unary bit inversion)
^
*, /, DIV, %, MOD
-, +
<<, >>
&
|
= (comparison), <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
&&, AND
XOR
||, OR
= (assignment), :=

```

The precedence of = depends on whether it is used as a comparison operator (= [1166]) or as an assignment operator (= [1173]). When used as a comparison operator, it has the same precedence as <=> [1167], >= [1167], > [1167], <= [1167], < [1167], <> [1167], != [1167], IS [1167], LIKE [1190], REGEXP [1193], and IN [1169]. When used as an assignment operator, it has the same precedence as := [1172]. Section 13.7.4, “SET Syntax”, and Section 9.4, “User-Defined Variables”, explain how MySQL determines which interpretation of = should apply.

The meaning of some operators depends on the SQL mode:

- By default, || [1172] is a logical OR [1172] operator. With PIPES\_AS\_CONCAT [607] enabled, || [1172] is string concatenation, with a precedence between ^ [1258] and the unary operators.
- By default, ! [1171] has a higher precedence than NOT. With HIGH\_NOT\_PRECEDENCE [603] enabled, ! [1171] and NOT have the same precedence.

See Section 5.1.7, “Server SQL Modes”.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```

mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9

```

### 12.3.2. Comparison Functions and Operators

Table 12.3. Comparison Operators

Name	Description
<code>BETWEEN ... AND ...</code> [1168]	Check whether a value is within a range of values
<code>COALESCE()</code> [1169]	Return the first non-NULL argument
<code>&lt;=&gt;</code> [1167]	NULL-safe equal to operator
<code>=</code> [1166]	Equal operator
<code>&gt;=</code> [1167]	Greater than or equal operator
<code>&gt;</code> [1167]	Greater than operator
<code>GREATEST()</code> [1169]	Return the largest argument
<code>IN()</code> [1169]	Check whether a value is within a set of values
<code>INTERVAL()</code> [1170]	Return the index of the argument that is less than the first argument
<code>IS NOT NULL</code> [1168]	NOT NULL value test
<code>IS NOT</code> [1168]	Test a value against a boolean
<code>IS NULL</code> [1168]	NULL value test
<code>IS</code> [1167]	Test a value against a boolean
<code>ISNULL()</code> [1170]	Test whether the argument is NULL
<code>LEAST()</code> [1170]	Return the smallest argument
<code>&lt;=</code> [1167]	Less than or equal operator
<code>&lt;</code> [1167]	Less than operator
<code>LIKE</code> [1190]	Simple pattern matching
<code>NOT BETWEEN ... AND ...</code> [1169]	Check whether a value is not within a range of values
<code>!=, &lt;&gt;</code> [1167]	Not equal operator
<code>NOT IN()</code> [1170]	Check whether a value is not within a set of values
<code>NOT LIKE</code> [1192]	Negation of simple pattern matching
<code>STRCMP()</code> [1192]	Compare two strings

Comparison operations result in a value of 1 (`TRUE`), 0 (`FALSE`), or `NULL`. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```
= > < >= <= <> !=
```

For examples of row comparisons, see [Section 13.2.10.5, “Row Subqueries”](#).

Some of the functions in this section return values other than 1 (`TRUE`), 0 (`FALSE`), or `NULL`. For example, `LEAST()` [1170] and `GREATEST()` [1169]. However, the value they return is based on comparison operations performed according to the rules described in [Section 12.2, “Type Conversion in Expression Evaluation”](#).

To convert a value to a specific type for comparison purposes, you can use the `CAST()` [1245] function. String values can be converted to a different character set using `CONVERT()` [1245]. See [Section 12.10, “Cast Functions and Operators”](#).

By default, string comparisons are not case sensitive and use the current character set. The default is `latin1` (cp1252 West European), which also works well for English.

- `=` [1166]

Equal:

```
mysql> SELECT 1 = 0;
-> 0
mysql> SELECT '0' = 0;
-> 1
mysql> SELECT '0.0' = 0;
-> 1
mysql> SELECT '0.01' = 0;
-> 0
mysql> SELECT '.01' = 0.01;
-> 1
```

- [<=> \[1167\]](#)

**NULL-safe equal.** This operator performs an equality comparison like the = [\[1166\]](#) operator, but returns 1 rather than NULL if both operands are NULL, and 0 rather than NULL if one operand is NULL.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
-> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
-> 1, NULL, NULL
```

- [<> \[1167\]](#), [!= \[1167\]](#)

Not equal:

```
mysql> SELECT '.01' <> '0.01';
-> 1
mysql> SELECT .01 <> '0.01';
-> 0
mysql> SELECT 'zapp' <> 'zapp';
-> 1
```

- [<= \[1167\]](#)

Less than or equal:

```
mysql> SELECT 0.1 <= 2;
-> 1
```

- [< \[1167\]](#)

Less than:

```
mysql> SELECT 2 < 2;
-> 0
```

- [>= \[1167\]](#)

Greater than or equal:

```
mysql> SELECT 2 >= 2;
-> 1
```

- [> \[1167\]](#)

Greater than:

```
mysql> SELECT 2 > 2;
-> 0
```

- [IS boolean\\_value \[1167\]](#)

Tests a value against a boolean value, where *boolean\_value* can be TRUE, FALSE, or UNKNOWN.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
```

```
-> 1, 1, 1
```

- `IS NOT boolean_value` [1168]

Tests a value against a boolean value, where *boolean\_value* can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- `IS NULL` [1168]

Tests whether a value is `NULL`.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using `IS NULL` [1168]:

- If `sql_auto_is_null` [543] variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` [1269] function. For details, including the return value after a multiple-row insert, see [Section 12.14, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` [1168] comparison can be disabled by setting `sql_auto_is_null = 0` [543]. See [Section 5.1.4, “Server System Variables”](#).

The default value of `sql_auto_is_null` [543] is 0 in MySQL 5.6.

- For `DATE` and `DATETIME` columns that are declared as `NOT NULL`, you can find the special date `'0000-00-00'` by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a `'0000-00-00'` date value.

See [Section 21.1.7.1.1, “Obtaining Auto-Increment Values”](#), and the description for the `FLAG_AUTO_IS_NULL` option at [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).

- `IS NOT NULL` [1168]

Tests whether a value is not `NULL`.

```
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

- `expr BETWEEN min AND max` [1168]

If *expr* is greater than or equal to *min* and *expr* is less than or equal to *max*, `BETWEEN` [1168] returns 1, otherwise it returns 0. This is equivalent to the expression `(min <= expr AND expr <= max)` if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in [Section 12.2, “Type Conversion in Expression Evaluation”](#), but applied to all the three arguments.

```
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 AND 1;
-> 1, 0
```

```
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
```

For best results when using `BETWEEN` [1168] with date or time values, use `CAST()` [1245] to explicitly convert the values to the desired data type. Examples: If you compare a `DATETIME` to two `DATE` values, convert the `DATE` values to `DATETIME` values. If you use a string constant such as `'2001-1-1'` in a comparison to a `DATE`, cast the string to a `DATE`.

- `expr NOT BETWEEN min AND max` [1169]

This is the same as `NOT (expr BETWEEN min AND max)`.

- `COALESCE(value,...)` [1169]

Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values.

```
mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL
```

- `GREATEST(value1,value2,...)` [1169]

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for `LEAST()` [1170].

```
mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'
```

`GREATEST()` [1169] returns `NULL` if any argument is `NULL`.

- `expr IN (value,...)` [1169]

Returns `1` if `expr` is equal to any of the values in the `IN` list, else returns `0`. If all values are constants, they are evaluated according to the type of `expr` and sorted. The search for the item then is done using a binary search. This means `IN` is very quick if the `IN` value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described in [Section 12.2, "Type Conversion in Expression Evaluation"](#), but applied to all the arguments.

```
mysql> SELECT 2 IN (0,3,5,7);
-> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
-> 1
```

You should never mix quoted and unquoted values in an `IN` list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an `IN` expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

The number of values in the `IN` list is only limited by the `max_allowed_packet` [502] value.

To comply with the SQL standard, `IN` returns `NULL` not only if the expression on the left hand side is `NULL`, but also if no match is found in the list and one of the expressions in the list is `NULL`.

`IN()` syntax can also be used to write certain types of subqueries. See [Section 13.2.10.3, “Subqueries with ANY, IN, or SOME”](#).

- `expr NOT IN (value,...)` [1170]

This is the same as `NOT (expr IN (value,...))`.

- `ISNULL(expr)` [1170]

If `expr` is `NULL`, `ISNULL()` [1170] returns 1, otherwise it returns 0.

```
mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
-> 1
```

`ISNULL()` [1170] can be used instead of `=` [1166] to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` [1166] always yields false.)

The `ISNULL()` [1170] function shares some special behaviors with the `IS NULL` [1168] comparison operator. See the description of `IS NULL` [1168].

- `INTERVAL(N,N1,N2,N3,...)` [1170]

Returns 0 if  $N < N1$ , 1 if  $N < N2$  and so on or -1 if  $N$  is `NULL`. All arguments are treated as integers. It is required that  $N1 < N2 < N3 < \dots < Nn$  for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- `LEAST(value1,value2,...)` [1170]

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is `NULL`, the result is `NULL`. No comparison is needed.
- If the return value is used in an `INTEGER` context or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a `REAL` context or all arguments are real-valued, they are compared as reals.
- If the arguments comprise a mix of numbers and strings, they are compared as numbers.
- If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
- In all other cases, the arguments are compared as binary strings.

```
mysql> SELECT LEAST(2,0);
-> 0
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
-> 3.0
mysql> SELECT LEAST('B','A','C');
-> 'A'
```

Note that the preceding conversion rules can produce strange results in some borderline cases:

```
mysql> SELECT CAST(LEAST(3600, 9223372036854775808.0) as SIGNED);
-> -9223372036854775808
```

This happens because MySQL reads 9223372036854775808.0 in an integer context. The integer representation is not good enough to hold the value, so it wraps to a signed integer.

### 12.3.3. Logical Operators

Table 12.4. Logical Operators

Name	Description
AND, && [1171]	Logical AND
NOT, ! [1171]	Negates value
, OR [1172]	Logical OR
XOR [1172]	Logical XOR

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as 1 (`TRUE`), 0 (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any nonzero value for `TRUE`.

MySQL evaluates any nonzero, non-`NULL` value to `TRUE`. For example, the following statements all assess to `TRUE`:

```
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- NOT [1171], ! [1171]

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and `NOT NULL` returns `NULL`.

```
mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT ! (1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1
```

The last example produces 1 because the expression evaluates the same way as `(!1)+1`.

- AND [1171], && [1171]

Logical AND. Evaluates to 1 if all operands are nonzero and not `NULL`, to 0 if one or more operands are 0, otherwise `NULL` is returned.

```
mysql> SELECT 1 && 1;
-> 1
mysql> SELECT 1 && 0;
-> 0
mysql> SELECT 1 && NULL;
-> NULL
mysql> SELECT 0 && NULL;
-> 0
mysql> SELECT NULL && 0;
-> 0
```

- [OR \[1172\]](#), [|| \[1172\]](#)

Logical OR. When both operands are non-NULL, the result is 1 if any operand is nonzero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is nonzero, and NULL otherwise. If both operands are NULL, the result is NULL.

```
mysql> SELECT 1 || 1;
-> 1
mysql> SELECT 1 || 0;
-> 1
mysql> SELECT 0 || 0;
-> 0
mysql> SELECT 0 || NULL;
-> NULL
mysql> SELECT 1 || NULL;
-> 1
```

- [XOR \[1172\]](#)

Logical XOR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is nonzero, otherwise 0 is returned.

```
mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1
```

$a \text{ XOR } b$  is mathematically equal to  $(a \text{ AND } (\text{NOT } b)) \text{ OR } ((\text{NOT } a) \text{ and } b)$ .

## 12.3.4. Assignment Operators

Table 12.5. Assignment Operators

Name	Description
<a href="#">= [1173]</a>	Assign a value (as part of a SET statement, or as part of the SET clause in an UPDATE statement)
<a href="#">:= [1172]</a>	Assign a value

- [:= \[1172\]](#)

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same SET statement. You can perform multiple assignments in the same statement-

Unlike [= \[1173\]](#), the [:= \[1172\]](#) operator is never interpreted as a comparison operator. This means you can use [:= \[1172\]](#) in any valid SQL statement (not just in SET statements) to assign a value to a variable.

```
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1
```

```
mysql> SELECT @var1:=COUNT(*) FROM t1;
-> 4
mysql> SELECT @var1;
-> 4
```

You can make value assignments using `:=` [1172] in other statements besides `SELECT`, such as `UPDATE`, as shown here:

```
mysql> SELECT @var1;
-> 4
mysql> SELECT * FROM t1;
-> 1, 3, 5, 7

mysql> UPDATE t1 SET c1 = 2 WHERE c1 = @var1:= 1;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT @var1;
-> 1
mysql> SELECT * FROM t1;
-> 2, 3, 5, 7
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the `:=` [1172] operator, this is not recommended. Section 9.4, “User-Defined Variables”, explains why you should avoid doing this.

- `=` [1173]

This operator is used to perform value assignments in two cases, described in the next two paragraphs.

Within a `SET` statement, `=` is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a `SET` statement, `=` is treated identically to `:=` [1172].) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, `=` also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, `=` is treated as a [comparison operator](#) [1166].

```
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1
```

For more information, see [Section 13.7.4, “SET Syntax”](#), [Section 13.2.11, “UPDATE Syntax”](#), and [Section 13.2.10, “Subquery Syntax”](#).

## 12.4. Control Flow Functions

Table 12.6. Flow Control Operators

Name	Description
<code>CASE</code> [1174]	Case operator

Name	Description
<code>IF()</code> [1174]	If/else construct
<code>IFNULL()</code> [1175]	Null if/else construct
<code>NULLIF()</code> [1175]	Return NULL if <code>expr1 = expr2</code>

- `CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN result ...] [ELSE result] END` [1174]

`CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END` [1174]

The first version returns the *result* where *value=compare\_value*. The second version returns the result for the first condition that is true. If there was no matching result value, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
->      WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
->      WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

The return type of a `CASE` [1174] expression is the compatible aggregated type of all return values, but also depends on the context in which it is used. If used in a string context, the result is returned as a string. If used in a numeric context, the result is returned as a decimal, real, or integer value.

#### Note

The syntax of the `CASE` [1174] expression shown here differs slightly from that of the SQL `CASE statement` described in Section 13.6.5.1, “`CASE Syntax`”, for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

- `IF(expr1,expr2,expr3)` [1174]

If *expr1* is `TRUE` (`expr1 <> 0` and `expr1 <> NULL`) then `IF()` [1174] returns *expr2*; otherwise it returns *expr3*. `IF()` [1174] returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

If only one of *expr2* or *expr3* is explicitly `NULL`, the result type of the `IF()` [1174] function is the type of the non-`NULL` expression.

The default return type of `IF()` [1174] (which may matter when it is stored into a temporary table) is calculated as follows.

Expression	Return Value
<i>expr2</i> or <i>expr3</i> returns a string	string
<i>expr2</i> or <i>expr3</i> returns a floating-point value	floating-point
<i>expr2</i> or <i>expr3</i> returns an integer	integer

If *expr2* and *expr3* are both strings, the result is case sensitive if either string is case sensitive.

**Note**

There is also an *IF statement*, which differs from the `IF()` [1174] function described here. See [Section 13.6.5.2, “IF Syntax”](#).

- `IFNULL(expr1,expr2)` [1175]

If `expr1` is not `NULL`, `IFNULL()` [1175] returns `expr1`; otherwise it returns `expr2`. `IFNULL()` [1175] returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'
```

The default result value of `IFNULL(expr1,expr2)` [1175] is the more “general” of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` [1175] in a temporary table:

```
mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| test  | varbinary(4) | NO   |     |         |       |
+-----+-----+-----+-----+-----+-----+
```

In this example, the type of the `test` column is `VARBINARY(4)`.

- `NULLIF(expr1,expr2)` [1175]

Returns `NULL` if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END` [1174].

```
mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

Note that MySQL evaluates `expr1` twice if the arguments are not equal.

## 12.5. String Functions

Table 12.7. String Operators

Name	Description
<code>ASCII()</code> [1177]	Return numeric value of left-most character
<code>BIN()</code> [1177]	Return a string containing binary representation of a number
<code>BIT_LENGTH()</code> [1177]	Return length of argument in bits
<code>CHAR_LENGTH()</code> [1178]	Return number of characters in argument
<code>CHAR()</code> [1177]	Return the character for each integer passed
<code>CHARACTER_LENGTH()</code> [1178]	A synonym for <code>CHAR_LENGTH()</code>
<code>CONCAT_WS()</code> [1179]	Return concatenate with separator
<code>CONCAT()</code> [1178]	Return concatenated string

Name	Description
<a href="#">ELT() [1179]</a>	Return string at index number
<a href="#">EXPORT_SET() [1179]</a>	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
<a href="#">FIELD() [1179]</a>	Return the index (position) of the first argument in the subsequent arguments
<a href="#">FIND_IN_SET() [1179]</a>	Return the index position of the first argument within the second argument
<a href="#">FORMAT() [1180]</a>	Return a number formatted to specified number of decimal places
<a href="#">FROM_BASE64() [1180]</a>	Decode to a base-64 string and return result
<a href="#">HEX() [1180]</a>	Return a hexadecimal representation of a decimal or string value
<a href="#">INSERT() [1180]</a>	Insert a substring at the specified position up to the specified number of characters
<a href="#">INSTR() [1181]</a>	Return the index of the first occurrence of substring
<a href="#">LCASE() [1181]</a>	Synonym for LOWER()
<a href="#">LEFT() [1181]</a>	Return the leftmost number of characters as specified
<a href="#">LENGTH() [1181]</a>	Return the length of a string in bytes
<a href="#">LIKE [1190]</a>	Simple pattern matching
<a href="#">LOAD_FILE() [1181]</a>	Load the named file
<a href="#">LOCATE() [1181]</a>	Return the position of the first occurrence of substring
<a href="#">LOWER() [1182]</a>	Return the argument in lowercase
<a href="#">LPAD() [1182]</a>	Return the string argument, left-padded with the specified string
<a href="#">LTRIM() [1182]</a>	Remove leading spaces
<a href="#">MAKE_SET() [1182]</a>	Return a set of comma-separated strings that have the corresponding bit in bits set
<a href="#">MATCH [1229]</a>	Perform full-text search
<a href="#">MID() [1183]</a>	Return a substring starting from the specified position
<a href="#">NOT LIKE [1192]</a>	Negation of simple pattern matching
<a href="#">NOT REGEXP [1193]</a>	Negation of REGEXP
<a href="#">OCT() [1183]</a>	Return a string containing octal representation of a number
<a href="#">OCTET_LENGTH() [1183]</a>	A synonym for LENGTH()
<a href="#">ORD() [1183]</a>	Return character code for leftmost character of the argument
<a href="#">POSITION() [1183]</a>	A synonym for LOCATE()
<a href="#">QUOTE() [1183]</a>	Escape the argument for use in an SQL statement
<a href="#">REGEXP [1193]</a>	Pattern matching using regular expressions
<a href="#">REPEAT() [1183]</a>	Repeat a string the specified number of times
<a href="#">REPLACE() [1183]</a>	Replace occurrences of a specified string
<a href="#">REVERSE() [1184]</a>	Reverse the characters in a string
<a href="#">RIGHT() [1184]</a>	Return the specified rightmost number of characters
<a href="#">RLIKE [1193]</a>	Synonym for REGEXP

Name	Description
<a href="#">RPAD() [1184]</a>	Append string the specified number of times
<a href="#">RTRIM() [1184]</a>	Remove trailing spaces
<a href="#">SOUNDEX() [1184]</a>	Return a soundex string
<a href="#">SOUNDS LIKE [1185]</a>	Compare sounds
<a href="#">SPACE() [1185]</a>	Return a string of the specified number of spaces
<a href="#">STRCMP() [1192]</a>	Compare two strings
<a href="#">SUBSTR() [1185]</a>	Return the substring as specified
<a href="#">SUBSTRING_INDEX() [1185]</a>	Return a substring from a string before the specified number of occurrences of the delimiter
<a href="#">SUBSTRING() [1185]</a>	Return the substring as specified
<a href="#">TO_BASE64() [1186]</a>	Return the argument converted to a base-64 string
<a href="#">TRIM() [1186]</a>	Remove leading and trailing spaces
<a href="#">UCASE() [1186]</a>	Synonym for UPPER()
<a href="#">UNHEX() [1186]</a>	Return a string containing hex representation of a number
<a href="#">UPPER() [1187]</a>	Convert to uppercase
<a href="#">WEIGHT_STRING() [1187]</a>	Return the weight string for a string

String-valued functions return `NULL` if the length of the result would be greater than the value of the `max_allowed_packet` [502] system variable. See [Section 8.11.2, “Tuning Server Parameters”](#).

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- [ASCII\(\*str\*\) \[1177\]](#)

Returns the numeric value of the leftmost character of the string *str*. Returns 0 if *str* is the empty string. Returns `NULL` if *str* is `NULL`. [ASCII\(\)](#) [1177] works for 8-bit characters.

```
mysql> SELECT ASCII('2');
-> 50
mysql> SELECT ASCII(2);
-> 50
mysql> SELECT ASCII('dx');
-> 100
```

See also the [ORD\(\)](#) [1183] function.

- [BIN\(\*N\*\) \[1177\]](#)

Returns a string representation of the binary value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to [CONV\(\*N\*, 10, 2\)](#) [1203]. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT BIN(12);
-> '1100'
```

- [BIT\\_LENGTH\(\*str\*\) \[1177\]](#)

Returns the length of the string *str* in bits.

```
mysql> SELECT BIT_LENGTH('text');
-> 32
```

- [CHAR\(\*N\*, ... \[USING \*charset\\_name\*\]\) \[1177\]](#)

`CHAR()` [1177] interprets each argument *N* as an integer and returns a string consisting of the characters given by the code values of those integers. `NULL` values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
-> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');
-> 'MMM'
```

`CHAR()` [1177] arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` [1177] is equivalent to `CHAR(1,0)` [1177], and `CHAR(256*256)` [1177] is equivalent to `CHAR(1,0,0)` [1177]:

```
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+-----+-----+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+-----+-----+
| 0100          | 0100          |
+-----+-----+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+-----+-----+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+-----+-----+
| 010000         | 010000         |
+-----+-----+
```

By default, `CHAR()` [1177] returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```
mysql> SELECT CHARSET(CHAR(0x65)), CHARSET(CHAR(0x65 USING utf8));
+-----+-----+
| CHARSET(CHAR(0x65)) | CHARSET(CHAR(0x65 USING utf8)) |
+-----+-----+
| binary              | utf8                             |
+-----+-----+
```

If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` [1177] becomes `NULL`.

- `CHAR_LENGTH(str)` [1178]

Returns the length of the string *str*, measured in characters. A multi-byte character counts as a single character. This means that for a string containing five 2-byte characters, `LENGTH()` [1181] returns 10, whereas `CHAR_LENGTH()` [1178] returns 5.

- `CHARACTER_LENGTH(str)` [1178]

`CHARACTER_LENGTH()` [1178] is a synonym for `CHAR_LENGTH()` [1178].

- `CONCAT(str1,str2,...)` [1178]

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

`CONCAT()` [1178] returns `NULL` if any argument is `NULL`.

```
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

- `CONCAT_WS(separator, str1, str2, ...)` [1179]

`CONCAT_WS()` [1179] stands for Concatenate With Separator and is a special form of `CONCAT()` [1178]. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is `NULL`, the result is `NULL`.

```
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
-> 'First name,Last Name'
```

`CONCAT_WS()` [1179] does not skip empty strings. However, it does skip any `NULL` values after the separator argument.

- `ELT(N, str1, str2, str3, ...)` [1179]

`ELT()` [1179] returns the  $N$ th element of the list of strings: `str1` if  $N = 1$ , `str2` if  $N = 2$ , and so on. Returns `NULL` if  $N$  is less than 1 or greater than the number of arguments. `ELT()` [1179] is the complement of `FIELD()` [1179].

```
mysql> SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
-> 'ej'
mysql> SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
-> 'foo'
```

- `EXPORT_SET(bits, on, off[, separator[, number_of_bits]])` [1179]

Returns a string such that for every bit set in the value `bits`, you get an `on` string and for every bit not set in the value, you get an `off` string. Bits in `bits` are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the `separator` string (the default being the comma character “,”). The number of bits examined is given by `number_of_bits`, which has a default of 64 if not specified. `number_of_bits` is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of  $-1$  is effectively the same as 64.

```
mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', 4);
-> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', ',', 10);
-> '0,1,1,0,0,0,0,0,0,0'
```

- `FIELD(str, str1, str2, str3, ...)` [1179]

Returns the index (position) of `str` in the `str1, str2, str3, ...` list. Returns 0 if `str` is not found.

If all arguments to `FIELD()` [1179] are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If `str` is `NULL`, the return value is 0 because `NULL` fails equality comparison with any value. `FIELD()` [1179] is the complement of `ELT()` [1179].

```
mysql> SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo');
-> 2
mysql> SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo');
-> 0
```

- `FIND_IN_SET(str, strlist)` [1179]

Returns a value in the range of 1 to  $N$  if the string `str` is in the string list `strlist` consisting of  $N$  substrings. A string list is a string composed of substrings separated by “,” characters. If the first

argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` [1179] function is optimized to use bit arithmetic. Returns `0` if `str` is not in `strlist` or if `strlist` is the empty string. Returns `NULL` if either argument is `NULL`. This function does not work properly if the first argument contains a comma (",") character.

```
mysql> SELECT FIND_IN_SET('b','a,b,c,d');
-> 2
```

- `FORMAT(X,D[,locale])` [1180]

Formats the number `x` to a format like '#,###,###.##', rounded to `D` decimal places, and returns the result as a string. If `D` is `0`, the result has no decimal point or fractional part.

The optional third parameter enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` [495] system variable (see [Section 10.7, "MySQL Server Locale Support"](#)). If no locale is specified, the default is `'en_US'`.

```
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1,4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2,0);
-> '12,332'
mysql> SELECT FORMAT(12332.2,2,'de_DE');
-> '12.332,20'
```

- `FROM_BASE64(str)` [1180]

Takes a string encoded with the base-64 encoded rules used by `TO_BASE64()` [1186] and returns the decoded result as a binary string. The result is `NULL` if the argument is `NULL` or not a valid base-64 string. See the description of `TO_BASE64()` [1186] for details about the encoding and decoding rules.

This function was added in MySQL 5.6.1.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

- `HEX(str)` [1180], `HEX(N)` [1180]

For a string argument `str`, `HEX()` [1180] returns a hexadecimal string representation of `str` where each character in `str` is converted to two hexadecimal digits. The inverse of this operation is performed by the `UNHEX()` [1186] function.

For a numeric argument `N`, `HEX()` [1180] returns a hexadecimal string representation of the value of `N` treated as a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,16)` [1203]. The inverse of this operation is performed by `CONV(HEX(N),16,10)` [1203].

```
mysql> SELECT 0x616263, HEX('abc'), UNHEX(HEX('abc'));
-> 'abc', 616263, 'abc'
mysql> SELECT HEX(255), CONV(HEX(255),16,10);
-> 'FF', 255
```

- `INSERT(str,pos,len,newstr)` [1180]

Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position `pos` if `len` is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
-> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
-> 'Quadratic'
```

```
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
-> 'QuWhat'
```

This function is multi-byte safe.

- [INSTR\(\*str\*,\*substr\*\) \[1181\]](#)

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of [LOCATE\(\) \[1181\]](#), except that the order of the arguments is reversed.

```
mysql> SELECT INSTR('foobarbar', 'bar');
-> 4
mysql> SELECT INSTR('xbar', 'foobar');
-> 0
```

This function is multi-byte safe, and is case sensitive only if at least one argument is a binary string.

- [LCASE\(\*str\*\) \[1181\]](#)

[LCASE\(\) \[1181\]](#) is a synonym for [LOWER\(\) \[1182\]](#).

- [LEFT\(\*str\*,\*len\*\) \[1181\]](#)

Returns the leftmost *len* characters from the string *str*, or [NULL](#) if any argument is [NULL](#).

```
mysql> SELECT LEFT('foobarbar', 5);
-> 'fooba'
```

This function is multi-byte safe.

- [LENGTH\(\*str\*\) \[1181\]](#)

Returns the length of the string *str*, measured in bytes. A multi-byte character counts as multiple bytes. This means that for a string containing five 2-byte characters, [LENGTH\(\) \[1181\]](#) returns 10, whereas [CHAR\\_LENGTH\(\) \[1178\]](#) returns 5.

```
mysql> SELECT LENGTH('text');
-> 4
```

- [LOAD\\_FILE\(\*file\\_name\*\) \[1181\]](#)

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the [FILE \[754\]](#) privilege. The file must be readable by all and its size less than [max\\_allowed\\_packet \[502\]](#) bytes. If the [secure\\_file\\_priv \[538\]](#) system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns [NULL](#).

The [character\\_set\\_filesystem \[468\]](#) system variable controls interpretation of file names that are given as literal strings.

```
mysql> UPDATE t
      SET blob_col=LOAD_FILE('/tmp/picture')
      WHERE id=1;
```

- [LOCATE\(\*substr\*,\*str\*\) \[1181\]](#), [LOCATE\(\*substr\*,\*str\*,\*pos\*\) \[1181\]](#)

The first syntax returns the position of the first occurrence of substring *substr* in string *str*. The second syntax returns the position of the first occurrence of substring *substr* in string *str*, starting at position *pos*. Returns 0 if *substr* is not in *str*.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
-> 4
```

```
mysql> SELECT LOCATE('xbar', 'foobar');
-> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
-> 7
```

This function is multi-byte safe, and is case-sensitive only if at least one argument is a binary string.

- [LOWER\(\*str\*\)](#) [1182]

Returns the string *str* with all characters changed to lowercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
```

[LOWER\(\)](#) [1182] (and [UPPER\(\)](#) [1187]) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion, convert the string to a nonbinary string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-----+-----+
| New York    | new york                          |
+-----+-----+
```

For Unicode character sets, [LOWER\(\)](#) [1182] and [UPPER\(\)](#) [1187] work accounting to Unicode Collation Algorithm (UCA) 5.2.0 for `xxx_unicode_520_ci` collations and for language-specific collations that are derived from them. For other Unicode collations, [LOWER\(\)](#) [1182] and [UPPER\(\)](#) [1187] work accounting to Unicode Collation Algorithm (UCA) 4.0.0. See [Section 10.1.14.1, “Unicode Character Sets”](#).

This function is multi-byte safe.

- [LPAD\(\*str\*, \*len\*, \*padstr\*\)](#) [1182]

Returns the string *str*, left-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```
mysql> SELECT LPAD('hi',4,'??');
-> '??hi'
mysql> SELECT LPAD('hi',1,'??');
-> 'h'
```

- [LTRIM\(\*str\*\)](#) [1182]

Returns the string *str* with leading space characters removed.

```
mysql> SELECT LTRIM('  barbar');
-> 'barbar'
```

This function is multi-byte safe.

- [MAKE\\_SET\(\*bits\*, \*str1\*, \*str2\*, ...\)](#) [1182]

Returns a set value (a string containing substrings separated by “,” characters) consisting of the strings that have the corresponding bit in *bits* set. *str1* corresponds to bit 0, *str2* to bit 1, and so on. `NULL` values in *str1*, *str2*, ... are not appended to the result.

```
mysql> SELECT MAKE_SET(1,'a','b','c');
-> 'a'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
-> 'hello,world'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
-> 'hello'
mysql> SELECT MAKE_SET(0,'a','b','c');
-> ''
```

- `MID(str,pos,len)` [1183]

`MID(str,pos,len)` [1183] is a synonym for `SUBSTRING(str,pos,len)` [1185].

- `OCT(N)` [1183]

Returns a string representation of the octal value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,8)` [1203]. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT OCT(12);
-> '14'
```

- `OCTET_LENGTH(str)` [1183]

`OCTET_LENGTH()` [1183] is a synonym for `LENGTH()` [1181].

- `ORD(str)` [1183]

If the leftmost character of the string *str* is a multi-byte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code * 256)
+ (3rd byte code * 2562) ...
```

If the leftmost character is not a multi-byte character, `ORD()` [1183] returns the same value as the `ASCII()` [1177] function.

```
mysql> SELECT ORD('2');
-> 50
```

- `POSITION(substr IN str)` [1183]

`POSITION(substr IN str)` [1183] is a synonym for `LOCATE(substr,str)` [1181].

- `QUOTE(str)` [1183]

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (“\”), single quote (“'”), ASCII `NULL`, and Control+Z preceded by a backslash. If the argument is `NULL`, the return value is the word “NULL” without enclosing single quotation marks.

```
mysql> SELECT QUOTE('Don\'t!');
-> 'Don\'t!'
mysql> SELECT QUOTE(NULL);
-> NULL
```

For comparison, see the quoting rules for literal strings and within the C API in [Section 9.1.1, “String Literals”](#), and [Section 21.8.6.54, “mysql\\_real\\_escape\\_string\(\)”](#).

- `REPEAT(str,count)` [1183]

Returns a string consisting of the string *str* repeated *count* times. If *count* is less than 1, returns an empty string. Returns `NULL` if *str* or *count* are `NULL`.

```
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- `REPLACE(str,from_str,to_str)` [1183]

Returns the string *str* with all occurrences of the string *from\_str* replaced by the string *to\_str*. `REPLACE()` [1183] performs a case-sensitive match when searching for *from\_str*.

```
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multi-byte safe.

- [REVERSE\(\*str\*\)](#) [1184]

Returns the string *str* with the order of the characters reversed.

```
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multi-byte safe.

- [RIGHT\(\*str\*, \*len\*\)](#) [1184]

Returns the rightmost *len* characters from the string *str*, or `NULL` if any argument is `NULL`.

```
mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'
```

This function is multi-byte safe.

- [RPAD\(\*str\*, \*len\*, \*padstr\*\)](#) [1184]

Returns the string *str*, right-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```
mysql> SELECT RPAD('hi',5,'?');
-> 'hi???'
mysql> SELECT RPAD('hi',1,'?');
-> 'h'
```

This function is multi-byte safe.

- [RTRIM\(\*str\*\)](#) [1184]

Returns the string *str* with trailing space characters removed.

```
mysql> SELECT RTRIM('barbar ');
-> 'barbar'
```

This function is multi-byte safe.

- [SOUNDEX\(\*str\*\)](#) [1184]

Returns a soundex string from *str*. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the [SOUNDEX\(\)](#) [1184] function returns an arbitrarily long string. You can use [SUBSTRING\(\)](#) [1185] on the result to get a standard soundex string. All nonalphabetic characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

#### Important

When using [SOUNDEX\(\)](#) [1184], you should be aware of the following limitations:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
- This function is not guaranteed to provide consistent results with strings that use multi-byte character sets, including `utf-8`.

We hope to remove these limitations in a future release. See Bug #22638 for more information.

```
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
```

```
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

**Note**

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- `expr1 SOUNDS LIKE expr2` [1185]

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)` [1184].

- `SPACE(N)` [1185]

Returns a string consisting of *N* space characters.

```
mysql> SELECT SPACE(6);
-> '      '
```

- `SUBSTR(str, pos)` [1185], `SUBSTR(str FROM pos)` [1185], `SUBSTR(str, pos, len)` [1185], `SUBSTR(str FROM pos FOR len)` [1185]

`SUBSTR()` [1185] is a synonym for `SUBSTRING()` [1185].

- `SUBSTRING(str, pos)` [1185], `SUBSTRING(str FROM pos)` [1185], `SUBSTRING(str, pos, len)` [1185], `SUBSTRING(str FROM pos FOR len)` [1185]

The forms without a *len* argument return a substring from string *str* starting at position *pos*. The forms with a *len* argument return a substring *len* characters long from string *str*, starting at position *pos*. The forms that use `FROM` are standard SQL syntax. It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function.

For all forms of `SUBSTRING()` [1185], the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

```
mysql> SELECT SUBSTRING('Quadratically',5);
-> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
-> 'ratica'
mysql> SELECT SUBSTRING('Sakila', -3);
-> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
-> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
-> 'ki'
```

This function is multi-byte safe.

If *len* is less than 1, the result is the empty string.

- `SUBSTRING_INDEX(str, delim, count)` [1185]

Returns the substring from string *str* before *count* occurrences of the delimiter *delim*. If *count* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *count* is negative, everything to the right of the final delimiter (counting from the right) is returned. `SUBSTRING_INDEX()` [1185] performs a case-sensitive match when searching for *delim*.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
-> 'www.mysql'
```

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
-> 'mysql.com'
```

This function is multi-byte safe.

- [TO\\_BASE64\(\*str\*\)](#) [1186]

Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is `NULL` if the argument is `NULL`. Base-64 encoded strings can be decoded using the [FROM\\_BASE64\(\)](#) [1180] function.

This function was added in MySQL 5.6.1.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

Different base-64 encoding schemes exist. These are the encoding and decoding rules used by [TO\\_BASE64\(\)](#) [1186] and [FROM\\_BASE64\(\)](#) [1180]:

- The encoding for alphabet value 62 is '+'.
- The encoding for alphabet value 63 is '/'.
- Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with '=' characters to a length of 4.
- A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
- Decoding recognizes and ignores newline, carriage return, tab, and space.
- [TRIM\(\[{BOTH | LEADING | TRAILING} \[\*remstr\*\] FROM\] \*str\*\)](#) [1186], [TRIM\(\[\*remstr\*\] FROM\] \*str\*\)](#) [1186]

Returns the string *str* with all *remstr* prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. *remstr* is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM(' bar ');
-> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
-> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
-> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxyz');
-> 'barx'
```

This function is multi-byte safe.

- [UCASE\(\*str\*\)](#) [1186]

[UCASE\(\)](#) [1186] is a synonym for [UPPER\(\)](#) [1187].

- [UNHEX\(\*str\*\)](#) [1186]

For a string argument *str*, [UNHEX\(\*str\*\)](#) [1186] performs the inverse operation of [HEX\(\*str\*\)](#) [1180]. That is, it interprets each pair of characters in the argument as a hexadecimal number and converts it to the character represented by the number. The return value is a binary string.

```
mysql> SELECT UNHEX('4D7953514C');
-> 'MySQL'
mysql> SELECT 0x4D7953514C;
```

```

-> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
-> 'string'
mysql> SELECT HEX(UNHEX('1267'));
-> '1267'

```

The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If the argument contains any nonhexadecimal digits, the result is `NULL`:

```

mysql> SELECT UNHEX('GG');
+-----+
| UNHEX('GG') |
+-----+
| NULL        |
+-----+

```

A `NULL` result can occur if the argument to `UNHEX()` [1186] is a `BINARY` column, because values are padded with `0x00` bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a `CHAR(3)` column as '41 ' and retrieved as '41' (with the trailing pad space stripped), so `UNHEX()` [1186] for the column value returns 'A'. By contrast '41' is stored into a `BINARY(3)` column as '41\0' and retrieved as '41\0' (with the trailing pad `0x00` byte not stripped). '\0' is not a legal hexadecimal digit, so `UNHEX()` [1186] for the column value returns `NULL`.

For a numeric argument *N*, the inverse of `HEX(N)` [1180] is not performed by `UNHEX()` [1186]. Use `CONV(HEX(N), 16, 10)` [1203] instead. See the description of `HEX()` [1180].

- `UPPER(str)` [1187]

Returns the string *str* with all characters changed to uppercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```

mysql> SELECT UPPER('Hej');
-> 'HEJ'

```

See the description of `LOWER()` [1182] for information that also applies to `UPPER()` [1187]. This included information about how to perform lettercase conversion of binary strings (`BINARY`, `VARBINARY`, `BLOB`) for which these functions are ineffective, and information about case folding for Unicode character sets.

This function is multi-byte safe.

- `WEIGHT_STRING(str [AS {CHAR|BINARY}(N)] [LEVEL levels] [flags])` [1187]

*levels*: *N* [ASC|DESC|REVERSE] [, *N* [ASC|DESC|REVERSE]] ...

This function returns the weight string for the input string. The return value is a binary string that represents the sorting and comparison value of the string. It has these properties:

- If `WEIGHT_STRING(str1)` [1187] = `WEIGHT_STRING(str2)` [1187], then *str1* = *str2* (*str1* and *str2* are considered equal)
- If `WEIGHT_STRING(str1)` [1187] < `WEIGHT_STRING(str2)` [1187], then *str1* < *str2* (*str1* sorts before *str2*)

`WEIGHT_STRING()` [1187] can be used for testing and debugging of collations, especially if you are adding a new collation. See [Section 10.4, “Adding a Collation to a Character Set”](#).

The input string, *str*, is a string expression. If the input is a nonbinary (character) string such as a `CHAR`, `VARCHAR`, or `TEXT` value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a `BINARY`, `VARBINARY`, or `BLOB` value, the return value is the same as the input (the weight for each byte in a binary string is the byte value). If the input is `NULL`, `WEIGHT_STRING()` [1187] returns `NULL`.

## Examples:

```
mysql> SET @s = _latin1 'AB' COLLATE latin1_swedish_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| AB    | 4142    | 4142                    |
+-----+-----+-----+
```

```
mysql> SET @s = _latin1 'ab' COLLATE latin1_swedish_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| ab    | 6162    | 4142                    |
+-----+-----+-----+
```

```
mysql> SET @s = CAST('AB' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| AB    | 4142    | 4142                    |
+-----+-----+-----+
```

```
mysql> SET @s = CAST('ab' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| ab    | 6162    | 6162                    |
+-----+-----+-----+
```

The preceding examples use `HEX()` [1180] to display the `WEIGHT_STRING()` [1187] result. Because the result is a binary value, `HEX()` [1180] can be especially useful when the result contains nonprinting values, to display it in printable form:

```
mysql> SET @s = CONVERT(0xC39F USING utf8) COLLATE utf8_czech_ci;
mysql> SELECT HEX(WEIGHT_STRING(@s));
+-----+
| HEX(WEIGHT_STRING(@s)) |
+-----+
| 0FEA0FEA                |
+-----+
```

For non-NULL return values, the data type of the value is `VARBINARY` if its length is within the maximum length for `VARBINARY`, otherwise the data type is `BLOB`.

The `AS` clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- `AS CHAR(N)` casts the string to a nonbinary string and pads it on the right with spaces to a length of `N` characters. `N` must be at least 1. If `N` is less than the length of the input string, the string is truncated to `N` characters. No warning occurs for truncation.
- `AS BINARY(N)` is similar but casts the string to a binary string, `N` is measured in bytes (not characters), and padding uses `0x00` bytes (not spaces).

```
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 41422020                            |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING('ab' AS BINARY(4)));
+-----+
```

```
| HEX(WEIGHT_STRING('ab' AS BINARY(4))) |
+-----+
| 61620000 |
+-----+
```

The `LEVEL` clause may be given to specify that the return value should contain weights for specific collation levels.

The `levels` specifier following the `LEVEL` keyword may be given either as a list of one or more integers separated by commas, or as a range of two integers separated by a dash. Whitespace around the punctuation characters does not matter.

Examples:

```
LEVEL 1
LEVEL 2, 3, 5
LEVEL 1-3
```

Any level less than 1 is treated as 1. Any level greater than the maximum for the input string collation is treated as maximum for the collation. The maximum varies per collation, but is never greater than 6.

In a list of levels, levels must be given in increasing order. In a range of levels, if the second number is less than the first, it is treated as the first number (for example, 4-2 is the same as 4-4).

If the `LEVEL` clause is omitted, MySQL assumes `LEVEL 1 - max`, where `max` is the maximum level for the collation.

If `LEVEL` is specified using list syntax (not range syntax), any level number can be followed by these modifiers:

- `ASC`: Return the weights without modification. This is the default.
- `DESC`: Return bitwise-inverted weights (for example, `0x78f0 DESC = 0x870f`).
- `REVERSE`: Return the weights in reverse order (that is, the weights for the reversed string, with the first character last and the last first).

Examples:

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1));
+-----+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1)) |
+-----+
| 007FFF |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC));
+-----+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC)) |
+-----+
| FF8000 |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 REVERSE));
+-----+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 REVERSE)) |
+-----+
| FF7F00 |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC REVERSE));
+-----+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC REVERSE)) |
+-----+
| 0080FF |
+-----+
```

The *flags* clause currently is unused.

## 12.5.1. String Comparison Functions

**Table 12.8. String Comparison Operators**

Name	Description
<a href="#">LIKE [1190]</a>	Simple pattern matching
<a href="#">NOT LIKE [1192]</a>	Negation of simple pattern matching
<a href="#">STRCMP() [1192]</a>	Compare two strings

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case sensitive, the comparison is performed in case-sensitive fashion.

- `expr LIKE pat [ESCAPE 'escape_char'] [1190]`

Pattern matching using SQL simple regular expression comparison. Returns `1` (`TRUE`) or `0` (`FALSE`). If either *expr* or *pat* is `NULL`, the result is `NULL`.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Per the SQL standard, [LIKE \[1190\]](#) performs matching on a per-character basis, thus it can produce results different from the `=` [\[1166\]](#) comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
+-----+
|                                          0 |
+-----+
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
+-----+
|                                          1 |
+-----+
```

In particular, trailing spaces are significant, which is not true for `CHAR` or `VARCHAR` comparisons performed with the `=` [\[1166\]](#) operator:

```
mysql> SELECT 'a' = 'a ', 'a' LIKE 'a ';
+-----+-----+
| 'a' = 'a ' | 'a' LIKE 'a ' |
+-----+-----+
|          1 |              0 |
+-----+-----+
1 row in set (0.00 sec)
```

With [LIKE \[1190\]](#) you can use the following two wildcard characters in the pattern.

Character	Description
<code>%</code>	Matches any number of characters, even zero characters
<code>_</code>	Matches exactly one character

```
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
```

```
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, “\” is assumed.

String	Description
<code>\%</code>	Matches one “%” character
<code>\_</code>	Matches one “_” character

```
mysql> SELECT 'David!' LIKE 'David\_';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
-> 1
```

The escape sequence should be empty or one character long. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` [604] SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case sensitive unless one of the operands is a binary string:

```
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

In MySQL, `LIKE` [1190] is permitted on numeric expressions. (This is an extension to the standard SQL `LIKE` [1190].)

```
mysql> SELECT 10 LIKE '1%';
-> 1
```

### Note

Because MySQL uses C escape syntax in strings (for example, “\n” to represent a newline character), you must double any “\” that you use in `LIKE` [1190] strings. For example, to search for “\n”, specify it as “\\n”. To search for “\”, specify it as “\\”;

Exception: At the end of the pattern string, backslash can be specified as “\\”. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```
mysql> SELECT filename FROM t1;
+-----+
| filename |
+-----+
| C:      |
| C:\     |
| C:\Programs |
| C:\Programs\ |
+-----+
```

To test for values that end with backslash, you can match the values using either of the following patterns:

```
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\' |
+-----+-----+
| C:       | 0 |
| C:\     | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+

mysql> SELECT filename, filename LIKE '%\\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\\' |
+-----+-----+
| C:       | 0 |
| C:\     | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+
```

- `expr NOT LIKE pat [ESCAPE 'escape_char']` [1192]

This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

### Note

Aggregate queries involving `NOT LIKE` [1192] comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving `NULL` and comparisons using `NOT RLIKE` [1193] or `NOT REGEXP` [1193]. In such cases, you must test explicitly for `NOT NULL` using `OR` [1172] (and not `AND` [1171]), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP(expr1, expr2)` [1192]

`STRCMP()` [1192] returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 0
```

`STRCMP()` [1192] performs the comparison using the collation of the arguments.

```
mysql> SET @s1 = _latin1 'x' COLLATE latin1_general_ci;
mysql> SET @s2 = _latin1 'X' COLLATE latin1_general_ci;
mysql> SET @s3 = _latin1 'x' COLLATE latin1_general_cs;
mysql> SET @s4 = _latin1 'X' COLLATE latin1_general_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
+-----+-----+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+-----+-----+
```

0	1
+-----+	

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See [Section 10.1.7.5, “Collation of Expressions”](#).

```
mysql> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000) at line 10: Illegal mix of collations (latin1_general_ci,IMPLICIT) and (latin1_ge
mysql> SELECT STRCMP(@s1, @s3 COLLATE latin1_general_ci);
+-----+
| STRCMP(@s1, @s3 COLLATE latin1_general_ci) |
+-----+
|                                           0 |
+-----+
```

## 12.5.2. Regular Expressions

**Table 12.9. String Regular Expression Operators**

Name	Description
<code>NOT REGEXP</code> [1193]	Negation of REGEXP
<code>REGEXP</code> [1193]	Pattern matching using regular expressions
<code>RLIKE</code> [1193]	Synonym for REGEXP

A regular expression is a powerful way of specifying a pattern for a complex search.

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. MySQL uses the extended version to support pattern-matching operations performed with the `REGEXP` [1193] operator in SQL statements.

This section summarizes, with examples, the special characters and constructs that can be used in MySQL for `REGEXP` [1193] operations. It does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory. See also [Section 3.3.4.7, “Pattern Matching”](#).

- `expr NOT REGEXP pat` [1193], `expr NOT RLIKE pat` [1193]

This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat` [1193], `expr RLIKE pat` [1193]

Performs a pattern match of a string expression `expr` against a pattern `pat`. The pattern can be an extended regular expression. The syntax for regular expressions is discussed in [Section 12.5.2, “Regular Expressions”](#). Returns 1 if `expr` matches `pat`; otherwise it returns 0. If either `expr` or `pat` is `NULL`, the result is `NULL`. `RLIKE` [1193] is a synonym for `REGEXP` [1193], provided for `mSQL` compatibility.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

**Note**

Because MySQL uses the C escape syntax in strings (for example, “\n” to represent the newline character), you must double any “\” that you use in your `REGEXP` [1193] strings.

`REGEXP` [1193] is not case sensitive, except when used with binary strings.

```
mysql> SELECT 'Monty!' REGEXP '.*';
-> 1
mysql> SELECT 'new*\n*line' REGEXP 'new\\*.*\\*line';
-> 1
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
```

```

-> 1 0
mysql> SELECT 'a' REGEXP '^[a-d]';
-> 1

```

`REGEXP` [1193] and `RLIKE` [1193] use the character set and collations of the arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in [Section 10.1.7.5, “Collation of Expressions”](#).

### Warning

The `REGEXP` [1193] and `RLIKE` [1193] operators work in byte-wise fashion, so they are not multi-byte safe and may produce unexpected results with multi-byte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|word` matches either the string `hello` or the string `word`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

A regular expression for the `REGEXP` [1193] operator may use any of the following special characters and constructs:

- `^`

Match the beginning of a string.

```

mysql> SELECT 'fo\ngo' REGEXP '^fo$';          -> 0
mysql> SELECT 'fofo' REGEXP '^fo';           -> 1

```

- `$`

Match the end of a string.

```

mysql> SELECT 'fo\ngo' REGEXP 'fo\ngo$';      -> 1
mysql> SELECT 'fo\ngo' REGEXP 'fo$';         -> 0

```

- `.`

Match any character (including carriage return and newline).

```

mysql> SELECT 'fofo' REGEXP '^f.*$';          -> 1
mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$';     -> 1

```

- `a*`

Match any sequence of zero or more `a` characters.

```

mysql> SELECT 'Ban' REGEXP '^Ba*n';          -> 1
mysql> SELECT 'Baaan' REGEXP '^Ba*n';       -> 1
mysql> SELECT 'Bn' REGEXP '^Ba*n';          -> 1

```

- `a+`

Match any sequence of one or more `a` characters.

```

mysql> SELECT 'Ban' REGEXP '^Ba+n';          -> 1
mysql> SELECT 'Bn' REGEXP '^Ba+n';          -> 0

```

- `a?`

Match either zero or one `a` character.

```
mysql> SELECT 'Bn' REGEXP '^Ba?n';      -> 1
mysql> SELECT 'Ban' REGEXP '^Ba?n';    -> 1
mysql> SELECT 'Baan' REGEXP '^Ba?n';   -> 0
```

- `de|abc`

Match either of the sequences `de` or `abc`.

```
mysql> SELECT 'pi' REGEXP 'pi|apa';     -> 1
mysql> SELECT 'axe' REGEXP 'pi|apa';    -> 0
mysql> SELECT 'apa' REGEXP 'pi|apa';    -> 1
mysql> SELECT 'apa' REGEXP '^pi|apa$';  -> 1
mysql> SELECT 'pi' REGEXP '^pi|apa$';   -> 1
mysql> SELECT 'pix' REGEXP '^pi|apa$';  -> 0
```

- `(abc)*`

Match zero or more instances of the sequence `abc`.

```
mysql> SELECT 'pi' REGEXP '^pi*$';      -> 1
mysql> SELECT 'pip' REGEXP '^pi*$';     -> 0
mysql> SELECT 'pipi' REGEXP '^pi*$';    -> 1
```

- `{1}, {2,3}`

`{n}` or `{m,n}` notation provides a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. `m` and `n` are integers.

- `a*`

Can be written as `a{0,}`.

- `a+`

Can be written as `a{1,}`.

- `a?`

Can be written as `a{0,1}`.

To be more precise, `a{n}` matches exactly `n` instances of `a`. `a{n,}` matches `n` or more instances of `a`. `a{m,n}` matches `m` through `n` instances of `a`, inclusive.

`m` and `n` must be in the range from 0 to `RE_DUP_MAX` (default 255), inclusive. If both `m` and `n` are given, `m` must be less than or equal to `n`.

```
mysql> SELECT 'abcde' REGEXP 'a[bcd]{2}e'; -> 0
mysql> SELECT 'abcde' REGEXP 'a[bcd]{3}e'; -> 1
mysql> SELECT 'abcde' REGEXP 'a[bcd]{1,10}e'; -> 1
```

- `[a-dX], [^a-dX]`

Matches any character that is (or is not, if `^` is used) either `a`, `b`, `c`, `d` or `X`. A `-` character between two other characters forms a range that matches all characters from the first character to the second. For example, `[0-9]` matches any decimal digit. To include a literal `]` character, it must immediately follow the opening bracket `[`. To include a literal `-` character, it must be written first or last. Any character that does not have a defined special meaning inside a `[ ]` pair matches only itself.

```
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]'; -> 1
mysql> SELECT 'aXbc' REGEXP '^[a-dXYZ]$'; -> 0
mysql> SELECT 'aXbc' REGEXP '^[a-dXYZ]+$'; -> 1
mysql> SELECT 'aXbc' REGEXP '^[^a-dXYZ]+$'; -> 0
```

```
mysql> SELECT 'gheis' REGEXP '^[^a-dXYZ]+$';      -> 1
mysql> SELECT 'gheisa' REGEXP '^[^a-dXYZ]+$';     -> 0
```

- [.characters.]

Within a bracket expression (written using [ and ]), matches the sequence of characters of that collating element. `characters` is either a single character or a character name like `newline`. The following table lists the permissible character names.

The following table shows the permissible character names and the characters that they match. For characters given as numeric values, the values are represented in octal.

Name	Character	Name	Character
NUL	0	SOH	001
STX	002	ETX	003
EOT	004	ENQ	005
ACK	006	BEL	007
alert	007	BS	010
backspace	'\b'	HT	011
tab	'\t'	LF	012
newline	'\n'	VT	013
vertical-tab	'\v'	FF	014
form-feed	'\f'	CR	015
carriage-return	'\r'	SO	016
SI	017	DLE	020
DC1	021	DC2	022
DC3	023	DC4	024
NAK	025	SYN	026
ETB	027	CAN	030
EM	031	SUB	032
ESC	033	IS4	034
FS	034	IS3	035
GS	035	IS2	036
RS	036	IS1	037
US	037	space	' '
exclamation-mark	'!'	quotation-mark	'\"'
number-sign	'#'	dollar-sign	'\$'
percent-sign	'%'	ampersand	'&'
apostrophe	'\''	left-parenthesis	'('
right-parenthesis	')'	asterisk	'*'
plus-sign	'+'	comma	','
hyphen	'-'	hyphen-minus	'-'
period	'.'	full-stop	'.'
slash	'/'	solidus	'/'
zero	'0'	one	'1'
two	'2'	three	'3'

Name	Character	Name	Character
four	'4'	five	'5'
six	'6'	seven	'7'
eight	'8'	nine	'9'
colon	':'	semicolon	';'
less-than-sign	'<'	equals-sign	'='
greater-than-sign	'>'	question-mark	'?'
commercial-at	'@'	left-square-bracket	'['
backslash	'\'	reverse-solidus	'\/'
right-square-bracket	']'	circumflex	'^'
circumflex-accent	'^'	underscore	'_'
low-line	'_'	grave-accent	'`'
left-brace	'{'	left-curly-bracket	'{'
vertical-line	' '	right-brace	'}'
right-curly-bracket	'}'	tilde	'~'
DEL	177		

```
mysql> SELECT '~' REGEXP '[[.~.]]';           -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]';      -> 1
```

- [=character\_class=]

Within a bracket expression (written using [ and ]), [=character\_class=] represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if o and (+) are the members of an equivalence class, [[=o=]], [[=(+)=]], and [o(+)] are all synonymous. An equivalence class may not be used as an endpoint of a range.

- [:character\_class:]

Within a bracket expression (written using [ and ]), [:character\_class:] represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the [ctype\(3\)](#) manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

Character Class Name	Meaning
alnum	Alphanumeric characters
alpha	Alphabetic characters
blank	Whitespace characters
cntrl	Control characters
digit	Digit characters
graph	Graphic characters
lower	Lowercase alphabetic characters
print	Graphic or space characters

Character Class Name	Meaning
<code>punct</code>	Punctuation characters
<code>space</code>	Space, tab, newline, and carriage return
<code>upper</code>	Uppercase alphabetic characters
<code>xdigit</code>	Hexadecimal digit characters

```
mysql> SELECT 'justalnums' REGEXP '[:alnum:]+';      -> 1
mysql> SELECT '!' REGEXP '[:alnum:]+';             -> 0
```

- `[[:<:]]`, `[[:>:]]`

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore (`_`).

```
mysql> SELECT 'a word a' REGEXP '[[:<:]]word[[:>:]]'; -> 1
mysql> SELECT 'a xword a' REGEXP '[[:<:]]word[[:>:]]'; -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (`\`) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2';                  -> 0
mysql> SELECT '1+2' REGEXP '1\+2';                 -> 0
mysql> SELECT '1+2' REGEXP '1\\+2';                 -> 1
```

## 12.6. Numeric Functions and Operators

Table 12.10. Numeric Functions and Operators

Name	Description
<code>ABS()</code> [1202]	Return the absolute value
<code>ACOS()</code> [1202]	Return the arc cosine
<code>ASIN()</code> [1202]	Return the arc sine
<code>ATAN2()</code> , <code>ATAN()</code> [1203]	Return the arc tangent of the two arguments
<code>ATAN()</code> [1202]	Return the arc tangent
<code>CEIL()</code> [1203]	Return the smallest integer value not less than the argument
<code>CEILING()</code> [1203]	Return the smallest integer value not less than the argument
<code>CONV()</code> [1203]	Convert numbers between different number bases
<code>COS()</code> [1203]	Return the cosine
<code>COT()</code> [1203]	Return the cotangent
<code>CRC32()</code> [1203]	Compute a cyclic redundancy check value
<code>DEGREES()</code> [1204]	Convert radians to degrees
<code>DIV</code> [1201]	Integer division
<code>/</code> [1200]	Division operator
<code>EXP()</code> [1204]	Raise to the power of
<code>FLOOR()</code> [1204]	Return the largest integer value not greater than the argument
<code>LN()</code> [1204]	Return the natural logarithm of the argument
<code>LOG10()</code> [1205]	Return the base-10 logarithm of the argument

Name	Description
<a href="#">LOG2 ( ) [1205]</a>	Return the base-2 logarithm of the argument
<a href="#">LOG ( ) [1204]</a>	Return the natural logarithm of the first argument
<a href="#">- [1200]</a>	Minus operator
<a href="#">MOD ( ) [1205]</a>	Return the remainder
<a href="#">% or MOD [1201]</a>	Modulo operator
<a href="#">PI ( ) [1205]</a>	Return the value of pi
<a href="#">+ [1200]</a>	Addition operator
<a href="#">POW ( ) [1206]</a>	Return the argument raised to the specified power
<a href="#">POWER ( ) [1206]</a>	Return the argument raised to the specified power
<a href="#">RADIANS ( ) [1206]</a>	Return argument converted to radians
<a href="#">RAND ( ) [1206]</a>	Return a random floating-point value
<a href="#">ROUND ( ) [1207]</a>	Round the argument
<a href="#">SIGN ( ) [1208]</a>	Return the sign of the argument
<a href="#">SIN ( ) [1208]</a>	Return the sine of the argument
<a href="#">SQRT ( ) [1208]</a>	Return the square root of the argument
<a href="#">TAN ( ) [1208]</a>	Return the tangent of the argument
<a href="#">* [1200]</a>	Multiplication operator
<a href="#">TRUNCATE ( ) [1209]</a>	Truncate to specified number of decimal places
<a href="#">- [1200]</a>	Change the sign of the argument

## 12.6.1. Arithmetic Operators

**Table 12.11. Arithmetic Operators**

Name	Description
<a href="#">DIV [1201]</a>	Integer division
<a href="#">/ [1200]</a>	Division operator
<a href="#">- [1200]</a>	Minus operator
<a href="#">% or MOD [1201]</a>	Modulo operator
<a href="#">+ [1200]</a>	Addition operator
<a href="#">* [1200]</a>	Multiplication operator
<a href="#">- [1200]</a>	Change the sign of the argument

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of [- \[1200\]](#), [+ \[1200\]](#), and [\\* \[1200\]](#), the result is calculated with [BIGINT \[64-bit\]](#) precision if both operands are integers.
- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the [NO\\_UNSIGNED\\_SUBTRACTION \[605\]](#) SQL mode is enabled, the result is signed even if any operand is unsigned.
- If any of the operands of a [+ \[1200\]](#), [- \[1200\]](#), [/ \[1200\]](#), [\\* \[1200\]](#), [% \[1201\]](#) is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
- In division performed with [/ \[1200\]](#), the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the [div\\_precision\\_increment \[478\]](#) system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence,  $(14620 / 9432456) / (24250 / 9432456)$ , resolves first to  $(0.0014) / (0.0026)$ , with the final result having 8 decimal places ( $0.60288653$ ).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See [Section 12.10, “Cast Functions and Operators”](#).

For information about handling of overflow in numeric expression evaluation, see [Section 11.2.6, “Out-of-Range and Overflow Handling”](#).

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD()` [1213]; see [Section 12.7, “Date and Time Functions”](#).

- [+ \[1200\]](#)

Addition:

```
mysql> SELECT 3+5;
-> 8
```

- [- \[1200\]](#)

Subtraction:

```
mysql> SELECT 3-5;
-> -2
```

- [- \[1200\]](#)

Unary minus. This operator changes the sign of the operand.

```
mysql> SELECT - 2;
-> -2
```

#### Note

If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of  $-2^{63}$ .

- [\\* \[1200\]](#)

Multiplication:

```
mysql> SELECT 3*5;
-> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
-> out-of-range error
```

The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See [Section 11.2, “Numeric Types”](#).)

- [/ \[1200\]](#)

Division:

```
mysql> SELECT 3/5;
-> 0.60
```

Division by zero produces a `NULL` result:

```
mysql> SELECT 102/(1-1);
```

```
-> NULL
```

A division is calculated with `BIGINT` arithmetic only if performed in a context where its result is converted to an integer.

- `DIV` [1201]

Integer division. Similar to `FLOOR()` [1204], but is safe with `BIGINT` values.

In MySQL 5.6, if either operand has a noninteger type, the operands are converted to `DECIMAL` and divided using `DECIMAL` arithmetic before converting the result to `BIGINT`. If the result exceeds `BIGINT` range, an error occurs.

```
mysql> SELECT 5 DIV 2;
-> 2
```

- `N % M` [1201], `N MOD M` [1201]

Modulo operation. Returns the remainder of `N` divided by `M`. For more information, see the description for the `MOD()` [1205] function in Section 12.6.2, “Mathematical Functions”.

## 12.6.2. Mathematical Functions

**Table 12.12. Mathematical Functions**

Name	Description
<code>ABS()</code> [1202]	Return the absolute value
<code>ACOS()</code> [1202]	Return the arc cosine
<code>ASIN()</code> [1202]	Return the arc sine
<code>ATAN2()</code> , <code>ATAN()</code> [1203]	Return the arc tangent of the two arguments
<code>ATAN()</code> [1202]	Return the arc tangent
<code>CEIL()</code> [1203]	Return the smallest integer value not less than the argument
<code>CEILING()</code> [1203]	Return the smallest integer value not less than the argument
<code>CONV()</code> [1203]	Convert numbers between different number bases
<code>COS()</code> [1203]	Return the cosine
<code>COT()</code> [1203]	Return the cotangent
<code>CRC32()</code> [1203]	Compute a cyclic redundancy check value
<code>DEGREES()</code> [1204]	Convert radians to degrees
<code>EXP()</code> [1204]	Raise to the power of
<code>FLOOR()</code> [1204]	Return the largest integer value not greater than the argument
<code>LN()</code> [1204]	Return the natural logarithm of the argument
<code>LOG10()</code> [1205]	Return the base-10 logarithm of the argument
<code>LOG2()</code> [1205]	Return the base-2 logarithm of the argument
<code>LOG()</code> [1204]	Return the natural logarithm of the first argument
<code>MOD()</code> [1205]	Return the remainder
<code>PI()</code> [1205]	Return the value of pi
<code>POW()</code> [1206]	Return the argument raised to the specified power
<code>POWER()</code> [1206]	Return the argument raised to the specified power
<code>RADIANS()</code> [1206]	Return argument converted to radians
<code>RAND()</code> [1206]	Return a random floating-point value

Name	Description
<a href="#">ROUND() [1207]</a>	Round the argument
<a href="#">SIGN() [1208]</a>	Return the sign of the argument
<a href="#">SIN() [1208]</a>	Return the sine of the argument
<a href="#">SQRT() [1208]</a>	Return the square root of the argument
<a href="#">TAN() [1208]</a>	Return the tangent of the argument
<a href="#">TRUNCATE() [1209]</a>	Truncate to specified number of decimal places

All mathematical functions return `NULL` in the event of an error.

- [ABS\(X\) \[1202\]](#)

Returns the absolute value of *X*.

```
mysql> SELECT ABS(2);
      -> 2
mysql> SELECT ABS(-32);
      -> 32
```

This function is safe to use with `BIGINT` values.

- [ACOS\(X\) \[1202\]](#)

Returns the arc cosine of *X*, that is, the value whose cosine is *X*. Returns `NULL` if *X* is not in the range `-1` to `1`.

```
mysql> SELECT ACOS(1);
      -> 0
mysql> SELECT ACOS(1.0001);
      -> NULL
mysql> SELECT ACOS(0);
      -> 1.5707963267949
```

- [ASIN\(X\) \[1202\]](#)

Returns the arc sine of *X*, that is, the value whose sine is *X*. Returns `NULL` if *X* is not in the range `-1` to `1`.

```
mysql> SELECT ASIN(0.2);
      -> 0.20135792079033
mysql> SELECT ASIN('foo');

+-----+
| ASIN('foo') |
+-----+
|          0 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;

+-----+-----+-----+
| Level | Code | Message
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo'
+-----+-----+-----+
```

- [ATAN\(X\) \[1202\]](#)

Returns the arc tangent of *X*, that is, the value whose tangent is *X*.

```
mysql> SELECT ATAN(2);
      -> 1.1071487177941
mysql> SELECT ATAN(-2);
      -> -1.1071487177941
```

- [ATAN\(\*Y\*,\*X\*\) \[1203\]](#), [ATAN2\(\*Y\*,\*X\*\) \[1203\]](#)

Returns the arc tangent of the two variables *X* and *Y*. It is similar to calculating the arc tangent of *Y* / *X*, except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2,2);
      -> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
      -> 1.5707963267949
```

- [CEIL\(\*X\*\) \[1203\]](#)

[CEIL\(\)](#) [1203] is a synonym for [CEILING\(\)](#) [1203].

- [CEILING\(\*X\*\) \[1203\]](#)

Returns the smallest integer value not less than *X*.

```
mysql> SELECT CEILING(1.23);
      -> 2
mysql> SELECT CEILING(-1.23);
      -> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- [CONV\(\*N\*,\*from\\_base\*,\*to\\_base\*\) \[1203\]](#)

Converts numbers between different number bases. Returns a string representation of the number *N*, converted from base *from\_base* to base *to\_base*. Returns *NULL* if any argument is *NULL*. The argument *N* is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If *to\_base* is a negative number, *N* is regarded as a signed number. Otherwise, *N* is treated as unsigned. [CONV\(\)](#) [1203] works with 64-bit precision.

```
mysql> SELECT CONV('a',16,2);
      -> '1010'
mysql> SELECT CONV('6E',18,8);
      -> '172'
mysql> SELECT CONV(-17,10,-18);
      -> '-H'
mysql> SELECT CONV(10+'10'+ '10'+0xa,10,10);
      -> '40'
```

- [COS\(\*X\*\) \[1203\]](#)

Returns the cosine of *X*, where *X* is given in radians.

```
mysql> SELECT COS(PI());
      -> -1
```

- [COT\(\*X\*\) \[1203\]](#)

Returns the cotangent of *X*.

```
mysql> SELECT COT(12);
      -> -1.5726734063977
mysql> SELECT COT(0);
      -> NULL
```

- [CRC32\(\*expr\*\) \[1203\]](#)

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is *NULL* if the argument is *NULL*. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
      -> 3259397556
```

```
mysql> SELECT CRC32('mysql');
-> 2501908538
```

- [DEGREES\(\*X\*\) \[1204\]](#)

Returns the argument *X*, converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
-> 180
mysql> SELECT DEGREES(PI() / 2);
-> 90
```

- [EXP\(\*X\*\) \[1204\]](#)

Returns the value of *e* (the base of natural logarithms) raised to the power of *X*. The inverse of this function is [LOG\(\*Y\*\) \[1204\]](#) (using a single argument only) or [LN\(\*Y\*\) \[1204\]](#).

```
mysql> SELECT EXP(2);
-> 7.3890560989307
mysql> SELECT EXP(-2);
-> 0.13533528323661
mysql> SELECT EXP(0);
-> 1
```

- [FLOOR\(\*X\*\) \[1204\]](#)

Returns the largest integer value not greater than *X*.

```
mysql> SELECT FLOOR(1.23);
-> 1
mysql> SELECT FLOOR(-1.23);
-> -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- [FORMAT\(\*X\*,\*D\*\) \[1180\]](#)

Formats the number *X* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 12.5, "String Functions"](#).

- [HEX\(\*N\\_or\\_S\*\) \[1180\]](#)

This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in [Section 12.5, "String Functions"](#), for details.

- [LN\(\*X\*\) \[1204\]](#)

Returns the natural logarithm of *X*; that is, the base-*e* logarithm of *X*. If *X* is less than or equal to 0, then `NULL` is returned.

```
mysql> SELECT LN(2);
-> 0.69314718055995
mysql> SELECT LN(-2);
-> NULL
```

This function is synonymous with [LOG\(\*X\*\) \[1204\]](#). The inverse of this function is the [EXP\(\*Y\*\) \[1204\]](#) function.

- [LOG\(\*X\*\) \[1204\]](#), [LOG\(\*B\*,\*X\*\) \[1204\]](#)

If called with one parameter, this function returns the natural logarithm of *X*. If *X* is less than or equal to 0, then `NULL` is returned.

The inverse of this function (when called with a single argument) is the [EXP\(\*Y\*\) \[1204\]](#) function.

```
mysql> SELECT LOG(2);
      -> 0.69314718055995
mysql> SELECT LOG(-2);
      -> NULL
```

If called with two parameters, this function returns the logarithm of  $X$  to the base  $B$ . If  $X$  is less than or equal to 0, or if  $B$  is less than or equal to 1, then `NULL` is returned.

```
mysql> SELECT LOG(2,65536);
      -> 16
mysql> SELECT LOG(10,100);
      -> 2
mysql> SELECT LOG(1,100);
      -> NULL
```

`LOG(B, X)` [1204] is equivalent to `LOG(X) / LOG(B)` [1204].

- `LOG2(X)` [1205]

Returns the base-2 logarithm of  $X$ .

```
mysql> SELECT LOG2(65536);
      -> 16
mysql> SELECT LOG2(-100);
      -> NULL
```

`LOG2()` [1205] is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression `LOG(X) / LOG(2)` [1204].

- `LOG10(X)` [1205]

Returns the base-10 logarithm of  $X$ .

```
mysql> SELECT LOG10(2);
      -> 0.30102999566398
mysql> SELECT LOG10(100);
      -> 2
mysql> SELECT LOG10(-100);
      -> NULL
```

`LOG10(X)` [1205] is equivalent to `LOG(10, X)` [1204].

- `MOD(N, M)` [1205], `N % M` [1201], `N MOD M` [1201]

Modulo operation. Returns the remainder of  $N$  divided by  $M$ .

```
mysql> SELECT MOD(234, 10);
      -> 4
mysql> SELECT 253 % 7;
      -> 1
mysql> SELECT MOD(29, 9);
      -> 2
mysql> SELECT 29 MOD 9;
      -> 2
```

This function is safe to use with `BIGINT` values.

`MOD()` [1205] also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5, 3);
      -> 1.5
```

`MOD(N, 0)` [1205] returns `NULL`.

- `PI()` [1205]

Returns the value of  $\pi$  (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
-> 3.141593
mysql> SELECT PI()+0.00000000000000000000;
-> 3.141592653589793116
```

- [POW\(X,Y\) \[1206\]](#)

Returns the value of  $X$  raised to the power of  $Y$ .

```
mysql> SELECT POW(2,2);
-> 4
mysql> SELECT POW(2,-2);
-> 0.25
```

- [POWER\(X,Y\) \[1206\]](#)

This is a synonym for [POW\(\)](#) [1206].

- [RADIANS\(X\) \[1206\]](#)

Returns the argument  $X$ , converted from degrees to radians. (Note that  $\pi$  radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

- [RAND\(\)](#) [1206], [RAND\(N\)](#) [1206]

Returns a random floating-point value  $v$  in the range  $0 \leq v < 1.0$ . If a constant integer argument  $N$  is specified, it is used as the seed value, which produces a repeatable sequence of column values. In the following example, note that the sequences of values produced by [RAND\(3\)](#) is the same both places where it occurs.

```
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i    | RAND()          |
+-----+-----+
| 1    | 0.61914388706828 |
| 2    | 0.93845168309142 |
| 3    | 0.83482678498591 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i    | RAND(3)         |
+-----+-----+
| 1    | 0.90576975597606 |
| 2    | 0.37307905813035 |
| 3    | 0.14808605345719 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i    | RAND()          |
+-----+-----+
```

```

+-----+-----+
| 1 | 0.35877890638893 |
| 2 | 0.28941420772058 |
| 3 | 0.37073435016976 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i | RAND(3) |
+-----+-----+
| 1 | 0.90576975597606 |
| 2 | 0.37307905813035 |
| 3 | 0.14808605345719 |
+-----+-----+
3 rows in set (0.01 sec)
    
```

With a constant initializer, the seed is initialized once when the statement is compiled, prior to execution. If a nonconstant initializer (such as a column name) is used as the argument, the seed is initialized with the value for each invocation of `RAND()` [1206]. (One implication of this is that for equal argument values, `RAND()` [1206] will return the same value each time.)

To obtain a random integer  $R$  in the range  $i \leq R < j$ , use the expression `FLOOR(i + RAND() * (j [1204] - i))`. For example, to obtain a random integer in the range the range  $7 \leq R < 12$ , you could use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

`RAND()` [1206] in a `WHERE` clause is re-evaluated every time the `WHERE` is executed.

You cannot use a column with `RAND()` [1206] values in an `ORDER BY` clause, because `ORDER BY` would evaluate the column multiple times. However, you can retrieve rows in random order like this:

```
mysql> SELECT * FROM tbl_name ORDER BY RAND();
```

`ORDER BY RAND()` combined with `LIMIT` is useful for selecting a random sample from a set of rows:

```
mysql> SELECT * FROM table1, table2 WHERE a=b AND c<d -> ORDER BY RAND() LIMIT 1000;
```

`RAND()` [1206] is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` [2010] is set to `STATEMENT`. (Bug #49222)

- `ROUND(X)` [1207], `ROUND(X,D)` [1207]

Rounds the argument  $X$  to  $D$  decimal places. The rounding algorithm depends on the data type of  $X$ .  $D$  defaults to 0 if not specified.  $D$  can be negative to cause  $D$  digits left of the decimal point of the value  $X$  to become zero.

```

mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
    
```

The return type is the same type as that of the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+-----+-----+
| ROUND(150.000,2) | ROUND(150,2) |
+-----+-----+
|          150.00 |          150 |
+-----+-----+
```

`ROUND()` [1207] uses the following rules depending on the type of the first argument:

- For exact-value numbers, `ROUND()` [1207] uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` [1207] uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For more information, see [Section 12.19, “Precision Math”](#).

- `SIGN(X)` [1208]

Returns the sign of the argument as `-1`, `0`, or `1`, depending on whether `X` is negative, zero, or positive.

```
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- `SIN(X)` [1208]

Returns the sine of `X`, where `X` is given in radians.

```
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- `SQRT(X)` [1208]

Returns the square root of a nonnegative number `X`.

```
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

- `TAN(X)` [1208]

Returns the tangent of `X`, where `X` is given in radians.

```
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1.5574077246549
```

- `TRUNCATE(X,D)` [1209]

Returns the number  $X$ , truncated to  $D$  decimal places. If  $D$  is 0, the result has no decimal point or fractional part.  $D$  can be negative to cause  $D$  digits left of the decimal point of the value  $X$  to become zero.

```
mysql> SELECT TRUNCATE(1.223,1);
-> 1.2
mysql> SELECT TRUNCATE(1.999,1);
-> 1.9
mysql> SELECT TRUNCATE(1.999,0);
-> 1
mysql> SELECT TRUNCATE(-1.999,1);
-> -1.9
mysql> SELECT TRUNCATE(122,-2);
-> 100
mysql> SELECT TRUNCATE(10.28*100,0);
-> 1028
```

All numbers are rounded toward zero.

## 12.7. Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See [Section 11.3, “Date and Time Types”](#), for a description of the range of values each date and time type has and the valid formats in which values may be specified.

**Table 12.13. Date/Time Functions**

Name	Description
<code>ADDDATE()</code> [1211]	Add time values (intervals) to a date value
<code>ADDTIME()</code> [1212]	Add time
<code>CONVERT_TZ()</code> [1212]	Convert from one timezone to another
<code>CURDATE()</code> [1212]	Return the current date
<code>CURRENT_DATE()</code> , <code>CURRENT_DATE</code> [1212]	Synonyms for <code>CURDATE()</code>
<code>CURRENT_TIME()</code> , <code>CURRENT_TIME</code> [1212]	Synonyms for <code>CURTIME()</code>
<code>CURRENT_TIMESTAMP()</code> , <code>CURRENT_TIMESTAMP</code> [1213]	Synonyms for <code>NOW()</code>
<code>CURTIME()</code> [1213]	Return the current time
<code>DATE_ADD()</code> [1213]	Add time values (intervals) to a date value
<code>DATE_FORMAT()</code> [1215]	Format date as specified
<code>DATE_SUB()</code> [1217]	Subtract a time value (interval) from a date
<code>DATE()</code> [1213]	Extract the date part of a date or datetime expression
<code>DATEDIFF()</code> [1213]	Subtract two dates
<code>DAY()</code> [1217]	Synonym for <code>DAYOFMONTH()</code>
<code>DAYNAME()</code> [1217]	Return the name of the weekday
<code>DAYOFMONTH()</code> [1217]	Return the day of the month (0-31)
<code>DAYOFWEEK()</code> [1217]	Return the weekday index of the argument

Name	Description
DAYOFYEAR ( ) [1217]	Return the day of the year (1-366)
EXTRACT ( ) [1217]	Extract part of a date
FROM_DAYS ( ) [1218]	Convert a day number to a date
FROM_UNIXTIME ( ) [1218]	Format UNIX timestamp as a date
GET_FORMAT ( ) [1218]	Return a date format string
HOUR ( ) [1219]	Extract the hour
LAST_DAY [1219]	Return the last day of the month for the argument
LOCALTIME ( ), LOCALTIME [1219]	Synonym for NOW()
LOCALTIMESTAMP, LOCALTIMESTAMP ( ) [1219]	Synonym for NOW()
MAKEDATE ( ) [1219]	Create a date from the year and day of year
MAKETIME [1219]	MAKETIME()
MICROSECOND ( ) [1220]	Return the microseconds from argument
MINUTE ( ) [1220]	Return the minute from the argument
MONTH ( ) [1220]	Return the month from the date passed
MONTHNAME ( ) [1220]	Return the name of the month
NOW ( ) [1220]	Return the current date and time
PERIOD_ADD ( ) [1221]	Add a period to a year-month
PERIOD_DIFF ( ) [1221]	Return the number of months between periods
QUARTER ( ) [1221]	Return the quarter from a date argument
SEC_TO_TIME ( ) [1221]	Converts seconds to 'HH:MM:SS' format
SECOND ( ) [1221]	Return the second (0-59)
STR_TO_DATE ( ) [1221]	Convert a string to a date
SUBDATE ( ) [1222]	A synonym for DATE_SUB() when invoked with three arguments
SUBTIME ( ) [1223]	Subtract times
SYSDATE ( ) [1223]	Return the time at which the function executes
TIME_FORMAT ( ) [1224]	Format as time
TIME_TO_SEC ( ) [1225]	Return the argument converted to seconds
TIME ( ) [1223]	Extract the time portion of the expression passed
TIMEDIFF ( ) [1223]	Subtract time
TIMESTAMP ( ) [1224]	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
TIMESTAMPADD ( ) [1224]	Add an interval to a datetime expression
TIMESTAMPDIFF ( ) [1224]	Subtract an interval from a datetime expression
TO_DAYS ( ) [1225]	Return the date argument converted to days
TO_SECONDS ( ) [1226]	Return the date or datetime argument converted to seconds since Year 0
UNIX_TIMESTAMP ( ) [1226]	Return a UNIX timestamp
UTC_DATE ( ) [1227]	Return the current UTC date
UTC_TIME ( ) [1227]	Return the current UTC time

Name	Description
<a href="#">UTC_TIMESTAMP() [1227]</a>	Return the current UTC date and time
<a href="#">WEEK() [1228]</a>	Return the week number
<a href="#">WEEKDAY() [1228]</a>	Return the weekday index
<a href="#">WEEKOFYEAR() [1229]</a>	Return the calendar week of the date (0-53)
<a href="#">YEAR() [1229]</a>	Return the year
<a href="#">YEARWEEK() [1229]</a>	Return the year and week

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
  -> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as [NOW\(\) \[1220\]](#) within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to [CURDATE\(\) \[1212\]](#), [CURTIME\(\) \[1213\]](#), [UTC\\_DATE\(\) \[1227\]](#), [UTC\\_TIME\(\) \[1227\]](#), [UTC\\_TIMESTAMP\(\) \[1227\]](#), and to any of their synonyms.

The [CURRENT\\_TIMESTAMP\(\) \[1213\]](#), [CURRENT\\_TIME\(\) \[1212\]](#), [CURRENT\\_DATE\(\) \[1212\]](#), and [FROM\\_UNIXTIME\(\) \[1218\]](#) functions return values in the connection's current time zone, which is available as the value of the [time\\_zone \[557\]](#) system variable. In addition, [UNIX\\_TIMESTAMP\(\) \[1226\]](#) assumes that its argument is a datetime value in the current time zone. See [Section 10.6, "MySQL Server Time Zone Support"](#).

Some date functions can be used with "zero" dates or incomplete dates such as `'2001-11-00'`, whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
  -> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
  -> NULL
mysql> SELECT DAYNAME('2006-05-00');
  -> NULL
```

As of MySQL 5.6.4, several functions are more strict when passed a [DATE\(\) \[1213\]](#) function value as their argument and reject incomplete dates with a day part of zero. These functions are affected: [CONVERT\\_TZ\(\) \[1212\]](#), [DATE\\_ADD\(\) \[1213\]](#), [DATE\\_SUB\(\) \[1217\]](#), [DAYOFYEAR\(\) \[1217\]](#), [LAST\\_DAY\(\) \[1219\]](#), [TIMESTAMPDIFF\(\) \[1224\]](#), [TO\\_DAYS\(\) \[1225\]](#), [TO\\_SECONDS\(\) \[1226\]](#), [WEEK\(\) \[1228\]](#), [WEEKDAY\(\) \[1228\]](#), [WEEKOFYEAR\(\) \[1229\]](#), [YEARWEEK\(\) \[1229\]](#). This restriction was relaxed for [LAST\\_DAY\(\) \[1219\]](#) in 5.6.5 to permit a day part of zero.

MySQL 5.6.4 and up supports fractional seconds for [TIME](#), [DATETIME](#), and [TIMESTAMP](#) values, with up to microsecond precision. Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate.

- [ADDDATE\(date,INTERVAL expr unit\) \[1211\]](#), [ADDDATE\(expr,days\) \[1211\]](#)

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` [1211] is a synonym for `DATE_ADD()` [1213]. The related function `SUBDATE()` [1222] is a synonym for `DATE_SUB()` [1217]. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()` [1213].

```
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

```
mysql> SELECT ADDDATE('2008-01-02', 31);
-> '2008-02-02'
```

- `ADDTIME(expr1, expr2)` [1212]

`ADDTIME()` [1212] adds `expr2` to `expr1` and returns the result. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2008-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'
```

- `CONVERT_TZ(dt, from_tz, to_tz)` [1212]

`CONVERT_TZ()` [1212] converts a datetime value `dt` from the time zone given by `from_tz` to the time zone given by `to_tz` and returns the resulting value. Time zones are specified as described in Section 10.6, “MySQL Server Time Zone Support”. This function returns `NULL` if the arguments are invalid.

If the value falls out of the supported range of the `TIMESTAMP` type when converted from `from_tz` to UTC, no conversion occurs. The `TIMESTAMP` range is described in Section 11.1.2, “Date and Time Type Overview”.

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', 'GMT', 'MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', '+00:00', '+10:00');
-> '2004-01-01 22:00:00'
```

#### Note

To use named time zones such as `'MET'` or `'Europe/Moscow'`, the time zone tables must be properly set up. See Section 10.6, “MySQL Server Time Zone Support”, for instructions.

- `CURDATE()` [1212]

Returns the current date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT CURDATE();
-> '2008-06-13'
mysql> SELECT CURDATE() + 0;
-> 20080613
```

- `CURRENT_DATE` [1212], `CURRENT_DATE()` [1212]

`CURRENT_DATE` [1212] and `CURRENT_DATE()` [1212] are synonyms for `CURDATE()` [1212].

- `CURRENT_TIME` [1212], `CURRENT_TIME([fsp])` [1212]

`CURRENT_TIME` [1212] and `CURRENT_TIME()` [1212] are synonyms for `CURTIME()` [1213].

- `CURRENT_TIMESTAMP` [1213], `CURRENT_TIMESTAMP([fsp])` [1213]

`CURRENT_TIMESTAMP` [1213] and `CURRENT_TIMESTAMP()` [1213] are synonyms for `NOW()` [1220].

- `CURTIME([fsp])` [1213]

Returns the current time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

As of MySQL 5.6.4, if the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits. Before 5.6.4, any argument is ignored.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

- `DATE(expr)` [1213]

Extracts the date part of the date or datetime expression *expr*.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- `DATEDIFF(expr1,expr2)` [1213]

`DATEDIFF()` [1213] returns *expr1* – *expr2* expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
-> -31
```

- `DATE_ADD(date,INTERVAL expr unit)` [1213], `DATE_SUB(date,INTERVAL expr unit)` [1217]

These functions perform date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a “-” for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted.

The `INTERVAL` keyword and the *unit* specifier are not case sensitive.

The following table shows the expected form of the *expr* argument for each *unit* value.

<i>unit</i> Value	Expected <i>expr</i> Format
MICROSECOND	MICROSECONDS
SECOND	SECONDS
MINUTE	MINUTES
HOUR	HOURS
DAY	DAYS
WEEK	WEEKS
MONTH	MONTHS

<i>unit</i> Value	Expected <i>expr</i> Format
QUARTER	QUARTERS
YEAR	YEARS
SECOND_MICROSECOND	'SECONDS.MICROSECONDS'
MINUTE_MICROSECOND	'MINUTES:SECONDS.MICROSECONDS'
MINUTE_SECOND	'MINUTES:SECONDS'
HOURL_MICROSECOND	'HOURS:MINUTES:SECONDS.MICROSECONDS'
HOURL_SECOND	'HOURS:MINUTES:SECONDS'
HOURL_MINUTE	'HOURS:MINUTES'
DAY_MICROSECOND	'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'
DAY_SECOND	'DAYS HOURS:MINUTES:SECONDS'
DAY_MINUTE	'DAYS HOURS:MINUTES'
DAY_HOUR	'DAYS HOURS'
YEAR_MONTH	'YEARS-MONTHS'

The return value depends on the arguments:

- `DATETIME` if the first argument is a `DATETIME` (or `TIMESTAMP`) value, or if the first argument is a `DATE` and the *unit* value uses `HOURS`, `MINUTES`, or `SECONDS`.
- String otherwise.

To ensure that the result is `DATETIME`, you can use `CAST( )` [1245] to convert the first argument to `DATETIME`.

MySQL permits any punctuation delimiter in the *expr* format. Those shown in the table are the suggested delimiters. If the *date* argument is a `DATE` value and your calculations involve only `YEAR`, `MONTH`, and `DAY` parts (that is, no time parts), the result is a `DATE` value. Otherwise, the result is a `DATETIME` value.

Date arithmetic also can be performed using `INTERVAL` together with the `+` [1200] or `-` [1200] operator:

```
date + INTERVAL expr unit
date - INTERVAL expr unit
```

`INTERVAL expr unit` is permitted on either side of the `+` [1200] operator if the expression on the other side is a date or datetime value. For the `-` [1200] operator, `INTERVAL expr unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2009-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2008-12-31';
-> '2009-01-01'
mysql> SELECT '2005-01-01' - INTERVAL 1 SECOND;
-> '2004-12-31 23:59:59'
mysql> SELECT DATE_ADD('2000-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2001-01-01 00:00:00'
mysql> SELECT DATE_ADD('2010-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2011-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2005-01-01 00:00:00',
```

```

-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2004-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'

```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the *unit* keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a *unit* of `DAY_SECOND`, the value of *expr* is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

Because *expr* is treated as a string, be careful if you specify a nonstring value with `INTERVAL`. For example, with an interval specifier of `HOURL_MINUTE`, `6/4` evaluates to `1.5000` and is treated as 1 hour, 5000 minutes:

```

mysql> SELECT 6/4;
-> 1.5000
mysql> SELECT DATE_ADD('2009-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2009-01-04 12:20:00'

```

To ensure interpretation of the interval value as you expect, a `CAST()` [1245] operation may be used. To treat `6/4` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```

mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00',
-> INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'

```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```

mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 DAY);
-> '2013-01-02'
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 HOUR);
-> '2013-01-01 01:00:00'

```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```

mysql> SELECT DATE_ADD('2009-01-30', INTERVAL 1 MONTH);
-> '2009-02-28'

```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2006-07-00'` or badly malformed dates:

```

mysql> SELECT DATE_ADD('2006-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL

```

- `DATE_FORMAT(date, format)` [1215]

Formats the *date* value according to the *format* string.

The following specifiers may be used in the *format* string. The “%” character is required before format specifier characters.

Specifier	Description
%a	Abbreviated weekday name (Sun..Sat)
%b	Abbreviated month name (Jan..Dec)
%c	Month, numeric (0..12)
%D	Day of the month with English suffix (0th, 1st, 2nd, 3rd, ...)
%d	Day of the month, numeric (00..31)
%e	Day of the month, numeric (0..31)
%f	Microseconds (000000..999999)
%H	Hour (00..23)
%h	Hour (01..12)
%I	Hour (01..12)
%i	Minutes, numeric (00..59)
%j	Day of year (001..366)
%k	Hour (0..23)
%l	Hour (1..12)
%M	Month name (January..December)
%m	Month, numeric (00..12)
%p	AM or PM
%r	Time, 12-hour (hh:mm:ss followed by AM or PM)
%S	Seconds (00..59)
%s	Seconds (00..59)
%T	Time, 24-hour (hh:mm:ss)
%U	Week (00..53), where Sunday is the first day of the week
%u	Week (00..53), where Monday is the first day of the week
%V	Week (01..53), where Sunday is the first day of the week; used with %X
%v	Week (01..53), where Monday is the first day of the week; used with %x
%W	Weekday name (Sunday..Saturday)
%w	Day of the week (0=Sunday..6=Saturday)
%X	Year for the week where Sunday is the first day of the week, numeric, four digits; used with %V
%x	Year for the week, where Monday is the first day of the week, numeric, four digits; used with %v
%Y	Year, numeric, four digits
%y	Year, numeric (two digits)
%%	A literal “%” character
%x	x, for any “x” not listed above

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as '2014-00-00'.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` [495] system variable (Section 10.7, “MySQL Server Locale Support”).

`DATE_FORMAT()` [1215] returns a string with a character set and collation given by `character_set_connection` [467] and `collation_connection` [469] so that it can return month and weekday names containing non-ASCII characters.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00',
->      '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
->      '%H %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- `DATE_SUB(date, INTERVAL expr unit)` [1217]

See the description for `DATE_ADD()` [1213].

- `DAY(date)` [1217]

`DAY()` [1217] is a synonym for `DAYOFMONTH()` [1217].

- `DAYNAME(date)` [1217]

Returns the name of the weekday for *date*. The language used for the name is controlled by the value of the `lc_time_names` [495] system variable (Section 10.7, “MySQL Server Locale Support”).

```
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

- `DAYOFMONTH(date)` [1217]

Returns the day of the month for *date*, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part.

```
mysql> SELECT DAYOFMONTH('2007-02-03');
-> 3
```

- `DAYOFWEEK(date)` [1217]

Returns the weekday index for *date* (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

- `DAYOFYEAR(date)` [1217]

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

- `EXTRACT(unit FROM date)` [1217]

The `EXTRACT()` [1217] function uses the same kinds of unit specifiers as `DATE_ADD()` [1213] or `DATE_SUB()` [1217], but extracts parts from the date rather than performing date arithmetic.

```
mysql> SELECT EXTRACT(YEAR FROM '2009-07-02');
-> 2009
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03');
-> 200907
```

```
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND
-> FROM '2003-01-02 10:30:00.000123');
-> 123
```

- [FROM\\_DAYS\(\*N\*\)](#) [1218]

Given a day number *N*, returns a [DATE](#) value.

```
mysql> SELECT FROM_DAYS(730669);
-> '2007-07-03'
```

Use [FROM\\_DAYS\(\)](#) [1218] with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See [Section 12.8, “What Calendar Is Used By MySQL?”](#).

- [FROM\\_UNIXTIME\(\*unix\\_timestamp\*\)](#) [1218],  
[FROM\\_UNIXTIME\(\*unix\\_timestamp\*,\*format\*\)](#) [1218]

Returns a representation of the *unix\_timestamp* argument as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone. *unix\_timestamp* is an internal timestamp value such as is produced by the [UNIX\\_TIMESTAMP\(\)](#) [1226] function.

If *format* is given, the result is formatted according to the *format* string, which is used the same way as listed in the entry for the [DATE\\_FORMAT\(\)](#) [1215] function.

```
mysql> SELECT FROM_UNIXTIME(1196440219);
-> '2007-11-30 10:30:19'
mysql> SELECT FROM_UNIXTIME(1196440219) + 0;
-> 20071130103019.000000
mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(),
-> '%Y %D %M %h:%i:%s %x');
-> '2007 30th November 10:30:59 2007'
```

Note: If you use [UNIX\\_TIMESTAMP\(\)](#) [1226] and [FROM\\_UNIXTIME\(\)](#) [1218] to convert between [TIMESTAMP](#) values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the [UNIX\\_TIMESTAMP\(\)](#) [1226] function.

- [GET\\_FORMAT\({DATE|TIME|DATETIME}, { 'EUR' | 'USA' | 'JIS' | 'ISO' | 'INTERNAL' }\)](#) [1218]

Returns a format string. This function is useful in combination with the [DATE\\_FORMAT\(\)](#) [1215] and the [STR\\_TO\\_DATE\(\)](#) [1221] functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the [DATE\\_FORMAT\(\)](#) [1215] function description). ISO format refers to ISO 9075, not ISO 8601.

Function Call	Result
<a href="#">GET_FORMAT(DATE, 'USA')</a> [1218]	'%m.%d.%Y'
<a href="#">GET_FORMAT(DATE, 'JIS')</a> [1218]	'%Y-%m-%d'
<a href="#">GET_FORMAT(DATE, 'ISO')</a> [1218]	'%Y-%m-%d'
<a href="#">GET_FORMAT(DATE, 'EUR')</a> [1218]	'%d.%m.%Y'
<a href="#">GET_FORMAT(DATE, 'INTERNAL')</a> [1218]	'%Y%m%d'
<a href="#">GET_FORMAT(DATETIME, 'USA')</a> [1218]	'%Y-%m-%d %H.%i.%s'
<a href="#">GET_FORMAT(DATETIME, 'JIS')</a> [1218]	'%Y-%m-%d %H:%i:%s'
<a href="#">GET_FORMAT(DATETIME, 'ISO')</a> [1218]	'%Y-%m-%d %H:%i:%s'

Function Call	Result
<code>GET_FORMAT(DATETIME, 'EUR')</code> [1218]	'%Y-%m-%d %H.%i.%s'
<code>GET_FORMAT(DATETIME, 'INTERNAL')</code> [1218]	'%Y%m%d%H%i%s'
<code>GET_FORMAT(TIME, 'USA')</code> [1218]	'%h:%i:%s %p'
<code>GET_FORMAT(TIME, 'JIS')</code> [1218]	'%H:%i:%s'
<code>GET_FORMAT(TIME, 'ISO')</code> [1218]	'%H:%i:%s'
<code>GET_FORMAT(TIME, 'EUR')</code> [1218]	'%H.%i.%s'
<code>GET_FORMAT(TIME, 'INTERNAL')</code> [1218]	'%H%i%s'

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT()` [1218], in which case the function returns the same values as for `DATETIME`.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'
```

- `HOOR(time)` [1219]

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so `HOOR` can return values greater than 23.

```
mysql> SELECT HOOR('10:05:03');
-> 10
mysql> SELECT HOOR('272:59:59');
-> 272
```

- `LAST_DAY(date)` [1219]

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
```

- `LOCALTIME` [1219], `LOCALTIME([fsp])` [1219]

`LOCALTIME` [1219] and `LOCALTIME()` [1219] are synonyms for `NOW()` [1220].

- `LOCALTIMESTAMP` [1219], `LOCALTIMESTAMP([fsp])` [1219]

`LOCALTIMESTAMP` [1219] and `LOCALTIMESTAMP()` [1219] are synonyms for `NOW()` [1220].

- `MAKEDATE(year,dayofyear)` [1219]

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is `NULL`.

```
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
-> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
-> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);
-> NULL
```

- `MAKETIME(hour,minute,second)` [1219]

Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

As of MySQL 5.6.4, the *second* argument can have a fractional part.

```
mysql> SELECT MAKETIME(12,15,30);
-> '12:15:30'
```

- `MICROSECOND(expr)` [1220]

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
-> 123456
mysql> SELECT MICROSECOND('2009-12-31 23:59:59.000010');
-> 10
```

- `MINUTE(time)` [1220]

Returns the minute for *time*, in the range 0 to 59.

```
mysql> SELECT MINUTE('2008-02-03 10:05:03');
-> 5
```

- `MONTH(date)` [1220]

Returns the month for *date*, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

```
mysql> SELECT MONTH('2008-02-03');
-> 2
```

- `MONTHNAME(date)` [1220]

Returns the full name of the month for *date*. The language used for the name is controlled by the value of the `lc_time_names` [495] system variable (Section 10.7, "MySQL Server Locale Support").

```
mysql> SELECT MONTHNAME('2008-02-03');
-> 'February'
```

- `NOW([fsp])` [1220]

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

As of MySQL 5.6.4, if the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits. Before 5.6.4, any argument is ignored.

```
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```

`NOW()` [1220] returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` [1220] returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()` [1223], which returns the exact time at which it executes.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
```

```

+-----+-----+-----+
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()          | SLEEP(2) | SYSDATE()          |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+

```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` [1220] but not by `SYSDATE()` [1223]. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()` [1223]. Setting the timestamp to a nonzero value causes each subsequent invocation of `NOW()` [1220] to return that value. Setting the timestamp to zero cancels this effect so that `NOW()` [1220] once again returns the current date and time.

See the description for `SYSDATE()` [1223] for additional information about the differences between the two functions.

- `PERIOD_ADD(P,N)` [1221]

Adds *N* months to period *P* (in the format `YYMM` or `YYYYMM`). Returns a value in the format `YYYYMM`. Note that the period argument *P* is *not* a date value.

```
mysql> SELECT PERIOD_ADD(200801,2);
-> 200803
```

- `PERIOD_DIFF(P1,P2)` [1221]

Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format `YYMM` or `YYYYMM`. Note that the period arguments *P1* and *P2* are *not* date values.

```
mysql> SELECT PERIOD_DIFF(200802,200703);
-> 11
```

- `QUARTER(date)` [1221]

Returns the quarter of the year for *date*, in the range 1 to 4.

```
mysql> SELECT QUARTER('2008-04-01');
-> 2
```

- `SECOND(time)` [1221]

Returns the second for *time*, in the range 0 to 59.

```
mysql> SELECT SECOND('10:05:03');
-> 3
```

- `SEC_TO_TIME(seconds)` [1221]

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

```
mysql> SELECT SEC_TO_TIME(2378);
-> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
-> 3938
```

- `STR_TO_DATE(str,format)` [1221]

This is the inverse of the `DATE_FORMAT()` [1215] function. It takes a string *str* and a format string *format*. `STR_TO_DATE()` [1221] returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If the date, time, or datetime value extracted from *str* is illegal, `STR_TO_DATE()` [1221] returns `NULL` and produces a warning.

The server scans *str* attempting to match *format* to it. The format string can contain literal characters and format specifiers beginning with %. Literal characters in *format* must match literally in *str*. Format specifiers in *format* must match a date or time part in *str*. For the specifiers that can be used in *format*, see the `DATE_FORMAT()` [1215] function description.

```
mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
-> '2013-05-01'
mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
-> '2013-05-01'
```

Scanning starts at the beginning of *str* and fails if *format* is found not to match. Extra characters at the end of *str* are ignored.

```
mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
-> '09:30:17'
mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
-> NULL
mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in *str* produce a result with some or all parts set to 0:

```
mysql> SELECT STR_TO_DATE('abc','abc');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('9','%m');
-> '0000-09-00'
mysql> SELECT STR_TO_DATE('9','%s');
-> '00:00:09'
```

Range checking on the parts of date values is as described in [Section 11.3.1, “The DATE, DATETIME, and TIMESTAMP Types”](#). This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000','%m/%d/%Y');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004','%m/%d/%Y');
-> '2004-04-31'
```

### Note

You cannot use format “%X%V” to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```
mysql> SELECT STR_TO_DATE('200442 Monday','%X%V %W');
-> '2004-10-18'
```

- `SUBDATE(date, INTERVAL expr unit)` [1222], `SUBDATE(expr, days)` [1222]

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` [1222] is a synonym for `DATE_SUB()` [1217]. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()` [1213].

```
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
```

The second form enables the use of an integer value for *days*. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression *expr*.

```
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
```

- [SUBTIME\(\*expr1\*,\*expr2\*\)](#) [1223]

[SUBTIME\(\)](#) [1223] returns  $expr1 - expr2$  expressed as a value in the same format as *expr1*. *expr1* is a time or datetime expression, and *expr2* is a time expression.

```
mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002');
-> '2007-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
-> '-00:59:59.999999'
```

- [SYSDATE\(\)](#) [1223]

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context.

[SYSDATE\(\)](#) [1223] returns the time at which it executes. This differs from the behavior for [NOW\(\)](#) [1220], which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, [NOW\(\)](#) [1220] returns the time at which the function or triggering statement began to execute.)

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()      | SLEEP(2) | SYSDATE()      |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the [SET TIMESTAMP](#) statement affects the value returned by [NOW\(\)](#) [1220] but not by [SYSDATE\(\)](#) [1223]. This means that timestamp settings in the binary log have no effect on invocations of [SYSDATE\(\)](#) [1223].

Because [SYSDATE\(\)](#) [1223] can return different values even within the same statement, and is not affected by [SET TIMESTAMP](#), it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

Alternatively, you can use the [--sysdate-is-now](#) [444] option to cause [SYSDATE\(\)](#) [1223] to be an alias for [NOW\(\)](#) [1220]. This works if the option is used on both the master and the slave.

The nondeterministic nature of [SYSDATE\(\)](#) [1223] also means that indexes cannot be used for evaluating expressions that refer to it.

- [TIME\(\*expr\*\)](#) [1223]

Extracts the time part of the time or datetime expression *expr* and returns it as a string.

This function is unsafe for statement-based replication. In MySQL 5.6, a warning is logged if you use this function when [binlog\\_format](#) [2010] is set to [STATEMENT](#). (Bug #47995)

```
mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'
```

- [TIMEDIFF\(\*expr1\*,\*expr2\*\)](#) [1223]

[TIMEDIFF\(\)](#) [1223] returns  $expr1 - expr2$  expressed as a time value. *expr1* and *expr2* are time or date-and-time expressions, but both must be of the same type.

The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` [1224] and `UNIX_TIMESTAMP()` [1226], both of which return integers.

```
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
-> '2000:01:01 00:00:00.000001');
-> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001',
-> '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

- `TIMESTAMP(expr)` [1224], `TIMESTAMP(expr1,expr2)` [1224]

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

```
mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
-> '2004-01-01 00:00:00'
```

- `TIMESTAMPADD(unit,interval,datetime_expr)` [1224]

Adds the integer expression `interval` to the date or datetime expression `datetime_expr`. The unit for `interval` is given by the `unit` argument, which should be one of the following values: `MICROSECOND` (microseconds), `SECOND`, `MINUTE`, `HOURL`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

The `unit` value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```
mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
-> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
-> '2003-01-09'
```

- `TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)` [1224]

Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part `'00:00:00'` where necessary. The unit for the result (an integer) is given by the `unit` argument. The legal values for `unit` are the same as those listed in the description of the `TIMESTAMPADD()` [1224] function.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
-> 128885
```

#### Note

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` [1224] function when invoked with 2 arguments.

- `TIME_FORMAT(time,format)` [1224]

This is used like the `DATE_FORMAT()` [1215] function, but the `format` string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or `0`.

If the *time* value contains an hour part that is greater than 23, the %H and %k hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- [TIME\\_TO\\_SEC\(\*time\*\) \[1225\]](#)

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- [TO\\_DAYS\(\*date\*\) \[1225\]](#)

Given a date *date*, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321
```

[TO\\_DAYS\(\)](#) [1225] is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 12.8, "What Calendar Is Used By MySQL?"](#), for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in [Section 11.3, "Date and Time Types"](#). For example, '2008-10-07' and '08-10-07' are seen as identical dates:

```
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687
```

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', [TO\\_DAYS\(\)](#) [1225] returns the values shown here:

```
mysql> SELECT TO_DAYS('0000-00-00');
+-----+
| to_days('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_DAYS('0000-01-01');
+-----+
| to_days('0000-01-01') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the [ALLOW\\_INVALID\\_DATES \[603\]](#) SQL server mode is enabled.

- `TO_SECONDS(expr)` [1226]

Given a date or datetime *expr*, returns a the number of seconds since the year 0. If *expr* is not a valid date or datetime value, returns `NULL`.

```
mysql> SELECT TO_SECONDS(950501);
      -> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
      -> 63426672000
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
      -> 63426721412
mysql> SELECT TO_SECONDS(NOW());
      -> 63426721458
```

Like `TO_DAYS()` [1225], `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 12.8, “What Calendar Is Used By MySQL?”](#), for details.

Like `TO_DAYS()` [1225], `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in [Section 11.3, “Date and Time Types”](#).

In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_SECONDS()` [1226] returns the values shown here:

```
mysql> SELECT TO_SECONDS('0000-00-00');
+-----+
| TO_SECONDS('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_SECONDS('0000-01-01');
+-----+
| TO_SECONDS('0000-01-01') |
+-----+
| 86400 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` [603] SQL server mode is enabled.

- `UNIX_TIMESTAMP()` [1226], `UNIX_TIMESTAMP(date)` [1226]

If called with no argument, returns a Unix timestamp (seconds since `'1970-01-01 00:00:00'` UTC) as an unsigned integer. If `UNIX_TIMESTAMP()` [1226] is called with a *date* argument, it returns the value of the argument as seconds since `'1970-01-01 00:00:00'` UTC. *date* may be a `DATE` string, a `DATETIME` string, a `TIMESTAMP`, or a number in the format `YYMMDD` or `YYYYMMDD`. The server interprets *date* as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in [Section 10.6, “MySQL Server Time Zone Support”](#).

```
mysql> SELECT UNIX_TIMESTAMP();
      -> 1196440210
mysql> SELECT UNIX_TIMESTAMP('2007-11-30 10:30:19');
```

```
-> 1196440219
```

When `UNIX_TIMESTAMP()` [1226] is used on a `TIMESTAMP` column, the function returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion. If you pass an out-of-range date to `UNIX_TIMESTAMP()` [1226], it returns 0.

Note: If you use `UNIX_TIMESTAMP()` [1226] and `FROM_UNIXTIME()` [1218] to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes, it is possible for two `UNIX_TIMESTAMP()` [1226] to map two `TIMESTAMP` values to the same Unix timestamp value. `FROM_UNIXTIME()` [1218] will map that value back to only one of the original `TIMESTAMP` values. Here is an example, using `TIMESTAMP` values in the `CET` time zone:

```
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+
```

If you want to subtract `UNIX_TIMESTAMP()` [1226] columns, you might want to cast the result to signed integers. See Section 12.10, “Cast Functions and Operators”.

- `UTC_DATE` [1227], `UTC_DATE()` [1227]

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- `UTC_TIME` [1227], `UTC_TIME([fsp])` [1227]

Returns the current UTC time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

As of MySQL 5.6.4, if the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits. Before 5.6.4, any argument is ignored.

```
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

- `UTC_TIMESTAMP` [1227], `UTC_TIMESTAMP([fsp])` [1227]

Returns the current UTC date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context.

As of MySQL 5.6.4, if the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits. Before 5.6.4, any argument is ignored.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
```

```
-> '2003-08-14 18:08:04', 20030814180804.000000
```

- [WEEK\(\*date\* \[, \*mode\*\]\) \[1228\]](#)

This function returns the week number for *date*. The two-argument form of [WEEK\(\)](#) [1228] enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the *mode* argument is omitted, the value of the [default\\_week\\_format](#) [475] system variable is used. See [Section 5.1.4, “Server System Variables”](#).

The following table describes how the *mode* argument works.

Mode	First day of week	Range	Week 1 is the first week ...
0	Sunday	0-53	with a Sunday in this year
1	Monday	0-53	with more than 3 days this year
2	Sunday	1-53	with a Sunday in this year
3	Monday	1-53	with more than 3 days this year
4	Sunday	0-53	with more than 3 days this year
5	Monday	0-53	with a Monday in this year
6	Sunday	1-53	with more than 3 days this year
7	Monday	1-53	with a Monday in this year

```
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
-> 53
```

Note that if a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that MySQL should return 52 for the [WEEK\(\)](#) [1228] function, because the given date actually occurs in the 52nd week of 1999. We decided to return 0 instead because we want the function to return “the week number in the given year.” This makes use of the [WEEK\(\)](#) [1228] function reliable when combined with other functions that extract a date part from a date.

If you would prefer the result to be evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the [YEARWEEK\(\)](#) [1229] function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- [WEEKDAY\(\*date\*\) \[1228\]](#)

Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
```

```
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- `WEEKOFYEAR(date)` [1229]

Returns the calendar week of the date as a number in the range from 1 to 53.

`WEEKOFYEAR()` [1229] is a compatibility function that is equivalent to `WEEK(date, 3)` [1228].

```
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
```

- `YEAR(date)` [1229]

Returns the year for *date*, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('1987-01-01');
-> 1987
```

- `YEARWEEK(date)` [1229], `YEARWEEK(date, mode)` [1229]

Returns year and week for a date. The *mode* argument works exactly like the *mode* argument to `WEEK()` [1228]. The year in the result may be different from the year in the date argument for the first and the last week of the year.

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198653
```

Note that the week number is different from what the `WEEK()` [1228] function would return (0) for optional arguments 0 or 1, as `WEEK()` [1228] then returns the week in the context of the given year.

## 12.8. What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
1	2	3	4	15	16	17
18	19	20	21	22	23	24
25	26	27	28	29	30	31

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL `DATE` or `DATETIME` values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

## 12.9. Full-Text Search Functions

`MATCH(col1,col2,...) AGAINST(expr [search_modifier])` [1229]

```

search_modifier:
{
  | IN NATURAL LANGUAGE MODE
  | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
  | IN BOOLEAN MODE
  | WITH QUERY EXPANSION
}

```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `InnoDB` or `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.
- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() ... AGAINST [1229]` syntax. `MATCH() [1229]` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators. The stopword list applies, controlled by `innodb_ft_enable_stopword [1724]`, `innodb_ft_server_stopword_table [1725]`, and `innodb_ft_user_stopword_table [1726]` for `InnoDB` search indexes, and `ft_stopword_file [485]` for `MyISAM` ones.
- Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given. For more information, see [Section 12.9.1, “Natural Language Full-Text Searches”](#).
- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see [Section 12.9.2, “Boolean Full-Text Searches”](#).
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see [Section 12.9.3, “Full-Text Searches with Query Expansion”](#).

For information about `FULLTEXT` query performance, see [Section 8.3.4, “Column Indexes”](#).

For more technical details about processing for `InnoDB FULLTEXT` indexes, see [Section 14.2.3.12.3, “FULLTEXT Indexes”](#).

Constraints on full-text searching are listed in [Section 12.9.5, “Full-Text Restrictions”](#).

The `myisam_ftdump` utility dumps the contents of a `MyISAM` full-text index. This may be helpful for debugging full-text queries. See [Section 4.6.2, “myisam\\_ftdump — Display Full-Text Index information”](#).

## 12.9.1. Natural Language Full-Text Searches

By default or with the `IN NATURAL LANGUAGE MODE` modifier, the `MATCH()` [1229] function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` [1229] returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` [1229] list.

```
mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO articles (title,body) VALUES
    ('MySQL Tutorial','DBMS stands for DataBase ...'),
    ('How To Use MySQL Well','After you went through a ...'),
    ('Optimizing MySQL','In this tutorial we will show ...'),
    ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
    ('MySQL vs. YourSQL','In the following database comparison ...'),
    ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.00 sec)
Records: 6 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM articles
    WHERE MATCH (title,body)
    AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a binary collation for the indexed columns. For example, a column that uses the `latin1` character set of can be assigned a collation of `latin1_bin` to make it case sensitive for full-text searches.

When `MATCH()` [1229] is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row, the number of unique words in that row, the total number of words in the collection, and the number of documents (rows) that contain a particular word.

To simply count matches, you could use a query like this:

```
mysql> SELECT COUNT(*) FROM articles
    WHERE MATCH (title,body)
    AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+
| COUNT(*) |
+-----+
| 2 |
+-----+
1 row in set (0.00 sec)
```

You might find it quicker to rewrite the query as follows:

```
mysql> SELECT
    COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
    AS count
    FROM articles;
+-----+
| count |
+-----+
```

```

+-----+
|      2 |
+-----+
1 row in set (0.03 sec)

```

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` [1229] function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` [1229] function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. To search the `title` or `body` separately, you would create separate `FULLTEXT` indexes for each column.

You can also perform a boolean search or a search with query expansion. These search types are described in [Section 12.9.2, "Boolean Full-Text Searches"](#), and [Section 12.9.3, "Full-Text Searches with Query Expansion"](#).

A full-text search that uses an index can name columns only from a single table in the `MATCH()` [1229] clause because an index cannot span multiple tables. A boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` [1229] function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```

mysql> SELECT id, MATCH (title,body)
        AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
        FROM articles;

```

id	score
1	0.22764469683170319
2	0
3	0.22764469683170319
4	0
5	0
6	0

```

6 rows in set (0.00 sec)

```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` [1229] twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` [1229] calls are identical and invokes the full-text search code only once.

```

mysql> SELECT id, body, MATCH (title,body) AGAINST
        ('Security implications of running MySQL as root'
         IN NATURAL LANGUAGE MODE) AS score
        FROM articles WHERE MATCH (title,body) AGAINST
        ('Security implications of running MySQL as root'
         IN NATURAL LANGUAGE MODE);

```

```

6 rows in set (0.00 sec)

```

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (“'”), but not more than one in a row. This means that `aaa 'bbb` is regarded as one word, but `aaa ' 'bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `'aaa 'bbb` would be parsed as `aaa 'bbb`.

The `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, “ ” (space), “,” (comma), and “.” (period). If words are not separated by delimiters (as in, for example, Chinese), the `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index, you must preprocess them so that they are separated by some arbitrary delimiter such as “ ”.

In MySQL 5.6, it is possible to write a plugin that replaces the built-in full-text parser. For details, see [Section 22.2, “The MySQL Plugin API”](#). For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for `InnoDB` search indexes, or four characters for `MyISAM`. You can control the cutoff by setting a configuration option before creating the index: `innodb_ft_min_token_size` [1725] configuration option for `InnoDB` search indexes, or `ft_min_word_len` [484] for `MyISAM`.
- Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overridden by a user-defined list. The stopword lists and related configuration options are different for `InnoDB` search indexes and `MyISAM` ones. Stopword processing is controlled by the configuration options `innodb_ft_enable_stopword` [1724], `innodb_ft_server_stopword_table` [1725], and `innodb_ft_user_stopword_table` [1726] for `InnoDB` search indexes, and `ft_stopword_file` [485] for `MyISAM` ones.

The default stopword lists are shown in [Section 12.9.4, “Full-Text Stopwords”](#). The default minimum word length and stopword list can be changed as described in [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

### MyISAM Limitation

For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on `MyISAM` tables. For example, although the word “MySQL” is present in every row of the `articles` table shown earlier, a search for the word in a `MyISAM` search index produces no results:

```
mysql> SELECT * FROM articles
      WHERE MATCH (title,body)
      AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopword. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.

The 50% threshold can surprise you when you first try full-text searching to see how it works, and makes [InnoDB](#) tables more suited to experimentation with full-text searches. If you create a [MyISAM](#) table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results until the table contains more rows. Users who need to bypass the 50% limitation can build search indexes on [InnoDB](#) tables, or the boolean search mode explained in [Section 12.9.2, “Boolean Full-Text Searches”](#).

## 12.9.2. Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the `+` and `-` operators indicate that a word must be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
      AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

id	title	body
1	MySQL Tutorial	DBMS stands for DataBase ...
2	How To Use MySQL Well	After you went through a ...
3	Optimizing MySQL	In this tutorial we will show ...
4	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...
6	MySQL Security	When configured properly, MySQL ...

**Note**

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- `+` stands for `AND`
- `-` stands for `NOT`
- `[no operator]` implies `OR`

Boolean full-text searches have these characteristics:

- They do not use the 50% threshold that applies to [MyISAM](#) search indexes.
- They do not automatically sort rows in order of decreasing relevance.
- Boolean queries against a [MyISAM](#) search index can work even without a `FULLTEXT` index, although a search executed in this fashion would be quite slow. [InnoDB](#) tables require a `FULLTEXT` index to perform boolean queries.
- The minimum and maximum word length full-text parameters apply: `innodb_ft_min_token_size` [1725] and `innodb_ft_max_token_size` [1724] for [InnoDB](#) search indexes, and `ft_min_word_len` [484] and `ft_max_word_len` [484] for [MyISAM](#) ones.
- The stopword list applies, controlled by `innodb_ft_enable_stopword` [1724], `innodb_ft_server_stopword_table` [1725], and `innodb_ft_user_stopword_table` [1726] for [InnoDB](#) search indexes, and `ft_stopword_file` [485] for [MyISAM](#) ones.

The boolean full-text search capability supports the following operators:

- `+`

A leading plus sign indicates that this word *must* be present in each row that is returned.

- -

A leading minus sign indicates that this word must *not* be present in any of the rows that are returned.

Note: The - operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by - returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither + nor - is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of `MATCH() ... AGAINST() [1229]` without the `IN BOOLEAN MODE` modifier.

- `@distance`

This operator works on `InnoDB` tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the `@distance` operator, for example, `MATCH(coll) AGAINST('"word1 word2 word3" @8' IN BOOLEAN MODE)`

- > <

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example following this list.

- ( )

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- ~

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the - operator.

- \*

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is *appended* to the word to be affected. Words match if they begin with the word preceding the \* operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopword. Whether a word is too short is determined from the `innodb_ft_min_token_size [1725]` setting for `InnoDB` tables, or `ft_min_word_len [484]` for `MyISAM` tables. The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for `'+word +the*'` could return fewer rows than a search for `'+word +the'`, because the second query ignores the too-short search term `the`.

- "

A phrase that is enclosed within double quote (“”) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`.

If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

Find rows that contain at least one of the two words.

- `'+apple +juice'`

Find rows that contain both words.

- `'+apple macintosh'`

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple -macintosh'`

Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the “” characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

### 12.9.3. Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
WHERE MATCH (title,body)
AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

```

+-----+-----+-----+
| id | title                | body                |
+-----+-----+-----+
| 1  | MySQL Tutorial       | DBMS stands for DataBase ... |
| 5  | MySQL vs. YourSQL   | In the following database comparison ... |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM articles
      WHERE MATCH (title,body)
      AGAINST ('database' WITH QUERY EXPANSION);
+-----+-----+-----+
| id | title                | body                |
+-----+-----+-----+
| 5  | MySQL vs. YourSQL   | In the following database comparison ... |
| 1  | MySQL Tutorial       | DBMS stands for DataBase ... |
| 3  | Optimizing MySQL    | In this tutorial we will show ... |
| 6  | MySQL Security      | When configured properly, MySQL ... |
| 2  | How To Use MySQL Well | After you went through a ... |
| 4  | 1001 MySQL Tricks   | 1. Never run mysqld as root. 2. ... |
+-----+-----+-----+
6 rows in set (0.00 sec)

```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

#### Note

Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.

## 12.9.4. Full-Text Stopwords

The stopwords list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopwords lookups if the stopwords file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopwords lookups depends on the server collation. For example, lookups are case insensitive if the collation is `latin1_swedish_ci`, whereas lookups are case sensitive if the collation is `latin1_general_cs` or `latin1_bin`.

### Stopwords for InnoDB Search Indexes

InnoDB has a relatively short list of default stopwords, because documents from technical, literary, and so on sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the list, query the table `information_schema.innodb_ft_default_stopword`. To define your own stopwords list used for all InnoDB tables, define a table with the same structure as `innodb_ft_default_stopword`, fill it with the desired stopwords, and set the value of the `innodb_ft_server_stopword_table` [1725] option to a value of the form `db_name/table_name` before creating the search index. To create special stopwords lists on a table-by-table basis, define other tables to hold these lists and specify the appropriate one in the `innodb_ft_user_stopword_table` [1726] option before creating the search index.

### Stopwords for MyISAM Search Indexes

In MySQL 5.6, the stopwords file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`. If any table was created with `FULLTEXT` indexes while the server character set was `ucs2`, `utf16`, `utf16le`, or `utf32`, it should be repaired using this statement:

## Full-Text Stopwords

```
REPAIR TABLE tbl_name QUICK;
```

The following table shows the default list of stopwords for [MyISAM](#) search indexes. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

## 12.9.5. Full-Text Restrictions

- Full-text searches are supported for [InnoDB](#) and [MyISAM](#) tables only. `FULLTEXT` index support for [InnoDB](#) tables requires MySQL 5.6.4 or higher.
- Full-text searches are not supported for partitioned tables. See [Section 17.6, "Restrictions and Limitations on Partitioning"](#).
- Full-text searches can be used with most multi-byte character sets. The exception is that for Unicode, the `utf8` character set can be used, but not the `ucs2` character set. Although `FULLTEXT` indexes on `ucs2` columns cannot be used, you can perform `IN BOOLEAN MODE` searches on a `ucs2` column that has no such index.

The remarks for `utf8` also apply to `utf8mb4`, and the remarks for `ucs2` also apply to `utf16`, `utf16le`, and `utf32`.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the `FULLTEXT` parser *cannot determine where words begin and end in these and other such languages*. The implications of this and some workarounds for the problem are described in [Section 12.9, "Full-Text Search Functions"](#).

- Although the use of multiple character sets within a single table is supported, all columns in a `FULLTEXT` index must use the same character set and collation.
- The `MATCH( )` [1229] column list must match exactly the column list in some `FULLTEXT` index definition for the table, unless this `MATCH( )` [1229] is `IN BOOLEAN MODE` on a `MyISAM` table. For `MyISAM` tables only, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.
- The argument to `AGAINST( )` must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.
- Index hints are more limited for `FULLTEXT` searches than for non-`FULLTEXT` searches. See [Section 13.2.9.3, “Index Hint Syntax”](#).

## 12.9.6. Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See [Section 2.9, “Installing MySQL from Source”](#).

Note that full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing so are given later in this section.

- The minimum and maximum lengths of words to be indexed are defined by the `innodb_ft_min_token_size` [1725] and `innodb_ft_max_token_size` [1724] for InnoDB search indexes, and `ft_min_word_len` [484] and `ft_max_word_len` [484] for `MyISAM` ones. After changing any of these options, rebuild your `FULLTEXT` indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```
[mysqld]
innodb_ft_min_token_size=2
ft_min_word_len=2
```

Then restart the server and rebuild your `FULLTEXT` indexes. For `MyISAM` tables, note particularly the remarks regarding `myisamchk` in the instructions following this list.

- To override the default stopword list, set the `ft_stopword_file` [485] system variable. (See [Section 5.1.4, “Server System Variables”](#).) The variable value should be the path name of the file containing the stopword list, or the empty string to disable stopword filtering. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopword file, restart the server and rebuild your `FULLTEXT` indexes.

The stopword list is free-form, separating stopwords with any nonalphanumeric character such as newline, space, or comma. Exceptions are the underscore character (“\_”) and a single apostrophe (“'”) which are treated as part of a word. The character set of the stopword list is the server's default character set; see [Section 10.1.3.1, “Server Character Set and Collation”](#).

- The 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

### Note

By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH( )` [1229] function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

- To change the operators used for boolean full-text searches on `MyISAM` tables, set the `ft_boolean_syntax` [483] system variable. (`InnoDB` does not have an equivalent setting.) This variable can be changed while the server is running, but you must have the `SUPER` [756] privilege to do so. No rebuilding of indexes is necessary in this case. See [Section 5.1.4, “Server System Variables”](#), which describes the rules governing how to set this variable.
- You can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each table that contains any `FULLTEXT` indexes. Suppose that you want to treat the hyphen character ('-') as a word character. Use one of these methods:
  - Modify the MySQL source: In `storage/myisam/ftdefs.h`, see the `true_word_char( )` and `misc_word_char( )` macros. Add '-' to one of those macros and recompile MySQL.
  - Modify a character set file: This requires no recompilation. The `true_word_char( )` macro uses a “character type” table to distinguish letters and numbers from other characters. . You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that '-' is a “letter.” Then use the given character set for your `FULLTEXT` indexes. For information about the `<ctype><map>` array format, see [Section 10.3.1, “Character Definition Arrays”](#).
  - Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation. For general information about adding collations, see [Section 10.4, “Adding a Collation to a Character Set”](#). For an example specific to full-text indexing, see [Section 12.9.7, “Adding a Collation for Full-Text Indexing”](#).

If you modify full-text variables that affect indexing (`innodb_ft_min_token_size` [1725], `innodb_ft_max_token_size` [1724], `innodb_ft_server_stopword_table` [1725], `innodb_ft_user_stopword_table` [1726], `innodb_ft_enable_stopword` [1724], `ft_min_word_len` [484], `ft_max_word_len` [484], or `ft_stopword_file` [485]), or if you change the stopword file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server. To rebuild the indexes in this case, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each `FULLTEXT` index. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

Note that if you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopword file values used by the server, specify the same `ft_min_word_len` [484],

`ft_max_word_len` [484], and `ft_stopword_file` [485] values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

## 12.9.7. Adding a Collation for Full-Text Indexing

This section describes how to add a new collation for full-text searches. The sample collation is like `latin1_swedish_ci` but treats the '-' character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in [Section 10.4, "Adding a Collation to a Character Set"](#); it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use this procedure:

1. Add a collation to the `Index.xml` file. The collation ID must be unused, so choose a value different from 1000 if that ID is already taken on your system.

```
<charset name="latin1">
...
<collation name="latin1_fulltext_ci" id="1000"/>
</charset>
```

2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

```
<collation name="latin1_fulltext_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D D7 D8 55 55 55 59 59 DE DF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D F7 D8 55 55 55 59 59 DE FF
</map>
</collation>
```

3. Modify the `ctype` array in `latin1.xml`. Change the value corresponding to 0x2D (which is the code for the '-' character) from 10 (punctuation) to 01 (small letter). In the following array, this is the element in the fourth row down, third value from the end.

```
<ctype>
```

```

<map>
00
20 20 20 20 20 20 20 20 20 28 28 28 28 28 20 20
20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
48 10 10 10 10 10 10 10 10 10 10 10 10 01 10 10
84 84 84 84 84 84 84 84 84 84 10 10 10 10 10 10
10 81 81 81 81 81 81 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 01 01 01 01 01 10 10 10 10
10 82 82 82 82 82 82 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 02 02 02 02 10 10 10 10 20
10 00 10 02 10 10 10 10 10 10 01 10 01 00 01 00
00 10 10 10 10 10 10 10 10 10 02 10 02 00 02 01
48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
01 01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 10 01 01 01 01 01 01 01 02
02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 10 02 02 02 02 02 02 02 02
</map>
</ctype>

```

4. Restart the server.
5. To employ the new collation, include it in the definition of columns that are to use it:

```

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)

mysql> CREATE TABLE t1 (
  a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
  FULLTEXT INDEX(a)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.47 sec)

```

6. Test the collation to verify that hyphen is considered as a word character:

```

mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+-----+
| a      |
+-----+
| ----  |
+-----+
1 row in set (0.00 sec)

```

## 12.10. Cast Functions and Operators

Table 12.14. Cast Functions

Name	Description
<a href="#">BINARY [1244]</a>	Cast a string to a binary string
<a href="#">CAST() [1245]</a>	Cast a value as a certain type
<a href="#">CONVERT() [1245]</a>	Cast a value as a certain type

- [BINARY \[1244\]](#)

The [BINARY \[1244\]](#) operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the comparison to be case sensitive even if the column is not defined as [BINARY](#) or [BLOB](#). [BINARY \[1244\]](#) also causes trailing spaces to be significant.

```

mysql> SELECT 'a' = 'A';
-> 1

```

```
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

In a comparison, `BINARY` [1244] affects the entire operation; it can be given before either operand with the same result.

`BINARY str` [1244] is shorthand for `CAST(str AS BINARY)` [1245].

Note that in some contexts, if you cast an indexed column to `BINARY`, MySQL is not able to use the index efficiently.

- `CAST(expr AS type)` [1245]

The `CAST()` [1245] function takes an expression of any type and produces a result value of a specified type, similar to `CONVERT()` [1245]. See the description of `CONVERT()` [1245] for more information.

- `CONVERT(expr, type)` [1245], `CONVERT(expr USING transcoding_name)` [1245]

The `CONVERT()` [1245] and `CAST()` [1245] functions take an expression of any type and produce a result value of a specified type.

The `type` for the result can be one of the following values:

- `BINARY[ (N) ]`
- `CHAR[ (N) ]`
- `DATE`
- `DATETIME`
- `DECIMAL[ (M[ , D] ) ]`
- `SIGNED [ INTEGER ]`
- `TIME`
- `UNSIGNED [ INTEGER ]`

`BINARY` produces a string with the `BINARY` data type. See [Section 11.4.2, “The `BINARY` and `VARBINARY` Types”](#) for a description of how this affects comparisons. If the optional length `N` is given, `BINARY(N)` causes the cast to use no more than `N` bytes of the argument. Values shorter than `N` bytes are padded with `0x00` bytes to a length of `N`.

`CHAR(N)` [1177] causes the cast to use no more than `N` characters of the argument.

`CAST()` [1245] and `CONVERT(... USING ...)` [1245] are standard SQL syntax. The non-`USING` form of `CONVERT()` [1245] is ODBC syntax.

`CONVERT()` [1245] with `USING` is used to convert data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string `'abc'` in the default character set to the corresponding string in the `utf8` character set:

```
SELECT CONVERT('abc' USING utf8);
```

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings have no character set, and thus no concept of lettercase. To perform a case-

insensitive comparison, use the `CONVERT()` [1245] function to convert the value to a nonbinary string. Comparisons of the result use the string collation. For example, if the character set of the result has a case-insensitive collation, a `LIKE` [1190] operation is not case sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) FROM tbl_name;
```

To use a different character set, substitute its name for `latin1` in the preceding statement. To specify a particular collation for the converted string, use a `COLLATE` clause following the `CONVERT()` [1245] call, as described in Section 10.1.9.2, “`CONVERT()` and `CAST()`”. For example, to use `latin1_german1_ci`:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) COLLATE latin1_german1_ci
FROM tbl_name;
```

`CONVERT()` [1245] can be used more generally for comparing strings that are represented in different character sets.

`LOWER()` [1182] (and `UPPER()` [1187]) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion, convert the string to a nonbinary string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+
```

The cast functions are useful when you want to create a column with a specific type in a `CREATE TABLE ... SELECT` statement:

```
CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE);
```

The functions also can be useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST(str AS BINARY)` [1245] is the same thing as `BINARY str` [1244]. `CAST(expr AS CHAR)` [1245] treats the expression as a string with the default character set.

`CAST()` [1245] also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ',CAST(NOW() AS DATE))` [1178].

You should not use `CAST()` [1245] to extract data in different formats but instead use string functions like `LEFT()` [1181] or `EXTRACT()` [1217]. See Section 12.7, “Date and Time Functions”.

To cast a string to a numeric value in numeric context, you normally do not have to do anything other than to use the string value as though it were a number:

```
mysql> SELECT 1+'1';
-> 2
```

If you use a string in an arithmetic operation, it is converted to a floating-point number during expression evaluation.

If you use a number in string context, the number automatically is converted to a string:

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see Section 12.2, “Type Conversion in Expression Evaluation”.

MySQL supports arithmetic with both signed and unsigned 64-bit values. If you are using numeric operators (such as + [1200] or - [1200]) and one of the operands is an unsigned integer, the result is unsigned by default (see [Section 12.6.1, “Arithmetic Operators”](#)). You can override this by using the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT CAST(1-2 AS UNSIGNED)
      -> 18446744073709551615
mysql> SELECT CAST(CAST(1-2 AS UNSIGNED) AS SIGNED);
      -> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
      -> -1.0
```

The SQL mode affects the result of conversion operations. Examples:

- If you convert a “zero” date string to a date, `CONVERT()` [1245] and `CAST()` [1245] return `NULL` and produce a warning when the `NO_ZERO_DATE` [606] SQL mode is enabled.
- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` [605] SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

For more information, see [Section 5.1.7, “Server SQL Modes”](#).

## 12.11. XML Functions

**Table 12.15. XML Functions**

Name	Description
<code>ExtractValue()</code> [1249]	Extracts a value from an XML string using XPath notation
<code>UpdateXML()</code> [1251]	Return replaced XML fragment

This section discusses XML and related functionality in MySQL.

### Note

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` [254] option. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this Manual, and you should refer to the [XML Path Language \(XPath\) 1.0 standard](#) for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

### Note

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 5.6 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the [MySQL XML User Forum](#).

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax `$_variable_name` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) `$_myvairable` is used where `$_myvariable` was intended.

Example:

```
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i =1, @j = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[$@i]');
+-----+-----+
| @i | ExtractValue(@xml, '//b[$@i]') |
+-----+-----+
| 1 | X |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[$@j]');
+-----+-----+
| @j | ExtractValue(@xml, '//b[$@j]') |
+-----+-----+
| 2 | Y |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @k, ExtractValue(@xml, '//b[$@k]');
+-----+-----+
| @k | ExtractValue(@xml, '//b[$@k]') |
+-----+-----+
| NULL | |
+-----+-----+
1 row in set (0.00 sec)
```

- **Variables in stored programs (strong checking).** Variables using the syntax `$_variable_name` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc ()
-> BEGIN
-> DECLARE i INT DEFAULT 1;
-> DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';
->
-> WHILE i < 4 DO
-> SELECT xml, i, ExtractValue(xml, '//a[$i]');
-> SET i = i+1;
-> END WHILE;
-> END |
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

**Parameters.** Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

### Note

Currently, a user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- [ExtractValue\(xml\\_frag, xpath\\_expr\) \[1249\]](#)

[ExtractValue\(\)](#) [1249] takes two string arguments, a fragment of XML markup *xml\_frag* and an XPath expression *xpath\_expr* (also known as a *locator*); it returns the text (CDATA) of the first text node which is a child of the elements or elements matched by the XPath expression. In MySQL 5.6.6 and earlier, the XPath expression could contain at most 127 characters. This limitation was lifted in MySQL 5.6.7. (Bug #13007062, Bug#62429)

Using this function is the equivalent of performing a match using the *xpath\_expr* after appending `/text()`. In other words, [ExtractValue\('<a><b>Sakila</b></a>', '/a/b'\)](#) [1249] and [ExtractValue\('<a><b>Sakila</b></a>', '/a/b/text\(\)'\)](#) [1249] produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`)—for whatever reason, as long as *xpath\_expr* is valid, and *xml\_frag* consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in *xml\_frag* or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```

mysql> SELECT ExtractValue('<a><b></b></a>', '/a/b');
+-----+
| ExtractValue('<a><b></b></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></c></a>', '/a/b');
+-----+
| ExtractValue('<a><c></c></a>', '/a/b') |
+-----+
|                                     |
+-----+

```

```
+-----+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
+-----+
| 0 |
+-----+
1 row in set (0.01 sec)
```

### Important

`ExtractValue()` [1249] returns only `CDATA`, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```
mysql> SELECT
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/b') AS val4,
-> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
+-----+-----+-----+-----+-----+
| val1 | val2 | val3 | val4 | val5 |
+-----+-----+-----+-----+-----+
| ccc | ddd | ddd |      | ddd eee |
+-----+-----+-----+-----+-----+
```

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()` [1178]), in taking into account the collation coercibility of their arguments; see [Section 10.1.7.5, “Collation of Expressions”](#), for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1523 | Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
```

```
+-----+
| c                                           |
+-----+
1 row in set (0.00 sec)
```

- `UpdateXML(xml_target, xpath_expr, new_xml)` [1251]

This function replaces a single portion of a given fragment of XML markup *xml\_target* with a new XML fragment *new\_xml*, and then returns the changed XML. The portion of *xml\_target* that is replaced matches an XPath expression *xpath\_expr* supplied by the user. In MySQL 5.6.6 and earlier, the XPath expression could contain at most 127 characters. This limitation is lifted in MySQL 5.6.7. (Bug #13007062, Bug #62429)

If no expression matching *xpath\_expr* is found, or if multiple matches are found, the function returns the original *xml\_target* XML fragment. All three arguments should be strings.

```
mysql> SELECT
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
-> UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
-> \G

***** 1. row *****
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
```

### Note

A discussion in depth of XPath syntax and usage are beyond the scope of this Manual. Please see the [XML Path Language \(XPath\) 1.0 specification](#) for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

Matches `<tag/>` if and only if `<tag/>` is the root element.

Example: `/a` has a match in `<a><b></b></a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<b><a></a></b>` because in this instance it is the child of another element.

- `/tag1/tag2`

Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

Example: `/a/b` matches the `b` element in the XML fragment `<a><b></b></a>` because it is a child of the root element `a`. It does not have a match in `<b><a></a></b>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c><b></b></c></a>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><b><c></c></b></a>`.

- `//tag`

Matches any instance of `<tag>`.

Example: `//a` matches the `a` element in any of the following: `<a><b><c/></b></a>`; `<c><a><b/></a></b>`; `<c><b><a/></b></c>`.

`//` can be combined with `/`. For example, `//a/b` matches the `b` element in either of the fragments `<a><b/></a>` or `<a><b><c/></b></a>`

### Note

`//tag` is the equivalent of `/descendant-or-self::*/tag`. A common error is to confuse this with `/descendant-or-self::tag`, although the latter expression can actually lead to very different results, as can be seen here:

```
mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @xml;
+-----+
| @xml |
+-----+
| <a><b><c>w</c><b>x</b><d>y</d>z</b></a> |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[1]');
+-----+
| ExtractValue(@xml, '//b[1]') |
+-----+
| x z |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[2]');
+-----+
| ExtractValue(@xml, '//b[2]') |
+-----+
| |
+-----+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[1]') |
+-----+
| x z |
+-----+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[2]') |
+-----+
| |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[1]') |
+-----+
| z |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
+-----+
```

```
| x |
+-----+
1 row in set (0.00 sec)
```

- The `*` operator acts as a “wildcard” that matches any element. For example, the expression `/*/b` matches the `b` element in either of the XML fragments `<a><b/></a>` or `<c><b/></c>`. However, the expression does not produce a match in the fragment `<b><a/></b>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `/*/b/*` will match any child of a `b` element that is itself not the root element.
- You can match any of several locators using the `|` (UNION) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
- It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/><c/><b id="idB"/></a>`. To match against *any* element having `attribute="value"`, use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `//b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]`. You can also use the logical `or` operator for this purpose: `//b[@c="23" or @c="17"]`.

#### Note

The difference between `or` and `|` is that `or` joins conditions, while `|` joins result sets.

**XPath Limitations.** The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=@d]'`) is not supported.
- All of the standard XPath comparison operators are supported. (Bug #22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue(
->   '<a><b c="1">X</b><b c="2">Y</b></a>',
->   'a/b'
-> ) AS result;
+-----+
| result |
+-----+
| X Y    |
+-----+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[@c="1"]/d`:

```
mysql> SELECT ExtractValue(
->   '<a>
->     <b c="1"><d>X</d></b>
->     <b c="2"><d>X</d></b>
->   </a>',
->   'a/b/d[../@c="1"]')
```

```

-> AS result;
+-----+
| result |
+-----+
| x      |
+-----+
1 row in set (0.00 sec)

```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.
- The `::` operator is not supported in combination with node types such as the following:
  - `axis::comment()`
  - `axis::text()`
  - `axis::processing-instructions()`
  - `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::b');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::b') |
+-----+
| x                                             |
+-----+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*') |
+-----+
| x y                                           |
+-----+
1 row in set (0.01 sec)

```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).
- The following XPath functions are not supported, or have known issues as indicated:
  - `id()`
  - `lang()`
  - `local-name()`
  - `name()`
  - `namespace-uri()`
  - `normalize-space()`
  - `starts-with()`
  - `string()`
  - `substring-after()`
  - `substring-before()`

- `translate()`
- The following axes are not supported:
  - `following-sibling`
  - `following`
  - `preceding-sibling`
  - `preceding`

XPath expressions passed as arguments to `ExtractValue()` [1249] and `UpdateXML()` [1251] may contain the colon character (":") in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----+
| ExtractValue(@xml, '//e:f') |
+-----+
| 444                          |
+-----+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+-----+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+-----+
| <a>111<g:h>555</g:h></a>                  |
+-----+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by [Apache Xalan](#) and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

**Error handling.** For both `ExtractValue()` [1249] and `UpdateXML()` [1251], the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '//*[@a]');
ERROR 1105 (HY000): XPATH syntax error: '//*[@a]'
```

If `xml_frag` does not consist of elements which are properly nested and closed, `NULL` is returned and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//*[@a]');
+-----+
| ExtractValue('<a>c</a><b', '//*[@a]') |
+-----+
| NULL                                |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message
+-----+-----+-----+
| Warning | 1523 | Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wan
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//*[@a]');
```

```

+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c |
+-----+
1 row in set (0.00 sec)

```

### Important

The replacement XML used as the third argument to `UpdateXML()` [1251] is *not* checked to determine whether it consists solely of elements which are properly nested and closed.

**XPath Injection.** *code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```

<?php

$file      = "users.xml";

$login     = $_POST["login"];
$password  = $_POST["password"];

$xmlpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";

if( file_exists($file) )
{
    $xml = simplexml_load_file($file);

    if($result = $xml->xpath($xmlpath))
        echo "You are now logged in as user $result[0].";
    else
        echo "Invalid login name or password.";
}
else
    exit("Failed to open $file.");

?>

```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in `$xmlpath` being evaluated as shown here:

```
//user[login/text()=' ' or 1=1 and password/text()=' ' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xmlpath`, forcing the values passed from a Web form to be converted to strings:

```
$xpath = "//user[login/text()=' $login' and password/text()=' $password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper [Blind XPath Injection](#) (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` [1249] function:

```
mysql> SELECT ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
-> ) AS id;
+-----+
| id      |
+-----+
| 00327 13579 02403 42354 28570 |
+-----+
1 row in set (0.01 sec)
```

Because `ExtractValue()` [1249] returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```
mysql> SELECT @id = ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
->     INSTR(@id, ' ') = 0,
->     @id,
->     'Unable to retrieve user ID')
-> AS singleID;
+-----+
| singleID      |
+-----+
| Unable to retrieve user ID |
+-----+
1 row in set (0.00 sec)
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

## 12.12. Bit Functions

Table 12.16. Bitwise Functions

Name	Description
<code>BIT_COUNT()</code> [1259]	Return the number of bits that are set
<code>&amp;</code> [1258]	Bitwise AND
<code>~</code> [1259]	Invert bits
<code> </code> [1258]	Bitwise OR
<code>^</code> [1258]	Bitwise XOR
<code>&lt;&lt;</code> [1258]	Left shift
<code>&gt;&gt;</code> [1258]	Right shift

MySQL uses `BIGINT` (64-bit) arithmetic for bit operations, so these operators have a maximum range of 64 bits.

- `|` [1258]

Bitwise OR:

```
mysql> SELECT 29 | 15;
-> 31
```

The result is an unsigned 64-bit integer.

- `&` [1258]

Bitwise AND:

```
mysql> SELECT 29 & 15;
-> 13
```

The result is an unsigned 64-bit integer.

- `^` [1258]

Bitwise XOR:

```
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
```

The result is an unsigned 64-bit integer.

- `<<` [1258]

Shifts a longlong (`BIGINT`) number to the left.

```
mysql> SELECT 1 << 2;
-> 4
```

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

- `>>` [1258]

Shifts a longlong (`BIGINT`) number to the right.

```
mysql> SELECT 4 >> 2;
```

```
-> 1
```

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

- [~ \[1259\]](#)

Invert all bits.

```
mysql> SELECT 5 & ~1;
-> 4
```

The result is an unsigned 64-bit integer.

- [BIT\\_COUNT\(N\) \[1259\]](#)

Returns the number of bits that are set in the argument *N*.

```
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
-> 4, 3
```

## 12.13. Encryption and Compression Functions

**Table 12.17. Encryption Functions**

Name	Description
<a href="#">AES_DECRYPT() [1260]</a>	Decrypt using AES
<a href="#">AES_ENCRYPT() [1260]</a>	Encrypt using AES

<a href="#">VALIDATE_PASSWORD_STRENGTH() [1265]</a>	Determine strength of password

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a [VARBINARY](#) or [BLOB](#) binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type ([CHAR](#), [VARCHAR](#), [TEXT](#)).

Some encryption functions return strings of ASCII characters: [MD5\(\) \[1263\]](#), [OLD\\_PASSWORD\(\) \[1263\]](#), [PASSWORD\(\) \[1263\]](#), [SHA\(\) \[1264\]](#), [SHA1\(\) \[1264\]](#), [SHA2\(\) \[1264\]](#). In MySQL 5.6, their return value is a nonbinary string that has a character set and collation determined by the [character\\_set\\_connection \[467\]](#) and [collation\\_connection \[469\]](#) system variables.

For versions in which functions such as `MD5()` or `SHA1()` return a string of hex digits as a binary string, the return value cannot be converted to uppercase or compared in case-insensitive fashion as is. You must convert the value to a nonbinary string. See the discussion of binary string conversion in [Section 12.10, “Cast Functions and Operators”](#).

If an application stores values from a function such as `MD5()` [1263] or `SHA1()` [1264] that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` [1186] and storing the result in a `BINARY(N)` column. Each pair of hex digits requires one byte in binary form, so the value of *N* depends on the length of the hex string. *N* is 16 for an `MD5()` [1263] value and 20 for a `SHA1()` [1264] value. For `SHA2()` [1264], *N* ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` [1263] string values in a `CHAR(32)` column:

```
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` [1186] and `BINARY(16)` instead as follows:

```
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

#### Note

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using one of the other encryption functions described in this section instead, such as `SHA2()` [1264].

#### Caution

Passwords or other sensitive values supplied as arguments to encryption functions are sent in plaintext to the MySQL server unless an SSL connection is used. Also, such values will appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- `AES_DECRYPT(crypt_str,key_str)` [1260]

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of `AES_ENCRYPT()` [1260].

- `AES_ENCRYPT(str,key_str)` [1260]

`AES_ENCRYPT()` [1260] and `AES_DECRYPT()` [1260] enable encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” Encoding with a 128-bit key length is used, but you can extend it up to 256 bits by modifying the source. We chose 128 bits because it is much faster and it is secure enough for most purposes.

`AES_ENCRYPT()` [1260] encrypts a string and returns a binary string. `AES_DECRYPT()` [1260] decrypts the encrypted string and returns the original string. The input arguments may be any length. If either argument is `NULL`, the result of this function is also `NULL`.

Because AES is a block-level algorithm, padding is used to encode uneven length strings and so the result string length may be calculated using this formula:

```
16 * (trunc(string_length / 16) + 1)
```

If `AES_DECRYPT()` [1260] detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` [1260] to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

You can use the AES functions to store data in an encrypted form by modifying your queries:

```
INSERT INTO t VALUES (1,AES_ENCRYPT('text','password'));
```

`AES_ENCRYPT()` [1260] and `AES_DECRYPT()` [1260] can be considered the most cryptographically secure encryption functions currently available in MySQL.

- `COMPRESS(string_to_compress)` [1261]

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()` [1265].

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
mysql> SELECT LENGTH(COMPRESS(''));
-> 0
mysql> SELECT LENGTH(COMPRESS('a'));
-> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
-> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra “.” character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)
- `DECODE(crypt_str,pass_str)` [1261]

Decrypts the encrypted string `crypt_str` using `pass_str` as the password. `crypt_str` should be a string returned from `ENCODE()` [1262].

- `DES_DECRYPT(encrypt_str[,key_str])` [1261]

Decrypts a string encrypted with `DES_ENCRYPT()` [1262]. If an error occurs, this function returns `NULL`.

This function works only if MySQL has been configured with SSL support. See [Section 6.3.9, “Using SSL for Secure Connections”](#).

If no `key_str` argument is given, `DES_DECRYPT()` [1261] examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the `SUPER` [756] privilege. The key file can be specified with the `--des-key-file` [421] server option.

If you pass this function a `key_str` argument, that string is used as the key for decrypting the message.

If the `crypt_str` argument does not appear to be an encrypted string, MySQL returns the given `crypt_str`.

- `DES_ENCRYPT(str[, {key_num|key_str}])` [1262]

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MySQL has been configured with SSL support. See [Section 6.3.9, “Using SSL for Secure Connections”](#).

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()` [1262], if one was given. With no argument, the first key from the DES key file is used. With a `key_num` argument, the given key number (0 to 9) from the DES key file is used. With a `key_str` argument, the given key string is used to encrypt `str`.

The key file can be specified with the `--des-key-file` [421] server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)` [1177]. If an error occurs, `DES_ENCRYPT()` [1262] returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, `key_num` is 127.

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each `key_num` value must be a number in the range from 0 to 9. Lines in the file may be in any order. `des_key_str` is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()` [1262].

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` [755] privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

```
mysql> SELECT customer_address FROM customer_table
> WHERE crypt_credit_card = DES_ENCRYPT('credit_card_number');
```

- `ENCODE(str, pass_str)` [1262]

Encrypt `str` using `pass_str` as the password. To decrypt the result, use `DECODE()` [1261].

The result is a binary string of the same length as `str`.

The strength of the encryption is based on how good the random generator is. It should suffice for short strings.

- `ENCRYPT(str[, salt])` [1262]

Encrypts `str` using the Unix `crypt()` system call and returns a binary string. The `salt` argument must be a string with at least two characters or the result will be `NULL`. If no `salt` argument is given, a random value is used.

```
mysql> SELECT ENCRYPT('hello');
-> 'VxuFAJXVARROc'
```

`ENCRYPT()` [1262] ignores all but the first eight characters of `str`, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

The use of `ENCRYPT()` [1262] with the `ucs2`, `utf16`, `utf16le`, or `utf32` multi-byte character sets is not recommended because the system call expects a string terminated by a zero byte.

If `crypt()` is not available on your system (as is the case with Windows), `ENCRYPT()` [1262] always returns `NULL`.

- `MD5(str)` [1263]

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hex digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a nonbinary string in the connection character set.

```
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

- `OLD_PASSWORD(str)` [1263]

`OLD_PASSWORD()` [1263] was added when the implementation of `PASSWORD()` [1263] was changed in MySQL 4.1 to improve security. `OLD_PASSWORD()` [1263] returns the value of the pre-4.1 implementation of `PASSWORD()` [1263] as a string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to your version 5.6 MySQL server without locking them out. See [Section 6.1.2.4, “Password Hashing in MySQL”](#).

The return value is a nonbinary string in the connection character set.

- `PASSWORD(str)` [1263]

Calculates and returns a hashed password string from the cleartext password `str` and returns a nonbinary string in the connection character set, or `NULL` if the argument is `NULL`. This function is the SQL interface to the algorithm used by the server to encrypt MySQL passwords for storage in the `mysql.user` grant table.

The password hashing method used by `PASSWORD()` [1263] depends on the value of the `old_passwords` [517] system variable:

```
mysql> SET old_passwords = 0;
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+

mysql> SET old_passwords = 1;
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| 6f8c114b58f2ce9e   |
+-----+
```

If `old_passwords=1`, `PASSWORD('str')` [1263] returns the same value as `OLD_PASSWORD('str')` [1263].

SHA-256 password hashing (`old_passwords=2` [517]) uses a random salt value, which makes the result from `PASSWORD()` [1263] nondeterministic. Consequently, statements that use this function are not safe for statement-based replication and cannot be stored in the query cache.

For descriptions of the permitted values of `old_passwords` [517], see Section 5.1.4, “Server System Variables”.

Encryption performed by `PASSWORD()` [1263] is one-way (not reversible). It is not the same type of encryption as used for Unix passwords; for that, use `ENCRYPT()` [1262].

#### Note

The `PASSWORD()` [1263] function is used by the authentication system in MySQL Server; you should *not* use it in your own applications. For that purpose, consider `MD5()` [1263] or `SHA2()` [1264] instead. Also see RFC 2195, section 2 (Challenge-Response Authentication Mechanism (CRAM)), for more information about handling passwords and authentication securely in your applications.

#### Important

Statements that invoke `PASSWORD()` [1263] may be recorded in server logs or in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. See Section 6.1.2, “Keeping Passwords Secure”.

- `SHA1(str)` [1264], `SHA(str)` [1264]

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hex digits, or `NULL` if the argument was `NULL`. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. You can also use `SHA1()` [1264] as a cryptographic function for storing passwords. `SHA()` [1264] is synonymous with `SHA1()` [1264].

The return value is a nonbinary string in the connection character set.

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

`SHA1()` [1264] can be considered a cryptographically more secure equivalent of `MD5()` [1263]. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- `SHA2(str, hash_length)` [1264]

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the cleartext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is `NULL` or the hash length is not one of the permitted values, the return value is `NULL`. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a nonbinary string in the connection character set.

```
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d8228642a477bda255b32aadbce4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See Section 6.3.9, “Using SSL for Secure Connections”.

`SHA2()` [1264] can be considered cryptographically more secure than `MD5()` [1263] or `SHA1()` [1264].

- `UNCOMPRESS(string_to_uncompress)` [1265]

Uncompresses a string compressed by the `COMPRESS()` [1261] function. If the argument is not a compressed value, the result is `NULL`. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- `UNCOMPRESSED_LENGTH(compressed_string)` [1265]

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

- `VALIDATE_PASSWORD_STRENGTH(str)` [1265]

Given an argument representing a cleartext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table.

Password Test	Return Value
Length < 4	0
Length ≥ 4 and < <code>validate_password_length</code> [744]	25
Satisfies policy 1 ( <code>LOW</code> )	50
Satisfies policy 2 ( <code>MEDIUM</code> )	75
Satisfies policy 3 ( <code>STRONG</code> )	100

Password assessment by `VALIDATE_PASSWORD_STRENGTH()` [1265] is done by the `validate_password` plugin. If that plugin is not installed, the function always returns 0. For information about installing the `validate_password` plugin, see [Section 6.1.2.6, “The Password Validation Plugin”](#). To examine or configure the parameters that affect password testing, check or set the system variables implemented by `validate_password` plugin. See [Section 6.1.2.6.2, “Password Validation Plugin Options and Variables”](#).

This function was added in MySQL 5.6.6.

## 12.14. Information Functions

**Table 12.18. Information Functions**

Name	Description
<code>BENCHMARK()</code> [1266]	Repeatedly execute an expression
<code>CHARSET()</code> [1266]	Return the character set of the argument
<code>COERCIBILITY()</code> [1266]	Return the collation coercibility value of the string argument
<code>COLLATION()</code> [1267]	Return the collation of the string argument
<code>CONNECTION_ID()</code> [1267]	Return the connection ID (thread ID) for the connection
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code> [1267]	The authenticated user name and host name
<code>DATABASE()</code> [1268]	Return the default (current) database name

Name	Description
<a href="#">FOUND_ROWS() [1268]</a>	For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause
<a href="#">LAST_INSERT_ID() [1269]</a>	Value of the AUTOINCREMENT column for the last INSERT
<a href="#">ROW_COUNT() [1272]</a>	The number of rows updated
<a href="#">SCHEMA() [1273]</a>	A synonym for DATABASE()
<a href="#">SESSION_USER() [1273]</a>	Synonym for USER()
<a href="#">SYSTEM_USER() [1273]</a>	Synonym for USER()
<a href="#">USER() [1273]</a>	The user name and host name provided by the client
<a href="#">VERSION() [1273]</a>	Returns a string that indicates the MySQL server version

- [BENCHMARK\(count,expr\) \[1266\]](#)

The [BENCHMARK\(\) \[1266\]](#) function executes the expression *expr* repeatedly *count* times. It may be used to time how quickly MySQL processes the expression. The result value is always 0. The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000,ENCODE('hello','goodbye'));
+-----+
| BENCHMARK(1000000,ENCODE('hello','goodbye')) |
+-----+
|                                             0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute [BENCHMARK\(\) \[1266\]](#) several times, and to interpret the result with regard to how heavily loaded the server machine is.

[BENCHMARK\(\) \[1266\]](#) is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, [BENCHMARK\(10, \(SELECT \\* FROM t\)\) \[1266\]](#) will fail if the table *t* has more than one column or more than one row.
- Executing a `SELECT expr` statement *N* times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation *N* times each. The latter involves only runtime evaluation *N* times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of [BENCHMARK\(\) \[1266\]](#) thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.
- [CHARSET\(str\) \[1266\]](#)

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
-> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
-> 'utf8'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```

- [COERCIBILITY\(str\) \[1266\]](#)

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

Coercibility	Meaning	Example
0	Explicit collation	Value with <code>COLLATE</code> clause
1	No collation	Concatenation of strings with different collations
2	Implicit collation	Column value, stored routine parameter or local variable
3	System constant	<code>USER()</code> [1273] return value
4	Coercible	Literal string
5	Ignorable	<code>NULL</code> or an expression derived from <code>NULL</code>

- [COLLATION\(\*str\*\)](#) [1267]

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
-> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
-> 'utf8_general_ci'
```

- [CONNECTION\\_ID\(\)](#) [1267]

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

```
mysql> SELECT CONNECTION_ID();
-> 23786
```

- [CURRENT\\_USER](#) [1267], [CURRENT\\_USER\(\)](#) [1267]

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.

The value of [CURRENT\\_USER\(\)](#) [1267] can differ from the value of [USER\(\)](#) [1273].

```
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the [USER\(\)](#) [1273] function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the [CURRENT\\_USER\(\)](#) [1267] value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` [1267] returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` [1267] returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` [1267] returns the account for the user who defined the object. To return the invoker, use `USER()` [1273] or `SESSION_USER()` [1273].

The following statements support use of the `CURRENT_USER()` [1267] function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` [1267] is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` [1267] has for replication in different releases of MySQL 5.6, see [Section 16.4.1.6, “Replication of `CURRENT\_USER\(\)`”](#).

- `DATABASE()` [1268]

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` [1268] returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` [1268] returns `NULL`.

- `FOUND_ROWS()` [1268]

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include a `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` [1268] afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
-> WHERE id > 100 LIMIT 10;
```

```
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS() [1268]` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS() [1268]` returns the number of rows up to the limit. For example, `FOUND_ROWS() [1268]` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS() [1268]` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS() [1268]` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using `FOUND_ROWS() [1268]` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS() [1268]` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS() [1268]` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS() [1268]` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS() [1268]` is undefined (for example, its value following a `SELECT` statement that fails with an error).

### Important

`FOUND_ROWS() [1268]` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `LAST_INSERT_ID() [1269]`, `LAST_INSERT_ID(expr) [1269]`

`LAST_INSERT_ID() [1269]` (with no argument) returns a `BIGINT` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID() [1269]` remains unchanged if no rows are successfully inserted.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()` [1269]. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` [1269] in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` [1269] will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` [1269] and `LAST_INSERT_ID(expr)` [1269], the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` [1269] is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` [1269] is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` [1269] is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` [1269] changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` [1269] that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()` [1269], the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection* basis. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column *by that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` [1269] is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

### Important

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` [1269] returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```
mysql> USE test;
Database changed
mysql> CREATE TABLE t (
->   id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
->   name VARCHAR(10) NOT NULL
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t VALUES (NULL, 'Bob');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t;
```

```

+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
+----+-----+
1 row in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO t VALUES
-> (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
|  2 | Mary |
|  3 | Jane |
|  4 | Lisa |
+----+-----+
4 rows in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                2 |
+-----+
1 row in set (0.00 sec)

```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was 2, and it is this value that is returned by `LAST_INSERT_ID()` [1269] for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `AUTO_INCREMENT` counter is not incremented and `LAST_INSERT_ID()` [1269] returns 0, which reflects that no row was inserted.

If *expr* is given as an argument to `LAST_INSERT_ID()` [1269], the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()` [1269]. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```

mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);

```

2. Use the table to generate sequence numbers like this:

```

mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();

```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` [1269] to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See [Section 21.8.6.37](#), “`mysql_insert_id()`”.

You can generate sequences without calling `LAST_INSERT_ID()` [1269], but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated

value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` [1269] after executing other SQL statements like `SELECT` or `SET`.

- `ROW_COUNT()` [1272]

In MySQL 5.6, `ROW_COUNT()` returns a value as follows:

- DDL statements: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- DML statements other than `SELECT`: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA INFILE`.
- `SELECT`: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1`, `ROW_COUNT()` [1272] returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` [1272] returns the number of rows written to the file.
- `SIGNAL` statements: 0.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value is 1 if the row is inserted as a new row and 2 if an existing row is updated.

The `ROW_COUNT()` [1272] value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|          3 |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|          2 |
+-----+
1 row in set (0.00 sec)
```

**Important**

`ROW_COUNT()` [1272] is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `SCHEMA()` [1273]

This function is a synonym for `DATABASE()` [1268].

- `SESSION_USER()` [1273]

`SESSION_USER()` [1273] is a synonym for `USER()` [1273].

- `SYSTEM_USER()` [1273]

`SYSTEM_USER()` [1273] is a synonym for `USER()` [1273].

- `USER()` [1273]

Returns the current MySQL user name and host name as a string in the `utf8` character set.

```
mysql> SELECT USER();
-> 'david@localhost'
```

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()` [1267].

You can extract only the user name part like this:

```
mysql> SELECT SUBSTRING_INDEX(USER(), '@', 1);
-> 'david'
```

- `VERSION()` [1273]

Returns a string that indicates the MySQL server version. The string uses the `utf8` character set. The value might have a suffix in addition to the version number. See the description of the `version` [563] system variable in [Section 5.1.4, “Server System Variables”](#).

This function is unsafe for statement-based replication. In MySQL 5.6, a warning is logged if you use this function when `binlog_format` [2010] is set to `STATEMENT`. (Bug #47995)

```
mysql> SELECT VERSION();
-> '5.6.12-standard'
```

## 12.15. GTID Functions

The functions described in this section are used with GTID-based replication (available in MySQL 5.6.5 and later). For more information about GTIDs and how these functions are used, see [Section 16.1.3, “Replication with Global Transaction Identifiers”](#).

**Note**

The union of two GTID sets is simply their string representations joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets like this:

```
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
RETURNS TEXT DETERMINISTIC
RETURN CONCAT(g1, ', ', g2);
```

Table 12.19. GTID Functions

Name	Description
<code>GTID_SUBSET()</code> [1274]	Return true if all GTIDs in subset are also in set; otherwise false.
<code>GTID_SUBTRACT()</code> [1274]	Return all GTIDs in set that are not in subset.
<code>SQL_THREAD_WAIT_AFTER_GTIDS()</code> [1274] (Deprecated since MySQL 5.6.9)	<b>OBSOLETE</b> Replaced by <code>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()</code>
<code>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()</code> [1274]	Wait until the slave SQL thread has executed all the given GTIDs. Returns: the number of events that were executed (or NULL, if GTID mode is not enabled).

- `GTID_SUBSET(subset, set)` [1274]

Given two sets of global transaction IDs *subset* and *set*, returns true if all GTIDs in *subset* are also in *set*. Returns false otherwise.

This function was added in MySQL 5.6.5.

- `GTID_SUBTRACT(set, subset)` [1274]

Given two sets of global transaction IDs *subset* and *set*, returns only those GTIDs from *set* that are not in *subset*.

This function was added in MySQL 5.6.5.

- `SQL_THREAD_WAIT_AFTER_GTIDS(gtid_set[, timeout])` [1274]

`SQL_THREAD_WAIT_AFTER_GTIDS()` was added in MySQL 5.6.5, and replaced by `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` [1274] in MySQL 5.6.9. (Bug #14775984)

For more information, see [Section 16.1.3, “Replication with Global Transaction Identifiers”](#).

- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout])` [1274]

Wait until the slave SQL thread has executed all of the transactions whose global transaction identifiers are contained in *gtid\_set* (see [Section 16.1.3.1, “GTID Concepts”](#), for a definition of “GTID sets”), or until *timeout* seconds have elapsed, whichever occurs first. *timeout* is optional; the default timeout is 0 seconds, in which case the master simply waits until all of the transactions in the GTID set have been executed.

Prior to MySQL 5.6.9, `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` was named `SQL_THREAD_WAIT_AFTER_GTIDS()` [1274]. (Bug #14775984)

For more information, see [Section 16.1.3, “Replication with Global Transaction Identifiers”](#).

```
mysql> SELECT WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
-> 5
```

The return value is the number of transactional events that were executed. Prior to MySQL 5.6.8, this function behaved unpredictably if no timeout was set and it was invoked while GTID-based replication was not active; in MySQL 5.6.8 and later, the function returns `NULL` whenever `gtid_mode` [2022] is `OFF`. (Bug #14640065)

## 12.16. Miscellaneous Functions

Table 12.20. Miscellaneous Functions

Name	Description
<code>DEFAULT()</code> [1275]	Return the default value for a table column

Name	Description
<a href="#">GET_LOCK() [1275]</a>	Get a named lock
<a href="#">INET_ATON() [1276]</a>	Return the numeric value of an IP address
<a href="#">INET_NTOA() [1276]</a>	Return the IP address from a numeric value
<a href="#">INET6_ATON() [1276]</a>	Return the numeric value of an IPv6 address
<a href="#">INET6_NTOA() [1277]</a>	Return the IPv6 address from a numeric value
<a href="#">IS_FREE_LOCK() [1278]</a>	Checks whether the named lock is free
<a href="#">IS_IPV4_COMPAT() [1278]</a>	Return true if argument is an IPv4-compatible address
<a href="#">IS_IPV4_MAPPED() [1278]</a>	Return true if argument is an IPv4-mapped address
<a href="#">IS_IPV4() [1278]</a>	Return true if argument is an IPv4 address
<a href="#">IS_IPV6() [1279]</a>	Return true if argument is an IPv6 address
<a href="#">IS_USED_LOCK() [1279]</a>	Checks whether the named lock is in use. Return connection identifier if true.
<a href="#">MASTER_POS_WAIT() [1279]</a>	Block until the slave has read and applied all updates up to the specified position
<a href="#">NAME_CONST() [1279]</a>	Causes the column to have the given name
<a href="#">RAND() [1206]</a>	Return a random floating-point value
<a href="#">RELEASE_LOCK() [1280]</a>	Releases the named lock
<a href="#">SLEEP() [1280]</a>	Sleep for a number of seconds
<a href="#">UUID_SHORT() [1281]</a>	Return an integer-valued universal identifier
<a href="#">UUID() [1280]</a>	Return a Universal Unique Identifier (UUID)
<a href="#">VALUES() [1281]</a>	Defines the values to be used during an INSERT

- [DEFAULT\(\*col\\_name\*\) \[1275\]](#)

Returns the default value for a table column. An error results if the column has no default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- [FORMAT\(\*X\*,\*D\*\) \[1180\]](#)

Formats the number *X* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 12.5, "String Functions"](#).

- [GET\\_LOCK\(\*str\*,\*timeout\*\) \[1275\]](#)

Tries to obtain a lock with a name given by the string *str*, using a timeout of *timeout* seconds. Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`). If you have a lock obtained with [GET\\_LOCK\(\) \[1275\]](#), it is released when you execute [RELEASE\\_LOCK\(\) \[1280\]](#), execute a new [GET\\_LOCK\(\) \[1275\]](#), or your connection terminates (either normally or abnormally). Locks obtained with [GET\\_LOCK\(\) \[1275\]](#) do not interact with transactions. That is, committing a transaction does not release any such locks obtained during the transaction.

This function can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked by one client, [GET\\_LOCK\(\) \[1275\]](#) blocks any request by another client for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to

reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

```
mysql> SELECT GET_LOCK('lock1',10);
-> 1
mysql> SELECT IS_FREE_LOCK('lock2');
-> 1
mysql> SELECT GET_LOCK('lock2',10);
-> 1
mysql> SELECT RELEASE_LOCK('lock2');
-> 1
mysql> SELECT RELEASE_LOCK('lock1');
-> NULL
```

The second `RELEASE_LOCK()` [1280] call returns `NULL` because the lock 'lock1' was automatically released by the second `GET_LOCK()` [1275] call.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined and depends on factors such as the thread library in use. In particular, applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

This function is unsafe for statement-based replication. In MySQL 5.6, a warning is logged if you use this function when `binlog_format` [2010] is set to `STATEMENT`. (Bug #47995)

- `INET_ATON(expr)` [1276]

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` [1276] returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as  $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$ .

`INET_ATON()` [1276] may or may not return a non-`NULL` result for short-form IP addresses (such as '127.1' as a representation of '127.0.0.1'). Because of this, `INET_ATON()` [1276] should not be used for such addresses.

#### Note

To store values generated by `INET_ATON()` [1276], use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See [Section 11.2.6, “Out-of-Range and Overflow Handling”](#).

- `INET_NTOA(expr)` [1276]

Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a nonbinary string in the connection character set. `INET_NTOA()` [1276] returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- `INET6_ATON(expr)` [1276]

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the `VARBINARY` data type: `VARBINARY(16)` for IPv6 addresses and `VARBINARY(4)` for IPv4 addresses. If the argument is not a valid address, `INET6_ATON()` [1276] returns `NULL`.

The following examples use `HEX()` to display the `INET6_ATON()` result in printable form:

```
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'FDFE0000000000005A55CAFFFEFA9089'
mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> '0A000509'
```

`INET6_ATON()` observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `192.168.1.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `192.168.1` are rejected. A trailing port number is not permitted, as in `192.168.1.2:8080`. Hexadecimal numbers in address components are not permitted, as in `192.0xa0.1.2`. Octal numbers are not supported: `192.168.010.1` is treated as `192.168.10.1`, not `192.168.8.1`. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address `expr` represented in numeric form as an `INT` value to an IPv6 address represented in numeric form as a `VARBINARY` value, use this expression:

```
INET6_ATON(INET_NTOA(expr))
```

For example:

```
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

This function was added in MySQL 5.6.3.

- `INET6_NTOA(expr)` [1277]

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a nonbinary string in the connection character set. If the argument is not a valid address, `INET6_NTOA()` [1277] returns `NULL`.

`INET6_NTOA()` [1277] has these properties:

- It does not use operating system functions to perform conversions, thus the output string is platform independent.
- The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

```
CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
```

The resulting table would have this definition:

```
CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
```

- The return string uses lowercase letters for IPv6 addresses.

```
mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
-> '10.0.5.9'

mysql> SELECT INET6_NTOA(UNHEX('FDFE0000000000005A55CAFFFEFA9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(UNHEX('0A000509'));
-> '10.0.5.9'
```

This function was added in MySQL 5.6.3.

- `IS_FREE_LOCK(str)` [1278]

Checks whether the lock named *str* is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

This function is unsafe for statement-based replication. In MySQL 5.6, a warning is logged if you use this function when `binlog_format` [2010] is set to `STATEMENT`. (Bug #47995)

- `IS_IPV4(expr)` [1278]

Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise.

```
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if `IS_IPV4()` [1278] returns 1, `INET_ATON()` [1276] (and `INET6_ATON()` [1276]) will return non-`NULL`. The converse statement is not true: In some cases, `INET_ATON()` [1276] returns non-`NULL` when `IS_IPV4()` [1278] returns 0.

As implied by the preceding remarks, `IS_IPV4()` [1278] is more strict than `INET_ATON()` [1276] about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use `INET6_ATON()` [1276] to convert IPv4 addresses to internal form and check for a `NULL` result (which indicates an invalid address). `INET6_ATON()` [1276] is equally strong as `IS_IPV4()` [1278] about checking IPv4 addresses.

This function was added in MySQL 5.6.3.

- `IS_IPV4_COMPAT(expr)` [1278]

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()` [1276]. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form `::ipv4_address`.

```
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
```

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, `192.168.0.1` has this raw hexadecimal value:

```
mysql> SELECT HEX(INET6_ATON('192.168.0.1'));
-> 'C0A80001'
```

Expressed in IPv4-compatible form, `::192.168.0.1` is equivalent to `::c0a8:0001` or (without leading zeros) `::c0a8:1`

```
mysql> SELECT
-> IS_IPV4_COMPAT(INET6_ATON('::192.168.0.1')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
```

This function was added in MySQL 5.6.3.

- `IS_IPV4_MAPPED(expr)` [1278]

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()` [1276]. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form `::ffff:ipv4_address`.

```
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with `IS_IPV4_COMPAT()` the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```
mysql> SELECT
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:192.168.0.1')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```

This function was added in MySQL 5.6.3.

- `IS_IPV6(expr)` [1279]

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` [1279] returns 1, `INET6_ATON()` [1276] will return non-NULL.

This function was added in MySQL 5.6.3.

- `IS_USED_LOCK(str)` [1279]

Checks whether the lock named *str* is in use (that is, locked). If so, it returns the connection identifier of the client that holds the lock. Otherwise, it returns NULL.

This function is unsafe for statement-based replication. In MySQL 5.6, a warning is logged if you use this function when `binlog_format` [2010] is set to `STATEMENT`. (Bug #47995)

- `MASTER_POS_WAIT(log_name, log_pos [, timeout])` [1279]

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns NULL if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns -1 if the timeout has been exceeded. If the slave SQL thread stops while `MASTER_POS_WAIT()` [1279] is waiting, the function returns NULL. If the slave is past the specified position, the function returns immediately.

If a *timeout* value is specified, `MASTER_POS_WAIT()` [1279] stops waiting when *timeout* seconds have elapsed. *timeout* must be greater than 0; a zero or negative *timeout* means no timeout.

This function is unsafe for statement-based replication. In MySQL 5.6, a warning is logged if you use this function when `binlog_format` [2010] is set to `STATEMENT`. (Bug #47995)

- `NAME_CONST(name, value)` [1279]

Returns the given value. When used to produce a result set column, `NAME_CONST()` [1279] causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in [Section 18.7, “Binary Logging of Stored Programs”](#). You might see this function in the output from `mysqlbinlog`.

- `RELEASE_LOCK(str)` [1280]

Releases the lock named by the string *str* that was obtained with `GET_LOCK()` [1275]. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` [1275] or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()` [1280]. See [Section 13.2.3, “DO Syntax”](#).

This function is unsafe for statement-based replication. In MySQL 5.6, a warning is logged if you use this function when `binlog_format` [2010] is set to `STATEMENT`. (Bug #47995)

- `SLEEP(duration)` [1280]

Sleeps (pauses) for the number of seconds given by the *duration* argument, then returns 0. If `SLEEP()` [1280] is interrupted, it returns 1. The duration may have a fractional part.

This function is unsafe for statement-based replication. In MySQL 5.6, a warning is logged if you use this function when `binlog_format` [2010] is set to `STATEMENT`. (Bug #47995)

- `UUID()` [1280]

Returns a Universal Unique Identifier (UUID) generated according to “DCE 1.1: Remote Procedure Call” (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 (Document Number C706, <http://www.opengroup.org/public/pubs/catalog/c706.htm>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` [1280] are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

A UUID is a 128-bit number represented by a `utf8` string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from a timestamp.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

Currently, the MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-0040f4311e29'
```

### Warning

Although `UUID()` [1280] values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

**Note**

`UUID()` [1280] does not work with statement-based replication.

- `UUID_SHORT()` [1281]

Returns a “short” universal identifier as a 64-bit unsigned integer (rather than a string-form 128-bit identifier as returned by the `UUID()` [1280] function).

The value of `UUID_SHORT()` [1281] is guaranteed to be unique if the following conditions hold:

- The `server_id` [539] of the current host is unique among your set of master and slave servers
- `server_id` [539] is between 0 and 255
- You do not set back your system time for your server between `mysqld` restarts
- You do not invoke `UUID_SHORT()` [1281] on average more than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` [1281] return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

Note that `UUID_SHORT()` [1281] does not work with statement-based replication.

- `VALUES(col_name)` [1281]

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` [1281] function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See [Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

## 12.17. Functions and Modifiers for Use with `GROUP BY` Clauses

### 12.17.1. `GROUP BY` (Aggregate) Functions

Table 12.21. Aggregate (`GROUP BY`) Functions

Name	Description
<code>AVG()</code> [1282]	Return the average value of the argument
<code>BIT_AND()</code> [1282]	Return bitwise and
<code>BIT_OR()</code> [1282]	Return bitwise or
<code>BIT_XOR()</code> [1283]	Return bitwise xor
<code>COUNT(DISTINCT)</code> [1283]	Return the count of a number of different values
<code>COUNT()</code> [1283]	Return a count of the number of rows returned
<code>GROUP_CONCAT()</code> [1283]	Return a concatenated string

Name	Description
<a href="#">MAX() [1284]</a>	Return the maximum value
<a href="#">MIN() [1284]</a>	Return the minimum value
<a href="#">STD() [1284]</a>	Return the population standard deviation
<a href="#">STDDEV_POP() [1285]</a>	Return the population standard deviation
<a href="#">STDDEV_SAMP() [1285]</a>	Return the sample standard deviation
<a href="#">STDDEV() [1285]</a>	Return the population standard deviation
<a href="#">SUM() [1285]</a>	Return the sum
<a href="#">VAR_POP() [1285]</a>	Return the population standard variance
<a href="#">VAR_SAMP() [1285]</a>	Return the sample variance
<a href="#">VARIANCE() [1285]</a>	Return the population standard variance

This section describes group (aggregate) functions that operate on sets of values. Unless otherwise stated, group functions ignore `NULL` values.

If you use a group function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows. For more information, see [Section 12.17.3, “MySQL Extensions to GROUP BY”](#).

For numeric arguments, the variance and standard deviation functions return a `DOUBLE` value. The [SUM\(\) \[1285\]](#) and [AVG\(\) \[1282\]](#) functions return a `DECIMAL` value for exact-value arguments (integer or `DECIMAL`), and a `DOUBLE` value for approximate-value arguments (`FLOAT` or `DOUBLE`).

The [SUM\(\) \[1285\]](#) and [AVG\(\) \[1282\]](#) aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;  
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as [SUM\(\) \[1285\]](#) or [AVG\(\) \[1282\]](#) that expect a numeric argument cast the argument to a number if necessary. For `SET` or `ENUM` values, the cast operation causes the underlying numeric value to be used.

- [AVG\(\[DISTINCT\] \*expr\*\) \[1282\]](#)

Returns the average value of *expr*. The `DISTINCT` option can be used to return the average of the distinct values of *expr*.

[AVG\(\) \[1282\]](#) returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, AVG(test_score)  
-> FROM student  
-> GROUP BY student_name;
```

- [BIT\\_AND\(\*expr\*\) \[1282\]](#)

Returns the bitwise `AND` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns `18446744073709551615` if there were no matching rows. (This is the value of an unsigned `BIGINT` value with all bits set to 1.)

- [BIT\\_OR\(\*expr\*\) \[1282\]](#)

Returns the bitwise `OR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns `0` if there were no matching rows.

- `BIT_XOR(expr)` [1283]

Returns the bitwise `XOR` [1172] of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns 0 if there were no matching rows.

- `COUNT(expr)` [1283]

Returns a count of the number of non-NULL values of *expr* in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

`COUNT()` [1283] returns 0 if there were no matching rows.

```
mysql> SELECT student.student_name,COUNT(*)
->      FROM student,course
->      WHERE student.student_id=course.student_id
->      GROUP BY student_name;
```

`COUNT(*)` [1283] is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

`COUNT(*)` [1283] is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization applies only to `MyISAM` tables only, because an exact row count is stored for this storage engine and can be accessed very quickly. For transactional storage engines such as `InnoDB`, storing an exact row count is more problematic because multiple transactions may be occurring, each of which may affect the count.

- `COUNT(DISTINCT expr, [expr...])` [1283]

Returns a count of the number of rows with different non-NULL *expr* values.

`COUNT(DISTINCT)` [1283] returns 0 if there were no matching rows.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain `NULL` by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)` [1283].

- `GROUP_CONCAT(expr)` [1283]

This function returns a string result with the concatenated non-NULL values from a group. It returns `NULL` if there are no non-NULL values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
              [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
->      GROUP_CONCAT(test_score)
->      FROM student
->      GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
->      GROUP_CONCAT(DISTINCT test_score
->                    ORDER BY test_score DESC SEPARATOR ' ')
->      FROM student
```

```
-> GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the `DISTINCT` clause. To sort values in the result, use the `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. The default separator between values in a group is comma (","). To specify a separator explicitly, use `SEPARATOR` followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify `SEPARATOR ''`.

The result is truncated to the maximum length that is given by the `group_concat_max_len` [486] system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of `max_allowed_packet` [502]. The syntax to change the value of `group_concat_max_len` [486] at runtime is as follows, where *val* is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is `TEXT` or `BLOB` unless `group_concat_max_len` [486] is less than or equal to 512, in which case the result type is `VARCHAR` or `VARBINARY`.

See also `CONCAT()` [1178] and `CONCAT_WS()` [1179]: Section 12.5, "String Functions".

- `MAX([DISTINCT] expr)` [1284]

Returns the maximum value of *expr*. `MAX()` [1284] may take a string argument; in such cases, it returns the maximum string value. See Section 8.3.1, "How MySQL Uses Indexes". The `DISTINCT` keyword can be used to find the maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

`MAX()` [1284] returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
-> FROM student
-> GROUP BY student_name;
```

For `MAX()` [1284], MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `MIN([DISTINCT] expr)` [1284]

Returns the minimum value of *expr*. `MIN()` [1284] may take a string argument; in such cases, it returns the minimum string value. See Section 8.3.1, "How MySQL Uses Indexes". The `DISTINCT` keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

`MIN()` [1284] returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
-> FROM student
-> GROUP BY student_name;
```

For `MIN()` [1284], MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `STD(expr)` [1284]

Returns the population standard deviation of *expr*. This is an extension to standard SQL. The standard SQL function `STDDEV_POP()` [1285] can be used instead.

This function returns `NULL` if there were no matching rows.

- `STDDEV(expr)` [1285]

Returns the population standard deviation of *expr*. This function is provided for compatibility with Oracle. The standard SQL function `STDDEV_POP()` [1285] can be used instead.

This function returns `NULL` if there were no matching rows.

- `STDDEV_POP(expr)` [1285]

Returns the population standard deviation of *expr* (the square root of `VAR_POP()` [1285]). You can also use `STD()` [1284] or `STDDEV()` [1285], which are equivalent but not standard SQL.

`STDDEV_POP()` [1285] returns `NULL` if there were no matching rows.

- `STDDEV_SAMP(expr)` [1285]

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()` [1285]).

`STDDEV_SAMP()` [1285] returns `NULL` if there were no matching rows.

- `SUM([DISTINCT] expr)` [1285]

Returns the sum of *expr*. If the return set has no rows, `SUM()` [1285] returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of *expr*.

`SUM()` [1285] returns `NULL` if there were no matching rows.

- `VAR_POP(expr)` [1285]

Returns the population standard variance of *expr*. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()` [1285], which is equivalent but is not standard SQL.

`VAR_POP()` [1285] returns `NULL` if there were no matching rows.

- `VAR_SAMP(expr)` [1285]

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one.

`VAR_SAMP()` [1285] returns `NULL` if there were no matching rows.

- `VARIANCE(expr)` [1285]

Returns the population standard variance of *expr*. This is an extension to standard SQL. The standard SQL function `VAR_POP()` [1285] can be used instead.

`VARIANCE()` [1285] returns `NULL` if there were no matching rows.

## 12.17.2. GROUP BY Modifiers

The `GROUP BY` clause permits a `WITH ROLLUP` modifier that causes extra rows to be added to the summary output. These rows represent higher-level (or super-aggregate) summary operations. `ROLLUP` thus enables you to answer questions at multiple levels of analysis with a single query. It can be used, for example, to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a table named `sales` has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
(
```

```

year      INT NOT NULL,
country  VARCHAR(20) NOT NULL,
product  VARCHAR(32) NOT NULL,
profit   INT
);

```

The table's contents can be summarized per year with a simple `GROUP BY` like this:

```

mysql> SELECT year, SUM(profit) FROM sales GROUP BY year;
+-----+-----+
| year | SUM(profit) |
+-----+-----+
| 2000 |          4525 |
| 2001 |          3010 |
+-----+-----+

```

This output shows the total profit for each year, but if you also want to determine the total profit summed over all years, you must add up the individual values yourself or run an additional query.

Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another row that shows the grand total over all year values:

```

mysql> SELECT year, SUM(profit) FROM sales GROUP BY year WITH ROLLUP;
+-----+-----+
| year | SUM(profit) |
+-----+-----+
| 2000 |          4525 |
| 2001 |          3010 |
| NULL |          7535 |
+-----+-----+

```

The grand total super-aggregate line is identified by the value `NULL` in the `year` column.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a “break” (change in value) in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary on the `sales` table based on `year`, `country`, and `product` might look like this:

```

mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product;
+-----+-----+-----+-----+
| year | country | product | SUM(profit) |
+-----+-----+-----+-----+
| 2000 | Finland | Computer |          1500 |
| 2000 | Finland | Phone    |           100 |
| 2000 | India   | Calculator |           150 |
| 2000 | India   | Computer |          1200 |
| 2000 | USA     | Calculator |            75 |
| 2000 | USA     | Computer |          1500 |
| 2001 | Finland | Phone    |            10 |
| 2001 | USA     | Calculator |            50 |
| 2001 | USA     | Computer |          2700 |
| 2001 | USA     | TV       |            250 |
+-----+-----+-----+-----+

```

The output indicates summary values only at the year/country/product level of analysis. When `ROLLUP` is added, the query produces several extra rows:

```

mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP;
+-----+-----+-----+-----+
| year | country | product | SUM(profit) |
+-----+-----+-----+-----+

```

2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200
2000	India	NULL	1350
2000	USA	Calculator	75
2000	USA	Computer	1500
2000	USA	NULL	1575
2000	NULL	NULL	4525
2001	Finland	Phone	10
2001	Finland	NULL	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250
2001	USA	NULL	3000
2001	NULL	NULL	3010
NULL	NULL	NULL	7535

For this query, adding `ROLLUP` causes the output to include summary information at four levels of analysis, not just one. Here is how to interpret the `ROLLUP` output:

- Following each set of product rows for a given year and country, an extra summary row is produced showing the total for all products. These rows have the `product` column set to `NULL`.
- Following each set of rows for a given year, an extra summary row is produced showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.
- Finally, following all other rows, an extra summary row is produced showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

### Other Considerations When using `ROLLUP`

The following items list some behaviors specific to the MySQL implementation of `ROLLUP`:

When you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` are mutually exclusive. However, you still have some control over sort order. `GROUP BY` in MySQL sorts results, and you can use explicit `ASC` and `DESC` keywords with columns named in the `GROUP BY` list to specify sort order for individual columns. (The higher-level summary rows added by `ROLLUP` still appear after the rows from which they are calculated, regardless of the sort order.)

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP
-> LIMIT 5;
```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has

changed value. For any column in the result set with a name that is a lexical match to any of those names, its value is set to `NULL`. (If you specify grouping columns by column number, the server identifies which columns to set to `NULL` by number.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as `NULL` values within the query itself. For example, you cannot add `HAVING product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface.

### 12.17.3. MySQL Extensions to `GROUP BY`

In standard SQL, a query that includes a `GROUP BY` clause cannot refer to nonaggregated columns in the select list that are not named in the `GROUP BY` clause. For example, this query is illegal in standard SQL because the `name` column in the select list does not appear in the `GROUP BY`:

```
SELECT o.custid, c.name, MAX(o.payment)
   FROM orders AS o, customers AS c
  WHERE o.custid = c.custid
  GROUP BY o.custid;
```

For the query to be legal, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

MySQL extends the use of `GROUP BY` so that the select list can refer to nonaggregated columns not named in the `GROUP BY` clause. This means that the preceding query is legal in MySQL. You can use this feature to get better performance by avoiding unnecessary column sorting and grouping. However, this is useful primarily when all values in each nonaggregated column not named in the `GROUP BY` are the same for each group. The server is free to choose any value from each group, so unless they are the same, the values chosen are indeterminate. Furthermore, the selection of values from each group cannot be influenced by adding an `ORDER BY` clause. Sorting of the result set occurs after values have been chosen, and `ORDER BY` does not affect which values within each group the server chooses.

A similar MySQL extension applies to the `HAVING` clause. In standard SQL, a query that includes a `GROUP BY` clause cannot refer to nonaggregated columns in the `HAVING` clause that are not named in the `GROUP BY` clause. A MySQL extension permits references to such columns to simplify calculations. This extension assumes that the nongrouped columns will have the same group-wise values. Otherwise, the result is indeterminate.

To disable the MySQL `GROUP BY` extension, enable the `ONLY_FULL_GROUP_BY [606]` SQL mode. This enables standard SQL behavior: Columns not named in the `GROUP BY` clause cannot be used in the select list or `HAVING` clause unless enclosed in an aggregate function.

`ONLY_FULL_GROUP_BY [606]` also affects use of aliases in the `HAVING` clauses. For example, the following query returns `name` values that occur only once in table `orders`:

```
SELECT name, COUNT(name) FROM orders
   GROUP BY name
  HAVING COUNT(name) = 1;
```

MySQL extends this behavior to permit the use of an alias in the `HAVING` clause for the aggregated column:

```
SELECT name, COUNT(name) AS c FROM orders
   GROUP BY name
  HAVING c = 1;
```

Enabling `ONLY_FULL_GROUP_BY [606]` disables this MySQL extension and a `non-grouping field 'c' is used in HAVING clause` error occurs because the column `c` in the `HAVING` clause is not enclosed in an aggregate function (instead, it is an aggregate function).

The select list extension also applies to `ORDER BY`. That is, you can refer to nonaggregated columns in the `ORDER BY` clause that do not appear in the `GROUP BY` clause. (However, as mentioned previously, `ORDER BY` does not affect which values are chosen from nonaggregated columns; it only sorts them after they have been chosen.) This extension does not apply if the `ONLY_FULL_GROUP_BY` [606] SQL mode is enabled.

In some cases, you can use `MIN()` [1284] and `MAX()` [1284] to obtain a specific column value even if it is not unique. If the `sort` column contains integers no larger than 6 digits, the following query gives the value of `column` from the row containing the smallest `sort` value:

```
SUBSTR(MIN(CONCAT(LPAD(sort,6,'0'),column)),7)
```

See Section 3.6.4, “The Rows Holding the Group-wise Maximum of a Certain Column”.

If you are trying to follow standard SQL, you cannot use expressions in `GROUP BY` clauses. As a workaround, use an alias for the expression:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

MySQL permits expressions in `GROUP BY` clauses, so the alias is unnecessary:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

## 12.18. Spatial Extensions

MySQL supports spatial extensions to enable the generation, storage, and analysis of geographic features. These features are available for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables.

For spatial columns, `MyISAM` supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in Section 13.1.11, “`CREATE INDEX` Syntax”.

This chapter covers the following topics:

- The basis of these spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

### Additional Resources

- The Open Geospatial Consortium publishes the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>.
- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <http://forums.mysql.com/list.php?23>.

### 12.18.1. Introduction to MySQL Spatial Support

MySQL implements spatial extensions following the specification of the Open Geospatial Consortium (OGC). This is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful

with all kinds of applications that manage spatial data. The OGC maintains a Web site at <http://www.opengis.org/>.

In 1997, the Open Geospatial Consortium published the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>. It contains additional information relevant to this chapter.

MySQL implements a subset of the **SQL with Geometry Types** environment proposed by OGC. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describe a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

**Geometry** is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

This chapter uses all of these terms synonymously: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. Here, the term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

## 12.18.2. The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

### 12.18.2.1. The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- **Geometry** (noninstantiable)
  - **Point** (instantiable)
  - **Curve** (noninstantiable)
    - **LineString** (instantiable)
      - **Line**
      - **LinearRing**
  - **Surface** (noninstantiable)
  - **Polygon** (instantiable)

- `GeometryCollection` (instantiable)
  - `MultiPoint` (instantiable)
  - `MultiCurve` (noninstantiable)
    - `MultiLineString` (instantiable)
  - `MultiSurface` (noninstantiable)
    - `MultiPolygon` (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It is an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with sub-subclasses `Line` and `LinearRing`.
- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiable classes.

### 12.18.2.2. Class `Geometry`

`Geometry` is the root class of the hierarchy. It is a noninstantiable class but has a number of properties that are common to all geometry values created from any of the `Geometry` subclasses. These properties are described in the following list. Particular subclasses have their own specific properties, described later.

#### Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

- Its **coordinates** in its Spatial Reference System, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geocentric** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (Minimum Bounding Rectangle), or Envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **nonsimple**. Geometry values of types ([LineString](#), [MultiPoint](#), [MultiLineString](#)) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.
- Whether the value is **closed** or **not closed**. Geometry values of types ([LineString](#), [MultiString](#)) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **nonempty** A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a [NULL](#) value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of -1, 0, 1, or 2:
  - -1 for an empty geometry.
  - 0 for a geometry with no length and no area.
  - 1 for a geometry with nonzero length and zero area.
  - 2 for a geometry with nonzero area.

[Point](#) objects have a dimension of zero. [LineString](#) objects have a dimension of 1. [Polygon](#) objects have a dimension of 2. The dimensions of [MultiPoint](#), [MultiLineString](#), and [MultiPolygon](#) objects are the same as the dimensions of the elements they consist of.

### 12.18.2.3. Class [Point](#)

A [Point](#) is a geometry that represents a single location in coordinate space.

#### [Point](#) Examples

- Imagine a large-scale map of the world with many cities. A [Point](#) object could represent each city.
- On a city map, a [Point](#) object could represent a bus stop.

#### [Point](#) Properties

- X-coordinate value.
- Y-coordinate value.
- [Point](#) is defined as a zero-dimensional geometry.

- The boundary of a [Point](#) is the empty set.

#### 12.18.2.4. Class [Curve](#)

A [Curve](#) is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of [Curve](#) define the type of interpolation between points. [Curve](#) is a noninstantiable class.

##### [Curve](#) Properties

- A [Curve](#) has the coordinates of its points.
- A [Curve](#) is defined as a one-dimensional geometry.
- A [Curve](#) is simple if it does not pass through the same point twice.
- A [Curve](#) is closed if its start point is equal to its endpoint.
- The boundary of a closed [Curve](#) is empty.
- The boundary of a nonclosed [Curve](#) consists of its two endpoints.
- A [Curve](#) that is simple and closed is a [LinearRing](#).

#### 12.18.2.5. Class [LineString](#)

A [LineString](#) is a [Curve](#) with linear interpolation between points.

##### [LineString](#) Examples

- On a world map, [LineString](#) objects could represent rivers.
- In a city map, [LineString](#) objects could represent streets.

##### [LineString](#) Properties

- A [LineString](#) has coordinates of segments, defined by each consecutive pair of points.
- A [LineString](#) is a [Line](#) if it consists of exactly two points.
- A [LineString](#) is a [LinearRing](#) if it is both closed and simple.

#### 12.18.2.6. Class [Surface](#)

A [Surface](#) is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is [Polygon](#).

##### [Surface](#) Properties

- A [Surface](#) is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple [Surface](#) as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple [Surface](#) is the set of closed curves corresponding to its exterior and interior boundaries.

#### 12.18.2.7. Class [Polygon](#)

A [Polygon](#) is a planar [Surface](#) representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the [Polygon](#).

### Polygon Examples

- On a region map, `Polygon` objects could represent forests, districts, and so on.

### Polygon Assertions

- The boundary of a `Polygon` consists of a set of `LinearRing` objects (that is, `LineString` objects that are both simple and closed) that make up its exterior and interior boundaries.
- A `Polygon` has no rings that cross. The rings in the boundary of a `Polygon` may intersect at a `Point`, but only as a tangent.
- A `Polygon` has no lines, spikes, or punctures.
- A `Polygon` has an interior that is a connected point set.
- A `Polygon` may have holes. The exterior of a `Polygon` with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a `Polygon` a simple geometry.

## 12.18.2.8. Class `GeometryCollection`

A `GeometryCollection` is a geometry that is a collection of one or more geometries of any class.

All the elements in a `GeometryCollection` must be in the same Spatial Reference System (that is, in the same coordinate system). There are no other constraints on the elements of a `GeometryCollection`, although the subclasses of `GeometryCollection` described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

## 12.18.2.9. Class `MultiPoint`

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

### `MultiPoint` Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

### `MultiPoint` Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

## 12.18.2.10. Class `MultiCurve`

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a noninstantiable class.

### `MultiCurve` Properties

- A `MultiCurve` is a one-dimensional geometry.

- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `MultiCurve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

#### 12.18.2.11. Class `MultiLineString`

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

##### `MultiLineString` Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

#### 12.18.2.12. Class `MultiSurface`

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a noninstantiable class. Its only instantiable subclass is `MultiPolygon`.

##### `MultiSurface` Assertions

- Two `MultiSurface` surfaces have no interiors that intersect.
- Two `MultiSurface` elements have boundaries that intersect at most at a finite number of points.

#### 12.18.2.13. Class `MultiPolygon`

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

##### `MultiPolygon` Examples

- On a region map, a `MultiPolygon` could represent a system of lakes.

##### `MultiPolygon` Assertions

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

##### `MultiPolygon` Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

### 12.18.3. Supported Spatial Data Formats

This section describes the standard spatial data formats that are used to represent geometry objects in queries. They are:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

#### 12.18.3.1. Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form. For a Backus-Naur grammar that specifies the formal production rules for writing WKT values, see the OpenGIS specification document referenced in [Section 12.18, “Spatial Extensions”](#).

Examples of WKT representations of geometry objects:

- A [Point](#):

```
POINT(15 20)
```

Note that point coordinates are specified with no separating comma. This differs from the syntax for the SQL [POINT\(\)](#) [1300] function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both extract the X-coordinate from a [Point](#) object. The first produces the object directly using the [POINT\(\)](#) [1300] function. The second uses a WKT representation converted to a [Point](#) with [GeomFromText\(\)](#).

```
mysql> SELECT X(POINT(15, 20));
+-----+
| X(POINT(15, 20)) |
+-----+
|                15 |
+-----+

mysql> SELECT X(GeomFromText('POINT(15 20)'));
+-----+
| X(GeomFromText('POINT(15 20)')) |
+-----+
|                15 |
+-----+
```

- A [LineString](#) with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

Note that point coordinate pairs are separated by commas.

- A [Polygon](#) with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A [MultiPoint](#) with three [Point](#) values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

- A [MultiLineString](#) with two [LineString](#) values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A [MultiPolygon](#) with two [Polygon](#) values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A `GeometryCollection` consisting of two `Point` values and one `LineString`:

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

### 12.18.3.2. Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation for geometric values is defined by the OpenGIS specification. It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB is used to exchange geometry data as binary streams represented by `BLOB` values containing geometric WKB information.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 1)` consists of this sequence of 21 bytes (each represented here by two hex digits):

```
010100000000000000000000F03F000000000000F03F
```

The sequence may be broken down into these components:

```
Byte order : 01
WKB type   : 01000000
X          : 00000000000000F03F
Y          : 00000000000000F03F
```

Component representation is as follows:

- The byte order may be either 1 or 0 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`.
- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values are represented by more complex data structures, as detailed in the OpenGIS specification.

## 12.18.4. Creating a Spatially Enabled MySQL Database

This section describes the data types you can use for representing spatial data in MySQL, and the functions available for creating and retrieving spatial values.

### 12.18.4.1. MySQL Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINestring`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINestring`, and `POLYGON`) restrict their values to a particular geometry type.

The other data types hold collections of values:

- `MULTIPOINT`
- `MULTILINESTRING`
- `MULTIPOLYGON`
- `GEOMETRYCOLLECTION`

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types (`MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON`, and `GEOMETRYCOLLECTION`) restrict collection members to those having a particular geometry type.

## 12.18.4.2. Creating Spatial Values

This section describes how to create spatial values using Well-Known Text and Well-Known Binary functions that are defined in the OpenGIS standard, and using MySQL-specific functions.

### 12.18.4.2.1. Creating Geometry Values Using WKT Functions

MySQL provides a number of functions that take as arguments a Well-Known Text representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` [1298] accepts a WKT of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromText(wkt[,srid])` [1298],  
`GeometryCollectionFromText(wkt[,srid])` [1298]

Constructs a `GEOMETRYCOLLECTION` value using its WKT representation and SRID.

- `GeomFromText(wkt[,srid])` [1298], `GeometryFromText(wkt[,srid])` [1298]

Constructs a geometry value of any type using its WKT representation and SRID.

- `LineFromText(wkt[,srid])` [1298], `LineStringFromText(wkt[,srid])` [1298]

Constructs a `LINestring` value using its WKT representation and SRID.

- `MLineFromText(wkt[,srid])` [1298], `MultiLineStringFromText(wkt[,srid])` [1298]

Constructs a `MULTILINESTRING` value using its WKT representation and SRID.

- `MPointFromText(wkt[,srid])` [1298], `MultiPointFromText(wkt[,srid])` [1298]

Constructs a `MULTIPOINT` value using its WKT representation and SRID.

- `MPolyFromText(wkt[,srid])` [1298], `MultiPolygonFromText(wkt[,srid])` [1298]

Constructs a `MULTIPOLYGON` value using its WKT representation and SRID.

- `PointFromText(wkt[,srid])` [1298]

Constructs a `POINT` value using its WKT representation and SRID.

- `PolyFromText(wkt[,srid])` [1298], `PolygonFromText(wkt[,srid])` [1298]

Constructs a `POLYGON` value using its WKT representation and SRID.

The OpenGIS specification also defines the following optional functions, which MySQL does not implement. These functions construct `Polygon` or `MultiPolygon` values based on the WKT representation of a collection of rings or closed `LineString` values. These values may intersect.

- `BdMPolyFromText(wkt, srid)` [1299]

Constructs a `MultiPolygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

- `BdPolyFromText(wkt, srid)` [1299]

Constructs a `Polygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

#### 12.18.4.2.2. Creating Geometry Values Using WKB Functions

MySQL provides a number of functions that take as arguments a `BLOB` containing a Well-Known Binary representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

These functions also accept geometry objects for compatibility with the return value of the functions in Section 12.18.4.2.3, “Creating Geometry Values Using MySQL-Specific Functions”. Thus, those functions may be used to provide the first argument to the functions in this section.

- `GeomCollFromWKB(wkb[, srid])` [1299],  
`GeometryCollectionFromWKB(wkb[, srid])` [1299]

Constructs a `GEOMETRYCOLLECTION` value using its WKB representation and SRID.

- `GeomFromWKB(wkb[, srid])` [1299], `GeometryFromWKB(wkb[, srid])` [1299]

Constructs a geometry value of any type using its WKB representation and SRID.

- `LineFromWKB(wkb[, srid])` [1299], `LineStringFromWKB(wkb[, srid])` [1299]

Constructs a `LINESTRING` value using its WKB representation and SRID.

- `MLineFromWKB(wkb[, srid])` [1299], `MultiLineStringFromWKB(wkb[, srid])` [1299]

Constructs a `MULTILINESTRING` value using its WKB representation and SRID.

- `MPointFromWKB(wkb[, srid])` [1299], `MultiPointFromWKB(wkb[, srid])` [1299]

Constructs a `MULTIPOINT` value using its WKB representation and SRID.

- `MPolyFromWKB(wkb[, srid])` [1299], `MultiPolygonFromWKB(wkb[, srid])` [1299]

Constructs a `MULTIPOLYGON` value using its WKB representation and SRID.

- `PointFromWKB(wkb[, srid])` [1299]

Constructs a `POINT` value using its WKB representation and SRID.

- `PolyFromWKB(wkb[, srid])` [1299], `PolygonFromWKB(wkb[, srid])` [1299]

Constructs a `POLYGON` value using its WKB representation and SRID.

The OpenGIS specification also describes optional functions for constructing `Polygon` or `MultiPolygon` values based on the WKB representation of a collection of rings or closed `LineString` values. These values may intersect. MySQL does not implement these functions:

- `BdMPolyFromWKB(wkb, srid)` [1299]

Constructs a `MultiPolygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.

- `BdPolyFromWKB(wkb, srid)` [1299]

Constructs a [Polygon](#) value from a [MultiLineString](#) value in WKB format containing an arbitrary collection of closed [LineString](#) values.

### 12.18.4.2.3. Creating Geometry Values Using MySQL-Specific Functions

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is `NULL`.

For example, you can insert the geometry return value from `Point()` [1300] directly into a `Point` column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- [GeometryCollection\(\*g1,g2,...\*\)](#) [1300]

Constructs a [GeometryCollection](#).

- [LineString\(\*pt1,pt2,...\*\)](#) [1300]

Constructs a [LineString](#) value from a number of [Point](#) or WKB [Point](#) arguments. If the number of arguments is less than two, the return value is `NULL`.

- [MultiLineString\(\*ls1,ls2,...\*\)](#) [1300]

Constructs a [MultiLineString](#) value using [LineString](#) or WKB [LineString](#) arguments.

- [MultiPoint\(\*pt1,pt2,...\*\)](#) [1300]

Constructs a [MultiPoint](#) value using [Point](#) or WKB [Point](#) arguments.

- [MultiPolygon\(\*poly1,poly2,...\*\)](#) [1300]

Constructs a [MultiPolygon](#) value from a set of [Polygon](#) or WKB [Polygon](#) arguments.

- [Point\(\*x,y\*\)](#) [1300]

Constructs a [Point](#) using its coordinates.

- [Polygon\(\*ls1,ls2,...\*\)](#) [1300]

Constructs a [Polygon](#) value from a number of [LineString](#) or WKB [LineString](#) arguments. If any argument does not represent a [LinearRing](#) (that is, not a closed and simple [LineString](#)), the return value is `NULL`.

### 12.18.4.3. Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Currently, spatial columns are supported for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. See also the annotations about spatial indexes under [Section 12.18.6.1, “Creating Spatial Indexes”](#).

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

### 12.18.4.4. Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values into internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));

SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

- Perform the conversion prior to the `INSERT`:

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples all use `GeomFromText()` [1298] to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));
```

Note that if a client application program wants to use WKB representations of geometry values, it is responsible for sending correctly formed WKB in queries to the server. However, there are several ways of satisfying this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```
mysql> INSERT INTO geom VALUES
-> (GeomFromWKB(0x01010000000000000000000000F03F000000000000F03F));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See [Section 21.8.6.54](#), “`mysql_real_escape_string()`”.

### 12.18.4.5. Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them into WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `AsText()` [1302] function converts a geometry from internal format into a WKT string.

```
SELECT AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `AsBinary()` [1302] function converts a geometry from internal format into a `BLOB` containing the WKB value.

```
SELECT AsBinary(g) FROM geom;
```

## 12.18.5. Spatial Analysis Functions

After populating spatial columns with values, you are ready to query and analyze them. MySQL provides a set of functions to perform various operations on spatial data. These functions can be grouped into four major categories according to the type of operation they perform:

- Functions that convert geometries between various formats
- Functions that provide access to qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

Spatial analysis functions can be used in many contexts, such as:

- Any interactive SQL program, such as `mysql`.
- Application programs written in any language that supports a MySQL client API

### 12.18.5.1. Geometry Format Conversion Functions

MySQL supports the following functions for converting geometry values between internal format and either WKT or WKB format:

- `AsBinary(g)` [1302], `AsWKB(g)` [1302]

Converts a value in internal geometry format to its WKB representation and returns the binary result.

```
SELECT AsBinary(g) FROM geom;
```

- `AsText(g)` [1302], `AsWKT(g)` [1302]

Converts a value in internal geometry format to its WKT representation and returns the string result.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+-----+
| AsText(GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
```

- `GeomFromText(wkt[, srid])` [1298]

Converts a string value from its WKT representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromText()` [1298] and `LineFromText()` [1298]. See Section 12.18.4.2.1, “Creating Geometry Values Using WKT Functions”.

- `GeomFromWKB(wkb[, srid])` [1299]

Converts a binary value from its WKB representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromWKB()` [1299] and `LineFromWKB()` [1299]. See Section 12.18.4.2.2, “Creating Geometry Values Using WKB Functions”.

## 12.18.5.2. Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, `Area()` [1306] returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

### 12.18.5.2.1. General Geometry Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)` [1303]

Returns the inherent dimension of the geometry value *g*. The result can be `-1`, `0`, `1`, or `2`. The meaning of these values is given in Section 12.18.2.2, “Class Geometry”.

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `Envelope(g)` [1303]

Returns the Minimum Bounding Rectangle (MBR) for the geometry value *g*. The result is returned as a `Polygon` value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)'))) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

- `GeometryType(g)` [1303]

Returns as a binary string the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
```

POINT
-------

- [IsSimple\(\*g\*\) \[1304\]](#)

Returns 1 if the geometry value *g* has no anomalous geometric points, such as self-intersection or self-tangency. [IsSimple\(\)](#) [1304] returns 0 if the argument is not simple, and `NULL` if it is `NULL`.

The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple. (See [Section 12.18.2.1, “The Geometry Class Hierarchy”](#).)

Prior to MySQL 5.6.1, this function always returns 0.

- [SRID\(\*g\*\) \[1304\]](#)

Returns an integer indicating the Spatial Reference System ID for the geometry value *g*.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----+
| 101 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- [Boundary\(\*g\*\) \[1304\]](#)

Returns a geometry that is the closure of the combinatorial boundary of the geometry value *g*.

- [IsEmpty\(\*g\*\) \[1304\]](#)

This function is a placeholder that returns 0 for any valid geometry value, 1 for any invalid geometry value or `NULL`.

MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

### 12.18.5.2.2. Point Functions

A `Point` consists of X and Y coordinates, which may be obtained using the following functions:

- [X\(\*p\*\) \[1304\]](#)

Returns the X-coordinate value for the `Point` object *p* as a double-precision number.

```
mysql> SELECT X(POINT(56.7, 53.34));
+-----+
| X(POINT(56.7, 53.34)) |
+-----+
| 56.7 |
+-----+
```

- [Y\(\*p\*\) \[1304\]](#)

Returns the Y-coordinate value for the `Point` object *p* as a double-precision number.

```
mysql> SELECT Y(POINT(56.7, 53.34));
+-----+
| Y(POINT(56.7, 53.34)) |
+-----+
| 53.34 |
+-----+
```

### 12.18.5.2.3. LineString Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

- `EndPoint(ls)` [1305]

Returns the `Point` that is the endpoint of the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `GLength(ls)` [1305]

Returns as a double-precision number the length of the `LineString` value `ls` in its associated spatial reference.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
| 2.8284271247462 |
+-----+
```

`GLength()` [1305] is a nonstandard name. It corresponds to the OpenGIS `Length()` [1181] function.

- `NumPoints(ls)` [1305]

Returns the number of `Point` objects in the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
| 3 |
+-----+
```

- `PointN(ls,N)` [1305]

Returns the `N`-th `Point` in the `LineString` value `ls`. Points are numbered beginning with 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `StartPoint(ls)` [1305]

Returns the `Point` that is the start point of the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- `IsRing(ls)` [1306]

Returns 1 if the `LineString` value *ls* is closed (that is, its `StartPoint()` [1305] and `EndPoint()` [1305] values are the same) and is simple (does not pass through the same point more than once). Returns 0 if *ls* is not a ring, and `-1` if it is `NULL`.

#### 12.18.5.2.4. MultiLineString Functions

These functions return properties of `MultiLineString` values.

- `GLength(mIs)` [1305]

Returns as a double-precision number the length of the `MultiLineString` value *mIs*. The length of *mIs* is equal to the sum of the lengths of its elements.

```
mysql> SET @mIs = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mIs));
+-----+
| GLength(GeomFromText(@mIs)) |
+-----+
|                4.2426406871193 |
+-----+
```

`GLength()` [1305] is a nonstandard name. It corresponds to the OpenGIS `Length()` [1181] function.

- `IsClosed(mIs)` [1306]

Returns 1 if the `MultiLineString` value *mIs* is closed (that is, the `StartPoint()` [1305] and `EndPoint()` [1305] values are the same for each `LineString` in *mIs*). Returns 0 if *mIs* is not closed, and `-1` if it is `NULL`.

```
mysql> SET @mIs = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT IsClosed(GeomFromText(@mIs));
+-----+
| IsClosed(GeomFromText(@mIs)) |
+-----+
|                                0 |
+-----+
```

#### 12.18.5.2.5. Polygon Functions

These functions return properties of `Polygon` values.

- `Area(poly)` [1306]

Returns as a double-precision number the area of the `Polygon` value *poly*, as measured in its spatial reference system.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT Area(GeomFromText(@poly));
+-----+
| Area(GeomFromText(@poly)) |
+-----+
|                4 |
+-----+
```

- `ExteriorRing(poly)` [1306]

Returns the exterior ring of the `Polygon` value *poly* as a `LineString`.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
```

```
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+
```

- [InteriorRingN\(\*poly\*,\*N\*\)](#) [1307]

Returns the *N*-th interior ring for the [Polygon](#) value *poly* as a [LineString](#). Rings are numbered beginning with 1.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+
```

- [NumInteriorRings\(\*poly\*\)](#) [1307]

Returns the number of interior rings in the [Polygon](#) value *poly*.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
| NumInteriorRings(GeomFromText(@poly)) |
+-----+
| 1 |
+-----+
```

### 12.18.5.2.6. MultiPolygon Functions

These functions return properties of [MultiPolygon](#) values.

- [Area\(\*mpoly\*\)](#) [1306]

Returns as a double-precision number the area of the [MultiPolygon](#) value *mpoly*, as measured in its spatial reference system.

```
mysql> SET @mpoly =
-> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+-----+
| Area(GeomFromText(@mpoly)) |
+-----+
| 8 |
+-----+
```

- [Centroid\(\*mpoly\*\)](#) [1307]

Returns the mathematical centroid for the [MultiPolygon](#) value *mpoly* as a [Point](#). The result is not guaranteed to be on the [MultiPolygon](#).

```
mysql> SET @poly =
-> GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT GeometryType(@poly),AsText(Centroid(@poly));
+-----+
| GeometryType(@poly) | AsText(Centroid(@poly)) |
+-----+
| POLYGON | POINT(4.958333333333333 4.958333333333333) |
+-----+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- [PointOnSurface\(\*mpoly\*\)](#)

Returns a [Point](#) value that is guaranteed to be on the [MultiPolygon](#) value *mpoly*.

### 12.18.5.2.7. GeometryCollection Functions

These functions return properties of `GeometryCollection` values.

- `GeometryN(gc,N)` [1308]

Returns the *N*-th geometry in the `GeometryCollection` value *gc*. Geometries are numbered beginning with 1.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
+-----+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+
| POINT(1 1) |
+-----+
```

- `NumGeometries(gc)` [1308]

Returns the number of geometries in the `GeometryCollection` value *gc*.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
+-----+
| NumGeometries(GeomFromText(@gc)) |
+-----+
| 2 |
+-----+
```

### 12.18.5.3. Functions That Create New Geometries from Existing Ones

The following sections describe functions that take geometry values as arguments and return new geometry values.

#### 12.18.5.3.1. Geometry Functions That Produce New Geometries

Section 12.18.5.2, “[Geometry Property Functions](#)”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `Envelope(g)` [1303]
- `StartPoint(ls)` [1305]
- `EndPoint(ls)` [1305]
- `PointN(ls,N)` [1305]
- `ExteriorRing(poly)` [1306]
- `InteriorRingN(poly,N)` [1307]
- `GeometryN(gc,N)` [1308]

#### 12.18.5.3.2. Spatial Operators

OpenGIS proposes a number of other functions that can produce geometries. They are designed to implement spatial operators.

- `Buffer(g,d)` [1308]

Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*.

`Buffer()` [1308] supports negative distances for polygons, multipolygons, and geometry collections containing polygons or multipolygons. For point, multipoint, linestring, multilinestring,

and geometry collections not containing any polygons or multipolygons, `Buffer()` [1308] with a negative distance returns `NULL`.

Prior to MySQL 5.6.1, this function is unimplemented.

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `ConvexHull(g)` [1309]

Returns a geometry that represents the convex hull of the geometry value *g*.

- `Difference(g1,g2)` [1309]

Returns a geometry that represents the point set difference of the geometry value *g1* with *g2*.

- `Intersection(g1,g2)` [1309]

Returns a geometry that represents the point set intersection of the geometry values *g1* with *g2*.

- `SymDifference(g1,g2)` [1309]

Returns a geometry that represents the point set symmetric difference of the geometry value *g1* with *g2*.

- `Union(g1,g2)` [1309]

Returns a geometry that represents the point set union of the geometry values *g1* and *g2*.

#### 12.18.5.4. Functions for Testing Spatial Relations Between Geometric Objects

The functions described in these sections take two geometries as input parameters and return a qualitative or quantitative relation between them.

##### 12.18.5.4.1. Relations on Geometry Minimal Bounding Rectangles (MBRs)

MySQL provides several functions that test relations between minimal bounding rectangles of two geometries *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

- `MBRContains(g1,g2)` [1309]

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* contains the Minimum Bounding Rectangle of *g2*. This tests the opposite relationship as `MBRWithin()` [1310].

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
+-----+-----+
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

- `MBRDisjoint(g1,g2)` [1309]

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).

- `MBREqual(g1,g2)` [1309]

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are the same.

- `MBRIntersects(g1,g2)` [1309]

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* intersect.

- `MBROverlaps(g1,g2)` [1310]

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* overlap. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

- `MBRTouches(g1,g2)` [1310]

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* touch. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- `MBRWithin(g1,g2)` [1310]

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* is within the Minimum Bounding Rectangle of *g2*. This tests the opposite relationship as `MBRContains()` [1309].

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+-----+-----+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

#### 12.18.5.4.2. Functions That Test Spatial Relationships Between Geometries

The OpenGIS specification defines the following functions. They test the relationship between two geometry values *g1* and *g2*.

The return values 1 and 0 indicate true and false, respectively.

#### Note

MySQL originally implemented these functions such that they used object bounding rectangles and returned the same result as the corresponding MBR-based functions. As of MySQL 5.6.1, corresponding versions are available that use precise object shapes. These versions are named with an `ST_` prefix. For example, `Contains()` [1311] uses object bounding rectangles, whereas `ST_Contains()` [1310] uses object shapes.

As of MySQL 5.6.1, there are also `ST_` aliases for existing spatial functions that were already exact. For example, `ST_IsEmpty()` is an alias for `IsEmpty()` [1304].

#### Functions That Use Object Shapes

- `ST_Contains(g1,g2)` [1310]

Returns 1 or 0 to indicate whether *g1* completely contains *g2*. This tests the opposite relationship as `ST_Within()` [1311].

- `ST_Crosses(g1,g2)` [1310]

Returns 1 if *g1* spatially crosses *g2*. Returns `NULL` if *g1* is a `Polygon` or a `MultiPolygon`, or if *g2* is a `Point` or a `MultiPoint`. Otherwise, returns 0.

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries
- `ST_Disjoint(g1,g2)` [1311]  
Returns 1 or 0 to indicate whether *g1* is spatially disjoint from (does not intersect) *g2*.
- `ST_Equals(g1,g2)` [1311]  
Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.
- `ST_Intersects(g1,g2)` [1311]  
Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.
- `ST_Overlaps(g1,g2)` [1311]  
Returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.
- `ST_Touches(g1,g2)` [1311]  
Returns 1 or 0 to indicate whether *g1* spatially touches *g2*. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.
- `ST_Within(g1,g2)` [1311]  
Returns 1 or 0 to indicate whether *g1* is spatially within *g2*. This tests the opposite relationship as `ST_Contains()` [1310].

### Functions That Use Bounding Rectangles

- `Contains(g1,g2)` [1311]  
Returns 1 or 0 to indicate whether *g1* completely contains *g2*. This tests the opposite relationship as `Within()` [1312].
- `Crosses(g1,g2)` [1311]  
Returns 1 if *g1* spatially crosses *g2*. Returns `NULL` if *g1* is a `Polygon` or a `MultiPolygon`, or if *g2* is a `Point` or a `MultiPoint`. Otherwise, returns 0.  
  
The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:
  - The two geometries intersect
  - Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
  - Their intersection is not equal to either of the two given geometries
- `Disjoint(g1,g2)` [1311]  
Returns 1 or 0 to indicate whether *g1* is spatially disjoint from (does not intersect) *g2*.
- `Equals(g1,g2)` [1311]

Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.

- `Intersects(g1,g2)` [1312]

Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.

- `Overlaps(g1,g2)` [1312]

Returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

- `Touches(g1,g2)` [1312]

Returns 1 or 0 to indicate whether *g1* spatially touches *g2*. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- `Within(g1,g2)` [1312]

Returns 1 or 0 to indicate whether *g1* is spatially within *g2*. This tests the opposite relationship as `Contains()` [1311].

## 12.18.6. Optimizing Spatial Analysis

For `MyISAM` tables, Search operations in nonspatial databases can be optimized using `SPATIAL` indexes. This is true for spatial databases as well. With the help of a great variety of multi-dimensional indexing methods that have previously been designed, it is possible to optimize spatial searches. The most typical of these are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the MBR of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 13.1.11, “CREATE INDEX Syntax”](#).

### 12.18.6.1. Creating Spatial Indexes

For `MyISAM` tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Currently, columns in spatial indexes must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g)) ENGINE=MyISAM;
```

- With `ALTER TABLE`:

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

For `MyISAM` tables, `SPATIAL INDEX` creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values will be useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see [Section 13.1.11](#), “`CREATE INDEX Syntax`”.

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
DROP INDEX sp_index ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| fid   | int(11)   |      | PRI | NULL    | auto_increment |
| g     | geometry  |      |     |         |                |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
|      32376 |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

### 12.18.6.2. Using a Spatial Index

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` [1309] or `MBRWithin()` [1310] in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000));'
mysql> SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g);
+-----+-----+-----+-----+-----+-----+
| fid | AsText(g)
+-----+-----+-----+-----+-----+-----+
| 21 | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30
| 22 | LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ...
| 23 | LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ...
| 24 | LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ...
| 25 | LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ...
| 26 | LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ...

| 7 | LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ... |
| 10 | LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ... |
| 11 | LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ... |
| 13 | LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ... |
| 154 | LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ... |
| 155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ... |
| 157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ... |
+-----+
20 rows in set (0.00 sec)
```

Use `EXPLAIN` to check the way this query is executed:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: range
possible_keys: g
          key: g
        key_len: 32
          ref: NULL
         rows: 50
      Extra: Using where
1 row in set (0.00 sec)
```

Check what would happen without a spatial index:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> EXPLAIN SELECT fid,AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: ALL
possible_keys: NULL
          key: NULL
        key_len: NULL
          ref: NULL
         rows: 32376
      Extra: Using where
1 row in set (0.00 sec)
```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
```

```

-> MBRContains(GeomFromText(@poly),g);
+-----+
| fid | AsText(g)
+-----+
| 1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ...
| 2 | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136, ...

| 249 | LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ...
+-----+
20 rows in set (0.46 sec)

```

## 12.18.7. MySQL Conformance and Compatibility

MySQL does not yet implement the following GIS features:

- Additional Metadata Views

OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` [1181] on `LineString` and `MultiLineString` currently should be called in MySQL as `GLength()` [1305]

The problem is that there is an existing SQL function `Length()` [1181] that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context. We need either to solve this somehow, or decide on another function name.

## 12.19. Precision Math

MySQL 5.6 provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND()` [1207] depends on its argument, not on environmental factors such as how the underlying C library works.

- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL 5.6 handles numeric operations precisely. For information about controlling the SQL mode, see [Section 5.1.7, "Server SQL Modes"](#).

### 12.19.1. Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (`DECIMAL` and integer types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

### 12.19.2. `DECIMAL` Data Type Changes

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms) in MySQL 5.6, with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of `DECIMAL` columns

Possible incompatibilities with applications that are written for older versions of MySQL (prior to 5.0.3) are noted throughout this section.

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments in MySQL 5.6 are as follows:

- `M` is the maximum number of digits (the precision). It has a range of 1 to 65. (Older versions of MySQL permitted a range of 1 to 254.)
- `D` is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than `M`.

The maximum value of 65 for `M` means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum

range of such literals differs from before. (In older versions of MySQL, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.)

Values for `DECIMAL` columns in MySQL 5.6 are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1–2	1
3–4	2
5–6	3
7–9	4

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

Unlike some older versions of MySQL, `DECIMAL` columns in MySQL 5.6 do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored. Applications that rely on the older behavior must be modified to account for this change.

`DECIMAL` columns in MySQL 5.6 do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column permits at most  $M - D$  digits to the left of the decimal point. This is not compatible with applications relying on older versions of MySQL that permitted storing an extra digit in lieu of a `+` sign.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly*  $M$  digits. For `DECIMAL(M,D)`, the standard requires a precision of at least  $M$  digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly  $M$  digits.

For more detailed information about porting applications that rely on the old treatment of the `DECIMAL` data type, see the *MySQL 5.0 Reference Manual*.

### 12.19.3. Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (Without strict mode, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.

- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` [545] system variable. (See Section 5.1.7, “Server SQL Modes”.) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` [607] or `STRICT_TRANS_TABLES` [607] mode values) and `ERROR_FOR_DIVISION_BY_ZERO` [603]. To turn on all restrictions, you can simply use `TRADITIONAL` [609] mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO` [603]:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in Section 12.19.4, “Rounding Behavior”.

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

By default, division by zero produces a result of `NULL` and no warning. With the `ERROR_FOR_DIVISION_BY_ZERO` [603] SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` [603] in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` [603] modes.

<code>sql_mode</code> [545] Value	Result
' ' (Default)	No warning, no error; <code>i</code> is set to <code>NULL</code> .
strict	No warning, no error; <code>i</code> is set to <code>NULL</code> .
<code>ERROR_FOR_DIVISION_BY_ZERO</code> [603]	Warning, no error; <code>i</code> is set to <code>NULL</code> .
strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code> [603]	Error condition; no row is inserted.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.

- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

## 12.19.4. Rounding Behavior

This section discusses precision math rounding for the `ROUND()` [1207] function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` [1207] function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` [1207] uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` [1207] uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d    |
+-----+
| 3    |
| 3    |
+-----+
```

## 12.19.5. Precision Math Examples

This section provides some examples that show precision math query results in MySQL 5.6. These examples demonstrate the principles described in [Section 12.19.3, “Expression Handling”](#), and [Section 12.19.4, “Rounding Behavior”](#).

**Example 1.** Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+-----+
| (.1 + .2) = .3 |
+-----+
| 1              |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
```

```

+-----+
| (.1E0 + .2E0) = .3E0 |
+-----+
|                          0 |
+-----+

```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;

```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```

+-----+
| d      | f      |
+-----+
| 1.0000 | 0.999999999999991 |
+-----+

```

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers `X1` and `X2` that have scale `S1` and `S2`, the scale of the result is `S1 + S2`:

```

mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+

```

**Example 3.** Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` [1207] function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. Values with a fractional part of `.5` or greater are rounded away from zero to the nearest integer, as shown here:

```

mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+
| 3          | -3          |
+-----+

```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```

mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+
| 2            | -2            |
+-----+

```

**Example 4.** In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127  |
+-----+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

**Example 5:** In strict mode and with [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO \[603\]](#) set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL  |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0
```

```
mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

**Example 6.** Exact-value literals are evaluated as exact values.

Prior to MySQL 5.0.3, exact-value and approximate-value literals both are evaluated as double-precision floating-point values:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 4.1.18-log |
+-----+
1 row in set (0.01 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.07 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | double(3,1)  |      |     | 0.0     |      |
| b     | double       |      |     | 0       |      |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.04 sec)
```

As of MySQL 5.0.3, the approximate-value literal is evaluated using floating point, but the exact-value literal is handled as **DECIMAL**:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 5.1.6-alpha-log |
+-----+
1 row in set (0.11 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |      |
| b     | double              | NO   |     | 0       |      |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

**Example 7.** If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Before MySQL 5.0.3, the result is a double no matter the argument type:

```
mysql> DESCRIBE y;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| AVG(i) | double(17,4) | YES  |     | NULL    |      |
+-----+-----+-----+-----+-----+-----+
```

AVG(d)	double(17,4)	YES		NULL	
AVG(f)	double	YES		NULL	

As of MySQL 5.0.3, the result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
```

Field	Type	Null	Key	Default	Extra
AVG(i)	decimal(14,4)	YES		NULL	
AVG(d)	decimal(14,4)	YES		NULL	
AVG(f)	double	YES		NULL	

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

This chapter describes the syntax for the [SQL](#) statements supported by MySQL.

## 13.1. Data Definition Statements

### 13.1.1. [ALTER DATABASE](#) Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
```

[ALTER DATABASE](#) enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use [ALTER DATABASE](#), you need the [ALTER \[753\]](#) privilege on the database. [ALTER SCHEMA](#) is a synonym for [ALTER DATABASE](#).

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

### National Language Characteristics

The [CHARACTER SET](#) clause changes the default database character set. The [COLLATE](#) clause changes the default database collation. [Section 10.1, “Character Set Support”](#), discusses character set and collation names.

You can see what character sets and collations are available using, respectively, the [SHOW CHARACTER SET](#) and [SHOW COLLATION](#) statements. See [Section 13.7.5.4, “SHOW CHARACTER SET Syntax”](#), and [Section 13.7.5.5, “SHOW COLLATION Syntax”](#), for more information.

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)

## Upgrading from Versions Older than MySQL 5.1

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see [Section 9.2.3, “Mapping of Identifiers to File Names”](#)). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has the name `a-b-c`, the name contains instances of the `-` (dash) character. In MySQL 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql150#a-b-c`, and you must refer to the name using the `#mysql150#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql150#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql150#` prefix.

### 13.1.2. ALTER EVENT Syntax

```
ALTER
[DEFINER = { user | CURRENT_USER }]
EVENT event_name
[ON SCHEDULE schedule]
[ON COMPLETION [NOT] PRESERVE]
[RENAME TO new_event_name]
[ENABLE | DISABLE | DISABLE ON SLAVE]
[COMMENT 'comment']
[DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 13.1.9, “CREATE EVENT Syntax”](#).)

Any user can alter an event defined on a database for which that user has the `EVENT [754]` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
> ON SCHEDULE
> EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
ON SCHEDULE
EVERY 6 HOUR
COMMENT 'A sample comment.'
DO
```

```
UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
ON SCHEDULE
EVERY 12 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
ON SCHEDULE
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO
TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT [754]` privilege on both the `olddb` and `newdb` databases.

#### Note

There is no `RENAME EVENT` statement.

The value `DISABLE ON SLAVE` is used on a replication slave instead of `ENABLED` or `DISABLED` to indicate an event that was created on the master and replicated to the slave, but that is not executed on the slave. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are

some circumstances under which you may want or need to change it manually. See [Section 16.4.1.10, “Replication of Invoked Features”](#), for more information.

### 13.1.3. ALTER FUNCTION Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
  COMMENT 'string'
| LANGUAGE SQL
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` [754] privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` [756] privilege, as described in [Section 18.7, “Binary Logging of Stored Programs”](#).

### 13.1.4. ALTER PROCEDURE Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
  COMMENT 'string'
| LANGUAGE SQL
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` [754] privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` [464] system variable. See [Section 18.2.2, “Stored Routines and MySQL Privileges”](#).

### 13.1.5. ALTER SERVER Syntax

```
ALTER SERVER server_name
  OPTIONS (option [, option] ...)
```

Alters the server information for *server\_name*, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` [756] privilege.

For example, to update the `USER` option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` does not cause an automatic commit.

In MySQL 5.6, `ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

Beginning with MySQL 5.6.11, `gtid_next` [2022] must be set to `AUTOMATIC` before issuing this statement (BUG#16062608).

### 13.1.6. ALTER TABLE Syntax

```

ALTER [IGNORE] TABLE tbl_name
  [alter_specification [, alter_specification] ...]
  [partition_options]

alter_specification:
  table_options
| ADD [COLUMN] col_name column_definition
  [FIRST | AFTER col_name ]
| ADD [COLUMN] (col_name column_definition,...)
| ADD {INDEX|KEY} [index_name]
  [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]] PRIMARY KEY
  [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
  UNIQUE [INDEX|KEY] [index_name]
  [index_type] (index_col_name,...) [index_option] ...
| ADD FULLTEXT [INDEX|KEY] [index_name]
  (index_col_name,...) [index_option] ...
| ADD SPATIAL [INDEX|KEY] [index_name]
  (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
  FOREIGN KEY [index_name] (index_col_name,...)
  reference_definition
| ALGORITHM [=] {DEFAULT|INPLACE|COPY}
| ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
| CHANGE [COLUMN] old_col_name new_col_name column_definition
  [FIRST|AFTER col_name]
| LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
| MODIFY [COLUMN] col_name column_definition
  [FIRST | AFTER col_name]
| DROP [COLUMN] col_name
| DROP PRIMARY KEY
| DROP {INDEX|KEY} index_name
| DROP FOREIGN KEY fk_symbol
| DISABLE KEYS
| ENABLE KEYS
| RENAME [TO|AS] new_tbl_name
| ORDER BY col_name [, col_name] ...
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
| [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
| DISCARD TABLESPACE
| IMPORT TABLESPACE
| FORCE
| ADD PARTITION (partition_definition)
| DROP PARTITION partition_names
| TRUNCATE PARTITION {partition_names | ALL}
| COALESCE PARTITION number
| REORGANIZE PARTITION partition_names INTO (partition_definitions)
| EXCHANGE PARTITION partition_name WITH TABLE tbl_name
| ANALYZE PARTITION {partition_names | ALL}
| CHECK PARTITION {partition_names | ALL}
| OPTIMIZE PARTITION {partition_names | ALL}
| REBUILD PARTITION {partition_names | ALL}
| REPAIR PARTITION {partition_names | ALL}
| REMOVE PARTITIONING

index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH}

index_option:
  KEY_BLOCK_SIZE [=] value
| index_type
| WITH PARSER parser_name
| COMMENT 'string'

table_options:
  table_option [[,] table_option] ... (see CREATE TABLE options)

```

```
partition_options:
  (see CREATE TABLE options)
```

`ALTER TABLE` changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, for adding, dropping, merging, and splitting partitions, and for performing partitioning maintenance. It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITION` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITION` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see [Section 13.1.6.1, “ALTER TABLE Partition Operations”](#).

Following the table name, specify the alterations to be made. If none are given, `ALTER TABLE` does nothing.

The syntax for many of the permissible alterations is similar to clauses of the `CREATE TABLE` statement. See [Section 13.1.14, “CREATE TABLE Syntax”](#), for more information.

Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with `SHOW WARNINGS`. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

For information on troubleshooting `ALTER TABLE`, see [Section C.5.7.1, “Problems with ALTER TABLE”](#).

## Storage, Performance, and Concurrency Considerations

In most cases, `ALTER TABLE` makes a temporary copy of the original table. MySQL waits for other operations that are modifying the table, then proceeds. It incorporates the alteration into the copy, deletes the original table, and renames the new one. While `ALTER TABLE` is executing, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table that begin after the `ALTER TABLE` operation begins are stalled until the new table is ready, then are automatically redirected to the new table without any failed updates. The temporary table is created in the database directory of the new table. This can differ from the database directory of the original table for `ALTER TABLE` operations that rename the table to a different database.

The exception referred to earlier is that `ALTER TABLE` blocks reads (not just writes) at the point where it is ready to install a new version of the table `.frm` file, discard the old file, and clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads (and writes).

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` [513] system variable to a high value.

For some operations, an in-place `ALTER TABLE` is possible that does not require a temporary table:

- For `ALTER TABLE tbl_name RENAME TO new_tbl_name` without any other options, MySQL simply renames any files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See [Section 13.1.26, “RENAME TABLE Syntax”](#).) Any privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- Alterations that modify only table metadata and not table data can be made immediately by altering the table's `.frm` file and not touching table contents. The following changes are fast alterations that can be made this way:

- Renaming a column, except for the [InnoDB](#) storage engine before MySQL 5.6.6.
- Changing the default value of a column.
- Changing the definition of an [ENUM](#) or [SET](#) column by adding new enumeration or set members to the *end* of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a [SET](#) column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this will require a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
- [ALTER TABLE](#) with [ADD PARTITION](#), [DROP PARTITION](#), [COALESCE PARTITION](#), [REBUILD PARTITION](#), or [REORGANIZE PARTITION](#) does not create any temporary tables (except when used with [NDB](#) tables); however, these operations can and do create temporary partition files.

[ADD](#) or [DROP](#) operations for [RANGE](#) or [LIST](#) partitions are immediate operations or nearly so. [ADD](#) or [COALESCE](#) operations for [HASH](#) or [KEY](#) partitions copy data between all partitions, unless [LINEAR HASH](#) or [LINEAR KEY](#) was used; this is effectively the same as creating a new table, although the [ADD](#) or [COALESCE](#) operation is performed partition by partition. [REORGANIZE](#) operations copy only changed partitions and do not touch unchanged ones.

- Renaming an index, except for [InnoDB](#).
- Adding or dropping an index, for [InnoDB](#).

You can force an [ALTER TABLE](#) operation that would otherwise not require a table copy to use the temporary table method (as supported in MySQL 5.0) by setting the `old_alter_table` [517] system variable to `ON`, or specifying `ALGORITHM=COPY` as one of the *alter\_specification* clauses. If there is a conflict between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence. (`ALGORITHM = DEFAULT` is the same as specifying no `ALGORITHM` clause at all.)

Specifying `ALGORITHM=INPLACE` makes the operation use the in-place technique for clauses and storage engines that support it, and fail with an error otherwise, thus avoiding a lengthy table copy if you try altering a table that uses a different storage engine than you expect. See [Section 5.5, “Online DDL for InnoDB Tables”](#) for information about online DDL for [InnoDB](#) tables.

You can control the level of concurrent reading and writing of the table while it is being altered, using the `LOCK` clause. Specifying a non-default value for this clause lets you require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available. The parameters for the `LOCK` clause are:

- `LOCK = DEFAULT`

Maximum level of concurrency for the given `ALGORITHM` clause (if any) and [ALTER TABLE](#) operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- `LOCK = NONE`

If supported, permit concurrent reads and writes. Otherwise, return an error message.

- `LOCK = SHARED`

If supported, permit concurrent reads but block writes. Note that writes will be blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and [ALTER TABLE](#) operation. If concurrent reads are not supported, return an error message.

- `LOCK = EXCLUSIVE`

Enforce exclusive access. This will be done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and [ALTER TABLE](#) operation.

As of MySQL 5.6.3, you can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table. Previously the `FORCE` option was recognized but ignored.

## Usage Notes

- To use `ALTER TABLE`, you need `ALTER` [753], `CREATE` [754], and `INSERT` [755] privileges for the table. Renaming a table requires `ALTER` [753] and `DROP` [754] on the old table, `ALTER` [753], `CREATE` [754], and `INSERT` [755] on the new table.
- `IGNORE` is a MySQL extension to standard SQL. It controls how `ALTER TABLE` works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If `IGNORE` is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If `IGNORE` is specified, only the first row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.
- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
- `table_option` signifies a table option of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, or `AVG_ROW_LENGTH`. (Section 13.1.14, “`CREATE TABLE Syntax`”, lists all table options.) However, `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

For example, to convert a table to be an `InnoDB` table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

See Section 5.4.3, “`Converting Tables from MyISAM to InnoDB`” for considerations when switching tables to the `InnoDB` storage engine.

When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.

The outcome of attempting to change a table's storage engine is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` [605] SQL mode, as described in Section 5.1.7, “`Server SQL Modes`”.

To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.

To change the value of the `AUTO_INCREMENT` counter to be used for new rows, do this:

```
ALTER TABLE t2 AUTO_INCREMENT = value;
```

You cannot reset the counter to a value less than or equal to any that have already been used. For `MyISAM`, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum plus one. For `InnoDB`, *if the value is less than the current maximum value in the column, no error occurs and the current sequence value is not changed.*

- You can issue multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- `CHANGE col_name`, `DROP col_name`, and `DROP INDEX` are MySQL extensions to standard SQL.
- The word `COLUMN` is optional and can be omitted.
- `column_definition` clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. See Section 13.1.14, “`CREATE TABLE Syntax`”.

- You can rename a column using a `CHANGE old_col_name new_col_name column_definition` clause. To do so, specify the old and new column names and the definition that the column currently has. For example, to rename an `INTEGER` column from `a` to `b`, you can do this:

```
ALTER TABLE t1 CHANGE a b INTEGER;
```

To change a column's type but not the name, `CHANGE` syntax still requires an old and new column name, even if they are the same. For example:

```
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
```

You can also use `MODIFY` to change a column's type without renaming it:

```
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
```

`MODIFY` is an extension to `ALTER TABLE` for Oracle compatibility.

When you use `CHANGE` or `MODIFY`, *column\_definition* must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

The resulting column will be defined as `BIGINT`, but will not include the attributes `UNSIGNED DEFAULT 1 COMMENT 'my column'`. To retain them, the statement should be:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

- When you change a data type using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

### Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see [Section 5.1.7, “Server SQL Modes”](#)).

- To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last. You can also use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations to reorder columns within a table.
- `ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in [Section 11.5, “Data Type Default Values”](#).
- `DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 13.1.20, “DROP INDEX Syntax”](#). If you are unsure of the index name, use `SHOW INDEX FROM tbl_name`.
- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` instead.

- `DROP PRIMARY KEY` drops the [primary key](#). If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for [InnoDB](#) tables, see [Section 8.3.2, “Using Primary Keys”](#).

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

- Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see [Section 13.1.11, “CREATE INDEX Syntax”](#). The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. For details about permissible `index_option` values, see [Section 13.1.11, “CREATE INDEX Syntax”](#).

- After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See [Section 13.7.5.23, “SHOW INDEX Syntax”](#).
- `ORDER BY` enables you to create the new table with the rows in a specific order. Note that the table does not remain in this order after inserts and deletes. This option is useful primarily when you know that you are mostly to query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for [InnoDB](#) tables that contain a user-defined clustered index (`PRIMARY KEY` or `NOT NULL UNIQUE` index). [InnoDB](#) always orders table rows according to such an index if one is present.

#### Note

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

- If you use `ALTER TABLE` on a [MyISAM](#) table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

This feature can be activated explicitly for a [MyISAM](#) table. `ALTER TABLE ... DISABLE KEYS` tells MySQL to stop updating nonunique indexes. `ALTER TABLE ... ENABLE KEYS` then should be used to re-create missing indexes. MySQL does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the [INDEX \[755\]](#) privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

- If `ALTER TABLE` for an [InnoDB](#) table results in changes to column values (for example, because a column is truncated), [InnoDB](#)'s `FOREIGN KEY` constraint checks do not notice possible violations caused by changing the values.
- The `FOREIGN KEY` and `REFERENCES` clauses are supported by the [InnoDB](#) storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...)` `REFERENCES ... (...)`. See [Section 5.4.5, “InnoDB and FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 13.1.14, “CREATE TABLE Syntax”](#). The reason for accepting but

ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.8.5, “MySQL Differences from Standard SQL”](#).

For `ALTER TABLE`, unlike `CREATE TABLE, ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...)
```

### Important

The inline `REFERENCES` specifications where the references are defined as part of the column specification are silently ignored by InnoDB. InnoDB only accepts `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

### Note

Partitioned InnoDB tables do not support foreign keys. See [Section 17.6.2, “Partitioning Limitations Relating to Storage Engines”](#), for more information.

- InnoDB supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

For more information, see [Section 5.4.5, “InnoDB and FOREIGN KEY Constraints”](#).

- You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. You must use separate statements.
- For an InnoDB table that is created with its own tablespace in an `.ibd` file, that file can be discarded and imported. To discard the `.ibd` file, use this statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

This deletes the current `.ibd` file, so be sure that you have a backup first. Attempting to modify the table contents while the tablespace file is discarded results in an error. You can perform the DDL operations listed in [Section 5.5, “Online DDL for InnoDB Tables”](#) while the tablespace file is discarded.

To import the backup `.ibd` file back into the table, copy it into the database directory, and then issue this statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

The tablespace file need not necessarily have been created on the server into which it is imported later. In MySQL 5.6, importing a tablespace file from another server works if the both servers have GA (General Availability) status and their versions are within the same series. Otherwise, the file must have been created on the server into which it is imported.

See [Section 5.4.1, “Managing InnoDB Tablespaces”](#).

- To change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

For a column that has a data type of `VARCHAR` or one of the `TEXT` types, `CONVERT TO CHARACTER SET` will change the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a `TEXT` column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a `latin1 TEXT` column, each character requires a single byte, so the column can store up to 65,535 characters. If

the column is converted to `utf8`, each character might require up to three bytes, for a maximum possible length of  $3 \times 65,535 = 196,605$  bytes. That length will not fit in a `TEXT` column's length bytes, so MySQL will convert the data type to `MEDIUMTEXT`, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a `VARCHAR` column might be converted to `MEDIUMTEXT`.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

If `charset_name` is `DEFAULT`, the database character set is used.

### Warning

The `CONVERT TO` operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`, and (when `IGNORE` is used) how many rows were deleted due to duplication of unique key values. See [Section 21.8.6.35](#), “`mysql_info()`”.

### 13.1.6.1. ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, for adding, dropping, merging, and splitting partitions, and for performing partitioning maintenance.

- Simply using a `partition_options` clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the `partition_options`. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the `partition_options` clause for `CREATE TABLE` (see [Section 13.1.14](#), “`CREATE TABLE Syntax`”, for more detailed information), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
PARTITION BY HASH(id)
PARTITIONS 8;
```

MySQL 5.6.11 and later supports an `ALGORITHM` option with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a `KEY` partitioned table that was created in MySQL 5.1, first execute `SHOW CREATE TABLE` and note the the exact columns and number of partitions shown. Now execute an `ALTER TABLE` statement using exactly the same column list and number of partitions as in the `CREATE TABLE` statement, while adding `ALGORITHM=2` immediately following the `PARTITION BY` keywords. (You should also include the `LINEAR` keyword if it was used for the original table definition.) An example from a session in the `mysql` client is shown here:

```
mysql> SHOW CREATE TABLE p\G
***** 1. row *****
Table: p

```

Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use `ALGORITHM=1` to force the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved `KEY` hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

#### Note

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1

server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Section 17.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See [Section 13.1.14, “CREATE TABLE Syntax”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than 2002 as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

Renames of partitioned table are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation makes a copy of the partition's data..

In MySQL 5.6, it is possible to delete rows from selected partitions using the `TRUNCATE PARTITION` option. This option takes a comma-separated list of one or more partition names. For example, consider the table `t1` as defined here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2003),
  PARTITION p4 VALUES LESS THAN (2007)
);
```

To delete all rows from partition `p0`, you can use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex [WHERE](#) conditions if done with [DELETE](#) statements. For example, this statement deletes all rows from partitions [p1](#) and [p3](#):

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent [DELETE](#) statement is shown here:

```
DELETE FROM t1 WHERE
  (year_col >= 1991 AND year_col < 1995)
  OR
  (year_col >= 2003 AND year_col < 2007);
```

You can also use the [ALL](#) keyword in place of the list of partition names; in this case, the statement acts on all partitions in the table.

[TRUNCATE PARTITION](#) merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

#### Note

[TRUNCATE PARTITION](#) does not work with subpartitions.

You can verify that the rows were dropped by checking the [INFORMATION\\_SCHEMA.PARTITIONS](#) table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_NAME = 't1';
```

[TRUNCATE PARTITION](#) is supported only for partitioned tables that use the [MyISAM](#), [InnoDB](#), or [MEMORY](#) storage engine. It also works on [BLACKHOLE](#) tables (but has no effect). It is not supported for [ARCHIVE](#) tables.

[COALESCE PARTITION](#) can be used with a table that is partitioned by [HASH](#) or [KEY](#) to reduce the number of partitions by *number*. Suppose that you have created table [t2](#) using the following definition:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

You can reduce the number of partitions used by [t2](#) from 6 to 4 using the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use [REORGANIZE PARTITION](#). This statement can be used in several ways:

- To merge a set of partitions into a single partition. This can be done by naming several partitions in the *partition\_names* list and supplying a single definition for *partition\_definition*.

- To split an existing partition into several partitions. You can accomplish this by naming a single partition for *partition\_names* and providing multiple *partition\_definitions*.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.

### Note

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see [Section 17.3.1, “Management of RANGE and LIST Partitions”](#).

- It is also possible in MySQL 5.6 to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where *pt* is the partitioned table and *p* is the partition or subpartition of *pt* to be exchanged with unpartitioned table *nt*, provided that the following statements are true:
  1. Table *nt* is not itself partitioned.
  2. Table *nt* is not a temporary table.
  3. The structures of tables *pt* and *nt* are otherwise identical.
  4. There are no rows in *nt* that lie outside the boundaries of the partition definition for *p*.
  5. Table *nt* contains no foreign key references, and no other table has any foreign keys that refer to *nt*.

Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.

Any `AUTO_INCREMENT` columns in the table to be exchanged with a partition are reset.

The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

For more information about and examples of `ALTER TABLE ... EXCHANGE PARTITION`, see [Section 17.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

- Several additional options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; see [Section 13.7.2, “Table Maintenance Statements”](#) for more information). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a *partition\_names* clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. You can also use the `ALL` keyword in place of *partition\_names*, in which case the statement acts on all partitions in the table. For more information and examples, see [Section 17.3.4, “Maintenance of Partitions”](#).

Some MySQL storage engines, such as `InnoDB`, do not support per-partition optimization. For a partitioned table using such a storage engine, `ALTER TABLE ... OPTIMIZE PARTITION` rebuilds the entire table. This is a known issue. (Bug #42822) Beginning with MySQL 5.6.9, running this statement on such a table causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825)

To work around this problem, use the statements `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not permitted for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename drop columns or indexes.
- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning.

Prior to MySQL 5.6.6, when `ALTER TABLE ... EXCHANGE PARTITION` or `ALTER TABLE ... TRUNCATE PARTITION` was run against a partitioned table that used `MyISAM` (or another storage engine that makes use of table-level locking), the entire partitioned table was locked; in MySQL 5.6.6 and later, in such cases, only those partitions that are actually read from are locked. This did not (and does not) affect partitioned tables using a storage engine—such as `InnoDB`—that employs row-level locking. See [Section 17.6.4, “Partitioning and Locking”](#).

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITION` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITION` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see [Section 13.1.6.1, “ALTER TABLE Partition Operations”](#).

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

### 13.1.6.2. ALTER TABLE Examples

Begin with a table `t1` that is created as shown here:

```
CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See [Section 5.1.4, “Server System Variables”](#).

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

### Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

## 13.1.7. ALTER VIEW Syntax

```
ALTER
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
```

```
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for [CREATE VIEW](#) and the effect is the same as for [CREATE OR REPLACE VIEW](#). See [Section 13.1.16, “CREATE VIEW Syntax”](#). This statement requires the [CREATE VIEW \[754\]](#) and [DROP \[754\]](#) privileges for the view, and some privilege for each column referred to in the [SELECT](#) statement. [ALTER VIEW](#) is permitted only to the definer or users with the [SUPER \[756\]](#) privilege.

### 13.1.8. CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
  [create_specification] ...
```

```
create_specification:
  [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
```

[CREATE DATABASE](#) creates a database with the given name. To use this statement, you need the [CREATE \[754\]](#) privilege for the database. [CREATE SCHEMA](#) is a synonym for [CREATE DATABASE](#).

An error occurs if the database exists and you did not specify [IF NOT EXISTS](#).

In MySQL 5.6, [CREATE DATABASE](#) is not permitted within a session that has an active [LOCK TABLES](#) statement.

*create\_specification* options specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The [CHARACTER SET](#) clause specifies the default database character set. The [COLLATE](#) clause specifies the default database collation. [Section 10.1, “Character Set Support”](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the [CREATE DATABASE](#) statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for permissible database names are given in [Section 9.2, “Schema Object Names”](#). If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of [SHOW DATABASES](#).

You can also use the `mysqladmin` program to create databases. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

### 13.1.9. CREATE EVENT Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  DO event_body;

schedule:
  AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
  [STARTS timestamp [+ INTERVAL interval] ...]
  [ENDS timestamp [+ INTERVAL interval] ...]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
            WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
```

```
DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see [Section 18.4.2, “Event Scheduler Configuration”](#).

`CREATE EVENT` requires the `EVENT [754]` privilege for the schema in which the event is to be created. It might also require the `SUPER [756]` privilege, depending on the `DEFINER` value, as described later in this section.

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 9.2, “Schema Object Names”](#).

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER [1267]`, or `CURRENT_USER() [1267]`. The default `DEFINER` value is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER [756]` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER [1267]`. You cannot set the definer to some other account.
- If you have the `SUPER [756]` privilege, you can specify any syntactically valid account name. If the account does not actually exist, a warning is generated.
- Although it is possible to create an event with a nonexistent `DEFINER` account, an error occurs at event execution time if the account does not exist.

For more information about event security, see [Section 18.6, “Access Control for Stored Programs and Views”](#).

Within an event, the `CURRENT_USER() [1267]` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see [Section 6.3.12, “SQL-Based MySQL Account Activity Auditing”](#).

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
->     ON SCHEDULE AT '2006-02-10 23:59:00'
->     DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
PRESERVE is set. The event was dropped immediately after
creation.
```

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.

You may use `CURRENT_TIMESTAMP` [1213] to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The `interval` portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the `DATE_ADD()` [1213] function (see Section 12.7, “Date and Time Functions”). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an `interval` as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a `timestamp` value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15'`

`HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a *timestamp* value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` [1275] function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` [557] value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the `mysql.event` table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see Section 18.4.4, “Event Metadata”. See also Section 13.7.5.19, “SHOW EVENTS Syntax”, and Section 19.7, “The INFORMATION\_SCHEMA EVENTS Table”.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the `DISABLE` keyword. Alternatively, you can use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see Section 13.1.2, “ALTER EVENT Syntax”).

A third value may also appear in place of `ENABLED` or `DISABLED`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See Section 16.4.1.10, “Replication of Invoked Features”.

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section E.1, “Restrictions on Stored Programs”.) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
EVERY 1 HOUR
```

```
COMMENT 'Clears out sessions table each hour.'
DO
DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` [545] system variable setting that is in effect at the time an event is created, and always executes the event with this setting in force, *regardless of the current server SQL mode*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

### Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |
CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See [Section 18.1, “Defining Stored Programs”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |
CREATE EVENT e
ON SCHEDULE
EVERY 5 SECOND
DO
BEGIN
DECLARE v INTEGER;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

SET v = 0;

WHILE v < 5 DO
INSERT INTO t1 VALUES (0);
UPDATE t2 SET s1 = s1 + 1;
SET v = v + 1;
END WHILE;
END |
delimiter ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```
CREATE EVENT e_call_myproc
  ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO CALL myproc(5, 27);
```

If an event's definer has the [SUPER \[756\]](#) privilege, the event can read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see [Section 18.2.1, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

### 13.1.10. CREATE FUNCTION Syntax

The `CREATE FUNCTION` statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see [Section 13.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).
- For information about creating user-defined functions, see [Section 13.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”](#).

### 13.1.11. CREATE INDEX Syntax

```
CREATE [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
  [index_type]
  ON tbl_name (index_col_name,...)
  [algorithm_option | lock_option] ...

index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH}

index_option:
  KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'

algorithm_option:
  ALGORITHM [=] {DEFAULT|INPLACE|COPY}

lock_option:
  LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 13.1.6, “ALTER TABLE Syntax”](#). `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 13.1.14, “CREATE TABLE Syntax”](#). This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

A column list of the form `(col1,col2,...)` creates a multiple-column index. Index key values are formed by concatenating the values of the given columns.

Indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns.
- `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given.
- Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first *length* bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns.
- For spatial columns, prefix values cannot be given, as described later in this section.

The statement shown here creates an index using the first 10 characters of the `name` column:

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 1000 bytes long for `MyISAM` tables, and 767 bytes for `InnoDB` tables.

#### Note

Prefix limits are measured in bytes, whereas the prefix length in `CREATE INDEX` statements is interpreted as number of characters for nonbinary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix.

`FULLTEXT` indexes are supported only for `InnoDB` and `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation.

The `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` storage engines support spatial columns such as (`POINT` and `GEOMETRY`). ([Section 12.18, “Spatial Extensions”](#), describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes are available according to the following rules.

Spatial indexes (created using `SPATIAL INDEX`) have these characteristics:

- Available only for `MyISAM` tables. Specifying `SPATIAL INDEX` for other storage engines results in an error.
- Indexed columns must be `NOT NULL`.
- In MySQL 5.6, column prefix lengths are prohibited. The full width of each column is indexed.

Characteristics of nonspatial indexes (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`):

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.

- The index type for a non-*SPATIAL* index depends on the storage engine. Currently, B-tree is used.

In MySQL 5.6:

- You can add an index on a column that can have *NULL* values only if you are using the *InnoDB*, *MyISAM*, or *MEMORY* storage engine.
- You can add an index on a *BLOB* or *TEXT* column only if you are using the *InnoDB* or *MyISAM* storage engine.
- When the `innodb_stats_persistent` [1747] setting is enabled, run the `ANALYZE TABLE` statement for an *InnoDB* table after creating an index on that table.

An *index\_col\_name* specification can end with *ASC* or *DESC*. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

Following the index column list, index options can be given. An *index\_option* value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

For *compressed* *InnoDB* tables, optionally specifies the size in bytes to use for *pages*. The value is treated as a hint; a different size could be used if necessary. A value of 0 represents the default compressed page size. See [Section 5.4.6, “Working with InnoDB Compressed Tables”](#) for usage details.

#### Note

Oracle recommends enabling `innodb_strict_mode` [1749] when using the `KEY_BLOCK_SIZE` clause for *InnoDB* tables. See [Section 14.2.5.7, “InnoDB Strict Mode”](#) for details.

- *index\_type*

Some storage engines permit you to specify an index type when creating an index. The permissible index type values supported by different storage engines are shown in the following table. Where multiple index types are listed, the first one is the default when no index type specifier is given.

Storage Engine	Permissible Index Types
<i>InnoDB</i>	<i>BTREE</i>
<i>MyISAM</i>	<i>BTREE</i>
<i>MEMORY/HEAP</i>	<i>HASH</i> , <i>BTREE</i>
<i>NDB</i>	<i>HASH</i> , <i>BTREE</i> (see note in text)

Example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

The *index\_type* clause cannot be used together with *SPATIAL INDEX*.

If you specify an index type that is not valid for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes *RTREE* as a type name, but currently this cannot be specified for any storage engine.

Use of this option before the `ON tbl_name` clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an *index\_type* option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

- `WITH PARSER parser_name`

This option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. See [Section 22.2, “The MySQL Plugin API”](#), for details on creating plugins.

- `COMMENT 'string'`

Index definitions can include an optional comment of up to 1024 characters.

As of MySQL 5.6.6, the `ALGORITHM` and `LOCK` clauses may be given. These influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 13.1.6, “ALTER TABLE Syntax”](#)

### 13.1.12. CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  PROCEDURE sp_name ([proc_parameter[,...]])
  [characteristic ...] routine_body

CREATE
  [DEFINER = { user | CURRENT_USER }]
  FUNCTION sp_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
  Any valid MySQL data type

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See [Section 22.3, “Adding New Functions to MySQL”](#). A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see [Section 13.2.1, “CALL Syntax”](#)). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE [754]` privilege. They might also require the `SUPER [756]` privilege, depending on the `DEFINER` value, as described later in

this section. If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` [756] privilege, as described in [Section 18.7, “Binary Logging of Stored Programs”](#).

By default, MySQL automatically grants the `ALTER ROUTINE` [754] and `EXECUTE` [754] privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` [464] system variable. See [Section 18.2.2, “Stored Routines and MySQL Privileges”](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` [604] SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` [604] is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

#### Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

Routine parameters cannot be referenced in statements prepared within the routine; see [Section E.1, “Restrictions on Stored Programs”](#).

The following example shows a simple stored procedure that uses an `OUT` parameter:

```
mysql> delimiter //
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |
+-----+
| 3     |
```

```
+-----+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See [Section 18.1, “Defining Stored Programs”](#).

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by the `CHARACTER SET` attribute.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in [Section 13.6, “MySQL Compound-Statement Syntax”](#).

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET [3687]`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT [3680]`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see [Section E.1, “Restrictions on Stored Programs”](#).

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 13.2.1, “CALL Syntax”](#).

MySQL stores the `sql_mode` [545] system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, *regardless of the server SQL mode in effect when the routine is invoked*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See [Section 18.7, “Binary Logging of Stored Programs”](#).

A routine that contains the `NOW()` [1220] function (or its synonyms) or `RAND()` [1206] is nondeterministic, but it might still be replication-safe. For `NOW()` [1220], the binary log includes the timestamp and replicates correctly. `RAND()` [1206] also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` [754] privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER` [1267], or `CURRENT_USER()` [1267]. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` or statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` [756] privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER` [1267]. You cannot set the definer to some other account.
- If you have the `SUPER` [756] privilege, you can specify any syntactically valid account name. If the account does not actually exist, a warning is generated.
- Although it is possible to create a routine with a nonexistent `DEFINER` account, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about stored routine security, see [Section 18.6, “Access Control for Stored Programs and Views”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` [1267] returns the routine's `DEFINER` value. For information about user auditing within stored routines, see [Section 6.3.12, “SQL-Based MySQL Account Activity Auditing”](#).

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` [754] privilege for it and `'admin'@'localhost'` has the `SELECT` [755] privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` [754] privilege for it and the `SELECT` [755] privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.

- For character data types, if there is a `CHARACTER SET` attribute in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation. If there is no `CHARACTER SET` attribute, the database character set and collation in effect at routine creation time are used. (The database character set and collation are given by the value of the `character_set_database` [468] and `collation_database` [469] system variables.)

If you change the database default character set or collation, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults.

### 13.1.13. CREATE SERVER Syntax

```
CREATE SERVER server_name
  FOREIGN DATA WRAPPER wrapper_name
  OPTIONS (option [, option] ...)

option:
{ HOST character-literal
  | DATABASE character-literal
  | USER character-literal
  | PASSWORD character-literal
  | SOCKET character-literal
  | OWNER character-literal
  | PORT numeric-literal }
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` [756] privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` should be `mysql`, and may be quoted with single quotation marks. Other values for `wrapper_name` are not currently supported.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

#### Note

The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
  FOREIGN DATA WRAPPER mysql
  OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 14.9, “The FEDERATED Storage Engine”](#).

`CREATE SERVER` causes an automatic commit.

In MySQL 5.6, `CREATE SERVER` is not written to the binary log, regardless of the logging format that is in use.

Beginning with MySQL 5.6.11, `gtid_next` [2022] must be set to `AUTOMATIC` before issuing this statement (BUG#16062608).

### 13.1.14. CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  (create_definition,...)
  [table_options]
  [partition_options]
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  [(create_definition,...)]
  [table_options]
  [partition_options]
  select_statement
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  { LIKE old_tbl_name | (LIKE old_tbl_name) }
```

```
create_definition:
  col_name column_definition
  | [CONSTRAINT [symbol]] PRIMARY KEY [index_type] (index_col_name,...)
    [index_option] ...
  | {INDEX|KEY} [index_name] [index_type] (index_col_name,...)
    [index_option] ...
  | [CONSTRAINT [symbol]] UNIQUE [INDEX|KEY]
    [index_name] [index_type] (index_col_name,...)

```

`CREATE TABLE` creates a table with the given name. You must have the `CREATE [754]` privilege for the table.

Rules for permissible table names are given in [Section 9.2, “Schema Object Names”](#). By default, the table is created in the default database, using the `InnoDB` storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

The table name can be specified as `db_name.tbl_name` to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

## Temporary Tables

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only to the current connection, and is dropped automatically when the connection is closed. This means that two different connections can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.) To create temporary tables, you must have the `CREATE TEMPORARY TABLES [754]` privilege.

### Note

`CREATE TABLE` does not automatically commit the current active transaction if you use the `TEMPORARY` keyword.

## Existing Table with Same Name

The keywords `IF NOT EXISTS` prevent an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

## Physical Representation

MySQL represents each table by an `.frm` table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For `InnoDB` tables, the file storage is controlled by the `innodb_file_per_table` [1718] configuration option. When this option is turned off, all `InnoDB` tables and indexes are stored in the `system tablespace`, represented by one or more `.ibd` files. For each `InnoDB` table created when this option is turned on, the table data and all associated indexes are stored in a `.ibd` file located inside the database directory.

For `MyISAM` tables, the storage engine creates data and index files. Thus, for each `MyISAM` table `tbl_name`, there are three disk files.

File	Purpose
<code>tbl_name.frm</code>	Table format (definition) file
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Chapter 14, *Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.3, “Mapping of Identifiers to File Names”.

## Data Types and Attributes for Columns

`data_type` represents the data type in a column definition. `spatial_type` represents a spatial data type. The data type syntax shown is representative only. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 11, *Data Types*, and Section 12.18, “Spatial Extensions”.

Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. `DEFAULT` does not apply to the `BLOB` or `TEXT` types.

- If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.
- An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` [1269] SQL function or the `mysql_insert_id()` C API function. See Section 12.14, “Information Functions”, and Section 21.8.6.37, “`mysql_insert_id()`”.

If the `NO_AUTO_VALUE_ON_ZERO` [604] SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See Section 5.1.7, “Server SQL Modes”.

### Note

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative

number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains 0.

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See [Section 3.6.9, “Using AUTO\\_INCREMENT”](#).

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

For information about `InnoDB` and `AUTO_INCREMENT`, see [Section 5.4.4, “AUTO\\_INCREMENT Handling in InnoDB”](#). For information about `AUTO_INCREMENT` and MySQL Replication, see [Section 16.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- Character data types (`CHAR`, `VARCHAR`, `TEXT`) can include `CHARACTER SET` and `COLLATE` attributes to specify the character set and collation for the column. For details, see [Section 10.1, “Character Set Support”](#). `CHARSET` is a synonym for `CHARACTER SET`. Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.6 interprets length specifications in character column definitions in characters. (Versions before MySQL 4.1 interpreted them in bytes.) Lengths for `BINARY` and `VARBINARY` are in bytes.

- The `DEFAULT` clause specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` [1220] or `CURRENT_DATE` [1212]. The exception is that you can specify `CURRENT_TIMESTAMP` [1213] as the default for a `TIMESTAMP` or (as of MySQL 5.6.5) `DATETIME` column. See [Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as described in [Section 11.5, “Data Type Default Values”](#).

`BLOB` and `TEXT` columns cannot be assigned a default value.

If the `NO_ZERO_DATE` [606] or `NO_ZERO_IN_DATE` [606] SQL mode is enabled and a date-valued default is not correct according to that mode, `CREATE TABLE` produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with `NO_ZERO_IN_DATE` [606] enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning. (Before MySQL 5.6.6, the statement produces an error even if strict mode is not enabled.)

- A comment for a column can be specified with the `COMMENT` option, up to 1024 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements.
- `KEY` is normally a synonym for `INDEX`. The key attribute `PRIMARY KEY` can also be specified as just `KEY` when given in a column definition. This was implemented for compatibility with other database systems.
- A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`.
- A `PRIMARY KEY` is a unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. The name of a `PRIMARY KEY` is always `PRIMARY`, which thus cannot be used as the name for any other kind of index.

If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

In `InnoDB` tables, keep the `PRIMARY KEY` short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See [Section 14.2.3.12](#), “`InnoDB Table and Index Structures`”.)

- In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.
- A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(index_col_name, ...)` clause.
- If a `PRIMARY KEY` or `UNIQUE` index consists of only one column that has an integer type, you can also refer to the column as `_rowid` in `SELECT` statements.
- In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2, _3, ...`) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 13.7.5.23](#), “`SHOW INDEX Syntax`”.
- Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`.

Example:

```
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for `USING` is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. For details about permissible `index_option` values, see [Section 13.1.11](#), “`CREATE INDEX Syntax`”.

For more information about indexes, see [Section 8.3.1](#), “`How MySQL Uses Indexes`”.

- In MySQL 5.6, only the `InnoDB`, `MyISAM`, and `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.
- For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. See [Section 8.3.4](#), “`Column Indexes`”.

Only the `InnoDB` and `MyISAM` storage engines support indexing on `BLOB` and `TEXT` columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for `InnoDB` tables). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters for nonbinary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

- An *index\_col\_name* specification can end with `ASC` or `DESC`. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.
- When you use `ORDER BY` or `GROUP BY` on a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length [508]` system variable.
- You can create special `FULLTEXT` indexes, which are used for full-text searches. Only the `InnoDB` and `MyISAM` storage engines support `FULLTEXT` indexes. They can be created only from `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation. A `WITH PARSER` clause can be specified as an *index\_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for `FULLTEXT` indexes. See [Section 22.2, “The MySQL Plugin API”](#), for details on creating plugins.
- You can create `SPATIAL` indexes on spatial data types. Spatial types are supported only for `MyISAM` tables and indexed columns must be declared as `NOT NULL`. See [Section 12.18, “Spatial Extensions”](#).
- In MySQL 5.6, index definitions can include an optional comment of up to 1024 characters.
- `InnoDB` tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys. For more detailed information and examples, see [Section 13.1.14.2, “Using FOREIGN KEY Constraints”](#). For information specific to foreign keys in `InnoDB`, see [Section 5.4.5, “InnoDB and FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 1.8.5.4, “Foreign Key Differences”](#).

### Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. `InnoDB` essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, `InnoDB` does not enforce any requirement that the referenced columns be declared `UNIQUE` or `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only keys that are both `UNIQUE` (or `PRIMARY`) and `NOT NULL`.

MySQL does not recognize or support “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of

the column specification. MySQL accepts [REFERENCES](#) clauses only when specified as part of a separate [FOREIGN KEY](#) specification.

#### Note

Partitioned tables employing the [InnoDB](#) storage engine do not support foreign keys. See [Section 17.6, “Restrictions and Limitations on Partitioning”](#), for more information.

- There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section E.10.4, “Limits on Table Column Count and Row Size”](#).

## Storage Engines

The [ENGINE](#) table option specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name 'DEFAULT' is recognized but ignored.

Storage Engine	Description
<a href="#">InnoDB</a>	Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See <a href="#">Section 14.2, “The InnoDB Storage Engine”</a> , and in particular <a href="#">Section 14.2.1.1, “InnoDB as the Default MySQL Storage Engine”</a> if you have MySQL experience but are new to <a href="#">InnoDB</a> .
<a href="#">MyISAM</a>	The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See <a href="#">Section 14.3, “The MyISAM Storage Engine”</a> .
<a href="#">MEMORY</a>	The data for this storage engine is stored only in memory. See <a href="#">Section 14.4, “The MEMORY Storage Engine”</a> .
<a href="#">CSV</a>	Tables that store rows in comma-separated values format. See <a href="#">Section 14.5, “The CSV Storage Engine”</a> .
<a href="#">ARCHIVE</a>	The archiving storage engine. See <a href="#">Section 14.6, “The ARCHIVE Storage Engine”</a> .
<a href="#">EXAMPLE</a>	An example engine. See <a href="#">Section 14.10, “The EXAMPLE Storage Engine”</a> .
<a href="#">FEDERATED</a>	Storage engine that accesses remote tables. See <a href="#">Section 14.9, “The FEDERATED Storage Engine”</a> .
<a href="#">HEAP</a>	This is a synonym for <a href="#">MEMORY</a> .
<a href="#">MERGE</a>	A collection of <a href="#">MyISAM</a> tables used as one table. Also known as <a href="#">MRG_MyISAM</a> . See <a href="#">Section 14.8, “The MERGE Storage Engine”</a> .

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is [MyISAM](#). For example, if a table definition includes the [ENGINE=INNODB](#) option but the MySQL server does not support [INNODB](#) tables, the table is created as a [MyISAM](#) table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are nontransactional (to get more speed). In MySQL 5.6, a warning occurs if the storage engine specification is not honored.

Engine substitution can be controlled by the setting of the [NO\\_ENGINE\\_SUBSTITUTION \[605\]](#) SQL mode, as described in [Section 5.1.7, “Server SQL Modes”](#).

#### Note

The older [TYPE](#) option that was synonymous with [ENGINE](#) was removed in MySQL 5.5. *When upgrading to MySQL 5.5 or later, you must convert existing applications that rely on [TYPE](#) to use [ENGINE](#) instead.*

## Optimizing Performance

The other table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `AUTO_INCREMENT`

The initial `AUTO_INCREMENT` value for the table. In MySQL 5.6, this works for `MyISAM`, `MEMORY`, `InnoDB`, and `ARCHIVE` tables. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- `AVG_ROW_LENGTH`

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a `MyISAM` table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for `MyISAM` data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` [511] system variable. (See [Section 5.1.4, “Server System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- `[DEFAULT] CHARACTER SET`

Specify a default character set for the table. `CHARSET` is a synonym for `CHARACTER SET`. If the character set name is `DEFAULT`, the database character set is used.

- `CHECKSUM`

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (`MyISAM` only.)

- `[DEFAULT] COLLATE`

Specify a default collation for the table.

- `COMMENT`

A comment for the table, up to 2048 characters long.

- `CONNECTION`

The connection string for a `FEDERATED` table.

**Note**

Older versions of MySQL used a `COMMENT` option for the connection string.

- `DATA DIRECTORY`, `INDEX DIRECTORY`

By using `DATA DIRECTORY='directory'`, you can specify where the InnoDB storage engine puts the `.ibd` tablespace file for a new table. This clause only applies when the `innodb_file_per_table` [1718] configuration option is enabled. The directory must be the full path name to the directory, not a relative path. See [Section 14.2.4.2.34, “Improved Tablespace Management”](#) for details about the performance aspects of tablespace management.

When creating MyISAM tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a MyISAM table's data file and index file respectively.

**Important**

Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` [441] option. Your operating system must also have a working, thread-safe `realpath()` call. See [Section 8.11.3.1.2, “Using Symbolic Links for MyISAM Tables on Unix”](#), for more complete information.

If a MyISAM table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if MyISAM finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the server with the `--keep_files_on_create` [491] option, in which case MyISAM will not overwrite existing files and returns an error instead.

If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It will not overwrite a file in the specified directory.

**Important**

You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- `DELAY_KEY_WRITE`

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` [475] system variable in [Section 5.1.4, “Server System Variables”](#). (MyISAM only.)

- `INSERT_METHOD`

If you want to insert data into a MERGE table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for MERGE tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See [Section 14.8, “The MERGE Storage Engine”](#).

- `KEY_BLOCK_SIZE`

For compressed InnoDB tables, optionally specifies the size in bytes to use for pages. The value is treated as a hint; a different size could be used if necessary. A value of 0 represents that the default compressed page size. See [Section 5.4.6, “Working with InnoDB Compressed Tables”](#) for usage details.

Individual index definitions can specify a `KEY_BLOCK_SIZE` value of their own to override the table value.

### Note

Oracle recommends enabling `innodb_strict_mode` [1749] when using the `KEY_BLOCK_SIZE` clause for InnoDB tables. See Section 14.2.5.7, “InnoDB Strict Mode” for details.

- `MAX_ROWS`

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- `PACK_KEYS`

`PACK_KEYS` takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

- `ROW_FORMAT`

Defines the physical format in which the rows are stored. The choices differ depending on the storage engine used for the table.

For `InnoDB` tables:

- Rows are stored in compact format (`ROW_FORMAT=COMPACT`) by default.

- The noncompact format used in older versions of MySQL can still be requested by specifying `ROW_FORMAT=REDUNDANT`.
- To enable compression for InnoDB tables, specify `ROW_FORMAT=COMPRESSED` and follow the procedures in [Section 5.4.6, “Working with InnoDB Compressed Tables”](#).
- For more efficient InnoDB storage of data types, especially BLOB types, specify `ROW_FORMAT=DYNAMIC` and follow the procedures in [Section 5.4.8.3, “DYNAMIC and COMPRESSED Row Formats”](#). Both the `COMPRESSED` and `DYNAMIC` row formats require creating the table with the configuration settings `innodb_file_per_table=1` [1718] and `innodb_file_format=barracuda` [1716].
- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` [1749] configuration option. See [Section 14.2.5.7, “InnoDB Strict Mode”](#) for details.

For MyISAM tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 14.3.3, “MyISAM Table Storage Formats”](#).

#### Note

When executing a `CREATE TABLE` statement, if you specify a row format that is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The information reported in this column in response to `SHOW TABLE STATUS` is the actual row format used. This may differ from the value in the `Create_options` column because the original `CREATE TABLE` definition is retained during creation.

- `STATS_AUTO_RECALC`

Specifies whether to automatically recalculate [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` [1746] configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see [Section 14.2.4.2.10, “Persistent Optimizer Statistics for InnoDB Tables”](#).

- `STATS_PERSISTENT`

Specifies whether to enable [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` [1747] configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see [Section 14.2.4.2.10, “Persistent Optimizer Statistics for InnoDB Tables”](#).

- `UNION`

`UNION` is used when you want to access a collection of identical MyISAM tables as one. This works only with `MERGE` tables. See [Section 14.8, “The MERGE Storage Engine”](#).

You must have `SELECT` [755], `UPDATE` [756], and `DELETE` [754] privileges for the tables you map to a `MERGE` table.

**Note**

Formerly, all tables used had to be in the same database as the `MERGE` table itself. This restriction no longer applies.

**Partitioning**

`partition_options` can be used to control partitioning of the table created with `CREATE TABLE`.

**Important**

Not all options shown in the syntax for `partition_options` at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 17, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

If used, a `partition_options` clause begins with `PARTITION BY`. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to `num`, where `num` is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.) The choices that are available for this function in MySQL 5.6 are shown in the following list:

- `HASH(expr)`: Hashes one or more columns to create a key for placing and locating rows. *expr* is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
  PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
  PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

`PARTITION BY HASH` uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 17.2.4, “HASH Partitioning”](#).

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND [1171]` operations. For discussion and examples of linear hashing, see [Section 17.2.4.1, “LINEAR HASH Partitioning”](#).

- `KEY(column_list)`: This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column\_list* argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY KEY(col3)
  PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `& [1258]` operator rather than the modulus (see [Section 17.2.4.1, “LINEAR HASH Partitioning”](#), and [Section 17.2.5, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY LINEAR KEY(col3)
  PARTITIONS 5;
```

The `ALGORITHM={1|2}` option is supported with `[SUB]PARTITION BY [LINEAR] KEY` beginning with MySQL 5.6.11. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see [Section 13.1.6.1, “ALTER TABLE Partition Operations”](#).

`mysqldump` in MySQL 5.6.11 and later writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50611 ALGORITHM = 1 */ /*!50100 ()
PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.5.31 or later MySQL 5.5 server where you use tables that are partitioned or subpartitioned by `KEY` into a MySQL 5.6 server previous to version 5.6.11, be sure to consult [Section 2.11.1.1, “Upgrading from MySQL 5.5 to 5.6”](#), before proceeding. (The information found there also applies if you are loading a dump containing `KEY` partitioned or subpartitioned tables made from a MySQL 5.6.11 or later server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- `RANGE(expr)`: In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

#### Note

For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 5.6, you can overcome this limitation in a table that is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

Partition Number:	Years Range:
0	1990 and earlier
1	1991 to 1994
2	1995 to 1998
3	1999 to 2002
4	2003 to 2005
5	2006 and later

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

Note that `VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- `RANGE COLUMNS(column_list)`: This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...` You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (
  a INT NOT NULL,
  b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (10,5),
  PARTITION p1 VALUES LESS THAN (20,10),
  PARTITION p2 VALUES LESS THAN (MAXVALUE,15),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see [Section 17.2.1, “RANGE Partitioning”](#), and [Section 17.4, “Partition Pruning”](#).

- **LIST(*expr*)**: This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to **RANGE**, except that only **VALUES IN** may be used to specify permissible values for each partition.

**VALUES IN** is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using **VALUES IN**. You cannot use **VALUES LESS THAN** with **PARTITION BY LIST**.

#### Note

For tables partitioned by **LIST**, the value list used with **VALUES IN** must consist of integer values only. In MySQL 5.6, you can overcome this limitation using partitioning by **LIST COLUMNS**, which is described later in this section.

- **LIST COLUMNS(*column\_list*)**: This variant on **LIST** facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as **WHERE a = 5 AND b = 5** or **WHERE a = 1 AND b = 10 AND c = 5**). It enables you to specify values in multiple columns by using a list of columns in the **COLUMNS** clause and a set of column values in each **PARTITION ... VALUES IN (*value\_list*)** partition definition clause.

The rules governing regarding data types for the column list used in **LIST COLUMNS(*column\_list*)** and the value list used in **VALUES IN(*value\_list*)** are the same as those for the column list used in **RANGE COLUMNS(*column\_list*)** and the value list used in **VALUES LESS THAN(*value\_list*)**, respectively, except that in the **VALUES IN** clause, **MAXVALUE** is not permitted, and you may use **NULL**.

There is one important difference between the list of values used for **VALUES IN** with **PARTITION BY LIST COLUMNS** as opposed to when it is used with **PARTITION BY LIST**. When used with **PARTITION BY LIST COLUMNS**, each element in the **VALUES IN** clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the **COLUMNS** clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the *column\_list* and in the elements making up the *value\_list* is 16.

The table defined by the following **CREATE TABLE** statement provides an example of a table using **LIST COLUMNS** partitioning:

```
CREATE TABLE lc (
  a INT NULL,
  b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
```

```
PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- The number of partitions may optionally be specified with a `PARTITIONS num` clause, where *num* is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, *num* must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

#### Note

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- Rigorous checking of the value used in `PARTITIONS` or `SUBPARTITIONS` clauses is applied and this value must adhere to the following rules:
  - The value must be a positive, nonzero integer.
  - No leading zeros are permitted.
  - The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not permitted, even though `0.2E+01` evaluates to 2. (Bug #15890)

#### Note

The expression (*expr*) used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

Each partition may be individually defined using a `partition_definition` clause. The individual parts making up this clause are as follows:

- `PARTITION partition_name`: This specifies a logical name for the partition.
- A `VALUES` clause: For range partitioning, each partition must include a `VALUES LESS THAN` clause; for list partitioning, you must specify a `VALUES IN` clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 17, Partitioning](#), for syntax examples.
- An optional `COMMENT` clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

Beginning with MySQL 5.6.6, the maximum length for a partition comment is 1024 characters. (Previously, this limit was not explicitly defined.)

- `DATA DIRECTORY` and `INDEX DIRECTORY` may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the `data_dir` and the `index_dir` must be absolute system path names. Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
  DATA DIRECTORY = '/var/appdata/95/data'
  INDEX DIRECTORY = '/var/appdata/95/idx',
```

```

PARTITION p2000 VALUES IN (1996, 2000, 2004)
  DATA DIRECTORY = '/var/appdata/96/data'
  INDEX DIRECTORY = '/var/appdata/96/idx',
PARTITION p2001 VALUES IN (1997, 2001, 2005)
  DATA DIRECTORY = '/var/appdata/97/data'
  INDEX DIRECTORY = '/var/appdata/97/idx',
PARTITION p2002 VALUES IN (1998, 2002, 2006)
  DATA DIRECTORY = '/var/appdata/98/data'
  INDEX DIRECTORY = '/var/appdata/98/idx'
);

```

`DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's `table_option` clause as used for `MyISAM` tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions of `MyISAM` tables, and the `INDEX DIRECTORY` option is not supported for individual partitions or subpartitions of `InnoDB` tables. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

#### Note

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` [604] is in effect. (Bug #24633)

- `MAX_ROWS` and `MIN_ROWS` may be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.
- The partitioning handler accepts a `[STORAGE] ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL`. We expect to lift this restriction on partitioning in a future MySQL release.
- The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See [Section 17.2.6, “Subpartitioning”](#).

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 13.1.6, “ALTER TABLE Syntax”](#). For more detailed descriptions and examples, see [Section 17.3, “Partition Management”](#).

#### Important

The original `CREATE TABLE` statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an `ALTER TABLE` statement, the original table options specified are retained. This enables you to change between `InnoDB` and `MyISAM` table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured (such as the

`ROW_FORMAT`), the active table definition (accessible through `DESCRIBE` or with `SHOW TABLE STATUS`) and the table creation string (accessible through `SHOW CREATE TABLE`) will report different values.

## Cloning or Copying a Table

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

For more information, see [Section 13.1.14.1, “CREATE TABLE ... SELECT Syntax”](#).

Use `LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT [755]` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

### Important

Beginning with MySQL 5.6.1, you cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

Also as of MySQL 5.6.1, `CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE` and does not just copy the `.frm` file. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

### 13.1.14.1. CREATE TABLE ... SELECT Syntax

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (a), KEY(b))
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n  |
+----+
| 1  |
```

```
+----+
mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m      | n      |
+-----+-----+
| NULL   | 1      |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, new rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements in MySQL 5.6.4 and later are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. See also [Section 16.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
  SELECT artist.name, COUNT(work.artist_id) AS number_of_works
  FROM artist LEFT JOIN work ON artist.id = work.artist_id
  GROUP BY artist.id;
```

You can also explicitly specify the data type for a generated column:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the destination table already exists, the result is version dependent. Before MySQL 5.5.6, MySQL handles the statement as follows:

- The table definition given in the `CREATE TABLE` part is ignored. No error occurs, even if the definition does not match that of the existing table. MySQL attempts to insert the rows from the `SELECT` part anyway.

- If there is a mismatch between the number of columns in the table and the number of columns produced by the `SELECT` part, the selected values are assigned to the rightmost columns. For example, if the table contains  $n$  columns and the `SELECT` produces  $m$  columns, where  $m < n$ , the selected values are assigned to the  $m$  rightmost columns in the table. Each of the initial  $n - m$  columns is assigned its default value, either that specified explicitly in the column definition or the implicit column data type default if the definition contains no default. If the `SELECT` part produces too many columns ( $m > n$ ), an error occurs.
- If strict SQL mode is enabled and any of these initial columns do not have an explicit default value, the statement fails with an error.

The following example illustrates `IF NOT EXISTS` handling:

```
mysql> CREATE TABLE t1 (i1 INT DEFAULT 0, i2 INT, i3 INT, i4 INT);
Query OK, 0 rows affected (0.05 sec)

mysql> CREATE TABLE IF NOT EXISTS t1 (c1 CHAR(10)) SELECT 1, 2;
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+-----+-----+-----+-----+
| i1   | i2   | i3   | i4   |
+-----+-----+-----+-----+
| 0    | NULL | 1    | 2    |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

As of MySQL 5.5.6, handling of `CREATE TABLE IF NOT EXISTS ... SELECT` statements was changed for the case that the destination table already exists. This change also involves a change in MySQL 5.1 beginning with 5.1.51.

- Previously, for `CREATE TABLE IF NOT EXISTS ... SELECT`, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, `CREATE TABLE ... SELECT` (without `IF NOT EXISTS`) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.
- MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when `IF NOT EXISTS` is present and an error when it is not.

This change means that, for the preceding example, the `CREATE TABLE IF NOT EXISTS ... SELECT` statement inserts nothing into the destination table as of MySQL 5.5.6.

This change in handling of `IF NOT EXISTS` results in an incompatibility for statement-based replication from a MySQL 5.1 master with the original behavior and a MySQL 5.5 slave with the new behavior. Suppose that `CREATE TABLE IF NOT EXISTS ... SELECT` is executed on the master and the destination table exists. The result is that rows are inserted on the master but not on the slave. (Row-based replication does not have this problem.)

To address this issue, statement-based binary logging for `CREATE TABLE IF NOT EXISTS ... SELECT` is changed in MySQL 5.1 as of 5.1.51:

- If the destination table does not exist, there is no change: The statement is logged as is.
- If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows will be inserted on both the master and slave. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the master first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the slave first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.

Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

### Important

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails. This represents a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.

This change can also have implications for statement-based replication from an older master to a MySQL 5.6 or newer slave. See [Section 16.4.1.4, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.

### 13.1.14.2. Using FOREIGN KEY Constraints

MySQL supports foreign keys, which let you cross-reference related data across tables, and [foreign key constraints](#), which help keep this spread-out data consistent. The essential syntax for a foreign key constraint definition in a `CREATE TABLE` or `ALTER TABLE` statement looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
REFERENCES tbl_name (index_col_name,...)
[ON DELETE reference_option]
[ON UPDATE reference_option]
```

*reference\_option*:

```
RESTRICT | CASCADE | SET NULL | NO ACTION
```

*index\_name* represents a foreign key ID. If given, this is ignored if an index for the foreign key is defined explicitly. Otherwise, if MySQL creates an index for the foreign key, it uses *index\_name* for the index name.

Foreign keys definitions are subject to the following conditions:

- Foreign key relationships involve a [parent table](#) that holds the central data values, and a [child table](#) with identical values pointing back to its parent. The `FOREIGN KEY` clause is specified in the child table. The parent and child tables must use the same storage engine. They must not be `TEMPORARY` tables.
- Corresponding columns in the foreign key and the referenced key must have similar data types. *The size and sign of integer types must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later, if you create another index that can be used to enforce the foreign key constraint. *index\_name*, if given, is used as described previously.

- **InnoDB** permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that **BLOB** and **TEXT** columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
- If the **CONSTRAINT** *symbol* clause is given, the *symbol* value, if used, must be unique in the database. If the clause is not given, or a *symbol* is not included following the **CONSTRAINT** keyword, a name for the constraint is created automatically.
- **InnoDB** does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

## Referential Actions

This section describes how foreign keys help guarantee [referential integrity](#).

For storage engines supporting foreign keys, MySQL rejects any **INSERT** or **UPDATE** operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table.

When an **UPDATE** or **DELETE** operation affects a key value in the parent table that has matching rows in the child table, the result depends on the *referential action* specified using **ON UPDATE** and **ON DELETE** subclauses of the **FOREIGN KEY** clause. MySQL supports five options regarding the action to be taken, listed here:

- **CASCADE**: Delete or update the row from the parent table, and automatically delete or update the matching rows in the child table. Both **ON DELETE CASCADE** and **ON UPDATE CASCADE** are supported. Between two tables, do not define several **ON UPDATE CASCADE** clauses that act on the same column in the parent table or in the child table.

### Note

Currently, cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table, and set the foreign key column or columns in the child table to **NULL**. Both **ON DELETE SET NULL** and **ON UPDATE SET NULL** clauses are supported.

If you specify a **SET NULL** action, *make sure that you have not declared the columns in the child table as **NOT NULL***.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying **RESTRICT** (or **NO ACTION**) is the same as omitting the **ON DELETE** or **ON UPDATE** clause.
- **NO ACTION**: A keyword from standard SQL. In MySQL, equivalent to **RESTRICT**. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and **NO ACTION** is a deferred check. In MySQL, foreign key constraints are checked immediately, so **NO ACTION** is the same as **RESTRICT**.
- **SET DEFAULT**: This action is recognized by the MySQL parser, but **InnoDB** rejects table definitions containing **ON DELETE SET DEFAULT** or **ON UPDATE SET DEFAULT** clauses.

For an **ON DELETE** or **ON UPDATE** that is not specified, the default action is always **RESTRICT**.

MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, “child table records” really refers to dependent records within the same table.

## Examples of Foreign Key Clauses

Here is a simple example that relates `parent` and `child` tables through a single-column foreign key:

```
CREATE TABLE parent (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
  id INT,
  parent_id INT,
  INDEX par_ind (parent_id),
  FOREIGN KEY (parent_id)
    REFERENCES parent(id)
    ON DELETE CASCADE
) ENGINE=INNODB;
```

A more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```
CREATE TABLE product (
  category INT NOT NULL, id INT NOT NULL,
  price DECIMAL,
  PRIMARY KEY(category, id)
) ENGINE=INNODB;

CREATE TABLE customer (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE product_order (
  no INT NOT NULL AUTO_INCREMENT,
  product_category INT NOT NULL,
  product_id INT NOT NULL,
  customer_id INT NOT NULL,

  PRIMARY KEY(no),
  INDEX (product_category, product_id),
  INDEX (customer_id),

  FOREIGN KEY (product_category, product_id)
    REFERENCES product(category, id)
    ON UPDATE CASCADE ON DELETE RESTRICT,

  FOREIGN KEY (customer_id)
    REFERENCES customer(id)
) ENGINE=INNODB;
```

## Adding foreign keys

You can add a new foreign key constraint to an existing table by using `ALTER TABLE`. The syntax relating to foreign keys for this statement is shown here:

```
ALTER TABLE tbl_name
  ADD [CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name,...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, *remember to create the required indexes first*.

## Dropping Foreign Keys

You can also use `ALTER TABLE` to drop foreign keys, using the syntax shown here:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the **FOREIGN KEY** clause included a **CONSTRAINT** name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the *fk\_symbol* value is generated internally when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use a **SHOW CREATE TABLE** statement, as shown here:

```
mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `_0_38775` FOREIGN KEY (`A`,`D`)
REFERENCES `ibtest11a` (`A`,`D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `_0_38776` FOREIGN KEY (`B`,`C`)
REFERENCES `ibtest11a` (`B`,`C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `_0_38775`;
```

You cannot add a foreign key and drop a foreign key in the same **ALTER TABLE** statement. A separate statements is required for each operation.

Before MySQL 5.6.7, using **ALTER TABLE** to change the definition of a foreign key column could cause a loss of referential integrity. For example, changing a foreign key column that contained **NULL** values to be **NOT NULL** caused the **NULL** values to be the empty string. Similarly, an **ALTER TABLE IGNORE** that removed rows in a parent table could break referential integrity.

As of 5.6.7, the server prohibits changes to foreign key columns with the potential to cause loss of referential integrity. A workaround is to use **ALTER TABLE ... DROP FOREIGN KEY** before changing the column definition and **ALTER TABLE ... ADD FOREIGN KEY** afterward.

## Foreign Keys and Other MySQL Statements

Table and column identifiers in a **FOREIGN KEY ... REFERENCES ...** clause can be quoted within backticks (```). Alternatively, double quotation marks (`"`) can be used if the **ANSI\_QUOTES** [603] SQL mode is enabled. The setting of the **lower\_case\_table\_names** [501] system variable is also taken into account.

You can view a child table's foreign key definitions as part of the output of the **SHOW CREATE TABLE** statement:

```
SHOW CREATE TABLE tbl_name;
```

You can also obtain information about foreign keys by querying the **INFORMATION\_SCHEMA.KEY\_COLUMN\_USAGE** table.

You can find information about foreign keys used by **InnoDB** tables in the **INNODB\_SYS\_FOREIGN** and **INNODB\_SYS\_FOREIGN\_COLS** tables, also in the **INFORMATION\_SCHEMA** database.

**mysqldump** produces correct definitions of tables in the dump file, including the foreign keys for child tables.

To make it easier to reload dump files for tables that have foreign key relationships, **mysqldump** automatically includes a statement in the dump output to set **foreign\_key\_checks** [483] to 0. This

avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET foreign_key_checks = 0;
mysql> SOURCE dump_file_name;
mysql> SET foreign_key_checks = 1;
```

This enables you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `foreign_key_checks` [483] to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `foreign_key_checks = 0` [483], MySQL does not permit the creation of a foreign key constraint where a column references a nonmatching column type. Also, if a table has foreign key constraints, `ALTER TABLE` cannot be used to alter the table to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

You cannot issue `DROP TABLE` for a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET foreign_key_checks = 0`. When you drop a table, any constraints that were defined in the statement used to create that table are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the correct column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns Error 1005 and refers to Error 150 in the error message, which means that a foreign key constraint was not correctly formed. Similarly, if an `ALTER TABLE` fails due to Error 150, this means that a foreign key definition would be incorrectly formed for the altered table.

For `InnoDB` tables, you can obtain a detailed explanation of the most recent `InnoDB` foreign key error in the MySQL Server, by checking the output of `SHOW ENGINE INNODB STATUS`.

### Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential-integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. MySQL essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance reasons. However, the system does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` (including `PRIMARY`) and `NOT NULL` keys.

Furthermore, MySQL does not recognize or support “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification. For storage engines that do not support foreign keys (such as `MyISAM`), MySQL Server parses and ignores foreign key specifications.

### 13.1.14.3. Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See [Section E.10.4, “Limits on Table Column Count and Row Size”](#).

- Columns that are part of a [PRIMARY KEY](#) are made [NOT NULL](#) even if not declared that way.
- Trailing spaces are automatically deleted from [ENUM](#) and [SET](#) member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 11.8, “Using Data Types from Other Database Engines”](#).
- If you include a [USING](#) clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a [VARCHAR](#) column with a length specification greater than 65535 is converted to [TEXT](#), and a [VARBINARY](#) column with a length specification greater than 65535 is converted to [BLOB](#). Otherwise, an error occurs in either of these cases.
- Specifying the [CHARACTER SET binary](#) attribute for a character data type causes the column to be created as the corresponding binary data type: [CHAR](#) becomes [BINARY](#), [VARCHAR](#) becomes [VARBINARY](#), and [TEXT](#) becomes [BLOB](#). For the [ENUM](#) and [SET](#) data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a [DESCRIBE](#) or [SHOW CREATE TABLE](#) statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using [myisampack](#). See [Section 14.3.3.3, “Compressed Table Characteristics”](#).

### 13.1.15. CREATE TRIGGER Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  TRIGGER trigger_name trigger_time trigger_event
  ON tbl_name FOR EACH ROW trigger_body
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named *tbl\_name*, which must refer to a permanent table. You cannot associate a trigger with a [TEMPORARY](#) table or a view.

[CREATE TRIGGER](#) requires the [TRIGGER \[756\]](#) privilege for the table associated with the trigger. The statement might also require the [SUPER \[756\]](#) privilege, depending on the [DEFINER](#) value, as described

later in this section. If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` [756] privilege, as described in [Section 18.7, “Binary Logging of Stored Programs”](#).

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time. See later in this section for more information.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

`trigger_event` indicates the kind of statement that activates the trigger. The `trigger_event` can be one of the following:

- `INSERT`: The trigger is activated whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE`: The trigger is activated whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE`: The trigger is activated whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. However, `DROP TABLE` and `TRUNCATE TABLE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either. See [Section 13.1.27, “TRUNCATE TABLE Syntax”](#).

It is important to understand that the `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger is activated by not only `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger will activate for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

There cannot be two triggers for a given table that have the same trigger action time and event. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_body` is the statement to execute when the trigger activates. If you want to execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are permissible within stored routines. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#). Some statements are not permitted in triggers; see [Section E.1, “Restrictions on Stored Programs”](#).

You can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

MySQL stores the `sql_mode` [545] system variable setting that is in effect at the time a trigger is created, and always executes the trigger with this setting in force, *regardless of the server SQL mode in effect when the event begins executing*.

#### Note

Currently, cascaded foreign key actions do not activate triggers.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER` [1267], or `CURRENT_USER()` [1267]. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` [756] privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER` [1267]. You cannot set the definer to some other account.
- If you have the `SUPER` [756] privilege, you can specify any syntactically valid account name. If the account does not actually exist, a warning is generated.
- Although it is possible to create a trigger with a nonexistent `DEFINER` account, it is not a good idea for such triggers to be activated until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` [756] privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  - The `TRIGGER` [756] privilege.
  - The `SELECT` [755] privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger definition.
  - The `UPDATE` [756] privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger definition.
  - Whatever other privileges normally are required for the statements executed by the trigger.

For more information about trigger security, see [Section 18.6, “Access Control for Stored Programs and Views”](#).

Within a trigger, the `CURRENT_USER()` [1267] function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see [Section 6.3.12, “SQL-Based MySQL Account Activity Auditing”](#).

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in [Section 13.3.5.2, “LOCK TABLES and Triggers”](#).

In MySQL 5.6, you can write triggers containing direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

delimiter |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;

delimiter ;

INSERT INTO test3 (a3) VALUES
```

```
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL);
```

```
INSERT INTO test4 (a4) VALUES
(0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
-> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

As a result, the data in the four tables will be as follows:

```
mysql> SELECT * FROM test1;
```

```
+-----+
| a1 |
+-----+
|  1 |
|  3 |
|  1 |
|  7 |
|  1 |
|  8 |
|  4 |
|  4 |
+-----+
```

```
8 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM test2;
```

```
+-----+
| a2 |
+-----+
|  1 |
|  3 |
|  1 |
|  7 |
|  1 |
|  8 |
|  4 |
|  4 |
+-----+
```

```

### 13.1.16. CREATE VIEW Syntax

```
CREATE
  [OR REPLACE]
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing one if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as `ALTER VIEW`.

The `select_statement` is a `SELECT` statement that provides the definition of the view. (When you select from the view, you select in effect using the `SELECT` statement.) `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time, so changes to the underlying tables afterward do not affect the view definition. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW [754]` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement you must have the `SELECT [755]` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP [754]` privilege for the view. `CREATE VIEW` might also require the `SUPER [756]` privilege, depending on the `DEFINER` value, as described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as `db_name.view_name` when you create it:

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional `column_list` clause can be given as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system or user variables.
- Within a stored program, the definition cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- Any tables named in the view definition must exist at definition time.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
```

```
| abc |
+-----+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively. The default `SQL SECURITY` value is `DEFINER`.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER [1267]`, or `CURRENT_USER() [1267]`. The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER [756]` privilege, the only valid `user` value is your own account, either specified literally or by using `CURRENT_USER [1267]`. You cannot set the definer to some other account.
- If you have the `SUPER [756]` privilege, you can specify any syntactically valid account name. If the account does not actually exist, a warning is generated.
- Although it is possible to create a view with a nonexistent `DEFINER` account, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about view security, see [Section 18.6, “Access Control for Stored Programs and Views”](#).

Within a view definition, `CURRENT_USER [1267]` returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER [1267]` returns the account for the view's invoker. For information about user auditing within views, see [Section 6.3.12, “SQL-Based MySQL Account Activity Auditing”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER [1267]` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER [1267]`.

View privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT [755]` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.
- The user who references a view must have appropriate privileges to access it (`SELECT [755]` to select from it, `INSERT [755]` to insert into it, and so forth.)
- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view `DEFINER` account or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges

of the `DEFINER` account. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY DEFINER`. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, [SELECT \[755\]](#)) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The `DEFINER` clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default `DEFINER` value is the account of the view creator.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. For more information, see [Section 18.5.2, “View Processing Algorithms”](#).

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADE` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADE` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADE`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see [Section 18.5.3, “Updatable and Insertable Views”](#).

### 13.1.17. DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the `DROP [754]` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

#### Important

When a database is dropped, user privileges on the database are *not* automatically dropped. See [Section 13.7.1.4, “GRANT Syntax”](#).

IF EXISTS is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the DATABASE() [1268] function returns NULL).

If you use DROP DATABASE on a symbolically linked database, both the link and the original database are deleted.

DROP DATABASE returns the number of tables that were removed. This corresponds to the number of .frm files removed.

The DROP DATABASE statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions.

.BAK	.DAT	.HSH	.MRG
.MYD	.MYI	.TRG	.TRN
.db	.frm	.ibd	.ndb
.par			

- The db.opt file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the DROP DATABASE statement again.

You can also drop databases with mysqladmin. See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.

### 13.1.18. DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named event\_name. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error ERROR 1517 (HY000): Unknown event 'event\_name' results. You can override this and cause the statement to generate a warning for nonexistent events instead using IF EXISTS.

This statement requires the EVENT [754] privilege for the schema to which the event to be dropped belongs.

### 13.1.19. DROP FUNCTION Syntax

The DROP FUNCTION statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see Section 13.1.21, “DROP PROCEDURE and DROP FUNCTION Syntax”.
- For information about dropping user-defined functions, see Section 13.7.3.2, “DROP FUNCTION Syntax”.

### 13.1.20. DROP INDEX Syntax

```
DROP INDEX index_name ON tbl_name
    [algorithm_option | lock_option] ...

algorithm_option:
    ALGORITHM [=] {DEFAULT|INPLACE|COPY}
```

```
lock_option:
  LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

`DROP INDEX` drops the index named `index_name` from the table `tbl_name`. This statement is mapped to an `ALTER TABLE` statement to drop the index. See [Section 13.1.6, “ALTER TABLE Syntax”](#).

To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX `PRIMARY` ON t;
```

As of MySQL 5.6.6, the `ALGORITHM` and `LOCK` clauses may be given. These influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 13.1.6, “ALTER TABLE Syntax”](#)

### 13.1.21. DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the `ALTER ROUTINE [754]` privilege for the routine. (If the `automatic_sp_privileges` system variable is enabled, that privilege and `EXECUTE [754]` are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See [Section 18.2.2, “Stored Routines and MySQL Privileges”](#).)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

`DROP FUNCTION` is also used to drop user-defined functions (see [Section 13.7.3.2, “DROP FUNCTION Syntax”](#)).

### 13.1.22. DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named `server_name`. The corresponding row in the `mysql.servers` table is deleted. This statement requires the `SUPER [756]` privilege.

Dropping a server for a table does not affect any `FEDERATED` tables that used this connection information when they were created. See [Section 13.1.13, “CREATE SERVER Syntax”](#).

`DROP SERVER` does not cause an automatic commit.

In MySQL 5.6, `DROP SERVER` is not written to the binary log, regardless of the logging format that is in use.

Beginning with MySQL 5.6.11, `gtid_next [2022]` must be set to `AUTOMATIC` before issuing this statement (BUG#16062608).

### 13.1.23. DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
  tbl_name [, tbl_name] ...
  [RESTRICT | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP [754]` privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which nonexisting tables it was unable to drop, but it also drops all of the tables in the list that do exist.

**Important**

When a table is dropped, user privileges on the table are *not* automatically dropped. See [Section 13.7.1.4, “GRANT Syntax”](#).

Note that for a partitioned table, `DROP TABLE` permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (`.par`) file associated with the dropped table.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. A `NOTE` is generated for each nonexistent table when using `IF EXISTS`. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE` are permitted to make porting easier. In MySQL 5.6, they do nothing.

**Note**

`DROP TABLE` automatically commits the current active transaction, unless you use the `TEMPORARY` keyword.

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A `TEMPORARY` table is visible only to the session that created it, so no check is necessary.)

Using `TEMPORARY` is a good way to ensure that you do not accidentally drop a non-`TEMPORARY` table.

## 13.1.24. DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER [756]` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a nonexistent trigger when using `IF EXISTS`. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

Triggers for a table are also dropped if you drop the table.

## 13.1.25. DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
  view_name [, view_name] ...
  [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP [754]` privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which nonexistent views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

## 13.1.26. RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
```

```
[, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables.

The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running. For example, if you have an existing table `old_table`, you can create another table `new_table` that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that `backup_table` does not already exist):

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
             new_table TO old_table,
             tmp_table TO new_table;
```

As long as two databases are on the same file system, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

If there are any triggers associated with a table which is moved to a different database using `RENAME TABLE`, then the statement fails with the error `Trigger in wrong schema`.

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

Any privileges granted specifically for the renamed table or view are not migrated to the new name. They must be changed manually.

When you execute `RENAME`, you cannot have any locked tables or active transactions. You must also have the `ALTER` [753] and `DROP` [754] privileges on the original table, and the `CREATE` [754] and `INSERT` [755] privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

You cannot use `RENAME` to rename a `TEMPORARY` table. However, you can use `ALTER TABLE` instead:

```
mysql> ALTER TABLE orig_name RENAME new_name;
```

### 13.1.27. TRUNCATE TABLE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` [754] privilege.

Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements. To achieve high performance, it bypasses the DML method of deleting data. Thus, it cannot be rolled back, it does not cause `ON DELETE` triggers to fire, and it cannot be performed for `InnoDB` tables with parent-child foreign key relationships.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways in MySQL 5.6:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back.
- Truncation operations cannot be performed if the session holds an active table lock.

- `TRUNCATE TABLE` fails for an `InnoDB` table if there are any `FOREIGN KEY` constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.
- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using `InnoDB` and other transactional storage engines where the transaction isolation level does not permit statement-based logging (`READ COMMITTED` or `READ UNCOMMITTED`), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replication slaves using `InnoDB` in the manner described previously.

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See [Section 20.9.8, “Performance Schema Summary Tables”](#).

## 13.2. Data Manipulation Statements

### 13.2.1. `CALL` Syntax

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` [1272] function; from the C API, call the `mysql_affected_rows()` function.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
```

```
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.3-m3-log | 11 |
+-----+-----+
```

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholders can be used for `IN` parameters. For `OUT` and `INOUT` parameters, placeholder support is available as of MySQL 5.5.3. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.3-m3-log | 11 |
+-----+-----+
```

Before MySQL 5.5.3, placeholder support is not available for `OUT` or `INOUT` parameters. To work around this limitation for `OUT` and `INOUT` parameters, forego the use of placeholders; instead, refer to user variables in the `CALL` statement itself and do not specify them in the `EXECUTE` statement:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(@version, @increment)';
mysql> EXECUTE s;
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.0-m2-log | 11 |
+-----+-----+
```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). In MySQL 5.6, `CLIENT_MULTI_RESULTS` is enabled by default.

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 21.8.16, “C API Support for Multiple Statement Execution”](#).

For programs written in a language that provides a MySQL interface, there is no native method prior to MySQL 5.5.3 for directly retrieving the results of `OUT` or `INOUT` parameters from `CALL` statements. To get the parameter values, pass user-defined variables to the procedure in the `CALL` statement and then execute a `SELECT` statement to produce a result set containing the variable values. To handle an `INOUT` parameter, execute a statement prior to the `CALL` that sets the corresponding user variable to the value to be passed to the procedure.

The following example illustrates the technique (without error checking) for the stored procedure `p` described earlier that has an `OUT` parameter and an `INOUT` parameter:

```
mysql_query(mysql, "SET @increment = 10");
mysql_query(mysql, "CALL p(@version, @increment)");
mysql_query(mysql, "SELECT @version, @increment");
result = mysql_store_result(mysql);
row = mysql_fetch_row(result);
mysql_free_result(result);
```

After the preceding code executes, `row[0]` and `row[1]` contain the values of `@version` and `@increment`, respectively.

In MySQL 5.6, C programs can use the prepared-statement interface to execute `CALL` statements and access `OUT` and `INOUT` parameters. This is done by processing the result of a `CALL` statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see [Section 21.8.19, “C API Support for Prepared CALL Statements”](#). Languages that provide a MySQL interface can use prepared `CALL` statements to directly retrieve `OUT` and `INOUT` procedure parameters.

As of MySQL 5.6.6, metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 8.9.4, “Caching of Prepared Statements and Stored Programs”](#).

## 13.2.2. DELETE Syntax

`DELETE` is a DML statement that removes rows from a table.

### Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
  [PARTITION (partition_name,...)]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

The `DELETE` statement deletes rows from `tbl_name` and returns the number of deleted rows. To check the number of deleted rows, call the `ROW_COUNT()` [\[1272\]](#) function described in [Section 12.14, “Information Functions”](#).

### Main Clauses

The conditions in the optional `WHERE` clause identify which rows to delete. With no `WHERE` clause, all rows are deleted.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 13.2.9, “SELECT Syntax”](#).

If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

### Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name [...] [, tbl_name [...]] ...
FROM table_references
  [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name [...] [, tbl_name [...]] ...
  USING table_references
```

```
[WHERE where_condition]
```

## Privileges

You need the [DELETE \[754\]](#) privilege on a table to delete rows from it. You need only the [SELECT \[755\]](#) privilege for any columns that are only read, such as those named in the [WHERE](#) clause.

## Performance

When you do not need to know the number of deleted rows, the [TRUNCATE TABLE](#) statement is a faster way to empty a table than a [DELETE](#) statement with no [WHERE](#) clause. Unlike [DELETE](#), [TRUNCATE TABLE](#) cannot be used within a transaction or if you have a lock on the table. See [Section 13.1.27, “TRUNCATE TABLE Syntax”](#) and [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

The speed of delete operations may also be affected by factors discussed in [Section 8.2.2.3, “Speed of DELETE Statements”](#).

To ensure that a given [DELETE](#) statement does not take too much time, the MySQL-specific [LIMIT row\\_count](#) clause for [DELETE](#) specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the [DELETE](#) statement until the number of affected rows is less than the [LIMIT](#) value.

## Subqueries

Currently, you cannot delete from a table and select from the same table in a subquery.

## Partitioned Tables

Beginning with MySQL 5.6.2, [DELETE](#) supports explicit partition selection using the [PARTITION](#) option, which takes a comma-separated list of the names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table *t* with a partition named *p0*, executing the statement [DELETE FROM t PARTITION \(p0\)](#) has the same effect on the table as executing [ALTER TABLE t TRUNCATE PARTITION \(p0\)](#); in both cases, all rows in partition *p0* are dropped.

[PARTITION](#) can be used along with a [WHERE](#) condition, in which case the condition is tested only on rows in the listed partitions. For example, [DELETE FROM t PARTITION \(p0\) WHERE c < 5](#) deletes rows only from partition *p0* for which the condition *c < 5* is true; rows in any other partitions are not checked and thus not affected by the [DELETE](#).

The [PARTITION](#) option can also be used in multiple-table [DELETE](#) statements. You can use up to one such option per table named in the [FROM](#) option.

See [Section 17.5, “Partition Selection”](#), for more information and examples.

## Auto-Increment Columns

If you delete the row containing the maximum value for an [AUTO\\_INCREMENT](#) column, the value is not reused for a [MyISAM](#) or [InnoDB](#) table. If you delete all rows in the table with [DELETE FROM tbl\\_name](#) (without a [WHERE](#) clause) in [autocommit \[464\]](#) mode, the sequence starts over for all storage engines except [InnoDB](#) and [MyISAM](#). There are some exceptions to this behavior for [InnoDB](#) tables, as discussed in [Section 5.4.4, “AUTO\\_INCREMENT Handling in InnoDB”](#).

For [MyISAM](#) tables, you can specify an [AUTO\\_INCREMENT](#) secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for [MyISAM](#) tables. See [Section 3.6.9, “Using AUTO\\_INCREMENT”](#).

## Modifiers

The [DELETE](#) statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- For `MyISAM` tables, if you use the `QUICK` keyword, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The `IGNORE` keyword causes MySQL to ignore all errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings.

## Order of Deletion

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

`ORDER BY` also helps to delete rows in an order required to avoid referential integrity violations.

## InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an `InnoDB` table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use `DELETE` at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use `RENAME TABLE` to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while `RENAME TABLE` executes, so the rename operation is not subject to concurrency problems. See [Section 13.1.26, “RENAME TABLE Syntax”](#).

## MyISAM Tables

In `MyISAM` tables, deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. To reclaim unused space and reduce file sizes, use the `OPTIMIZE TABLE` statement or the `myisamchk` utility to reorganize tables. `OPTIMIZE TABLE` is easier to use, but `myisamchk` is faster. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The `QUICK` modifier affects whether index leaves are merged for delete operations. `DELETE QUICK` is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

`DELETE QUICK` is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of `QUICK` can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed `AUTO_INCREMENT` column.

2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using `DELETE QUICK`.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of `QUICK`. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use `DELETE` without `QUICK`, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use `OPTIMIZE TABLE`.

If you are going to delete many rows from a table, it might be faster to use `DELETE QUICK` followed by `OPTIMIZE TABLE`. This rebuilds the index rather than performing many index block merge operations.

## Multi-Table Deletes

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the condition in the `WHERE` clause. You cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The `table_references` clause lists the tables involved in the join, as described in [Section 13.2.9.2, "JOIN Syntax"](#).

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples use `INNER JOIN`, but multiple-table `DELETE` statements can use other types of join permitted in `SELECT` statements, such as `LEFT JOIN`. For example, to delete rows that exist in `t1` that have no match in `t2`, use a `LEFT JOIN`:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits `.*` after each `tbl_name` for compatibility with `Access`.

If you use a multiple-table `DELETE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly.

### Note

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table `DELETE` should be declared only in the `table_references` part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

```
DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

```
DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

### 13.2.3. DO Syntax

```
DO expr [, expr] ...
```

**DO** executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT *expr*, ...**, but has the advantage that it is slightly faster when you do not care about the result.

**DO** is useful primarily with functions that have side effects, such as [RELEASE\\_LOCK\(\)](#) [1280].

### 13.2.4. HANDLER Syntax

```
HANDLER tbl_name OPEN [ [AS] alias ]
```

```
HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
[ WHERE where_condition ] [LIMIT ... ]
```

```
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
[ WHERE where_condition ] [LIMIT ... ]
```

```
HANDLER tbl_name READ { FIRST | NEXT }
[ WHERE where_condition ] [LIMIT ... ]
```

```
HANDLER tbl_name CLOSE
```

The **HANDLER** statement provides direct access to table storage engine interfaces. It is available for **InnoDB** and **MyISAM** tables.

The **HANDLER ... OPEN** statement opens a table, making it accessible using subsequent **HANDLER ... READ** statements. This table object is not shared by other sessions and is not closed until the session calls **HANDLER ... CLOSE** or the session terminates. If you open the table using an alias, further references to the open table with other **HANDLER** statements must use the alias rather than the table name.

The first **HANDLER ... READ** syntax fetches a row where the index specified satisfies the given values and the **WHERE** condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index **my\_idx** includes three columns named **col\_a**, **col\_b**, and **col\_c**, in that order. The **HANDLER** statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
```

```
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
```

```
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the **HANDLER** interface to refer to a table's **PRIMARY KEY**, use the quoted identifier **`PRIMARY`**:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second **HANDLER ... READ** syntax fetches a row from the table in index order that matches the **WHERE** condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 13.2.9, “SELECT Syntax”](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
  - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.
  - The handler interface does not have to provide a consistent look of the data (for example, [dirty reads](#) are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.
- `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface. (See [Section 14.2.9, “InnoDB Integration with memcached”](#) for an alternative way to adapt applications that use the key-value store paradigm.)
- `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

### 13.2.5. INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
      [INTO] tbl_name
      [PARTITION (partition_name,...)]
      [(col_name,...)]
      {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
      [ ON DUPLICATE KEY UPDATE
```

```
col_name=expr
[, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name,...)]
SET col_name={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
col_name=expr
[, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name,...)]
[(col_name,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
col_name=expr
[, col_name=expr] ... ]
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in [Section 13.2.5.1, “INSERT ... SELECT Syntax”](#).

In MySQL 5.6.2 and later, when inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The `PARTITION` option takes a comma-separated list of the names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given `INSERT` statement do not match one of the partitions listed, the `INSERT` statement fails with the error `Found a row not matching the given partition set`. See [Section 17.5, “Partition Selection”](#), for more information and examples.

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See [Section 13.2.8, “REPLACE Syntax”](#).

`tbl_name` is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.
- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.
- The `SET` clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 11.5, “Data Type Default Values”](#). See also [Section 1.8.6.3, “Constraints on Invalid Data”](#).

If you want an `INSERT` statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See [Section 5.1.7, “Server SQL Modes”](#).

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the `VALUES` list.

You can also use `DEFAULT(col_name)` [1275] as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression `expr` to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string `'1999.0e-2'` into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column results in the values `1999`, `19.9921`, `19.992100`, and `1999` being inserted, respectively. The reason the value stored in the `INT` and `YEAR` columns is `1999` is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a `0`.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, and either may be used whether there is a single values list or multiple lists.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` [1272] function (see Section 12.14, "Information Functions"), or the `mysql_affected_rows()` C API function (see Section 21.8.6.1, "`mysql_affected_rows()`").

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is `0` for numeric types, the empty string ( `' '` ) for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as `'10.34 a'` to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to `0`.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 21.8.6.35](#), “`mysql_info()`”.

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the SQL `LAST_INSERT_ID()` [1269] function. From within the C API, use the `mysql_insert_id()` function. However, you should note that the two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 12.14](#), “Information Functions”, and [Section 21.8.6.37](#), “`mysql_insert_id()`”.

The `INSERT` statement supports the following modifiers:

- If you use the `DELAYED` keyword, the server puts the row or rows to be inserted into a buffer, and the client issuing the `INSERT DELAYED` statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See [Section 13.2.5.2](#), “`INSERT DELAYED Syntax`”.

`DELAYED` is ignored with `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE`.

`DELAYED` is also disregarded for an `INSERT` that uses functions accessing tables or triggers, or that is called from a function or a trigger.

#### Note

As of MySQL 5.6.6, `INSERT DELAYED` is deprecated, and will be removed in a future release. Use `INSERT` (without `DELAYED`) instead.

- If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time (or even

forever) in a read-heavy environment. (This is in contrast to `INSERT DELAYED`, which lets the client continue at once.) Note that `LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 8.10.3, “Concurrent Inserts”](#).

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates [430]` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 8.10.3, “Concurrent Inserts”](#).

`LOW_PRIORITY` and `HIGH_PRIORITY` affect only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` keyword, errors that occur while executing the `INSERT` statement are treated as warnings instead. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row still is not inserted, but no error is issued.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error; however, when `INSERT IGNORE` is used, the insert operation fails silently for the row containing the unmatched value, but any rows that are matched are inserted. For an example, see [Section 17.2.2, “LIST Partitioning”](#).

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. The affected-rows value per row is 1 if the row is inserted as a new row and 2 if an existing row is updated. See [Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Inserting into a table requires the `INSERT [755]` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE [756]` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT [755]` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

Prior to MySQL 5.6.6, an `INSERT` that affected a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locked all partitions of the table. This was true even for `INSERT ... PARTITION` statements. (This did not and does not occur with storage engines such as `InnoDB` that employ row-level locking.) In MySQL 5.6.6 and later, MySQL uses partition lock pruning, so that only partitions into which rows are inserted are actually locked. For more information, see [Section 17.6.4, “Partitioning and Locking”](#).

### 13.2.5.1. INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- `DELAYED` is ignored with `INSERT ... SELECT`.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. (This was not possible in some older versions of MySQL.) However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into a table at the same time, MySQL creates a temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, it remains true that you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement (see [Section C.5.7.2, “TEMPORARY Table Problems”](#)).

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements.
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

Starting with MySQL 5.6.2, you can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` option following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, then it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option, else the `INSERT ... SELECT` statement fails. For more information and examples, see [Section 17.5, “Partition Selection”](#).

In the values part of `ON DUPLICATE KEY UPDATE`, you can refer to columns in other tables, as long as you do not use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify nonunique column names in the values part.

The order in which rows are returned by a `SELECT` statement with no `ORDER BY` clause is not determined. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave; this can lead to inconsistencies between them. To prevent this from occurring, you should always write `INSERT ... SELECT` statements that are to be replicated as `INSERT ... SELECT ... ORDER BY column`. The choice of `column` does not matter as long as the same order for returning the rows is enforced on both the master and the slave. See also [Section 16.4.1.15, “Replication and LIMIT”](#).

Due to this issue, beginning with MySQL 5.6.4, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also [Section 16.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Prior to MySQL 5.6.6, an `INSERT ... SELECT` statement that acted on partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locked all partitions of the source and target tables. (This did not and does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) In MySQL 5.6.6 and later, only those partitions of the source table that are actually read are locked, although all partitions of the target table are locked. See [Section 17.6.4, “Partitioning and Locking”](#), for more information.

### 13.2.5.2. INSERT DELAYED Syntax

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL that can be used for certain kinds of tables (such as `MyISAM`). When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

### Note

`INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

As of MySQL 5.6.6, `INSERT DELAYED` is deprecated, and will be removed in a future release. Use `INSERT` (without `DELAYED`) instead.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate `mysqld` forcibly (for example, with `kill -9`) or if `mysqld` dies unexpectedly, *any queued rows that have not been written to disk are lost*.

There are some constraints on the use of `DELAYED`:

- `INSERT DELAYED` works only with `MyISAM`, `MEMORY`, `ARCHIVE`, and `BLACKHOLE` tables. For engines that do not support `DELAYED`, an error occurs.
- An error occurs for `INSERT DELAYED` if used with a table that has been locked with `LOCK TABLES` because the insert must be handled by a separate thread, not by the session that holds the lock.
- For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`.
- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.
- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` [1269] to get the `AUTO_INCREMENT` value that the statement might generate.
- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.
- Prior to MySQL 5.6, `INSERT DELAYED` was treated as a normal `INSERT` if the statement inserted multiple rows, binary logging was enabled, and the global logging format was statement-based (that is, whenever `binlog_format` [2010] was set to `STATEMENT`). Beginning with MySQL 5.6, `INSERT DELAYED` is always handled as a simple `INSERT` (that is, without the `DELAYED` option) whenever the value of `binlog_format` [2010] is `STATEMENT` or `MIXED`. (In the latter case, the statement no longer triggers a switch to row-based logging, and so is logged using the statement-based format.)

This does not apply when using row-based binary logging mode (`binlog_format` [2010] set to `ROW`), in which `INSERT DELAYED` statements are always executed using the `DELAYED` option as specified, and logged as row-update events.

- `DELAYED` is ignored on slave replication servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on slaves. This is because `DELAYED` could cause the slave to have different data than the master.
- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
- `INSERT DELAYED` is not supported for views.
- `INSERT DELAYED` is not supported for partitioned tables.

The following describes in detail what happens when you use the `DELAYED` option to `INSERT` or `REPLACE`. In this description, the “thread” is the thread that received an `INSERT DELAYED` statement and “handler” is the thread that handles all `INSERT DELAYED` statements for a particular table.

- When a thread executes a `DELAYED` statement for a table, a handler thread is created to process all `DELAYED` statements for the table, if no such handler already exists.
- The thread checks whether the handler has previously acquired a `DELAYED` lock; if not, it tells the handler thread to do so. The `DELAYED` lock can be obtained even if other threads have a `READ` or `WRITE` lock on the table. However, the handler waits for all `ALTER TABLE` locks or `FLUSH TABLES` statements to finish, to ensure that the table structure is up to date.
- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.
- The client cannot obtain from the server the number of duplicate rows or the `AUTO_INCREMENT` value for the resulting row, because the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function does not return anything meaningful, for the same reason.)
- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.
- Each time that `delayed_insert_limit` [476] rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it permits these to execute before continuing.
- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` [476] seconds, the handler terminates.
- If more than `delayed_queue_size` [477] rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that `mysqld` does not use all memory for the delayed memory queue.
- The handler thread shows up in the MySQL process list with `delayed_insert` in the `Command` column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before exiting, it first stores all queued rows into the table. During this time it does not accept any new `INSERT` statements from other threads. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

Note that this means that `INSERT DELAYED` statements have higher priority than normal `INSERT` statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty, someone terminates the handler thread (with `KILL thread_id`), or someone executes a `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements.

Status Variable	Meaning
<code>Delayed_insert_threads</code> [588]	Number of handler threads
<code>Delayed_writes</code> [588]	Number of rows written with <code>INSERT DELAYED</code>
<code>Not_flushed_delayed_rows</code> [594]	Number of rows waiting to be written

You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysqladmin extended-status` command.

### 13.2.5.3. `INSERT ... ON DUPLICATE KEY UPDATE` Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, MySQL performs an `UPDATE` of the old row. For example, if

column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

(The effects are not identical for an `InnoDB` table where `a` is an auto-increment column. With an auto-increment column, an `INSERT` statement increases the auto-increment value but `UPDATE` does not.)

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, and 2 if an existing row is updated.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` [1281] function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` [1281] in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` [1281] function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` [1269] function returns the `AUTO_INCREMENT` value.

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements for the master and the slave to diverge. Thus, in MySQL 5.6.4 and later, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. In addition, beginning with MySQL 5.6.6, an `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637) See also [Section 16.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Prior to MySQL 5.6.6, an `INSERT ... ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locked all partitions of the table. (This did not and does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) In MySQL 5.6.6 and later, such statements lock only those partitions in which a partitioning key column is updated. See [Section 17.6.4, “Partitioning and Locking”](#), for more information.

## 13.2.6. LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[ {FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES | ROWS}]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]
```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. `LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local [300]` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress [299]` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 8.2.2.1, “Speed of INSERT Statements”](#).

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem [468]` system variable controls the interpretation of the file name.

In MySQL 5.6.2 and later, `LOAD DATA` supports explicit partition selection using the `PARTITION` option with a comma-separated list of more or more names of partitions, subpartitions, or both. When this option is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error `Found a row not matching the given partition set`. For more information, see [Section 17.5, “Partition Selection”](#).

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, `LOAD DATA` cannot prune any partition locks. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Section 17.6.4, “Partitioning and Locking”](#).

The character set indicated by the `character_set_database [468]` system variable is used to interpret the information in the file. `SET NAMES` and the setting of `character_set_client [467]` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

**Note**

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

With row-based replication, `CONCURRENT` is replicated regardless of MySQL version. With statement-based replication `CONCURRENT` is not replicated prior to MySQL 5.5.1 (see Bug #34628). For more information, see [Section 16.4.1.16, “Replication and LOAD DATA INFILE”](#).

The `LOCAL` keyword affects expected location of the file and error handling, as described later. `LOCAL` works only if your server and your client both have been configured to permit it. For example, if `mysqld` was started with `--local-infile=0` [496], `LOCAL` does not work. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

The `LOCAL` keyword affects where the file is expected to be found:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

When using `LOCAL` with `LOAD DATA`, a copy of the file is created in the server's temporary directory. This is *not* the directory determined by the value of `tmpdir` [559] or `slave_load_tmpdir` [1992], but rather the operating system's temporary directory, and is not configurable in the MySQL Server. (Typically the system temporary directory is `/tmp` on Linux systems and `C:\WINDOWS\TEMP` on Windows.) Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
  - If the file name is an absolute path name, the server uses it as given.
  - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
  - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by all. Also, to use `LOAD DATA INFILE` on server files, you must have the `FILE` [754] privilege. See [Section 6.2.1, “Privileges Provided by MySQL”](#). For non-`LOCAL` load operations, if the `secure_file_priv` [538] system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE [754]` privilege to load local files.

`LOCAL` also affects error handling:

- With `LOAD DATA INFILE`, data-interpretation and duplicate-key errors terminate the operation.
- With `LOAD DATA LOCAL INFILE`, data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if `IGNORE` is specified. `IGNORE` is explained further later in this section.

The `REPLACE` and `IGNORE` keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 13.2.8, “REPLACE Syntax”](#).
- If you specify `IGNORE`, input rows that duplicate an existing row on a unique key value are skipped.
- If you do not specify either option, the behavior depends on whether the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

To ignore foreign key constraints during the load operation, issue a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 8.2.2.1, “Speed of INSERT Statements”](#).

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, [OPTIONALLY] `ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'  
LINES TERMINATED BY '\n' STARTING BY ''
```

(Backslash is the MySQL escape character within strings in SQL statements, so to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences `'\t'` and `'\n'` specify tab and newline characters, respectively.)

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.

- Interpret characters preceded by the escape character “\” as escape sequences. For example, “\t”, “\n”, and “\\” signify tab, newline, and backslash, respectively. See the discussion of [FIELDS ESCAPED BY](#) later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use “\” to escape instances of tab, newline, or “\” that occur within field values.
- Write newlines at the ends of lines.

#### Note

If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be (`"abc",1`) and (`"def",2`). The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
  FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED BY` keywords.

Any of the field- or line-handling options can specify an empty string ( `' '` ). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a \", quote and comma","102.20"
```

If you specify `OPTIONALLY`, the `ENCLOSED BY` character is used only to enclose values from columns that have a string data type (such as `CHAR`, `BINARY`, `TEXT`, or `ENUM`):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Note that occurrences of the `ENCLOSED BY` character within a field value are escaped by prefixing them with the `ESCAPED BY` character. Also note that if you specify an empty `ESCAPED BY` value, it is possible to inadvertently generate output that cannot be read properly by `LOAD DATA INFILE`. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the `ENCLOSED BY` character, if present, is stripped from the ends of field values. (This is true regardless of whether `OPTIONALLY` is specified; `OPTIONALLY` has no effect on input interpretation.) Occurrences of the `ENCLOSED BY` character preceded by the `ESCAPED BY` character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line **TERMINATED BY** sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are interpreted as a single instance of the character. For example, if **ENCLOSED BY ' '** is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss     -> The "BIG" boss
The ""BIG"" boss   -> The ""BIG"" boss
```

**FIELDS ESCAPED BY** controls how to read or write special characters:

- For input, if the **FIELDS ESCAPED BY** character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using “\” for the escape character). The rules for **NULL** handling are described later in this section.

Character	Escape Sequence
\0	An ASCII NUL (0x00) character
\b	A backspace character
\n	A newline (linefeed) character
\r	A carriage return character
\t	A tab character.
\z	ASCII 26 (Control+Z)
\N	NULL

For more information about “\”-escape syntax, see [Section 9.1.1, “String Literals”](#).

If the **FIELDS ESCAPED BY** character is empty, escape-sequence interpretation does not occur.

- For output, if the **FIELDS ESCAPED BY** character is not empty, it is used to prefix the following characters on output:
  - The **FIELDS ESCAPED BY** character
  - The **FIELDS [OPTIONALLY] ENCLOSED BY** character
  - The first character of the **FIELDS TERMINATED BY** and **LINES TERMINATED BY** values
  - ASCII 0 (what is actually written following the escape character is ASCII “0”, not a zero-valued byte)

If the **FIELDS ESCAPED BY** character is empty, no characters are escaped and **NULL** is output as **NULL**, not **\N**. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If **LINES TERMINATED BY** is an empty string and **FIELDS TERMINATED BY** is nonempty, lines are also terminated with **FIELDS TERMINATED BY**.
- If the **FIELDS TERMINATED BY** and **FIELDS ENCLOSED BY** values are both empty ( ' ' ), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For **TINYINT**, **SMALLINT**, **MEDIUMINT**, **INT**, and **BIGINT**, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to `' '`. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later. Note that fixed-size format does not work if you are using a multi-byte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `"\"`).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. Note that this causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 11.5, "Data Type Default Values"](#).

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY ' ' ENCLOSED BY ' '
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @var1)
SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 11.5, “Data Type Default Values”](#).

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 11.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode= 'TRADITIONAL [545]`, conversion of an empty value or a value such as `'x'` for a numeric column results in an error, not conversion to 0. (With `LOCAL`, warnings occur rather than errors, even with a restrictive `sql_mode [545]` value, because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded using binary notation (for example, `b'011010'`). To work around this, specify the values as regular integers and use the `SET` clause to convert them so that MySQL performs a numeric type conversion and loads them into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
2
127
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
-> INTO TABLE bit_test (@var1) SET b = CAST(@var1 AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| bin(b+0) |
+-----+
| 10      |
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Note that you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see [Section 13.2.5, “INSERT Syntax”](#)), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` [504] warnings as information about what went wrong. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 21.8.6.35, “mysql\\_info\(\)”](#).

## 13.2.7. LOAD XML Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE [db_name.]tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<tagname>']
[IGNORE number {LINES | ROWS}]
[(column_or_user_var,...)]
```

```
[SET col_name = expr,...]
```

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

`LOAD XML` acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml [254]` option). To write data from a table to an XML file, use a command such as the following one from the system shell:

```
shell> mysql --xml -e 'SELECT * FROM mytable' > file.xml
```

To read the file back into a table, use `LOAD XML INFILE`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All 3 formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`
- `PARTITION`
- `CHARACTER SET`
- `(column_or_user_var,...)`
- `SET`

See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#), for more information about these clauses.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first `number` rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

To illustrate how this statement is used, suppose that we have a table created as follows:

```
USE test;

CREATE TABLE person (
```

```

person_id INT NOT NULL PRIMARY KEY,
fname VARCHAR(40) NULL,
lname VARCHAR(40) NULL,
created TIMESTAMP
);

```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```

<?xml version="1.0"?>
<list>
  <person person_id="1" fname="Pekka" lname="Nousiainen"/>
  <person person_id="2" fname="Jonas" lname="Oreland"/>
  <person person_id="3"><fname>Mikael</fname><lname>Ronström</lname></person>
  <person person_id="4"><fname>Lars</fname><lname>Thalman</lname></person>
  <person><field name="person_id">5</field><field name="fname">Tomas</field>
  <field name="lname">Ulin</field></person>
  <person><field name="person_id">6</field><field name="fname">Martin</field>
  <field name="lname">Sköld</field></person>
</list>

```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```

mysql> LOAD XML LOCAL INFILE 'person.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';

Query OK, 6 rows affected (0.00 sec)
Records: 6 Deleted: 0 Skipped: 0 Warnings: 0

```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```

ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)

```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 6 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```

mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Pekka | Nousiainen | 2007-07-13 16:18:47 |
| 2 | Jonas | Oreland | 2007-07-13 16:18:47 |
| 3 | Mikael | Ronström | 2007-07-13 16:18:47 |
| 4 | Lars | Thalman | 2007-07-13 16:18:47 |
| 5 | Tomas | Ulin | 2007-07-13 16:18:47 |
| 6 | Martin | Sköld | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
6 rows in set (0.00 sec)

```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read in using `LOAD XML`.

The inverse of the above operation—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

#### Note

The `--xml` [254] option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option.

```

shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>

<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Pekka</field>
    <field name="lname">Nousiainen</field>
    <field name="created">2007-07-13 16:18:47</field>
  </row>

  <row>
    <field name="person_id">2</field>
    <field name="fname">Jonas</field>
    <field name="lname">Oreland</field>
    <field name="created">2007-07-13 16:18:47</field>
  </row>

  <row>
    <field name="person_id">3</field>
    <field name="fname">Mikael</field>
    <field name="lname">Ronström</field>
    <field name="created">2007-07-13 16:18:47</field>
  </row>

  <row>
    <field name="person_id">4</field>
    <field name="fname">Lars</field>
    <field name="lname">Thalmann</field>
    <field name="created">2007-07-13 16:18:47</field>
  </row>

  <row>
    <field name="person_id">5</field>
    <field name="fname">Tomas</field>
    <field name="lname">Ulin</field>
    <field name="created">2007-07-13 16:18:47</field>
  </row>

  <row>
    <field name="person_id">6</field>
    <field name="fname">Martin</field>
    <field name="lname">Sköld</field>
    <field name="created">2007-07-13 16:18:47</field>
  </row>
</resultset>

```

You can verify that the dump is valid by creating a copy of the `person` and then importing the dump file into the new table, like this:

```

mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 6 rows affected (0.01 sec)
Records: 6 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Pekka | Nousiainen | 2007-07-13 16:18:47 |
| 2 | Jonas | Oreland | 2007-07-13 16:18:47 |
| 3 | Mikael | Ronström | 2007-07-13 16:18:47 |
| 4 | Lars | Thalmann | 2007-07-13 16:18:47 |
| 5 | Tomas | Ulin | 2007-07-13 16:18:47 |
| 6 | Martin | Sköld | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
6 rows in set (0.00 sec)

```

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```
<?xml version="1.0"?>
<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>

  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>
</list>
```

You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql> TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW CREATE TABLE person\G
***** 1. row *****
      Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```
CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created          |
+-----+-----+-----+-----+
|          1 | Robert | Jones | 2007-07-24 17:37:06 |
|          2 | Mary  | Smith | 2007-07-24 17:37:06 |
+-----+-----+-----+-----+
```

```
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE address
-> ROWS IDENTIFIED BY '<address>';
Query OK, 3 rows affected (0.00 sec)
Records: 3 Deleted: 0 Skipped: 0 Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```
mysql> SELECT * FROM address;
+-----+-----+-----+-----+-----+-----+
| address_id | person_id | street          | zip   | city          | created          |
+-----+-----+-----+-----+-----+-----+
|          1 |          1 | Mill Creek Road | 45365 | Sidney       | 2007-07-24 17:37:37 |
|          2 |          1 | Main Street     | 28681 | Taylorsville | 2007-07-24 17:37:37 |
|          3 |          2 | River Road      | 80239 | Denver       | 2007-07-24 17:37:37 |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` [496] or `--local-infile=OFF` [496]. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` [754] privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

### Important

Revoking the `FILE` [754] privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML INFILE` statement (as well as the `LOAD_FILE()` [1181] function; it does *not* prevent the user from executing `LOAD XML LOCAL INFILE`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the `FILE` [754] privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, `LOAD XML` cannot prune any partition locks. This does not apply to tables using storage engines which employ

row-level locking, such as [InnoDB](#). For more information, see [Section 17.6.4, “Partitioning and Locking”](#).

### 13.2.8. REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
```

**REPLACE** works exactly like **INSERT**, except that if an old row in the table has the same value as a new row for a **PRIMARY KEY** or a **UNIQUE** index, the old row is deleted before the new row is inserted. See [Section 13.2.5, “INSERT Syntax”](#).

**REPLACE** is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL—that either inserts or *updates*—see [Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Note that unless the table has a **PRIMARY KEY** or **UNIQUE** index, using a **REPLACE** statement makes no sense. It becomes equivalent to **INSERT**, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the **REPLACE** statement. Any missing columns are set to their default values, just as happens for **INSERT**. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)` [1275], so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To use **REPLACE**, you must have both the **INSERT** [755] and **DELETE** [754] privileges for the table.

Beginning with MySQL 5.6.2, **REPLACE** supports explicit partition selection using the **PARTITION** option with a comma-separated list of names of partitions, subpartitions, or both. As with **INSERT**, if it is not possible to insert the new row into any of these partitions or subpartitions, the **REPLACE** statement fails with the error `Found a row not matching the given partition set`. See [Section 17.5, “Partition Selection”](#), for more information.

The **REPLACE** statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row **REPLACE**, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether **REPLACE** only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

Currently, you cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
  - a. Delete from the table the conflicting row that has the duplicate key value
  - b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the master and the slave to diverge. For this reason, in MySQL 5.6.4 and later, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using the `STATEMENT` binary logging mode, and are logged using the row-based format when using `MIXED` mode. See also [Section 16.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Prior to MySQL 5.6.6, a `REPLACE` that affected a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locked all partitions of the table. This was true even for `REPLACE ... PARTITION` statements. (This did not and does not occur with storage engines such as `InnoDB` that employ row-level locking.) In MySQL 5.6.6 and later, MySQL uses partition lock pruning, so that only partitions containing rows matching the `REPLACE` statement's `WHERE` clause are actually locked, as long as none of the table's partitioning columns are updated; otherwise the entire table is locked. For more information, see [Section 17.6.4, “Partitioning and Locking”](#).

### 13.2.9. SELECT Syntax

```
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
  [FROM table_references
  [PARTITION partition_list]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]
  [PROCEDURE procedure_name(argument_list)]
  [INTO OUTFILE 'file_name'
  [CHARACTER SET charset_name]
  export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name]]
  [FOR UPDATE | LOCK IN SHARE MODE]]
```

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements and subqueries. See [Section 13.2.9.4, “UNION Syntax”](#), and [Section 13.2.10, “Subquery Syntax”](#).

The most commonly used clauses of `SELECT` statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.
- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 13.2.9.2, “JOIN Syntax”](#).
- Starting in MySQL 5.6.2, `SELECT` supports explicit partition selection using the `PARTITION` keyword with a list of partitions or subpartitions (or both) following the name of the table in a `table_reference` (see [Section 13.2.9.2, “JOIN Syntax”](#)). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see [Section 17.5, “Partition Selection”](#).

In MySQL 5.6.6 and later, `SELECT ... PARTITION` from tables using storage engines such as `MyISAM` that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the `PARTITION` option.

See [Section 17.6.4, “Partitioning and Locking”](#), for more information.

- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

In the `WHERE` expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Section 9.5, “Expression Syntax”](#), and [Chapter 12, Functions and Operators](#).

`SELECT` can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify `DUAL` as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MySQL may ignore the clauses. MySQL does not require `FROM DUAL` if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a `HAVING` clause must come after any `GROUP BY` clause and before any `ORDER BY` clause. The exception is that the `INTO` clause can appear either as shown in the syntax description or immediately following the `select_expr` list. For more information about `INTO`, see [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).

The list of `select_expr` terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use `*`-shorthand:

- A select list consisting only of a single unqualified `*` can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- `tbl_name.*` can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name.*` reference

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other `SELECT` clauses:

- A `select_expr` can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```
SELECT CONCAT(last_name, ', ', first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The `AS` keyword is optional when aliasing a `select_expr` with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ', ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two `select_expr` expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See [Section C.5.5.4, “Problems with Column Aliases”](#).

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 13.2.9.2, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 13.2.9.3, “Index Hint Syntax”](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.1.4, “Server System Variables”](#).

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See [Section 9.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
```

```
ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;

SELECT college, region, seed FROM tournament
ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a subquery and also is applied in the outer query, the outermost `ORDER BY` takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

Relying on implicit `GROUP BY` sorting in MySQL 5.6 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in [Section 12.17, “Functions and Modifiers for Use with GROUP BY Clauses”](#).
- `GROUP BY` permits a `WITH ROLLUP` modifier. See [Section 12.17.2, “GROUP BY Modifiers”](#).
- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The **HAVING** clause can refer to aggregate functions, which the **WHERE** clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one *select\_expr* with the same name. This is an extension to standard SQL. Because MySQL also permits **GROUP BY** and **HAVING** to refer to *select\_expr* values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name *a*. To ensure that the correct column is used for grouping, use different names for each *select\_expr*.

- MySQL resolves unqualified column or alias references in **ORDER BY** clauses by searching in the *select\_expr* values, then in the columns of the tables in the **FROM** clause. For **GROUP BY** or **HAVING** clauses, it searches the **FROM** clause before searching in the *select\_expr* values. (For **GROUP BY** and **HAVING**, this differs from the pre-MySQL 5.0 behavior that used the same rules as for **ORDER BY**.)
- The **LIMIT** clause can be used to constrain the number of rows returned by the **SELECT** statement. **LIMIT** takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
  - Within prepared statements, **LIMIT** parameters can be specified using `?` placeholder markers.
  - Within stored programs, **LIMIT** parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, **LIMIT row\_count** is equivalent to **LIMIT 0, row\_count**.

For prepared statements, you can use placeholders. The following statements will return one row from the *tbl* table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the *tbl* table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see [Section 8.4.2.4, “Using PROCEDURE ANALYSE”](#), which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.
- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See [Section 14.2.3.4, “Locking Reads \(SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE\)”](#).

In addition, you cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...` (If you attempt to do so, the statement is rejected with the error `Can't update table 'old_table' while 'new_table' is being created`.) This is a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.

Following the `SELECT` keyword, you can use a number of options that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and options beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` options specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both options. `DISTINCTROW` is a synonym for `DISTINCT`.
- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 13.2.9.2, “JOIN Syntax”](#).

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` [898] or `system` [898] table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#). This exception may not apply to `const` [898] or `system` [898] tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`).

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL

directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This option can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.14, “Information Functions”](#).
- The `SQL_CACHE` and `SQL_NO_CACHE` options affect caching of query results in the query cache (see [Section 8.9.3, “The MySQL Query Cache”](#)). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` [529] system variable is `2` or `DEMAND`. With `SQL_NO_CACHE`, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the `SQL_NO_CACHE` keyword; a nonspace such as a newline causes the server to check the query cache to see whether the result is already cached.)

For views, `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query. For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of a view referred to by the query.

In MySQL 5.6, these two options are mutually exclusive and an error occurs if they are both specified. Also, these options are not permitted in subqueries (including subqueries in the `FROM` clause), and `SELECT` statements in unions other than the first `SELECT`.

Prior to MySQL 5.6.6, a `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locked all partitions of the table. This was true even for `SELECT ... PARTITION` queries. (This did not and does not occur with storage engines such as `InnoDB` that employ row-level locking.) In MySQL 5.6.6 and later, MySQL uses partition lock pruning, so that only partitions containing rows matching the `SELECT` statement's `WHERE` clause are actually locked. For more information, see [Section 17.6.4, “Partitioning and Locking”](#).

### 13.2.9.1. `SELECT ... INTO` Syntax

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and into variables.
- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.
- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

The `SELECT` syntax description (see [Section 13.2.9, “SELECT Syntax”](#)) shows the `INTO` clause near the end of the statement. It is also possible to use `INTO` immediately following the `select_expr` list.

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context.

The `INTO` clause can name a list of one or more variables, which can be user-defined variables, stored procedure or function parameters, or stored program local variables. (Within a prepared `SELECT ... INTO OUTFILE` statement, only user-defined variables are permitted; see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).)

The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple

rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 9.4, “User-Defined Variables”](#).

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE [754]` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. The `character_set_filesystem [468]` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some other host than the server host, you normally cannot use `SELECT ... INTO OUTFILE` since there is no way to write a path to the file relative to the server host's file system.

However, if the MySQL client software is installed on the remote machine, you can instead use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

It is also possible to create the resulting file on a different host other than the server host, if the location of the file on the remote host can be accessed using a network-mapped path on the server's file system. In this case, the presence of `mysql` (or some other MySQL client program) is not required on the target host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#), for information about the `FIELDS` and `LINES` clauses, including their default values and permissible values.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII “0”, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
```

```

FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
FROM test_table;

```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

#### Note

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` [538] system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 18.4.5, “Event Scheduler Status”](#).

### 13.2.9.2. JOIN Syntax

MySQL supports the following `JOIN` syntaxes for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```

table_references:
    escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference:
    table_reference
    | { OJ table_reference }

table_reference:
    table_factor
    | join_table

table_factor:
    tbl_name [PARTITION (partition_names)]
    [[AS] alias] [index_hint_list]
    | table_subquery [AS] alias
    | ( table_references )

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
    | table_reference STRAIGHT_JOIN table_factor
    | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
    | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
    | table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
    | USING (column_list)

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
    | IGNORE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
    | FORCE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

```

```
index_list:
    index_name [, index_name] ...
```

A table reference is also known as a join expression.

In MySQL 5.6.2 and later, a table reference (when it refers to a partitioned table) may contain a [PARTITION](#) option, including a comma-separated list of partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions—in other words, any partitions or subpartitions not named in the list are ignored. For more information, see [Section 17.5, “Partition Selection”](#).

The syntax of *table\_factor* is extended in comparison with the SQL Standard. The latter accepts only *table\_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of *table\_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, [JOIN](#), [CROSS JOIN](#), and [INNER JOIN](#) are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. [INNER JOIN](#) is used with an [ON](#) clause, [CROSS JOIN](#) is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins (see [Section 8.13.9, “Nested Join Optimization”](#)).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 13.2.9.3, “Index Hint Syntax”](#).

The following list describes general factors to take into account when writing joins.

- A table reference can be aliased using *tbl\_name AS alias\_name* or *tbl\_name alias\_name*:

```
SELECT t1.name, t2.salary
    FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
    FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A *table\_subquery* is also known as a subquery in the [FROM](#) clause. Such subqueries *must* include an alias to give the subquery result a table name. A trivial example follows; see also [Section 13.2.10.8, “Subqueries in the FROM Clause”](#).

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- [INNER JOIN](#) and [,](#) (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than of [INNER JOIN](#), [CROSS JOIN](#), [LEFT JOIN](#), and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The *conditional\_expr* used with [ON](#) is any conditional expression of the form that can be used in a [WHERE](#) clause. Generally, you should use the [ON](#) clause for conditions that specify how to join tables, and the [WHERE](#) clause to restrict which rows you want in the result set.

- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). This assumes that `right_tbl.id` is declared `NOT NULL`. See [Section 8.13.7, “LEFT JOIN and RIGHT JOIN Optimization”](#).

- The `USING(column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1,c2,c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- `STRAIGHT_JOIN` is similar to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

Some join examples:

```
SELECT * FROM table1, table2;

SELECT * FROM table1 INNER JOIN table2 ON table1.id=table2.id;

SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;

SELECT * FROM table1 LEFT JOIN table2 USING (id);

SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
LEFT JOIN table3 ON table2.id=table3.id;
```

### Join Processing Changes in MySQL 5.0.12

#### Note

Natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard. The goal was to align the syntax and semantics of MySQL with respect to `NATURAL JOIN` and `JOIN ... USING` according to SQL:2003. However, these changes in join processing can result in different output columns for some joins. Also, some queries that appeared to work correctly in older versions (prior to 5.0.12) must be rewritten to comply with the standard.

These changes have five main aspects:

- The way that MySQL determines the result columns of `NATURAL` or `USING` join operations (and thus the result of the entire `FROM` clause).
- Expansion of `SELECT *` and `SELECT tbl_name.*` into a list of selected columns.
- Resolution of column names in `NATURAL` or `USING` joins.
- Transformation of `NATURAL` or `USING` joins into `JOIN ... ON`.
- Resolution of column names in the `ON` condition of a `JOIN ... ON`.

The following list provides more detail about several effects of current join processing versus join processing in older versions. The term “previously” means “prior to MySQL 5.0.12.”

- The columns of a `NATURAL` join or a `USING` join may be different from previously. Specifically, redundant output columns no longer appear, and the order of columns for `SELECT *` expansion may be different from before.

Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

Previously, the statements produced this output:

```
+-----+-----+-----+
| i   | j   | k   | j   |
+-----+-----+-----+
|  1  |  1  |  1  |  1  |
+-----+-----+-----+
| i   | j   | k   | j   |
+-----+-----+-----+
|  1  |  1  |  1  |  1  |
+-----+-----+-----+
```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice. But in both cases, the redundant column is not eliminated. Also, the order of the columns is not correct according to standard SQL.

Now the statements produce this output:

```
+-----+-----+-----+
| j   | i   | k   |
+-----+-----+-----+
|  1  |  1  |  1  |
+-----+-----+-----+
| j   | i   | k   |
+-----+-----+-----+
|  1  |  1  |  1  |
+-----+-----+-----+
```

The redundant column is eliminated and the column order is correct according to standard SQL:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN V1 IS NOT NULL THEN V1 ELSE V2 END)
```

If the join operation is any other join, the result columns of the join consists of the concatenation of all columns of the joined tables. This is the same as previously.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-NULL column if one of the two columns is always NULL. If neither or both columns are NULL, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a JOIN. Suppose that the tables `t1(a,b)` and `t2(a,c)` have the following contents:

```
t1    t2
----  ----
1 x   2 z
2 y   3 w
```

Then:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

Here column `a` contains the values of `t1.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
| 2     | z     | y     |
| 3     | w     | NULL  |
+-----+-----+-----+
```

Here column `a` contains the values of `t2.a`.

Compare these results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 1     | x     | NULL  | NULL  |
| 2     | y     | 2     | z     |
+-----+-----+-----+-----+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 2     | y     | 2     | z     |
| NULL  | NULL  | 3     | w     |
+-----+-----+-----+-----+
```

- Previously, a `USING` clause could be rewritten as an `ON` clause that compares corresponding columns. For example, the following two clauses were semantically identical:

```
a LEFT JOIN b USING (c1,c2,c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

Now the two clauses no longer are quite the same:

- With respect to determining which rows satisfy the join condition, both joins remain semantically identical.
- With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the preceding `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1,b.c1), COALESCE(a.c2,b.c2), COALESCE(a.c3,b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1,b.c1)` [1169] is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column will be omitted from the result.

- The evaluation of multi-way natural joins differs in a very important way that affects the result of `NATURAL` or `USING` joins and that can require query rewriting. Suppose that you have three tables `t1(a,b)`, `t2(c,b)`, and `t3(a,c)` that each have one row: `t1(1,2)`, `t2(10,2)`, and `t3(7,10)`. Suppose also that you have this `NATURAL JOIN` on the three tables:

```
SELECT ... FROM t1 NATURAL JOIN t2 NATURAL JOIN t3;
```

Previously, the left operand of the second join was considered to be `t2`, whereas it should be the nested join (`t1 NATURAL JOIN t2`). As a result, the columns of `t3` are checked for common columns only in `t2`, and, if `t3` has common columns with `t1`, these columns are not used as equi-join columns. Thus, previously, the preceding query was transformed to the following equi-join:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c;
```

That join is missing one more equi-join predicate (`t1.a = t3.a`). As a result, it produces one row, not the empty result that it should. The correct equivalent query is this:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c AND t1.a = t3.a;
```

If you require the same query result in current versions of MySQL as in older versions, rewrite the natural join as the first equi-join.

- Previously, the comma operator (`,`) and `JOIN` both had the same precedence, so the join expression `t1, t2 JOIN t3` was interpreted as `((t1, t2) JOIN t3)`. Now `JOIN` has higher precedence, so the expression is interpreted as `(t1, (t2 JOIN t3))`. This change affects statements that use an `ON` clause, because that clause can refer only to columns in the operands of the join, and the change in precedence changes interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
INSERT INTO t3 VALUES(1,1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

Previously, the `SELECT` was legal due to the implicit grouping of `t1,t2` as `(t1,t2)`. Now the `JOIN` takes precedence, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'`

error. To allow the join to be processed, group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1,t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

Alternatively, avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

This change also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which now have higher precedence than the comma operator.

- Previously, the `ON` clause could refer to columns in tables named to its right. Now an `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

Previously, the `SELECT` statement was legal. Now the statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. The statement should be rewritten as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- Resolution of column names in `NATURAL` or `USING` joins is different than previously. For column names that are outside the `FROM` clause, MySQL now handles a superset of the queries compared to previously. That is, in cases when MySQL formerly issued an error that some column is ambiguous, the query now is handled correctly. This is due to the fact that MySQL now treats the common columns of `NATURAL` or `USING` joins as a single column, so when a query refers to such columns, the query compiler does not consider them as ambiguous.

Example:

```
SELECT * FROM t1 NATURAL JOIN t2 WHERE b > 1;
```

Previously, this query would produce an error `ERROR 1052 (23000): Column 'b' in where clause is ambiguous`. Now the query produces the correct result:

```
+-----+-----+-----+
| b    | c    | y    |
+-----+-----+-----+
|    4 |    2 |    3 |
+-----+-----+-----+
```

One extension of MySQL compared to the SQL:2003 standard is that MySQL enables you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins (just as previously), while the standard disallows that.

### 13.2.9.3. Index Hint Syntax

You can provide hints to give the optimizer information about how to choose indexes during query processing. [Section 13.2.9.2, "JOIN Syntax"](#), describes the general syntax for specifying tables in a `SELECT` statement. The syntax for an individual table, including that for index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
```

```

USE {INDEX|KEY}
  [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
| IGNORE {INDEX|KEY}
  [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
| FORCE {INDEX|KEY}
  [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

```

```

index_list:
  index_name [, index_name] ...

```

By specifying `USE INDEX (index_list)`, you can tell MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` can be used to tell MySQL to not use some particular index or indexes. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

You can also use `FORCE INDEX`, which acts like `USE INDEX (index_list)` but with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is used only if there is no way to use one of the given indexes to find rows in the table.

Each hint requires the names of *indexes*, not the names of columns. The name of a `PRIMARY KEY` is `PRIMARY`. To see the index names for a table, use `SHOW INDEX`.

An *index\_name* value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Examples:

```

SELECT * FROM table1 USE INDEX (col1_index,col2_index)
  WHERE col1=1 AND col2=2 AND col3=3;

SELECT * FROM table1 IGNORE INDEX (col3_index)
  WHERE col1=1 AND col2=2 AND col3=3;

```

The syntax for index hints has the following characteristics:

- It is syntactically valid to specify an empty *index\_list* for `USE INDEX`, which means “use no indexes.” Specifying an empty *index\_list* for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.
- You can specify the scope of a index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over the optimizer's selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use `FOR JOIN`. To influence index usage for sorting or grouping rows, use `FOR ORDER BY` or `FOR GROUP BY`. (However, if there is a covering index for the table and it is used to access the table, the optimizer will ignore `IGNORE INDEX FOR {ORDER BY|GROUP BY}` hints that disable that index.)
- You can specify multiple index hints:

```

SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;

```

It is not a error to name the same index in several hints (even within the same hint):

```

SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);

```

However, it is an error to mix `USE INDEX` and `FORCE INDEX` for the same table:

```

SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);

```

if you specify no `FOR` clause for an index hint, the hint by default applies to all parts of the statement. For example, this hint:

```

IGNORE INDEX (i1)

```

is equivalent to this combination of hints:

```

IGNORE INDEX FOR JOIN (i1)

```

```
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

To cause the server to use the older behavior for hint scope when no `FOR` clause is present (so that hints apply only to row retrieval), enable the `old [517]` system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

When index hints are processed, they are collected in a single list by type (`USE`, `FORCE`, `IGNORE`) and by scope (`FOR JOIN`, `FOR ORDER BY`, `FOR GROUP BY`). For example:

```
SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. `{USE|FORCE} INDEX` is applied if present. (If not, the optimizer-determined set of indexes is used.)
2. `IGNORE INDEX` is applied over the result of the previous step. For example, the following two queries are equivalent:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);
SELECT * FROM t1 USE INDEX (i1);
```

For `FULLTEXT` searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, `IGNORE INDEX(i)` is ignored with no warning and the index is still used.

For boolean mode searches, index hints with `FOR ORDER BY` or `FOR GROUP BY` are silently ignored. Index hints with `FOR JOIN` or no `FOR` modifier are honored. In contrast to how hints apply for non-`FULLTEXT` searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-`FULLTEXT` index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
  USE INDEX (index1)
  IGNORE INDEX (index1) FOR ORDER BY
  IGNORE INDEX (index1) FOR GROUP BY
  WHERE ... IN BOOLEAN MODE ... ;

SELECT * FROM t
  USE INDEX (index1)
  WHERE ... IN BOOLEAN MODE ... ;
```

#### 13.2.9.4. UNION Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

`UNION` is used to combine the result from multiple `SELECT` statements into a single result set.

The column names from the first `SELECT` statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all of the `SELECT` statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a              |
| bbbbbbbbbbb   |
+-----+
```

The `SELECT` statements are normal select statements, but with the following restrictions:

- Only the last `SELECT` statement can use `INTO OUTFILE`. (However, the entire `UNION` result is written to the file.)
- `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.

The default behavior for `UNION` is that duplicate rows are removed from the result. The optional `DISTINCT` keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

However, use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, the use of `ORDER BY` in this context is typically in conjunction with `LIMIT`, so that it is used to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a **UNION** result to consist of the sets of rows retrieved by each **SELECT** one after the other, select an additional column in each **SELECT** to use as a sort column and add an **ORDER BY** following the last **SELECT**:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual **SELECT** results, add a secondary column to the **ORDER BY** clause:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which **SELECT** each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

### 13.2.10. Subquery Syntax

A subquery is a **SELECT** statement within another statement.

Starting with MySQL 4.1, all subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, **SELECT \* FROM t1 ...** is the *outer query* (or *outer statement*), and **(SELECT column1 FROM t2)** is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
  WHERE NOT EXISTS
    (SELECT * FROM t3
     WHERE ROW(5*t2.s1,77)=
      (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
       (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`.

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA INFILE`.

For information about how the optimizer handles subqueries, see [Section 8.13.16, "Subquery Optimization"](#). For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see [Section E.4, "Restrictions on Subqueries"](#).

### 13.2.10.1. The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value ('abcde') that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA INFILE` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct (`SELECT column1 FROM t1`), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is `2` because there is a row in `t2` containing a column `s1` that has a value of `2`.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 13.2.10.2. Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <> != <=>
```

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table *t1* for which the *column1* value is equal to a maximum value in table *t2*:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table *t1* containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See [Section 13.2.10.5, “Row Subqueries”](#).

### 13.2.10.3. Subqueries with **ANY**, **IN**, or **SOME**

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <> !=
```

The **ANY** keyword, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ANY** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table *t1* containing (10). The expression is **TRUE** if table *t2* contains (21,14,7) because there is a value 7 in *t2* that is less than 10. The expression is **FALSE** if table *t2* contains (20,10), or if table *t2* is empty. The expression is *unknown* (that is, **NULL**) if table *t2* contains (NULL,NULL,NULL).

When used with a subquery, the word **IN** is an alias for = **ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

**IN** and = **ANY** are not synonyms when used with an expression list. **IN** can take an expression list, but = **ANY** cannot. See [Section 12.3.2, “Comparison Functions and Operators”](#).

**NOT IN** is not an alias for <> **ANY**, but for <> **ALL**. See [Section 13.2.10.4, “Subqueries with ALL”](#).

The word **SOME** is an alias for **ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word **SOME** is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using **<> SOME** instead helps ensure that everyone understands the true meaning of the query.

#### 13.2.10.4. Subqueries with **ALL**

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word **ALL**, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ALL** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table **t1** containing (10). The expression is **TRUE** if table **t2** contains (-5, 0, +5) because 10 is greater than all three values in **t2**. The expression is **FALSE** if table **t2** contains (12, 6, NULL, -100) because there is a single value 12 in table **t2** that is greater than 10. The expression is *unknown* (that is, **NULL**) if table **t2** contains (0, NULL, 1).

Finally, the expression is **TRUE** if table **t2** is empty. So, the following expression is **TRUE** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

**NOT IN** is an alias for **<> ALL**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

#### 13.2.10.5. Row Subqueries

The discussion to this point has been of scalar or column subqueries; that is, subqueries that return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
= > < >= <= <> != <=>
```

Here are two examples:

```
SELECT * FROM t1
WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table **t2** contains a single row with **id = 10**, the subquery returns a single row. If this row has **col3** and **col4** values equal to the **col1** and **col2** values of any rows in **t1**, the **WHERE** expression is **TRUE** and each query returns those **t1** rows. If the **t2** row **col3** and **col4** values are not equal the **col1** and **col2** values of any **t1** row, the expression is **FALSE** and the query returns an empty result set. The expression is *unknown* (that is, **NULL**) if the subquery produces no rows. An

error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

The expressions `(1, 2)` and `ROW(1, 2)` are sometimes called *row constructors*. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1, column2) = (1, 1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1, column2, column3
FROM t1
WHERE (column1, column2, column3) IN
      (SELECT column1, column2, column3 FROM t2);
```

### 13.2.10.6. Subqueries with **EXISTS** or **NOT EXISTS**

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is `x TRUE` for all `y`?”

### 13.2.10.7. Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
                     WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5,6)` is not equal to `(5,7)`), so the expression as a whole is `FALSE`.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
                  WHERE x.column1 = (SELECT column1 FROM t3
                                    WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.
