
- In MySQL 5.6, an event is uniquely identified by its name and the schema to which it is assigned.
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 13.6, “MySQL Compound-Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK( )` [\[1275\]](#) function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 18.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 13.1.2, “ALTER EVENT Syntax”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT [754]` privilege on the database for which the event is defined. See [Section 18.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section E.1, “Restrictions on Stored Programs”](#).

## 18.4.2. Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS [755]` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler [480]` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. **OFF** is the default value for `event_scheduler [480]`.

When the Event Scheduler is stopped (`event_scheduler [480]` is **OFF**), it can be started by setting the value of `event_scheduler [480]` to **ON**. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 1
  User: root
  Host: localhost
  db: NULL
Command: Query
  Time: 0
  State: NULL
  Info: show processlist
***** 2. row *****
  Id: 2
  User: event_scheduler
  Host: localhost
  db: NULL
Command: Daemon
  Time: 3
  State: Waiting for next activation
  Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` [480] to **OFF**.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` [480] can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` [480] by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. *DISABLED has no numeric equivalent*. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` [480] without specifying it as a global variable causes an error:

```
mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL
```

### Important

It is possible to set the Event Scheduler to **DISABLED** only at server startup. If `event_scheduler` [480] is **ON** or **OFF**, you cannot set it to **DISABLED** at runtime. Also, if the Event Scheduler is set to **DISABLED** at startup, you cannot change the value of `event_scheduler` [480] at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` [422] command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` [422] in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

#### Note

You can issue event-manipulation statements when `event_scheduler` [480] is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` [439] option causes `event_scheduler` [480] to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see [Section 18.4.3, “Event Syntax”](#).

MySQL 5.6 provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 18.4.4, “Event Metadata”](#), and [Section 19.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 18.4.6, “The Event Scheduler and MySQL Privileges”](#).

### 18.4.3. Event Syntax

MySQL 5.6 provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 13.1.9, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 13.1.2, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 13.1.18, “DROP EVENT Syntax”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 13.1.9, “CREATE EVENT Syntax”](#).

An event can be dropped by any user having the `EVENT` [754] privilege for the database on which the event is defined. See [Section 18.4.6, “The Event Scheduler and MySQL Privileges”](#).

### 18.4.4. Event Metadata

Metadata about events can be obtained as follows:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 19.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#).

- Use the `SHOW CREATE EVENT` statement. See [Section 13.7.5.9, “SHOW CREATE EVENT Syntax”](#).
- Use the `SHOW EVENTS` statement. See [Section 13.7.5.19, “SHOW EVENTS Syntax”](#).

### Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` [557] value that is initialized from the server's global `time_zone` [557] value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

Value	<code>mysql.event</code>	<code>INFORMATION_SCHEMA.EVENTS</code>	<code>SHOW EVENTS</code>
Execute at	UTC	ETZ	ETZ
Starts	UTC	ETZ	ETZ
Ends	UTC	ETZ	ETZ
Last executed	UTC	ETZ	n/a
Created	STZ	STZ	n/a
Last altered	STZ	STZ	n/a

## 18.4.5. Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See [Section 18.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA       : init_scheduler:313
LUA       : init_scheduler:318
WOC       : NO
Workers   : 0
Executed  : 0
Data locked: NO

Event queue status:
Element count : 1
Data locked   : NO
Attempting lock : NO
```

```
LLA      : init_queue:148
LUA      : init_queue:168
WOC      : NO
Next activation : 0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

## 18.4.6. The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` [\[480\]](#) system variable. This requires the `SUPER` [\[756\]](#) privilege.

The `EVENT` [\[754\]](#) privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` [\[754\]](#) privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` [\[754\]](#) privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` [\[754\]](#) privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` [\[754\]](#) privilege for `myschema`. Suppose also that this user has the `SELECT` [\[755\]](#) privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
EVERY 10 SECOND
DO
INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` [\[755\]](#) privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:39:54 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:40:04 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT [754]` privilege, use the `REVOKE` statement. In this example, the `EVENT [754]` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

### Important

Revoking the `EVENT [754]` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT [754]` and `INSERT [755]` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT [754]` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 19.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
  WHERE db = 'myschema'
        AND definer = 'jon@ghidora'
        AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Users' `EVENT [754]` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT [754]` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT [754]` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but *not* of statements executed by events; see [Section E.1, “Restrictions on Stored Programs”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

## 18.5. Using Views

Views (including updatable views) are available in MySQL Server 5.6. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.6 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

### Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section B.6, “MySQL 5.6 FAQ: Views”](#).
- There are some restrictions on the use of views; see [Section E.5, “Restrictions on Views”](#).

## 18.5.1. View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 13.1.16](#), “`CREATE VIEW Syntax`”). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 13.1.7](#), “`ALTER VIEW Syntax`”), or `DROP VIEW` (see [Section 13.1.25](#), “`DROP VIEW Syntax`”).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
| 5 | 60 | 300 |
+-----+-----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 5 | 60 | 300 |
+-----+-----+-----+
```

## 18.5.2. View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` [1171] connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()` [1285], `MIN()` [1284], `MAX()` [1284], `COUNT()` [1283], and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Refers only to literal values (in this case, there is no underlying table)

### 18.5.3. Updatable and Insertable Views

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()` [1285], `MIN()` [1284], `MAX()` [1284], `COUNT()` [1283], and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`

- `UNION` or `UNION ALL`
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Nonupdatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- Uses `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are not permitted even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()` [1269], because the side effects of inserting default values into columns not part of the view should not be visible.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
  -> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
  -> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
  -> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` [562] system variable. See [Section 5.1.4, "Server System Variables"](#).

## 18.5.4. View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 19.29, "The INFORMATION\\_SCHEMA VIEWS Table"](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 13.7.5.14, "SHOW CREATE VIEW Syntax"](#).

## 18.6. Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute, and, if there is one, their `SQL SECURITY` characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a `DEFINER` attribute that names a MySQL account. If the `DEFINER` attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the `SQL SECURITY` characteristic is omitted, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` [754] to call a stored procedure or `SELECT` [755] to select from a view), but when the object executes, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as a `root` account), the object can perform powerful operations *no matter who invokes it*.
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` [754] privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in `DEFINER` security context and thus executes with the privileges of `'admin'@'localhost'`, the account named in the `DEFINER` attribute. This account must have the `EXECUTE` [754] privilege for `p1` as well as the `UPDATE` [756] privilege for the table `t1`. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

`p2`, unlike `p1`, executes in `INVOKER` security context. The `DEFINER` attribute is irrelevant and `p2` executes with the privileges of the invoking user. `p2` fails if the invoker lacks the `EXECUTE` [754] privilege for `p2` or the `UPDATE` [756] privilege for the table `t1`.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

- You can specify a `DEFINER` value other than your own account only if you have the `SUPER` [756] privilege.
- If you do not have the `SUPER` [756] privilege, the only legal user value is your own account, either specified literally or by using `CURRENT_USER` [1267]. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the `SUPER` [756] privilege, specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.
- Administrators can prevent users from specifying highly privileged `DEFINER` accounts by not granting them the `SUPER` [756] privilege.

- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
  - A stored procedure or function cannot be referenced by a user who does not have the `EXECUTE` [754] privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` [755] to select from it, `INSERT` [755] to insert into it, and so forth).

However, no such control exists for triggers because users do not reference them directly. A trigger always executes in `DEFINER` context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the `DEFINER` account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the `SUPER` [756] and `TRIGGER` [756] privileges needed to create the trigger are revoked from the account of the user who created it. Administrators should be especially careful about granting users that combination of privileges.

## 18.7. Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 16.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.3.2, “Using Backups for Recovery”](#).

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, triggers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.6 handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see [Section 16.1.2, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` [2002] option. (See Section 5.2.4, “The Binary Log”.) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.6 can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` [756] privilege, in addition to the `CREATE ROUTINE` [754] or `ALTER ROUTINE` [754] privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` [756] might be required regardless of whether binary logging is enabled. See Section 13.1.12, “`CREATE PROCEDURE` and `CREATE FUNCTION Syntax`”.)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()` [1280], which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.
- To relax the preceding conditions on function creation (that you must have the `SUPER` [756] privilege and that a function must be declared deterministic or to not modify data), set the global

`log_bin_trust_function_creators` [497] system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` [2003] option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` [497] does not apply. `SUPER` [756] is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 16.4.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` [1280] function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the

log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE [754]` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
->   IF @@server_id=2 THEN dangerous_statement; END IF;
->   RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER [756]` privilege, in addition to the usual `CREATE ROUTINE [754]` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER [756]` privilege in addition to the `ALTER ROUTINE [754]` privilege. Without the `SUPER [756]` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER [756]` privilege (for example, if all users with the `CREATE ROUTINE [754]` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators [497]` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1 [2003]` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators [497]` does not apply. `SUPER [756]` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if

neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` [497] to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` [1279] has a value of `var_value`, and a "name" of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` [1279] enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` [1279] can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` [1279] expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where *value* is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
  - Updates to transactional tables are not logged.
  - Updates to nontransactional tables are logged because rollback does not cancel them.
  - Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

19.31.1.	The <code>INFORMATION_SCHEMA</code> <code>TP_THREAD_STATE</code> Table .....	2226
19.31.2.	The <code>INFORMATION_SCHEMA</code> <code>TP_THREAD_GROUP_STATE</code> Table .....	2226
19.31.3.	The <code>INFORMATION_SCHEMA</code> <code>TP_THREAD_GROUP_STATS</code> Table .....	2228
19.32.	Extensions to <code>SHOW</code> Statements .....	2229

`INFORMATION_SCHEMA` provides access to database *metadata*, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are *data dictionary* and *system catalog*.

## Usage Notes for the `INFORMATION_SCHEMA` Database

`INFORMATION_SCHEMA` is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The `INFORMATION_SCHEMA` database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select `INFORMATION_SCHEMA` as the default database with a `USE` statement, you can only read the contents of tables, not perform `INSERT`, `UPDATE`, or `DELETE` operations on them.

## Example

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name;
```

table_name	table_type	engine
fk	BASE TABLE	InnoDB
fk2	BASE TABLE	InnoDB
goto	BASE TABLE	MyISAM
into	BASE TABLE	MyISAM
k	BASE TABLE	MyISAM
kurs	BASE TABLE	MyISAM
loop	BASE TABLE	MyISAM
pk	BASE TABLE	InnoDB
t	BASE TABLE	MyISAM
t2	BASE TABLE	MyISAM
t3	BASE TABLE	MyISAM
t7	BASE TABLE	MyISAM
tables	BASE TABLE	MyISAM
v	VIEW	NULL
v2	VIEW	NULL
v3	VIEW	NULL
v56	VIEW	NULL

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

## Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see [Section 10.1.7.9, “Collation and INFORMATION\\_SCHEMA Searches”](#).

## INFORMATION\_SCHEMA as Alternative to SHOW Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in [Section 19.32, “Extensions to SHOW Statements”](#).

## Privileges

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges see `NULL`. These restrictions do not apply for `InnoDB` tables; you can see them with only the `PROCESS [755]` privilege.

The same privileges apply to selecting information from `INFORMATION_SCHEMA` and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

## Performance Considerations

`INFORMATION_SCHEMA` queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune `INFORMATION_SCHEMA` queries, see [Section 8.2.4, “Optimizing INFORMATION\\_SCHEMA Queries”](#).

## Standards Considerations

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: [http://web.archive.org/web/20070409075643rn\\_1/www.dbazine.com/db2/db2-disarticles/gulutzan5](http://web.archive.org/web/20070409075643rn_1/www.dbazine.com/db2/db2-disarticles/gulutzan5).

## Conventions in the `INFORMATION_SCHEMA` Reference Sections

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

For information about `INFORMATION_SCHEMA` tables specific to the `InnoDB` storage engine, see [Section 19.30, “`INFORMATION\_SCHEMA` Tables for `InnoDB`”](#). For information about `INFORMATION_SCHEMA` tables specific to the thread pool plugin, see [Section 19.31, “Thread Pool `INFORMATION\_SCHEMA` Tables”](#).

For answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database, see [Section B.7, “MySQL 5.6 FAQ: `INFORMATION\_SCHEMA`”](#).

### 19.1. The `INFORMATION_SCHEMA CHARACTER_SETS` Table

The `CHARACTER_SETS` table provides information about available character sets.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CHARACTER_SET_NAME</code>	Charset	
<code>DEFAULT_COLLATE_NAME</code>	Default collation	
<code>DESCRIPTION</code>	Description	MySQL extension
<code>MAXLEN</code>	Maxlen	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

### 19.2. The `INFORMATION_SCHEMA COLLATIONS` Table

The `COLLATIONS` table provides information about collations for each character set.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>COLLATION_NAME</code>	Collation	

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CHARACTER_SET_NAME</code>	Charset	MySQL extension
<code>ID</code>	Id	MySQL extension
<code>IS_DEFAULT</code>	Default	MySQL extension
<code>IS_COMPILED</code>	Compiled	MySQL extension
<code>SORTLEN</code>	Sortlen	MySQL extension

- `COLLATION_NAME` is the collation name.
- `CHARACTER_SET_NAME` is the name of the character set with which the collation is associated.
- `ID` is the collation ID.
- `IS_DEFAULT` indicates whether the collation is the default for its character set.
- `IS_COMPILED` indicates whether the character set is compiled into the server.
- `SORTLEN` is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the `SHOW COLLATION` statement. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
[WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
[LIKE 'wild']
```

### 19.3. The `INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY` Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>COLLATION_NAME</code>	Collation	
<code>CHARACTER_SET_NAME</code>	Charset	

### 19.4. The `INFORMATION_SCHEMA COLUMNS` Table

The `COLUMNS` table provides information about columns in tables.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>TABLE_CATALOG</code>		def
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>COLUMN_NAME</code>	Field	
<code>ORDINAL_POSITION</code>		see notes
<code>COLUMN_DEFAULT</code>	Default	
<code>IS_NULLABLE</code>	Null	
<code>DATA_TYPE</code>	Type	
<code>CHARACTER_MAXIMUM_LENGTH</code>	Type	
<code>CHARACTER_OCTET_LENGTH</code>		

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>NUMERIC_PRECISION</code>	Type	
<code>NUMERIC_SCALE</code>	Type	
<code>DATETIME_PRECISION</code>	Type	
<code>CHARACTER_SET_NAME</code>		
<code>COLLATION_NAME</code>	Collation	
<code>COLUMN_TYPE</code>	Type	MySQL extension
<code>COLUMN_KEY</code>	Key	MySQL extension
<code>EXTRA</code>	Extra	MySQL extension
<code>PRIVILEGES</code>	Privileges	MySQL extension
<code>COLUMN_COMMENT</code>	Comment	MySQL extension

**Notes:**

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW`, `SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multi-byte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.
- `DATETIME_PRECISION` was added in MySQL 5.6.4.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

## 19.5. The `INFORMATION_SCHEMA COLUMN_PRIVILEGES` Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>GRANTEE</code>		' <i>user_name</i> '@' <i>host_name</i> ' value
<code>TABLE_CATALOG</code>		<code>def</code>
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>COLUMN_NAME</code>		
<code>PRIVILEGE_TYPE</code>		
<code>IS_GRANTABLE</code>		

**Notes:**

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT [755]`, `INSERT [755]`, `UPDATE [756]`, `REFERENCES [755]`.
- If the user has `GRANT OPTION [755]` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION [755]` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES

SHOW GRANTS ...
```

## 19.6. The `INFORMATION_SCHEMA.ENGINES` Table

The `ENGINES` table provides information about storage engines.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>ENGINE</code>	<code>Engine</code>	MySQL extension
<code>SUPPORT</code>	<code>Support</code>	MySQL extension
<code>COMMENT</code>	<code>Comment</code>	MySQL extension
<code>TRANSACTIONS</code>	<code>Transactions</code>	MySQL extension
<code>XA</code>	<code>XA</code>	MySQL extension
<code>SAVEPOINTS</code>	<code>Savepoints</code>	MySQL extension

**Notes:**

- The `ENGINES` table is a nonstandard table.

See also [Section 13.7.5.17](#), “`SHOW ENGINES` Syntax”.

## 19.7. The `INFORMATION_SCHEMA.EVENTS` Table

The `EVENTS` table provides information about scheduled events, which are discussed in [Section 18.4](#), “Using the Event Scheduler”. The `SHOW` Name values correspond to column names of the `SHOW EVENTS` statement.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>EVENT_CATALOG</code>		<code>def</code> , MySQL extension
<code>EVENT_SCHEMA</code>	<code>Db</code>	MySQL extension
<code>EVENT_NAME</code>	<code>Name</code>	MySQL extension
<code>DEFINER</code>	<code>Definer</code>	MySQL extension
<code>TIME_ZONE</code>	<code>Time zone</code>	MySQL extension
<code>EVENT_BODY</code>		MySQL extension
<code>EVENT_DEFINITION</code>		MySQL extension
<code>EVENT_TYPE</code>	<code>Type</code>	MySQL extension
<code>EXECUTE_AT</code>	<code>Execute at</code>	MySQL extension

INFORMATION_SCHEMA Name	SHOW Name	Remarks
INTERVAL_VALUE	Interval value	MySQL extension
INTERVAL_FIELD	Interval field	MySQL extension
SQL_MODE		MySQL extension
STARTS	Starts	MySQL extension
ENDS	Ends	MySQL extension
STATUS	Status	MySQL extension
ON_COMPLETION		MySQL extension
CREATED		MySQL extension
LAST_ALTERED		MySQL extension
LAST_EXECUTED		MySQL extension
EVENT_COMMENT		MySQL extension
ORIGINATOR	Originator	MySQL extension
CHARACTER_SET_CLIENT	character_set_client	MySQL extension
COLLATION_CONNECTION	collation_connection [468]	MySQL extension
DATABASE_COLLATION	Database Collation	MySQL extension

**Notes:**

- The `EVENTS` table is a nonstandard table.
- `EVENT_CATALOG`: The value of this column is always `def`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The account of the user who created the event, in `'user_name'@'host_name'` format.
- `TIME_ZONE`: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.
- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 5.6, this is always `SQL`.

This column is not to be confused with the column of the same name (now named `EVENT_DEFINITION`) that existed in earlier MySQL versions.

- `EVENT_DEFINITION`: The text of the SQL statement making up the event's `DO` clause; in other words, the statement executed by this event.
- `EVENT_TYPE`: The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).
- `EXECUTE_AT`: For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be `'2006-02-10 20:05:30'`.

If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- `INTERVAL_VALUE`: For recurring events, this column contains the numeric portion of the event's `EVERY` clause.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column is `NULL`.

- `INTERVAL_FIELD`: For recurring events, this column contains the units portion of the `EVERY` clause governing the timing of the event. Thus, this column contains a value such as `'YEAR'`, `'QUARTER'`, `'DAY'`, and so on.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column is `NULL`.

- `SQL_MODE`: The SQL mode in effect at the time the event was created or altered.
- `STARTS`: For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used.

If there is no `STARTS` clause affecting the timing of the event, this column is `NULL`.

- `ENDS`: For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used.

If there is no `ENDS` clause affecting the timing of the event, this column is `NULL`.

- `STATUS`: One of the three values `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.

`SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 16.4.1.10, “Replication of Invoked Features”](#), for more information.

- `ON_COMPLETION`: One of the two values `PRESERVE` or `NOT PRESERVE`.
- `CREATED`: The date and time when the event was created. This is a `DATETIME` value.
- `LAST_ALTERED`: The date and time when the event was last modified. This is a `DATETIME` value. If the event has not been modified since its creation, this column holds the same value as the `CREATED` column.
- `LAST_EXECUTED`: The date and time when the event last executed. A `DATETIME` value. If the event has never executed, this column is `NULL`.

`LAST_EXECUTED` indicates when the event started. As a result, the `ENDS` column is never less than `LAST_EXECUTED`.

- `EVENT_COMMENT`: The text of a comment, if the event has one. If not, the value of this column is an empty string.
- `ORIGINATOR`: The server ID of the MySQL server on which the event was created; used in replication. The default value is 0.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` [467] system variable when the event was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` [469] system variable when the event was created. `DATABASE_COLLATION` is the collation of the database with which the event is associated.

**Example:** Suppose that the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |
```

```

CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
DELIMITER ;

ALTER EVENT e_daily
ENABLED;

```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: def
EVENT_SCHEMA: test
EVENT_NAME: e_daily
DEFINER: paul@localhost
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE:
STARTS: 2008-09-03 12:13:39
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2008-09-03 12:13:39
LAST_ALTERED: 2008-09-03 12:13:39
LAST_EXECUTED: NULL
EVENT_COMMENT: Saves total number of sessions then clears the
table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: latin1
COLLATION_CONNECTION: latin1_swedish_ci
DATABASE_COLLATION: latin1_swedish_ci

```

Times in the `EVENTS` table are displayed using the event time zone or the current session time zone, as described in [Section 18.4.4, “Event Metadata”](#).

See also [Section 13.7.5.19, “SHOW EVENTS Syntax”](#).

## 19.8. The `INFORMATION_SCHEMA.FILES` Table

The `FILES` table provides information about the files in which MySQL tablespace data is stored.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>FILE_ID</code>		MySQL extension
<code>FILE_NAME</code>		MySQL extension

INFORMATION_SCHEMA Name	SHOW Name	Remarks
FILE_TYPE		MySQL extension
TABLESPACE_NAME		MySQL extension
TABLE_CATALOG		MySQL extension
TABLE_SCHEMA		MySQL extension
TABLE_NAME		MySQL extension
LOGFILE_GROUP_NAME		MySQL extension
LOGFILE_GROUP_NUMBER		MySQL extension
ENGINE		MySQL extension
FULLTEXT_KEYS		MySQL extension
DELETED_ROWS		MySQL extension
UPDATE_COUNT		MySQL extension
FREE_EXTENTS		MySQL extension
TOTAL_EXTENTS		MySQL extension
EXTENT_SIZE		MySQL extension
INITIAL_SIZE		MySQL extension
MAXIMUM_SIZE		MySQL extension
AUTOEXTEND_SIZE		MySQL extension
CREATION_TIME		MySQL extension
LAST_UPDATE_TIME		MySQL extension
LAST_ACCESS_TIME		MySQL extension
RECOVER_TIME		MySQL extension
TRANSACTION_COUNTER		MySQL extension
VERSION		MySQL extension
ROW_FORMAT		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
STATUS		MySQL extension
EXTRA		MySQL extension

**Notes:**

- `FILE_ID` column values are auto-generated.
- `FILE_NAME` is the name of a data file created by `CREATE TABLESPACE` or `ALTER TABLESPACE`.
- `FILE_TYPE` is the tablespace file type.

- `TABLESPACE_NAME` is the name of the tablespace with which the file is associated.
- Currently, the value of the `TABLESPACE_CATALOG` column is always `NULL`.
- `TABLE_NAME` is the name of the table with which the file is associated, if any.
- The `EXTENT_SIZE` is always 0.
- There are no `SHOW` statements associated with the `FILES` table.

## 19.9. The `INFORMATION_SCHEMA` `GLOBAL_STATUS` and `SESSION_STATUS` Tables

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see [Section 13.7.5.36](#), “`SHOW STATUS Syntax`”).

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>VARIABLE_NAME</code>	Variable_name	
<code>VARIABLE_VALUE</code>	Value	

### Notes:

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`.

## 19.10. The `INFORMATION_SCHEMA` `GLOBAL_VARIABLES` and `SESSION_VARIABLES` Tables

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see [Section 13.7.5.40](#), “`SHOW VARIABLES Syntax`”).

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>VARIABLE_NAME</code>	Variable_name	
<code>VARIABLE_VALUE</code>	Value	

### Notes:

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`.

## 19.11. The `INFORMATION_SCHEMA` `KEY_COLUMN_USAGE` Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CONSTRAINT_CATALOG</code>		def
<code>CONSTRAINT_SCHEMA</code>		
<code>CONSTRAINT_NAME</code>		
<code>TABLE_CATALOG</code>		def
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>COLUMN_NAME</code>		
<code>ORDINAL_POSITION</code>		

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>POSITION_IN_UNIQUE_CONSTRAINT</code>		
<code>REFERENCED_TABLE_SCHEMA</code>		
<code>REFERENCED_TABLE_NAME</code>		
<code>REFERENCED_COLUMN_NAME</code>		

**Notes:**

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME` = 'PRIMARY', `TABLE_NAME` = 't1', `COLUMN_NAME` = 's3', `ORDINAL_POSITION` = 1, `POSITION_IN_UNIQUE_CONSTRAINT` = `NULL`.
- One row with `CONSTRAINT_NAME` = 'CO', `TABLE_NAME` = 't3', `COLUMN_NAME` = 's2', `ORDINAL_POSITION` = 1, `POSITION_IN_UNIQUE_CONSTRAINT` = 1.

## 19.12. The `INFORMATION_SCHEMA OPTIMIZER_TRACE` Table

The `OPTIMIZER_TRACE` table provides information produced by the optimizer tracing capability. To enable tracking, use the `optimizer_trace` [523] system variable. For details, see [MySQL Internals: Tracing the Optimizer](#).

The `OPTIMIZER_TRACE` table was added in MySQL 5.6.3.

## 19.13. The `INFORMATION_SCHEMA PARAMETERS` Table

The `PARAMETERS` table provides information about stored procedure and function parameters, and about return values for stored functions. Parameter information is similar to the contents of the `param_list` column in the `mysql.proc` table.

<code>INFORMATION_SCHEMA</code> Name	<code>mysql.proc</code> Name	Remarks
<code>SPECIFIC_CATALOG</code>		<code>def</code>

<code>INFORMATION_SCHEMA</code> Name	<code>mysql.proc</code> Name	Remarks
<code>SPECIFIC_SCHEMA</code>	<code>db</code>	routine database
<code>SPECIFIC_NAME</code>	<code>name</code>	routine name
<code>ORDINAL_POSITION</code>		1, 2, 3, ... for parameters, 0 for function <code>RETURNS</code> clause
<code>PARAMETER_MODE</code>		<code>IN</code> , <code>OUT</code> , <code>INOUT</code> ( <code>NULL</code> for <code>RETURNS</code> )
<code>PARAMETER_NAME</code>		parameter name ( <code>NULL</code> for <code>RETURNS</code> )
<code>DATA_TYPE</code>		same as for <code>COLUMNS</code> table
<code>CHARACTER_MAXIMUM_LENGTH</code>		same as for <code>COLUMNS</code> table
<code>CHARACTER_OCTET_LENGTH</code>		same as for <code>COLUMNS</code> table
<code>NUMERIC_PRECISION</code>		same as for <code>COLUMNS</code> table
<code>NUMERIC_SCALE</code>		same as for <code>COLUMNS</code> table
<code>DATETIME_PRECISION</code>		same as for <code>COLUMNS</code> table
<code>CHARACTER_SET_NAME</code>		same as for <code>COLUMNS</code> table
<code>COLLATION_NAME</code>		same as for <code>COLUMNS</code> table
<code>DTD_IDENTIFIER</code>		same as for <code>COLUMNS</code> table
<code>ROUTINE_TYPE</code>	<code>type</code>	same as for <code>ROUTINES</code> table

**Notes:**

- For successive parameters of a stored procedure or function, the `ORDINAL_POSITION` values are 1, 2, 3, and so forth. For a stored function, there is also a row that describes the data type for the `RETURNS` clause. The return value is not a true parameter, so the row that describes it has these unique characteristics:
  - The `ORDINAL_POSITION` value is 0.
  - The `PARAMETER_NAME` and `PARAMETER_MODE` values are `NULL` because the return value has no name and the mode does not apply.
  - `DATETIME_PRECISION` was added in MySQL 5.6.4.

## 19.14. The `INFORMATION_SCHEMA PARTITIONS` Table

The `PARTITIONS` table provides information about table partitions. See [Chapter 17, Partitioning](#), for more information about partitioning tables.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>TABLE_CATALOG</code>		MySQL extension
<code>TABLE_SCHEMA</code>		MySQL extension
<code>TABLE_NAME</code>		MySQL extension
<code>PARTITION_NAME</code>		MySQL extension
<code>SUBPARTITION_NAME</code>		MySQL extension
<code>PARTITION_ORDINAL_POSITION</code>		MySQL extension
<code>SUBPARTITION_ORDINAL_POSITION</code>		MySQL extension
<code>PARTITION_METHOD</code>		MySQL extension
<code>SUBPARTITION_METHOD</code>		MySQL extension

INFORMATION_SCHEMA Name	SHOW Name	Remarks
PARTITION_EXPRESSION		MySQL extension
SUBPARTITION_EXPRESSION		MySQL extension
PARTITION_DESCRIPTION		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
PARTITION_COMMENT		MySQL extension
NODEGROUP		MySQL extension
TABLESPACE_NAME		MySQL extension

**Notes:**

- The `PARTITIONS` table is a nonstandard table.  
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `def`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.
- `SUBPARTITION_NAME`: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- `PARTITION_ORDINAL_POSITION`: All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- `SUBPARTITION_ORDINAL_POSITION`: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- `PARTITION_METHOD`: One of the values `RANGE`, `LIST`, `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available partitioning types as discussed in [Section 17.2, “Partitioning Types”](#).
- `SUBPARTITION_METHOD`: One of the values `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available subpartitioning types as discussed in [Section 17.2.6, “Subpartitioning”](#).
- `PARTITION_EXPRESSION`: This is the expression for the partitioning function used in the `CREATE TABLE` or `ALTER TABLE` statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
```

```

    c2 INT,
    c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;

```

The `PARTITION_EXPRESSION` column in a `PARTITIONS` table record for a partition from this table displays `c1 + c2`, as shown here:

```

mysql> SELECT DISTINCT PARTITION_EXPRESSION
>       FROM INFORMATION_SCHEMA.PARTITIONS
>       WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
1 row in set (0.09 sec)

```

- **SUBPARTITION\_EXPRESSION**: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as `PARTITION_EXPRESSION` does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is `NULL`.

- **PARTITION\_DESCRIPTION**: This column is used for `RANGE` and `LIST` partitions. For a `RANGE` partition, it contains the value set in the partition's `VALUES LESS THAN` clause, which can be either an integer or `MAXVALUE`. For a `LIST` partition, this column contains the values defined in the partition's `VALUES IN` clause, which is a comma-separated list of integer values.

For partitions whose `PARTITION_METHOD` is other than `RANGE` or `LIST`, this column is always `NULL`.

- **TABLE\_ROWS**: The number of table rows in the partition.

For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column is only an estimated value used in SQL optimization, and may not always be exact.

- **AVG\_ROW\_LENGTH**: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as `DATA_LENGTH` divided by `TABLE_ROWS`.

- **DATA\_LENGTH**: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.
- **MAX\_DATA\_LENGTH**: The maximum number of bytes that can be stored in this partition or subpartition.
- **INDEX\_LENGTH**: The length of the index file for this partition or subpartition, in bytes.
- **DATA\_FREE**: The number of bytes allocated to the partition or subpartition but not used.
- **CREATE\_TIME**: The time of the partition's or subpartition's creation.
- **UPDATE\_TIME**: The time that the partition or subpartition was last modified.
- **CHECK\_TIME**: The last time that the table to which this partition or subpartition belongs was checked.

#### Note

Some storage engines do not update this time; for tables using these storage engines, this value is always `NULL`.

- **CHECKSUM**: The checksum value, if any; otherwise, this column is `NULL`.
- **PARTITION\_COMMENT**: This column contains the text of any comment made for the partition.

Prior to MySQL 5.6.6, the display width of this column was 80 characters, and partition comments which exceeded this length were truncated to fit. As of MySQL 5.6.6, the maximum length for a partition comment is defined as 1024 characters, and the display width of the `PARTITION_COMMENT` column is increased to 1024 characters to match this limit (Bug #11748924, Bug #37728).

The default value for this column is an empty string.

- `NODEGROUP`: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.
- `TABLESPACE_NAME`: This column contains the name of the tablespace to which the partition belongs. Currently, the value of this column is always `DEFAULT`.
- A nonpartitioned table has one record in `INFORMATION_SCHEMA.PARTITIONS`; however, the values of the `PARTITION_NAME`, `SUBPARTITION_NAME`, `PARTITION_ORDINAL_POSITION`, `SUBPARTITION_ORDINAL_POSITION`, `PARTITION_METHOD`, `SUBPARTITION_METHOD`, `PARTITION_EXPRESSION`, `SUBPARTITION_EXPRESSION`, and `PARTITION_DESCRIPTION` columns are all `NULL`. (The `PARTITION_COMMENT` column in this case is blank.)

## 19.15. The `INFORMATION_SCHEMA PLUGINS` Table

The `PLUGINS` table provides information about server plugins.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>PLUGIN_NAME</code>	Name	MySQL extension
<code>PLUGIN_VERSION</code>		MySQL extension
<code>PLUGIN_STATUS</code>	Status	MySQL extension
<code>PLUGIN_TYPE</code>	Type	MySQL extension
<code>PLUGIN_TYPE_VERSION</code>		MySQL extension
<code>PLUGIN_LIBRARY</code>	Library	MySQL extension
<code>PLUGIN_LIBRARY_VERSION</code>		MySQL extension
<code>PLUGIN_AUTHOR</code>		MySQL extension
<code>PLUGIN_DESCRIPTION</code>		MySQL extension
<code>PLUGIN_LICENSE</code>		MySQL extension
<code>LOAD_OPTION</code>		MySQL extension

### Notes:

- The `PLUGINS` table is a nonstandard table.
- `PLUGIN_NAME` is the name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- `PLUGIN_VERSION` is the version from the plugin's general type descriptor.
- `PLUGIN_STATUS` indicates the plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- `PLUGIN_TYPE` indicates the type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- `PLUGIN_TYPE_VERSION` is the version from the plugin's type-specific descriptor.
- `PLUGIN_LIBRARY` is the name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` [525] system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- `PLUGIN_LIBRARY_VERSION` indicates the plugin API interface version.
- `PLUGIN_AUTHOR` names the plugin author.
- `PLUGIN_DESCRIPTION` provides a short description of the plugin.
- `PLUGIN_LICENSE` indicates how the plugin is licensed; for example, `GPL`.
- `LOAD_OPTION` indicates how the plugin was loaded. The value is `OFF`, `ON`, `FORCE`, or `FORCE_PLUS_PERMANENT`. See [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBRARY` values are also registered in the `mysql.plugin` table.

These statements are equivalent:

```
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see [Section 22.2, “The MySQL Plugin API”](#).

Plugin information is also available using the `SHOW PLUGINS` statement. See [Section 13.7.5.26, “SHOW PLUGINS Syntax”](#).

## 19.16. The `INFORMATION_SCHEMA` `PROCESSLIST` Table

The `PROCESSLIST` table provides information about which threads are running.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>ID</code>	<code>Id</code>	MySQL extension
<code>USER</code>	<code>User</code>	MySQL extension
<code>HOST</code>	<code>Host</code>	MySQL extension
<code>DB</code>	<code>db</code>	MySQL extension
<code>COMMAND</code>	<code>Command</code>	MySQL extension
<code>TIME</code>	<code>Time</code>	MySQL extension
<code>STATE</code>	<code>State</code>	MySQL extension
<code>INFO</code>	<code>Info</code>	MySQL extension

For an extensive description of the table columns, see [Section 13.7.5.30, “SHOW PROCESSLIST Syntax”](#).

### Notes:

- The `PROCESSLIST` table is a nonstandard table.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS [755]` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.
- Process information is also available from the `performance_schema.threads` table. However, access to `threads` does not require a mutex and has minimal impact on server performance.

`INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

## 19.17. The `INFORMATION_SCHEMA.PROFILING` Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see [Section 13.7.5.32](#), “`SHOW PROFILES` Syntax”). The table is empty unless the `profiling` [526] session variable is set to 1.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>QUERY_ID</code>	<code>Query_ID</code>	
<code>SEQ</code>		
<code>STATE</code>	<code>Status</code>	
<code>DURATION</code>	<code>Duration</code>	
<code>CPU_USER</code>	<code>CPU_user</code>	
<code>CPU_SYSTEM</code>	<code>CPU_system</code>	
<code>CONTEXT_VOLUNTARY</code>	<code>Context_voluntary</code>	
<code>CONTEXT_INVOLUNTARY</code>	<code>Context_involuntary</code>	
<code>BLOCK_OPS_IN</code>	<code>Block_ops_in</code>	
<code>BLOCK_OPS_OUT</code>	<code>Block_ops_out</code>	
<code>MESSAGES_SENT</code>	<code>Messages_sent</code>	
<code>MESSAGES_RECEIVED</code>	<code>Messages_received</code>	
<code>PAGE_FAULTS_MAJOR</code>	<code>Page_faults_major</code>	
<code>PAGE_FAULTS_MINOR</code>	<code>Page_faults_minor</code>	
<code>SWAPS</code>	<code>Swaps</code>	
<code>SOURCE_FUNCTION</code>	<code>Source_function</code>	
<code>SOURCE_FILE</code>	<code>Source_file</code>	
<code>SOURCE_LINE</code>	<code>Source_line</code>	

### Notes:

- `QUERY_ID` is a numeric statement identifier.
- `SEQ` is a sequence number indicating the display order for rows with the same `QUERY_ID` value.
- `STATE` is the profiling state to which the row measurements apply.
- `DURATION` indicates how long statement execution remained in the given state, in seconds.
- `CPU_USER` and `CPU_SYSTEM` indicate user and system CPU use, in seconds.
- `CONTEXT_VOLUNTARY` and `CONTEXT_INVOLUNTARY` indicate how many voluntary and involuntary context switches occurred.
- `BLOCK_OPS_IN` and `BLOCK_OPS_OUT` indicate the number of block input and output operations.

- `MESSAGES_SENT` and `MESSAGES_RECEIVED` indicate the number of communication messages sent and received.
- `PAGE_FAULTS_MAJOR` and `PAGE_FAULTS_MINOR` indicate the number of major and minor page faults.
- `SWAPS` indicates how many swaps occurred.
- `SOURCE_FUNCTION`, `SOURCE_FILE`, and `SOURCE_LINE` provide information indicating where in the source code the profiled state executes.

## 19.18. The `INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS` Table

The `REFERENTIAL_CONSTRAINTS` table provides information about foreign keys.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CONSTRAINT_CATALOG</code>		def
<code>CONSTRAINT_SCHEMA</code>		
<code>CONSTRAINT_NAME</code>		
<code>UNIQUE_CONSTRAINT_CATALOG</code>		def
<code>UNIQUE_CONSTRAINT_SCHEMA</code>		
<code>UNIQUE_CONSTRAINT_NAME</code>		
<code>MATCH_OPTION</code>		
<code>UPDATE_RULE</code>		
<code>DELETE_RULE</code>		
<code>TABLE_NAME</code>		
<code>REFERENCED_TABLE_NAME</code>		

### Notes:

- `TABLE_NAME` has the same value as `TABLE_NAME` in `INFORMATION_SCHEMA.TABLE_CONSTRAINTS`.
- `CONSTRAINT_SCHEMA` and `CONSTRAINT_NAME` identify the foreign key.
- `UNIQUE_CONSTRAINT_SCHEMA`, `UNIQUE_CONSTRAINT_NAME`, and `REFERENCED_TABLE_NAME` identify the referenced key.
- The only valid value at this time for `MATCH_OPTION` is `NONE`.
- The possible values for `UPDATE_RULE` or `DELETE_RULE` are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

## 19.19. The `INFORMATION_SCHEMA ROUTINES` Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs).

The column named “`mysql.proc name`” indicates the `mysql.proc` table column that corresponds to the `INFORMATION_SCHEMA.ROUTINES` table column, if any.

<code>INFORMATION_SCHEMA</code> Name	<code>mysql.proc</code> Name	Remarks
<code>SPECIFIC_NAME</code>	<code>specific_name</code>	

INFORMATION_SCHEMA Name	mysql.proc Name	Remarks
ROUTINE_CATALOG		def
ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
ROUTINE_TYPE	type	{PROCEDURE   FUNCTION}
DATA_TYPE		same as for COLUMNS table
CHARACTER_MAXIMUM_LENGTH		same as for COLUMNS table
CHARACTER_OCTET_LENGTH		same as for COLUMNS table
NUMERIC_PRECISION		same as for COLUMNS table
NUMERIC_SCALE		same as for COLUMNS table
DATETIME_PRECISION		same as for COLUMNS table
CHARACTER_SET_NAME		same as for COLUMNS table
COLLATION_NAME		same as for COLUMNS table
DTD_IDENTIFIER		data type descriptor
ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body_utf8	
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
SQL_PATH		NULL
SECURITY_TYPE	security_type	
CREATED	created	
LAST_ALTERED	modified	
SQL_MODE	sql_mode [545]	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

**Notes:**

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
  - If `mysql.proc.language = 'SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
  - Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` [467] system variable when the routine was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` [469] system variable when the routine was created. `DATABASE_COLLATION` is the collation of the database with which the routine is associated.
- The `DATA_TYPE`, `CHARACTER_MAXIMUM_LENGTH`, `CHARACTER_OCTET_LENGTH`, `NUMERIC_PRECISION`, `NUMERIC_SCALE`, `DATETIME_PRECISION`, `CHARACTER_SET_NAME`,

and `COLLATION_NAME` columns provide information about the data type for the `RETURNS` clause of stored functions. If a stored routine is a stored procedure, these columns all are `NULL`. `DATETIME_PRECISION` was added in MySQL 5.6.4.

- Information about stored function `RETURNS` data types is also available in the `PARAMETERS` table. The return value data type row for a function can be identified as the row that has an `ORDINAL_POSITION` value of 0.

## 19.20. The `INFORMATION_SCHEMA.SCHEMATA` Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CATALOG_NAME</code>		<code>def</code>
<code>SCHEMA_NAME</code>		Database
<code>DEFAULT_CHARACTER_SET_NAME</code>		
<code>DEFAULT_COLLATION_NAME</code>		
<code>SQL_PATH</code>		<code>NULL</code>

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']
```

```
SHOW DATABASES
[LIKE 'wild']
```

## 19.21. The `INFORMATION_SCHEMA.SCHEMA_PRIVILEGES` Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>GRANTEE</code>		<code>'user_name'@'host_name'</code> value, MySQL extension
<code>TABLE_CATALOG</code>		<code>def</code> , MySQL extension
<code>TABLE_SCHEMA</code>		MySQL extension
<code>PRIVILEGE_TYPE</code>		MySQL extension
<code>IS_GRANTABLE</code>		MySQL extension

**Notes:**

- This is a nonstandard table. It takes its values from the `mysql.db` table.

## 19.22. The `INFORMATION_SCHEMA.STATISTICS` Table

The `STATISTICS` table provides information about table indexes.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>TABLE_CATALOG</code>		<code>def</code>
<code>TABLE_SCHEMA</code>		= Database

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

**Notes:**

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
     AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name
```

## 19.23. The INFORMATION\_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		def
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	The version number of the table's <code>.frm</code> file, MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>DATA_LENGTH</code>	<code>Data_length</code>	MySQL extension
<code>MAX_DATA_LENGTH</code>	<code>Max_data_length</code>	MySQL extension
<code>INDEX_LENGTH</code>	<code>Index_length</code>	MySQL extension
<code>DATA_FREE</code>	<code>Data_free</code>	MySQL extension
<code>AUTO_INCREMENT</code>	<code>Auto_increment</code>	MySQL extension
<code>CREATE_TIME</code>	<code>Create_time</code>	MySQL extension
<code>UPDATE_TIME</code>	<code>Update_time</code>	MySQL extension
<code>CHECK_TIME</code>	<code>Check_time</code>	MySQL extension
<code>TABLE_COLLATION</code>	<code>Collation</code>	MySQL extension
<code>CHECKSUM</code>	<code>Checksum</code>	MySQL extension
<code>CREATE_OPTIONS</code>	<code>Create_options</code>	MySQL extension
<code>TABLE_COMMENT</code>	<code>Comment</code>	MySQL extension

**Notes:**

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. Currently, the `TABLES` table does not list `TEMPORARY` tables.
- For partitioned tables, the `ENGINE` column shows the name of the storage engine used by all partitions. (Previously, this column showed `PARTITION` for such tables.)
- The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database.

For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)

- The `DATA_FREE` column shows the free space in bytes for `InnoDB` tables.
- We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.
- The `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  WHERE table_schema = 'db_name'
  [AND table_name LIKE 'wild' ]

SHOW TABLES
  FROM db_name
  [LIKE 'wild' ]
```

## 19.24. The `INFORMATION_SCHEMA TABLESPACES` Table

The `TABLESPACES` table provides information about active tablespaces.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>TABLESPACE_NAME</code>		MySQL extension
<code>ENGINE</code>		MySQL extension
<code>TABLESPACE_TYPE</code>		MySQL extension

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>LOGFILE_GROUP_NAME</code>		MySQL extension
<code>EXTENT_SIZE</code>		MySQL extension
<code>AUTOEXTEND_SIZE</code>		MySQL extension
<code>MAXIMUM_SIZE</code>		MySQL extension
<code>NODEGROUP_ID</code>		MySQL extension
<code>TABLESPACE_COMMENT</code>		MySQL extension

## 19.25. The `INFORMATION_SCHEMA TABLE_CONSTRAINTS` Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CONSTRAINT_CATALOG</code>		def
<code>CONSTRAINT_SCHEMA</code>		
<code>CONSTRAINT_NAME</code>		
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>CONSTRAINT_TYPE</code>		

### Notes:

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

## 19.26. The `INFORMATION_SCHEMA TABLE_PRIVILEGES` Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>GRANTEE</code>		' <i>user_name</i> '@' <i>host_name</i> ' value
<code>TABLE_CATALOG</code>		def
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>PRIVILEGE_TYPE</code>		
<code>IS_GRANTABLE</code>		

### Notes:

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT` [755], `INSERT` [755], `UPDATE` [756], `REFERENCES` [755], `ALTER` [753], `INDEX` [755], `DROP` [754], `CREATE VIEW` [754].

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

## 19.27. The INFORMATION\_SCHEMA TRIGGERS Table

The TRIGGERS table provides information about triggers. You can see results only for databases and tables for which you have the TRIGGER [756] privilege.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		def
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	
EVENT_OBJECT_CATALOG		def
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		0
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

### Notes:

- The TRIGGER\_SCHEMA and TRIGGER\_NAME columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The EVENT\_MANIPULATION column contains one of the values 'INSERT', 'DELETE', or 'UPDATE'.
- As noted in Section 18.3, “Using Triggers”, every trigger is associated with exactly one table. The EVENT\_OBJECT\_SCHEMA and EVENT\_OBJECT\_TABLE columns contain the database in which this table occurs, and the table's name.
- The ACTION\_ORDER column contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same EVENT\_MANIPULATION and ACTION\_TIMING on the same table.

- The `ACTION_STATEMENT` column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the `Statement` column of the output from `SHOW TRIGGERS`. Note that this text uses UTF-8 encoding.
- The `ACTION_ORIENTATION` column always contains the value `'ROW'`.
- The `ACTION_TIMING` column contains one of the two values `'BEFORE'` or `'AFTER'`.
- The columns `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW` contain the old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value `'OLD'` and `ACTION_REFERENCE_NEW_ROW` always contains the value `'NEW'`.
- The `SQL_MODE` column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the `sql_mode` [545] system variable. See Section 5.1.7, “Server SQL Modes”.
- The `DEFINER` column indicates who defined the trigger.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` [467] system variable when the trigger was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` [469] system variable when the trigger was created. `DATABASE_COLLATION` is the collation of the database with which the trigger is associated.
- The following columns currently always contain `NULL`: `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, `ACTION_REFERENCE_NEW_TABLE`, and `CREATED`.

Example, using the `ins_sum` trigger defined in Section 18.3, “Using Triggers”:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
      TRIGGER_CATALOG: def
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: def
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 0
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: NULL
      SQL_MODE:
      DEFINER: me@localhost
```

See also Section 13.7.5.39, “`SHOW TRIGGERS` Syntax”.

## 19.28. The `INFORMATION_SCHEMA.USER_PRIVILEGES` Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>GRANTEE</code>		<code>'user_name'@'host_name'</code> value, MySQL extension
<code>TABLE_CATALOG</code>		<code>def</code> , MySQL extension
<code>PRIVILEGE_TYPE</code>		MySQL extension

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>IS_GRANTABLE</code>		MySQL extension

**Notes:**

- This is a nonstandard table. It takes its values from the `mysql.user` table.

## 19.29. The `INFORMATION_SCHEMA VIEWS` Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` [756] privilege to access this table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>TABLE_CATALOG</code>		def
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>VIEW_DEFINITION</code>		
<code>CHECK_OPTION</code>		
<code>IS_UPDATABLE</code>		
<code>DEFINER</code>		
<code>SECURITY_TYPE</code>		
<code>CHARACTER_SET_CLIENT</code>		MySQL extension
<code>COLLATION_CONNECTION</code>		MySQL extension

**Notes:**

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column has a value of `NONE`, `CASCADE`, or `LOCAL`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 13.1.16](#), “`CREATE VIEW Syntax`”.)
- The `DEFINER` column indicates who defined the view. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` [467] system variable when the view was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` [469] system variable when the view was created.

MySQL lets you use different `sql_mode` [545] settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` [608] SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` [545] setting to a value different from `ANSI` [608] could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` [1178] function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
       -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` [545] will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

## 19.30. INFORMATION\_SCHEMA Tables for InnoDB

The InnoDB tables related to the InnoDB storage engine serve two purposes:

- You can monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues that do occur. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly. The monitoring information deals with:
  - InnoDB table compression, a feature whose use depends on a balance between I/O reduction, CPU usage, buffer pool management, and how much compression is possible for your data.
  - Transactions and locks, features that balance high performance for a single operation, against the ability to run multiple operations concurrently. (Transactions are the high-level, user-visible aspect of concurrency. Locks are the low-level mechanism that transactions use to avoid reading or writing unreliable data.)
- You can extract information about schema objects managed by InnoDB, using the `INNODB_SYS_*` tables. This information comes from the InnoDB data dictionary, which cannot be queried directly like regular InnoDB tables. Traditionally, you would get this type of information using the techniques from Section 14.2.4.4, “`SHOW ENGINE INNODB STATUS` and the InnoDB Monitors”, setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` command. The InnoDB interface offers a simpler, familiar technique to access this data.

### 19.30.1. The INFORMATION\_SCHEMA INNODB\_CMP and INNODB\_CMP\_RESET Tables

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information on operations related to compressed InnoDB tables.

**Table 19.1. Columns of `INNODB_CMP` and `INNODB_CMP_RESET`**

Column name	Description
<code>PAGE_SIZE</code>	Compressed page size in bytes.

Column name	Description
<code>COMPRESS_OPS</code>	Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.
<code>COMPRESS_OPS_OK</code>	Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been successfully compressed. This count should never exceed <code>COMPRESS_OPS</code> .
<code>COMPRESS_TIME</code>	Total time in seconds spent in attempts to compress B-tree pages of the size <code>PAGE_SIZE</code> .
<code>UNCOMPRESS_OPS</code>	Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool.
<code>UNCOMPRESS_TIME</code>	Total time in seconds spent in uncompressing B-tree pages of the size <code>PAGE_SIZE</code> .

**Notes:**

- Use these tables to measure the effectiveness of `InnoDB` table `compression` in your database.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 5.4.6.4, “Monitoring Compression at Runtime”](#) and [Section 14.2.4.3.1.3, “Using the Compression Information Schema Tables”](#). For general information about `InnoDB` table compression, see [Section 5.4.6, “Working with InnoDB Compressed Tables”](#).

## 19.30.2. The `INFORMATION_SCHEMA INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` Tables

The `INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` tables contain status information on operations related to `compressed` `InnoDB` tables and indexes, with separate statistics for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed `InnoDB` table, both the table data and all the `secondary indexes` are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the `clustered index`.

**Table 19.2. Columns of `INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET`**

Column name	Description
<code>DATABASE_NAME</code>	Database containing the applicable table.
<code>TABLE_NAME</code>	Table to monitor for compression statistics.
<code>INDEX_NAME</code>	Index to monitor for compression statistics.
<code>COMPRESS_OPS</code>	Number of compression operations attempted. <code>Pages</code> are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.
<code>COMPRESS_OPS_OK</code>	Number of successful compression operations. Subtract from the <code>COMPRESS_OPS</code> value to get the number of <code>compression failures</code> . Divide by the <code>COMPRESS_OPS</code> value to get the percentage of compression failures.
<code>COMPRESS_TIME</code>	Total amount of CPU time, in seconds, used for compressing data in this index.

Column name	Description
<code>UNCOMPRESS_OPS</code>	Number of uncompression operations performed. Compressed <code>InnoDB</code> pages are uncompressed whenever compression <code>fails</code> , or the first time a compressed page is accessed in the <code>buffer pool</code> and the uncompressed page does not exist.
<code>UNCOMPRESS_TIME</code>	Total amount of CPU time, in seconds, used for uncompressing data in this index.

**Notes:**

- Use these tables to measure the effectiveness of `InnoDB` table `compression` for specific tables, indexes, or both.
- You must have the `PROCESS` privilege to query these tables.
- Because collecting separate measurements for every index imposes substantial performance overhead, enable the `innodb_cmp_per_index_enabled` [1712] configuration option before performing the operations on compressed tables that you want to monitor.
- For usage information, see [Section 5.4.6.4, “Monitoring Compression at Runtime”](#) and [Section 14.2.4.3.1.3, “Using the Compression Information Schema Tables”](#). For general information about `InnoDB` table compression, see [Section 5.4.6, “Working with InnoDB Compressed Tables”](#).

### 19.30.3. The `INFORMATION_SCHEMA INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` Tables

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information on compressed pages within the `InnoDB buffer pool`.

**Table 19.3. Columns of `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET`**

Column name	Description
<code>PAGE_SIZE</code>	Block size in bytes. Each record of this table describes blocks of this size.
<code>PAGES_USED</code>	Number of blocks of the size <code>PAGE_SIZE</code> that are currently in use.
<code>PAGES_FREE</code>	Number of blocks of the size <code>PAGE_SIZE</code> that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.
<code>RELOCATION_OPS</code>	Number of times a block of the size <code>PAGE_SIZE</code> has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the table <code>INNODB_CMPMEM_RESET</code> resets this count.
<code>RELOCATION_TIME</code>	Total time in microseconds spent in relocating blocks of the size <code>PAGE_SIZE</code> . Reading from the table <code>INNODB_CMPMEM_RESET</code> resets this count.

**Notes:**

- Use these tables to measure the effectiveness of `InnoDB` table `compression` in your database.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 5.4.6.4, “Monitoring Compression at Runtime”](#) and [Section 14.2.4.3.1.3, “Using the Compression Information Schema Tables”](#). For general information about `InnoDB` table compression, see [Section 5.4.6, “Working with InnoDB Compressed Tables”](#).

### 19.30.4. The `INFORMATION_SCHEMA INNODB_TRX` Table

The `INNODB_TRX` table contains information about every transaction currently executing inside `InnoDB`, including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing.

**Table 19.4. INNODB\_TRX Columns**

Column name	Description
<code>TRX_ID</code>	Unique transaction ID number, internal to <code>InnoDB</code> . (Starting in MySQL 5.6, these IDs are not created for transactions that are read-only and non-locking. See <a href="#">Section 14.2.4.2.3, “Optimizations for Read-Only Transactions”</a> for details.)
<code>TRX_WEIGHT</code>	The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, <code>InnoDB</code> selects the transaction with the smallest weight as the “victim” to rollback. Transactions that have changed non-transactional tables are considered heavier than others, regardless of the number of altered and locked rows.
<code>TRX_STATE</code>	Transaction execution state. One of <code>RUNNING</code> , <code>LOCK WAIT</code> , <code>ROLLING BACK</code> or <code>COMMITTING</code> .
<code>TRX_STARTED</code>	Transaction start time.
<code>TRX_REQUESTED_LOCK_ID</code>	ID of the lock the transaction is currently waiting for (if <code>TRX_STATE</code> is <code>LOCK WAIT</code> , otherwise <code>NULL</code> ). Details about the lock can be found by joining with <code>INNODB_LOCKS</code> on <code>LOCK_ID</code> .
<code>TRX_WAIT_STARTED</code>	Time when the transaction started waiting on the lock (if <code>TRX_STATE</code> is <code>LOCK WAIT</code> , otherwise <code>NULL</code> ).
<code>TRX_MYSQL_THREAD_ID</code>	MySQL thread ID. Can be used for joining with <code>PROCESSLIST</code> on <code>ID</code> . See <a href="#">Section 14.2.4.3.4.3, “Possible Inconsistency with PROCESSLIST”</a> .
<code>TRX_QUERY</code>	The SQL query that is being executed by the transaction.
<code>TRX_OPERATION_STATE</code>	The transaction's current operation, or <code>NULL</code> .
<code>TRX_TABLES_IN_USE</code>	The number of <code>InnoDB</code> tables used while processing the current SQL statement of this transaction.
<code>TRX_TABLES_LOCKED</code>	Number of <code>InnoDB</code> tables that currently have any locks. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)
<code>TRX_LOCK_STRUCTS</code>	The number of locks reserved by the transaction.
<code>TRX_LOCK_MEMORY_BYTES</code>	Total size taken up by the lock structures of this transaction in memory.
<code>TRX_ROWS_LOCKED</code>	Approximate number of rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.
<code>TRX_ROWS_MODIFIED</code>	The number of modified and inserted rows in this transaction.
<code>TRX_CONCURRENCY_TICKETS</code>	A value indicating how much work the current transaction can do before being swapped out, as specified by the <code>innodb_concurrency_tickets</code> option.
<code>TRX_ISOLATION_LEVEL</code>	The isolation level of the current transaction.
<code>TRX_UNIQUE_CHECKS</code>	Whether unique checks are turned on or off for the current transaction. (They might be turned off during a bulk data load, for example.)

Column name	Description
<code>TRX_FOREIGN_KEY_CHECKS</code>	Whether foreign key checks are turned on or off for the current transaction. (They might be turned off during a bulk data load, for example.)
<code>TRX_LAST_FOREIGN_KEY_ERROR</code>	Detailed error message for last FK error, or <code>NULL</code> .
<code>TRX_ADAPTIVE_HASH_LATCHED</code>	Whether or not the adaptive hash index is locked by the current transaction. (Only a single transaction at a time can modify the adaptive hash index.)
<code>TRX_ADAPTIVE_HASH_TIMEOUT</code>	Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no AHI contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup.
<code>TRX_IS_READ_ONLY</code>	A value of 1 indicates the transaction is read-only. (5.6.4 and up.)
<code>TRX_AUTO_COMMIT_NON_LOCKING</code>	A value of 1 indicates the transaction is a <code>SELECT</code> statement that does not use the <code>FOR UPDATE</code> or <code>LOCK IN SHARED MODE</code> clauses, and is executing with the <code>autocommit</code> setting turned on so that the transaction will only contain this one statement. (5.6.4 and up.) When this column and <code>TRX_IS_READ_ONLY</code> are both 1, <code>InnoDB</code> optimizes the transaction to reduce the overhead associated with transactions that change table data.

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.2.4.3.2.4, “Using the Transaction Information Schema Tables”](#).

### 19.30.5. The `INFORMATION_SCHEMA INNODB_LOCKS` Table

The `INNODB_LOCKS` table contains information about each lock that an `InnoDB` transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

**Table 19.5. `INNODB_LOCKS` Columns**

Column name	Description
<code>LOCK_ID</code>	Unique lock ID number, internal to <code>InnoDB</code> . Treat it as an opaque string. Although <code>LOCK_ID</code> currently contains <code>TRX_ID</code> , the format of the data in <code>LOCK_ID</code> is not guaranteed to remain the same in future releases. Do not write programs that parse the <code>LOCK_ID</code> value.
<code>LOCK_TRX_ID</code>	ID of the transaction holding this lock. Details about the transaction can be found by joining with <code>INNODB_TRX</code> on <code>TRX_ID</code> .
<code>LOCK_MODE</code>	Mode of the lock. One of <code>S</code> , <code>X</code> , <code>IS</code> , <code>IX</code> , <code>S_GAP</code> , <code>X_GAP</code> , <code>IS_GAP</code> , <code>IX_GAP</code> , or <code>AUTO_INC</code> for shared, exclusive, intention shared, intention exclusive row locks, shared and exclusive gap locks, intention shared and intention exclusive gap locks, and auto-increment table level lock, respectively. Refer to the sections <a href="#">Section 14.2.3.2, “InnoDB Lock Modes”</a> and <a href="#">Section 14.2.3.1, “The InnoDB Transaction Model and Locking”</a> for information on <code>InnoDB</code> locking.
<code>LOCK_TYPE</code>	Type of the lock. One of <code>RECORD</code> or <code>TABLE</code> for record (row) level or table level locks, respectively.

Column name	Description
<code>LOCK_TABLE</code>	Name of the table that has been locked or contains locked records.
<code>LOCK_INDEX</code>	Name of the index if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> .
<code>LOCK_SPACE</code>	Tablespace ID of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> .
<code>LOCK_PAGE</code>	Page number of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> .
<code>LOCK_REC</code>	Heap number of the locked record within the page if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> .
<code>LOCK_DATA</code>	Primary key of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> . This column contains the value(s) of the primary key column(s) in the locked row, formatted as a valid SQL string (ready to be copied to SQL commands). If there is no primary key then the <code>InnoDB</code> internal unique row ID number is used. When the page containing the locked record is not in the buffer pool (in the case that it was paged out to disk while the lock was held), <code>InnoDB</code> does not fetch the page from disk, to avoid unnecessary disk operations. Instead, <code>LOCK_DATA</code> is set to <code>NULL</code> .

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.2.4.3.2.4, “Using the Transaction Information Schema Tables”](#).

**19.30.6. The `INFORMATION_SCHEMA INNODB_LOCK_WAITS` Table**

The `INNODB_LOCK_WAITS` table contains one or more rows for each blocked `InnoDB` transaction, indicating the lock it has requested and any locks that are blocking that request.

**Table 19.6. `INNODB_LOCK_WAITS` Columns**

Column name	Description
<code>REQUESTING_TRX_ID</code>	ID of the requesting transaction.
<code>REQUESTED_LOCK_ID</code>	ID of the lock for which a transaction is waiting. Details about the lock can be found by joining with <code>INNODB_LOCKS</code> on <code>LOCK_ID</code> .
<code>BLOCKING_TRX_ID</code>	ID of the blocking transaction.
<code>BLOCKING_LOCK_ID</code>	ID of a lock held by a transaction blocking another transaction from proceeding. Details about the lock can be found by joining with <code>INNODB_LOCKS</code> on <code>LOCK_ID</code> .

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.2.4.3.2.4, “Using the Transaction Information Schema Tables”](#).

**19.30.7. The `INFORMATION_SCHEMA INNODB_SYS_TABLES` Table**

The `INNODB_SYS_TABLES` table provides status information about `InnoDB` tables, equivalent to the information from the `SYS_TABLES` table in the `InnoDB` data dictionary.

**Table 19.7. `INNODB_SYS_TABLES` Columns**

Column name	Description
<code>TABLE_ID</code>	An identifier for each <code>InnoDB</code> table that is unique across all databases in the instance.
<code>NAME</code>	The name of the table. Preceded by the database name where appropriate, for example <code>test/t1</code> . <code>InnoDB</code> system table names are in all uppercase. Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the <code>lower_case_table_names</code> [501] setting.
<code>FLAG</code>	0 = <code>InnoDB</code> system table, 1 = user table.
<code>N_COLS</code>	The number of columns in the table.
<code>SPACE</code>	An identifier for the tablespace where the table resides. 0 means the <code>InnoDB system tablespace</code> . Any other number represents a table created in <code>file-per-table</code> mode with a separate <code>.ibd</code> file. This identifier stays the same after a <code>TRUNCATE TABLE</code> statement. Other than the zero value, this identifier is unique for tables across all the databases in the instance.

**Notes:**

- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

**19.30.8. The `INFORMATION_SCHEMA INNODB_SYS_INDEXES` Table**

The `INNODB_SYS_INDEXES` table provides status information about `InnoDB` indexes, equivalent to the information from the `SYS_INDEXES` table in the `InnoDB` data dictionary.

**Table 19.8. `INNODB_SYS_INDEXES` Columns**

Column name	Description
<code>INDEX_ID</code>	An identifier for each index that is unique across all the databases in an instance.
<code>NAME</code>	The name of the index. User-created indexes have names in all lowercase. Indexes created implicitly by <code>InnoDB</code> have names in all lowercase. The index names are not necessarily unique. Indexes created implicitly by <code>InnoDB</code> have consistent names: <code>PRIMARY</code> for a primary key index, <code>GEN_CLUST_INDEX</code> for the index representing a primary key when one is not specified, <code>ID_IND</code> , <code>FOR_IND</code> for validating a foreign key constraint, and <code>REF_IND</code> .
<code>TABLE_ID</code>	An identifier representing the table associated with the index; the same value from <code>INNODB_SYS_TABLES.TABLE_ID</code> .
<code>TYPE</code>	A numeric identifier signifying the kind of index, in the range 0..3.
<code>N_FIELDS</code>	The number of columns in the index key. For the <code>GEN_CLUST_INDEX</code> indexes, this value is 0 because the index is created using an artificial value rather than a real table column.
<code>PAGE_NO</code>	
<code>SPACE</code>	An identifier for the tablespace where the index resides. 0 means the <code>InnoDB system tablespace</code> . Any other number represents a table created in <code>file-per-table</code> mode with a separate <code>.ibd</code> file. This identifier stays the same after a <code>TRUNCATE TABLE</code> statement. Because all indexes

Column name	Description
	for a table reside in the same tablespace as the table, this value is not necessarily unique.

**Notes:**

- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

### 19.30.9. The `INFORMATION_SCHEMA INNODB_SYS_COLUMNS` Table

The `INNODB_SYS_COLUMNS` table provides status information about `InnoDB` table columns, equivalent to the information from the `SYS_COLUMNS` table in the `InnoDB` data dictionary.

**Table 19.9. `INNODB_SYS_COLUMNS` Columns**

Column name	Description
<code>TABLE_ID</code>	An identifier representing the table associated with the column; the same value from <code>INNODB_SYS_TABLES.TABLE_ID</code> .
<code>NAME</code>	The name of each column in each table. These names can be uppercase or lowercase depending on the <code>lower_case_table_names</code> [501] setting. There are no special system-reserved names for columns.
<code>POS</code>	The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.
<code>MTYPE</code>	A numeric identifier for the column type. 1 = <code>VARCHAR</code> , 2 = <code>CHAR</code> , 3 = <code>FIXBINARY</code> , 4 = <code>BINARY</code> , 5 = <code>BLOB</code> , 6 = <code>INT</code> , 7 = <code>SYS_CHILD</code> , 8 = <code>SYS</code> , 9 = <code>FLOAT</code> , 10 = <code>DOUBLE</code> , 11 = <code>DECIMAL</code> , 12 = <code>VARMYSQL</code> , 13 = <code>MYSQL</code> .
<code>PRTYPE</code>	The <code>InnoDB</code> “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.
<code>LEN</code>	The column length, for example 4 for <code>INT</code> and 8 for <code>BIGINT</code> . For character columns in multi-byte character sets, this length value is the maximum length in bytes needed to represent a definition such as <code>VARCHAR(N)</code> ; that is, it might be $2*N$ , $3*N$ , and so on depending on the character encoding.

**Notes:**

- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

### 19.30.10. The `INFORMATION_SCHEMA INNODB_SYS_FIELDS` Table

The `INNODB_SYS_FIELDS` table provides status information about the key columns (fields) of `InnoDB` indexes, equivalent to the information from the `SYS_FIELDS` table in the `InnoDB` data dictionary.

**Table 19.10. `INNODB_SYS_FIELDS` Columns**

Column name	Description
<code>INDEX_ID</code>	An identifier for the index associated with this key field, using the same value as in <code>INNODB_SYS_INDEXES.INDEX_ID</code> .

Column name	Description
<code>NAME</code>	The name of the original column from the table, using the same value as in <code>INNODB_SYS_COLUMNS.NAME</code> .
<code>POS</code>	The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

**Notes:**

- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

### 19.30.11. The `INFORMATION_SCHEMA INNODB_SYS_FOREIGN` Table

The `INNODB_SYS_FOREIGN` table provides status information about `InnoDB` foreign keys, equivalent to the information from the `SYS_FOREIGN` table in the `InnoDB` data dictionary.

**Table 19.11. `INNODB_SYS_FOREIGN` Columns**

Column name	Description
<code>ID</code>	The name (not a numeric value) of the foreign key index. Preceded by the database name, for example, <code>test/products_fk</code> .
<code>FOR_NAME</code>	The name of the <code>child table</code> in this foreign key relationship.
<code>REF_NAME</code>	The name of the <code>parent table</code> in this foreign key relationship.
<code>N_COLS</code>	The number of columns in the foreign key index.
<code>TYPE</code>	A collection of bit flags with information about the foreign key column, ORed together. 1 = <code>ON DELETE CASCADE</code> , 2 = <code>ON UPDATE SET NULL</code> , 4 = <code>ON UPDATE CASCADE</code> , 8 = <code>ON UPDATE SET NULL</code> , 16 = <code>ON DELETE NO ACTION</code> , 32 = <code>ON UPDATE NO ACTION</code> .

**Notes:**

- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

### 19.30.12. The `INFORMATION_SCHEMA INNODB_SYS_FOREIGN_COLS` Table

The `INNODB_SYS_FOREIGN_COLS` table provides status information about the columns of `InnoDB` foreign keys, equivalent to the information from the `SYS_FOREIGN_COLS` table in the `InnoDB` data dictionary.

**Table 19.12. `INNODB_SYS_FOREIGN_COLS` Columns**

Column name	Description
<code>ID</code>	The foreign key index associated with this index key field, using the same value as <code>INNODB_SYS_FOREIGN.ID</code> .
<code>FOR_COL_NAME</code>	The name of the associated column in the child table.
<code>REF_COL_NAME</code>	The name of the associated column in the parent table.
<code>POS</code>	The ordinal position of this key field within the foreign key index, starting from 0.

**Notes:**

- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

**19.30.13. The `INFORMATION_SCHEMA INNODB_SYS_TABLESTATS` View**

The `INNODB_SYS_TABLESTATS` view provides status information about performance statistics for `InnoDB` tables. These statistics represent low-level information used by the MySQL optimizer to calculate which index to use when querying an `InnoDB` table. This information is derived from in-memory data structures rather than corresponding to data stored on disk.

`InnoDB` tables are represented in this view if they have been opened since the last server restart, and not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.

**Table 19.13. `INNODB_SYS_TABLESTATS` Columns**

Column name	Description
<code>TABLE_ID</code>	An identifier representing the table for which statistics are available, using the same value as <code>INNODB_SYS_TABLES.TABLE_ID</code> .
<code>NAME</code>	The name of the table, using the same value as <code>INNODB_SYS_TABLES.NAME</code> .
<code>STATS_INITIALIZED</code>	The value is <code>Initialized</code> if the statistics are already collected, <code>Uninitialized</code> if not.
<code>NUM_ROWS</code>	The current estimated number of rows in the table. Updated after each DML operation. Could be imprecise if uncommitted transactions are inserting into or deleting from the table.
<code>CLUST_INDEX_SIZE</code>	Number of pages on disk that store the clustered index, which holds the <code>InnoDB</code> table data in primary key order. This value might be null if no statistics are collected yet for the table.
<code>OTHER_INDEX_SIZE</code>	Number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.
<code>MODIFIED_COUNTER</code>	The number of rows modified by DML operations, such as <code>INSERT</code> , <code>UPDATE</code> , <code>DELETE</code> , and also cascade operations from foreign keys.
<code>AUTOINC</code>	
<code>REF_COUNT</code>	When this counter reaches zero, the table metadata can be evicted from the table cache.

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

**19.30.14. The `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` Table**

The `INNODB_BUFFER_PAGE` table holds information about each `page` in the `InnoDB` buffer pool.

**Table 19.14. `INNODB_BUFFER_PAGE` Columns**

Column name	Description
<code>POOL_ID</code>	Buffer Pool ID. An identifier to distinguish between multiple buffer pool instances.
<code>BLOCK_ID</code>	Buffer Pool Block ID.
<code>SPACE</code>	Tablespace ID. Uses the same value as in <code>INNODB_SYS_TABLES.SPACE</code> .
<code>PAGE_NUMBER</code>	Page number.
<code>PAGE_TYPE</code>	Page type string. One of <code>allocated</code> (Freshly allocated page), <code>index</code> (B-tree node), <code>undo_log</code> (Undo log page), <code>inode</code> (Index node), <code>ibuf_free_list</code> (Insert buffer free list), <code>ibuf_bitmap</code> (Insert buffer bitmap), <code>system</code> (System page), <code>trx_system</code> (Transaction system data), <code>file_space_header</code> (File space header), <code>extent_descriptor</code> (Extent descriptor page), <code>blob</code> (Uncompressed BLOB page), <code>compressed_blob</code> (First compressed BLOB page), <code>compressed_blob2</code> (Subsequent comp BLOB page), <code>unknown</code> (unknown).
<code>FLUSH_TYPE</code>	Flush type.
<code>FIX_COUNT</code>	Number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.
<code>IS_HASHED</code>	Whether hash index has been built on this page.
<code>NEWEST_MODIFICATION</code>	Log Sequence Number of the youngest modification.
<code>OLDEST_MODIFICATION</code>	Log Sequence Number of the oldest modification.
<code>ACCESS_TIME</code>	Time of first access.
<code>TABLE_NAME</code>	Name of the table the page belongs to.
<code>INDEX_NAME</code>	Name of the index the page belongs to. It can be the name of a clustered index or a secondary index.
<code>NUMBER_RECORDS</code>	Number of records within the page.
<code>DATA_SIZE</code>	Sum of the sizes of the records.
<code>COMPRESSED_SIZE</code>	Compressed page size. Null for pages that are not compressed.
<code>PAGE_STATE</code>	Page state. A page with valid data has one of the following states: <code>FILE_PAGE</code> (buffers a page of data from a file), <code>MEMORY</code> (buffers a page from an in-memory object), Other possible states (managed by <code>InnoDB</code> ) are: <code>null</code> , <code>READY_FOR_USE</code> , <code>NOT_USED</code> , <code>REMOVE_HASH</code> .
<code>IO_FIX</code>	Specifies whether any I/O is pending for this page: <code>IO_NONE</code> = no pending I/O, <code>IO_READ</code> = read pending, <code>IO_WRITE</code> = write pending.
<code>IS_OLD</code>	<code>bpage-&gt;old</code> .
<code>FREE_PAGE_CLOCK</code>	<code>bpage-&gt;freed_page_clock</code> .

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

**19.30.15. The `INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU` Table**

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered in the LRU list that determines which pages to `evict` from the buffer pool when it becomes full.

The definition for this page is the same as for `INNODB_BUFFER_PAGE`, except this table has an `LRU_POSITION` column instead of `BLOCK_ID`.

### Notes:

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.

Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.

- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes time the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.

## 19.30.16. The `INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS` Table

The `INNODB_BUFFER_POOL_STATS` table represents the same kinds of `InnoDB` buffer pool information as the output from `SHOW ENGINE INNODB STATUS`.

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the `sublists` at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of `eviction`.

Column meanings in this table are intended to be self-explanatory for developers who formerly parsed the `SHOW ENGINE INNODB STATUS` to get these values.

**Table 19.15. `INNODB_BUFFER_POOL_STATS` Columns**

Column name	Description
<code>POOL_ID</code>	
<code>POOL_SIZE</code>	
<code>FREE_BUFFERS</code>	
<code>DATABASE_PAGES</code>	
<code>OLD_DATABASE_PAGES</code>	
<code>MODIFIED_DATABASE_PAGES</code>	
<code>PENDING_DECOMPRESS</code>	
<code>PENDING_READS</code>	
<code>PENDING_FLUSH_LRU</code>	
<code>PENDING_FLUSH_LIST</code>	
<code>PAGES_MADE_YOUNG</code>	
<code>PAGES_NOT_MADE_YOUNG</code>	
<code>PAGES_MADE_YOUNG_RATE</code>	
<code>PAGES_MADE_NOT_YOUNG_RATE</code>	

Column name	Description
<code>NUMBER_PAGES_READ</code>	
<code>NUMBER_PAGES_CREATED</code>	
<code>NUMBER_PAGES_WRITTEN</code>	
<code>PAGES_READ_RATE</code>	
<code>PAGES_CREATE_RATE</code>	
<code>PAGES_WRITTEN_RATE</code>	
<code>NUMBER_PAGES_GET</code>	
<code>HIT_RATE</code>	
<code>YOUNG_MAKE_PER_THOUSAND_GETS</code>	
<code>NOT_YOUNG_MAKE_PER_THOUSAND_GETS</code>	
<code>NUMBER_PAGES_READ_AHEAD</code>	
<code>NUMBER_READ_AHEAD_EVICTED</code>	
<code>READ_AHEAD_RATE</code>	
<code>READ_AHEAD_EVICTED_RATE</code>	
<code>LRU_IO_TOTAL</code>	
<code>LRU_IO_CURRENT</code>	
<code>UNCOMPRESS_TOTAL</code>	
<code>UNCOMPRESS_CURRENT</code>	

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

### 19.30.17. The `INFORMATION_SCHEMA INNODB_METRICS` Table

This `INFORMATION_SCHEMA` table presents a wide variety of `InnoDB` performance information, complementing the specific focus areas of the `PERFORMANCE_SCHEMA` tables for `InnoDB`. With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the `InnoDB` source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

**Table 19.16. `INNODB_METRICS` Columns**

Column name	Description
<code>NAME</code>	Unique name for the counter.
<code>SUBSYSTEM</code>	The aspect of <code>InnoDB</code> that the metric applies to. See the list following the table for the corresponding module names to use with the <code>SET GLOBAL</code> syntax.
<code>COUNT</code>	Value since the counter is enabled.
<code>MAX_COUNT</code>	Maximum value since the counter is enabled.

Column name	Description
<a href="#">MIN_COUNT</a>	Minimum value since the counter is enabled.
<a href="#">AVG_COUNT</a>	Average value since the counter is enabled.
<a href="#">COUNT_RESET</a>	Counter value since it was last reset. (The <a href="#">_RESET</a> fields act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in the <a href="#">COUNT</a> , <a href="#">MAX_COUNT</a> , and so on fields.)
<a href="#">MAX_COUNT_RESET</a>	Maximum counter value since it was last reset.
<a href="#">MIN_COUNT_RESET</a>	Minimum counter value since it was last reset.
<a href="#">AVG_COUNT_RESET</a>	Average counter value since it was last reset.
<a href="#">TIME_ENABLED</a>	Timestamp of last start.
<a href="#">TIME_DISABLED</a>	Timestamp of last stop.
<a href="#">TIME_ELAPSED</a>	Elapsed time in seconds since the counter started.
<a href="#">TIME_RESET</a>	Timestamp of last stop.
<a href="#">STATUS</a>	Whether the counter is still running (Y) or stopped (N).
<a href="#">TYPE</a>	Whether the item is a cumulative counter, or measures the current value of some resource.
<a href="#">COMMENT</a>	Additional description.

**Notes:**

- You must have the [PROCESS](#) privilege to query this table.
- By default, relatively little data is collected. To start, stop, and reset counters, you set one of the the configuration options [innodb\\_monitor\\_enable](#) [1737], [innodb\\_monitor\\_disable](#) [1736], [innodb\\_monitor\\_reset](#) [1737], or [innodb\\_monitor\\_reset\\_all](#) [1737], using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword `all`. For example:

```
-- Turn on a counter:
set global innodb_monitor_enable = counter_name;
-- Turn off a counter:
set global innodb_monitor_disable = counter_name;
-- Reset a counter:
set global innodb_monitor_reset = counter_name;
-- Reset all the counter values:
set global innodb_monitor_reset_all = counter_name;
-- Turn on a group of counters:
set global innodb_monitor_enable = module_name;
-- Turn off a group of counters:
set global innodb_monitor_disable = module_name;
-- Turn on monitor "dml_num_inserts":
set global innodb_monitor_enable = dml_num_inserts;
-- Reset all values for "dml_num_inserts":
set global innodb_monitor_reset_all = dml_num_inserts;
-- Reset the counters for all dml monitors
set global innodb_monitor_reset = "dml_%";
-- Turn on all monitors for the transaction subsystem
set global innodb_monitor_enable = module_trx;
-- Turn off all monitors
set global innodb_monitor_disable = all;
```

- The module names correspond to, but are not identical to, the values from the [SUBSYSTEM](#) column. Here are the values you can use for `module_name` with the [innodb\\_monitor\\_enable](#) [1737] and related configuration options, along with the corresponding [SUBSYSTEM](#) names:
  - `module_metadata` (subsystem = `metadata`)
  - `module_lock` (subsystem = `lock`)

- `module_buffer` (subsystem = `buffer`)
  - `module_buf_page` (subsystem = `buffer_page_io`)
  - `module_os` (subsystem = `os`)
  - `module_trx` (subsystem = `transaction`)
  - `module_purge` (subsystem = `purge`)
  - `module_compress` (subsystem = `compression`)
  - `module_file` (subsystem = `file_system`)
  - `module_index` (subsystem = `index`)
  - `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
  - `module_ibuf_system` (subsystem = `change_buffer`)
  - `module_srv` (subsystem = `server`)
  - `module_ddl` (subsystem = `ddl`)
  - `module_dml` (subsystem = `dml`)
  - `module_log` (subsystem = `recovery`)
  - `module_icp` (subsystem = `icp`)
- Because each counter imposes some degree of runtime overhead on the server, typically you enable more counters on test and development servers during experimentation and benchmarking, and only enable counters on production servers to diagnose known issues or monitor aspects that are likely to be bottlenecks for a particular server and workload.
  - The items represented in the `innodb_metrics` table are subject to change, so for the most up-to-date list, query a running MySQL server. As of MySQL 5.6.10, the items include:

```
mysql: select name, subsystem from information_schema.innodb_metrics order by name;
```

name	subsystem

### 19.30.18. The `INFORMATION_SCHEMA INNODB_FT_CONFIG` Table

The `INNODB_FT_CONFIG` table displays metadata about the `FULLTEXT` index and associated processing for an `InnoDB` table.

This table is only accessible to users with the `SUPER` privilege.

**Table 19.17. `INNODB_FT_CONFIG` Columns**

Column name	Description
<code>KEY</code>	The name designating an item of metadata for an <code>InnoDB</code> table containing a <code>FULLTEXT</code> index.
<code>VALUE</code>	The value associated with the corresponding <code>KEY</code> column, reflecting some limit or current value for an aspect of a <code>FULLTEXT</code> index for an <code>InnoDB</code> table.

**Notes:**

- This table is only intended for internal configuration. It is not intended for statistical information purposes.
- You must have the `PROCESS` privilege to query this table.

- The values for the `KEY` column might evolve depending on the needs for performance tuning and debugging for InnoDB full-text processing. Currently, the key values include `optimize_checkpoint_limit`, `synced_doc_id`, `deleted_doc_count`, `stopword_table_name`, and `use_stopword`.
- For more information, see [Section 12.9, “Full-Text Search Functions”](#).

### 19.30.19. The `INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD` Table

The `INNODB_FT_DEFAULT_STOPWORD` table holds a list of [stopwords](#) that are used by default when creating a `FULLTEXT` index on an InnoDB table.

**Table 19.18. `INNODB_FT_DEFAULT_STOPWORD` Columns**

Column name	Description
<code>value</code>	A word that is used by default as a <a href="#">stopword</a> for <code>FULLTEXT</code> indexes on InnoDB tables. Not used if you override the default <a href="#">stopword processing</a> with either the <code>innodb_ft_server_stopword_table</code> [1725] or the <code>innodb_ft_user_stopword_table</code> [1726] option.

**Notes:**

- You must have the `PROCESS` privilege to query this table.
- For more information, see [Section 12.9, “Full-Text Search Functions”](#).

### 19.30.20. The `INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE` Table

The `INNODB_FT_INDEX_TABLE` table displays information about the inverted index used to process text searches against the `FULLTEXT` index of an InnoDB table.

This table is only accessible to users with the `SUPER` privilege. Before you query this table, set the configuration variable `innodb_ft_aux_table` [1723] to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

**Table 19.19. `INNODB_FT_INDEX_TABLE` Columns**

Column name	Description
<code>WORD</code>	A word extracted from the text of the columns that are part of a <code>FULLTEXT</code> .
<code>FIRST_DOC_ID</code>	The first document ID that this word appears in in the <code>FULLTEXT</code> index.
<code>LAST_DOC_ID</code>	The last document ID that this word appears in in the <code>FULLTEXT</code> index.
<code>DOC_COUNT</code>	The number of rows this word appears in in the <code>FULLTEXT</code> index. The same word can occur several times within the cache table, once for each combination of <code>DOC_ID</code> and <code>POSITION</code> values.
<code>DOC_ID</code>	The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table does not contain a suitable column.
<code>POSITION</code>	The position of this particular instance of the word within the relevant document identified by the <code>DOC_ID</code> value.

**Notes:**

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table` [1723].
- You must have the `PROCESS` privilege to query this table.

- For more information, see [Section 12.9, “Full-Text Search Functions”](#).

### 19.30.21. The `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` Table

The `INNODB_FT_INDEX_CACHE` table displays token information about newly inserted rows in a `FULLTEXT` index for an `InnoDB` table. To avoid expensive index reorganization during DML operations for an `InnoDB FULLTEXT` index, the information about newly indexed words is stored separately, and combined with the main search index only when you issue the `OPTIMIZE TABLE` statement for the `InnoDB` table.

This table is only accessible to users with the `SUPER` privilege. Before you query this table, set the configuration variable `innodb_ft_aux_table` [1723] to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

**Table 19.20. `INNODB_FT_INDEX_CACHE` Columns**

Column name	Description
<code>WORD</code>	A word extracted from the text of a newly inserted row.
<code>FIRST_DOC_ID</code>	The first document ID that this word appears in in the <code>FULLTEXT</code> index.
<code>LAST_DOC_ID</code>	The last document ID that this word appears in in the <code>FULLTEXT</code> index.
<code>DOC_COUNT</code>	The number of rows this word appears in in the <code>FULLTEXT</code> index. The same word can occur several times within the cache table, once for each combination of <code>DOC_ID</code> and <code>POSITION</code> values.
<code>DOC_ID</code>	The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column.
<code>POSITION</code>	The position of this particular instance of the word within the relevant document identified by the <code>DOC_ID</code> value. The value does not represent an absolute position; it is an offset added to the <code>POSITION</code> of the previous instance of that word.

**Notes:**

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table` [1723].
- You must have the `PROCESS` privilege to query this table.
- For more information, see [Section 12.9, “Full-Text Search Functions”](#).

### 19.30.22. The `INFORMATION_SCHEMA.INNODB_FT_DELETED` Table

The `INNODB_FT_DELETED` table records rows that are deleted from the `FULLTEXT` index for an `InnoDB` table. To avoid expensive index reorganization during DML operations for an `InnoDB FULLTEXT` index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue the `OPTIMIZE TABLE` statement for the `InnoDB` table.

This table is only accessible to users with the `SUPER` privilege. Before you query this table, set the configuration variable `innodb_ft_aux_table` [1723] to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

**Table 19.21. `INNODB_FT_DELETED` Columns**

Column name	Description
<code>DOC_ID</code>	The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it

Column name	Description
	can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column. This value is used to skip rows in the <code>innodb_ft_index_table</code> table, when you do text searches before data for deleted rows is physically removed from the <code>FULLTEXT</code> index by an <code>OPTIMIZE TABLE</code> statement.

**Notes:**

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table` [1723].
- You must have the `PROCESS` privilege to query this table.
- For more information, see [Section 12.9, “Full-Text Search Functions”](#).

**19.30.23. The `INFORMATION_SCHEMA INNODB_FT_BEING_DELETED` Table**

The `INNODB_FT_BEING_DELETED` table is a temporary work table while document IDs in the `INNODB_FT_DELETED` table are being removed from an `InnoDB FULLTEXT` index during an `OPTIMIZE TABLE` operation. Because its contents typically have a short lifetime, this table has limited utility for monitoring or debugging.

This table is only accessible to users with the `SUPER` privilege. This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table` [1723].

**Table 19.22. `INNODB_FT_BEING_DELETED` Columns**

Column name	Description
<code>DOC_ID</code>	The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column. This value is used to skip rows in the <code>innodb_ft_index_table</code> table, when you do text searches before data for deleted rows is physically removed from the <code>FULLTEXT</code> index by an <code>OPTIMIZE TABLE</code> statement.

**Notes:**

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table` [1723].
- You must have the `PROCESS` privilege to query this table.
- For more information, see [Section 12.9, “Full-Text Search Functions”](#).

**19.31. Thread Pool `INFORMATION_SCHEMA` Tables**

The following sections describe the `INFORMATION_SCHEMA` tables associated with the thread pool plugin. They provide information about thread pool operation:

- `TP_THREAD_STATE`: Information about thread pool thread states
- `TP_THREAD_GROUP_STATE`: Information about thread pool thread group states
- `TP_THREAD_GROUP_STATS`: Thread group statistics

Rows in these tables represent snapshots in time. In the case of `TP_THREAD_STATE`, all rows for a thread group comprise a snapshot in time. Thus, the MySQL server holds the mutex of the thread

group while producing the snapshot. But it does not hold mutexes on all thread groups at the same time, to prevent a statement against `TP_THREAD_STATE` from blocking the entire MySQL server.

The thread pool `INFORMATION_SCHEMA` tables are implemented by individual plugins and the decision whether to load one can be made independently of the others (see [Section 8.11.6.1, “Thread Pool Components and Installation”](#)). However, the content of all the tables depends on the thread pool plugin being enabled. If a table plugin is enabled but the thread pool plugin is not, the table becomes visible and can be accessed but will be empty.

### 19.31.1. The `INFORMATION_SCHEMA TP_THREAD_STATE` Table

This table has one row per thread created by the thread pool to handle connections. The table has these columns:

- `TP_GROUP_ID`

The thread group ID.

- `TP_THREAD_NUMBER`

The ID of the thread within its thread group. `TP_GROUP_ID` and `TP_THREAD_NUMBER` together provide a unique key within the table.

- `PROCESS_COUNT`

The 10ms interval in which the statement that uses this thread is currently executing. 0 means no statement is executing, 1 means it is in the first 10ms, and so forth.

- `WAIT_TYPE`

The type of wait for the thread. `NULL` means the thread is not blocked. Otherwise, the thread is blocked by a call to `thd_wait_begin()` and the value specifies the type of wait. The `xxx_WAIT` columns of the `TP_THREAD_GROUP_STATS` table accumulate counts for each wait type.

The `WAIT_TYPE` value is a string that describes the type of wait, as shown in the following table.

**Table 19.23. `WAIT_TYPE` Values**

Wait Type	Meaning
<code>THD_WAIT_SLEEP</code>	Waiting for sleep
<code>THD_WAIT_DISKIO</code>	Waiting for Disk IO
<code>THD_WAIT_ROW_LOCK</code>	Waiting for row lock
<code>THD_WAIT_GLOBAL_LOCK</code>	Waiting for global lock
<code>THD_WAIT_META_DATA_LOCK</code>	Waiting for metadata lock
<code>THD_WAIT_TABLE_LOCK</code>	Waiting for table lock
<code>THD_WAIT_USER_LOCK</code>	Waiting for user lock
<code>THD_WAIT_BINLOG</code>	Waiting for binlog
<code>THD_WAIT_GROUP_COMMIT</code>	Waiting for group commit
<code>THD_WAIT_SYNC</code>	Waiting for fsync

### 19.31.2. The `INFORMATION_SCHEMA TP_THREAD_GROUP_STATE` Table

This table has one row per thread group in the thread pool. Each row provides information about the current state of a group. The table has these columns:

- `TP_GROUP_ID`

The thread group ID. This is a unique key within the table.

- `CONSUMER_THREADS`

The number of consumer threads. There is at most one thread ready to start executing if the active threads become stalled or blocked.

- `RESERVE_THREADS`

The number of threads in the reserved state. This means that they will not be started until there is a need to wake a new thread and there is no consumer thread. This is where most threads end up when the thread group has created more threads than needed for normal operation. Often a thread group needs additional threads for a short while and then does not need them again for a while. In this case, they go into the reserved state and remain until needed again. They take up some extra memory resources, but no extra computing resources.

- `CONNECTION_COUNT`

The number of connections using this thread group.

- `QUEUED_QUERIES`

The number of statements waiting in the high-priority queue.

- `QUEUED_TRANSACTIONS`

The number of statements waiting in the low-priority queue. These are the initial statements for transactions that have not started, so they also represent queued transactions.

- `STALL_LIMIT`

The value of the `thread_pool_stall_limit` [556] variable on the thread group. This is the same value for all thread groups.

- `PRIO_KICKUP_TIMER`

The value of the `thread_pool_prio_kickup_timer` [555] on the thread group. This is the same value for all thread groups.

- `ALGORITHM`

The value of the `thread_pool_algorithm` [554] on the thread group. This is the same value for all thread groups.

- `THREAD_COUNT`

The number of threads started in the thread pool as part of this thread group.

- `ACTIVE_THREAD_COUNT`

The number of threads active executing statements.

- `MAX_THREAD_IDS_IN_GROUP`

The maximum thread ID of the threads in the group. This is the same as `MAX(TP_THREAD_NUMBER)` [1284] for the threads when selected from the `TP_THREAD_GROUP_STATE` table. That is, these two queries are equivalent:

```
SELECT TP_GROUP_ID, MAX_THREAD_IDS_IN_GROUP
FROM TP_THREAD_GROUP_STATE;

SELECT TP_GROUP_ID, MAX(TP_THREAD_NUMBER)
FROM TP_THREAD_STATE GROUP BY TP_GROUP_ID;
```

- `STALLED_THREAD_COUNT`

The number of stalled statements in the thread group. A stalled statement could be executing, but from a thread pool perspective it is stalled and making no progress. A long-running statement quickly ends up in this category.

- `WAITING_THREAD_NUMBER`

If there is a thread handling the polling of statements in the thread group, this specifies the thread number within this thread group. It is possible that this thread could be executing a statement.

- `OLDEST_QUEUED`

How long in milliseconds the oldest queued statement has been waiting for execution.

### 19.31.3. The `INFORMATION_SCHEMA TP_THREAD_GROUP_STATS` Table

This table reports statistics per thread group. There is one row per group. The table has these columns:

- `TP_GROUP_ID`

The thread group ID. This is a unique key within the table.

- `CONNECTIONS_STARTED`

The number of connections started.

- `CONNECTIONS_CLOSED`

The number of connections closed.

- `QUERIES_EXECUTED`

The number of statements executed. This number is incremented when a statement starts executing, not when it finishes.

- `QUERIES_QUEUED`

The number of statements received that were queued for execution. This does not count statements that the thread group was able to begin executing immediately without queuing, which can happen under the conditions described in [Section 8.11.6.2, “Thread Pool Operation”](#).

- `THREADS_STARTED`

The number of threads started.

- `PRIO_KICKUPS`

The number of statements that have been moved from low-priority queue to high-priority queue based on the value of the `thread_pool_prio_kickup_timer` [555] system variable. If this number increases quickly, consider increasing the value of that variable. A quickly increasing counter means that the priority system is not keeping transactions from starting too early. For `InnoDB`, this most likely means deteriorating performance due to too many concurrent transactions..

- `STALLED_QUERIES_EXECUTED`

The number of statements that have become defined as stalled due to executing for a time longer than the value of the `thread_pool_stall_limit` [556] system variable.

- `BECOME_CONSUMER_THREAD`

The number of times thread have been assigned the consumer thread role.

- `BECOME_RESERVE_THREAD`

The number of times threads have been assigned the reserve thread role.

- `BECOME_WAITING_THREAD`

The number of times threads have been assigned the waiter thread role. When statements are queued, this happens very often, even in normal operation, so rapid increases in this value are normal in the case of a highly loaded system where statements are queued up.

- `WAKE_THREAD_STALL_CHECKER`

The number of times the stall check thread decided to wake or create a thread to possibly handle some statements or take care of the waiter thread role.

- `SLEEP_WAITS`

The number of `THD_WAIT_SLEEP` waits. These occur when threads go to sleep; for example, by calling the `SLEEP( )` [1280] function.

- `DISK_IO_WAITS`

The number of `THD_WAIT_DISKIO` waits. These occur when threads perform disk I/O that is likely to not hit the file system cache. Such waits occur when the buffer pool reads and writes data to disk, not for normal reads from and writes to files.

- `ROW_LOCK_WAITS`

The number of `THD_WAIT_ROW_LOCK` waits for release of a row lock by another transaction.

- `GLOBAL_LOCK_WAITS`

The number of `THD_WAIT_GLOBAL_LOCK` waits for a global lock to be released.

- `META_DATA_LOCK_WAITS`

The number of `THD_WAIT_META_DATA_LOCK` waits for a metadata lock to be released.

- `TABLE_LOCK_WAITS`

The number of `THD_WAIT_TABLE_LOCK` waits for a table to be unlocked that the statement needs to access.

- `USER_LOCK_WAITS`

The number of `THD_WAIT_USER_LOCK` waits for a special lock constructed by the user thread.

- `BINLOG_WAITS`

The number of `THD_WAIT_BINLOG_WAITS` waits for the binary log to become free.

- `GROUP_COMMIT_WAITS`

The number of `THD_WAIT_GROUP_COMMIT` waits. These occur when a group commit must wait for the other parties to complete their part of a transaction.

- `FSYNC_WAITS`

The number of `THD_WAIT_SYNC` waits for a file sync operation.

## 19.32. Extensions to `SHOW` Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS                |
| COLLATIONS                    |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                      |
| COLUMN_PRIVILEGES             |
| ENGINES                      |
| EVENTS                        |
| FILES                         |
| GLOBAL_STATUS                 |
| GLOBAL_VARIABLES             |
| KEY_COLUMN_USAGE              |
| PARTITIONS                    |
| PLUGINS                      |
| PROCESSLIST                   |
| REFERENTIAL_CONSTRAINTS      |
| ROUTINES                     |
| SCHEMATA                      |
| SCHEMA_PRIVILEGES            |
| SESSION_STATUS               |
| SESSION_VARIABLES            |
| STATISTICS                    |
| TABLES                       |
| TABLE_CONSTRAINTS           |
| TABLE_PRIVILEGES            |
| TRIGGERS                     |
| USER_PRIVILEGES              |
| VIEWS                         |
+-----+
27 rows in set (0.00 sec)
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE [1190]` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
```

big5	Big5 Traditional Chinese	big5_chinese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
cp850	DOS West European	cp850_general_ci	1
hp8	HP West European	hp8_english_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
...			

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
```

Charset	Description	Default collation	Maxlen
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
utf8	UTF-8 Unicode	utf8_general_ci	3
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema has these characteristics:

- The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the [PERFORMANCE\\_SCHEMA](#) storage engine and the [performance\\_schema](#) database. The Performance Schema focuses primarily on performance data. This differs from [INFORMATION\\_SCHEMA](#), which serves for inspection of metadata.
- The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Currently, event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.
- Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).
- Performance Schema events are specific to a given instance of the MySQL Server. In MySQL 5.6.9 and later, Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log. (Bug #14741537)
- Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took.

Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.

- The `PERFORMANCE_SCHEMA` storage engine collects event data using “instrumentation points” in server source code.
- Collected events are stored in tables in the `performance_schema` database. These tables can be queried using `SELECT` statements like other tables.
- Performance Schema configuration can be modified dynamically by updating tables in the `performance_schema` database through SQL statements. Configuration changes affect data collection immediately.
- Tables in the `performance_schema` database are views or temporary tables that use no persistent on-disk storage.
- Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also [Section E.8, “Restrictions on Performance Schema”](#).

- Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by `EXPLAIN`) to change.
- No memory allocation is done beyond that which occurs during server startup. By using early allocation of structures with a fixed size, it is never necessary to resize or reallocate them, which is critical for achieving good runtime performance.
- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.
- The parser is unchanged. There are no new keywords or statements.
- Execution of server code proceeds normally even if the Performance Schema fails internally.
- When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.
- It is easy to add new instrumentation points.
- Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code will continue to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

## 20.1. Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see [Section 20.15, “Using the Performance Schema to Diagnose Problems”](#).

For the Performance Schema to be available, support for it must have been configured when MySQL was built. You can verify whether this is the case by checking the server's help output. If the

Performance Schema is available, the output will mention several variables with names that begin with `performance_schema`:

```
shell> mysqld --verbose --help
...
--performance_schema
           Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
           Number of rows in events_waits_history_long.
...
```

If such variables do not appear in the output, your server has not been built to support the Performance Schema. In this case, see [Section 20.2, “Performance Schema Configuration”](#).

Assuming that the Performance Schema is available, it is enabled by default as of MySQL 5.6.6. Before 5.6.6, it is disabled by default. To enable or disable it explicitly, start the server with the `performance_schema` [2307] variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=on
```

When the server starts, it sees `performance_schema` [2307] and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON   |
+-----+-----+
```

A value of `ON` means that the Performance Schema initialized successfully and is ready for use. A value of `OFF` means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine. If this engine is available (which you should already have checked earlier), you should see it listed with a `SUPPORT` value of `YES` in the output from the `INFORMATION_SCHEMA.ENGINES` table or the `SHOW ENGINES` statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE='PERFORMANCE_SCHEMA'\G
***** 1. row *****
ENGINE: PERFORMANCE_SCHEMA
SUPPORT: YES
COMMENT: Performance Schema
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO

mysql> SHOW ENGINES\G
...
Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
XA: NO
Savepoints: NO
...
```

The `PERFORMANCE_SCHEMA` storage engine operates on tables in the `performance_schema` database. You can make `performance_schema` the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Many examples in this chapter assume that `performance_schema` is the default database.

Performance Schema tables are stored in the `performance_schema` database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the `INFORMATION_SCHEMA` database or by using `SHOW` statements. For example, use either of these statements to see what Performance Schema tables exist:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'performance_schema';
+-----+
| TABLE_NAME |
+-----+
| accounts |
| cond_instances |
| events_stages_current |
| events_stages_history |
| events_stages_history_long |
| events_stages_summary_by_account_by_event_name |
| events_stages_summary_by_host_by_event_name |
| events_stages_summary_by_thread_by_event_name |
| events_stages_summary_by_user_by_event_name |
| events_stages_summary_global_by_event_name |
| events_statements_current |
| events_statements_history |
| events_statements_history_long |
| ... |
| file_instances |
| file_summary_by_event_name |
| file_summary_by_instance |
| host_cache |
| hosts |
| mutex_instances |
| objects_summary_global_by_type |
| performance_timers |
| rwlock_instances |
| session_account_connect_attrs |
| session_connect_attrs |
| setup_actors |
| setup_consumers |
| setup_instruments |
| setup_objects |
| setup_timers |
| socket_instances |
| socket_summary_by_event_name |
| socket_summary_by_instance |
| table_io_waits_summary_by_index_usage |
| table_io_waits_summary_by_table |
| table_lock_waits_summary_by_table |
| threads |
| users |
+-----+

mysql> SHOW TABLES FROM performance_schema;
+-----+
| Tables_in_performance_schema |
+-----+
| accounts |
| cond_instances |
| events_stages_current |
| events_stages_history |
| events_stages_history_long |
| ... |
```

The number of Performance Schema tables is expected to increase over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE setup_timers\G
```

```

***** 1. row *****
      Table: setup_timers
Create Table: CREATE TABLE `setup_timers` (
  `NAME` varchar(64) NOT NULL,
  `TIMER_NAME` enum('CYCLE','NANOSECOND','MICROSECOND','MILLISECOND','TICK')
  NOT NULL
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8

```

Table structure is also available by selecting from tables such as [INFORMATION\\_SCHEMA.COLUMNS](#) or by using statements such as [SHOW COLUMNS](#).

Tables in the [performance\\_schema](#) database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see [Section 20.9, “Performance Schema Table Descriptions”](#).

To see what the server is doing at the moment, examine the [events\\_waits\\_current](#) table. It contains one row per thread showing each thread's most recent monitored event:

```

mysql> SELECT * FROM events_waits_current\G
***** 1. row *****
      THREAD_ID: 0
      EVENT_ID: 5523
      EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
      SOURCE: thr_lock.c:525
      TIMER_START: 201660494489586
      TIMER_END: 201660494576112
      TIMER_WAIT: 86526
      SPINS: NULL
      OBJECT_SCHEMA: NULL
      OBJECT_NAME: NULL
      OBJECT_TYPE: NULL
OBJECT_INSTANCE_BEGIN: 142270668
      NESTING_EVENT_ID: NULL
      OPERATION: lock
      NUMBER_OF_BYTES: NULL
      FLAGS: 0
...

```

This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on [THR\\_LOCK::mutex](#), a mutex in the [mysys](#) subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.
- [EVENT\\_NAME](#) indicates what was instrumented and [SOURCE](#) indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the [TIMER\\_END](#) and [TIMER\\_WAIT](#) values are [NULL](#). Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see [Section 20.2.3.1, “Performance Schema Event Timing”](#).

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The [events\\_waits\\_history](#) and [events\\_waits\\_history\\_long](#) tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```

mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
-> FROM events_waits_history WHERE THREAD_ID = 13
-> ORDER BY EVENT_ID;
+-----+-----+-----+
| EVENT_ID | EVENT_NAME | TIMER_WAIT |
+-----+-----+-----+
| 86 | wait/synch/mutex/mysys/THR_LOCK::mutex | 686322 |
| 87 | wait/synch/mutex/mysys/THR_LOCK_malloc | 320535 |
+-----+-----+-----+

```

88	wait/synch/mutex/mysys/THR_LOCK_malloc	339390
89	wait/synch/mutex/mysys/THR_LOCK_malloc	377100
90	wait/synch/mutex/sql/LOCK_plugin	614673
91	wait/synch/mutex/sql/LOCK_open	659925
92	wait/synch/mutex/sql/THD::LOCK_thd_data	494001
93	wait/synch/mutex/mysys/THR_LOCK_malloc	222489
94	wait/synch/mutex/mysys/THR_LOCK_malloc	214947
95	wait/synch/mutex/mysys/LOCK_alarm	312993

As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```
mysql> SELECT EVENT_NAME, COUNT_STAR
-> FROM events_waits_summary_global_by_event_name
-> ORDER BY COUNT_STAR DESC LIMIT 10;
```

EVENT_NAME	COUNT_STAR
wait/synch/mutex/mysys/THR_LOCK_malloc	6419
wait/io/file/sql/FRM	452
wait/synch/mutex/sql/LOCK_plugin	337
wait/synch/mutex/mysys/THR_LOCK_open	187
wait/synch/mutex/mysys/LOCK_alarm	147
wait/synch/mutex/sql/THD::LOCK_thd_data	115
wait/io/file/myisam/kfile	102
wait/synch/mutex/sql/LOCK_global_system_variables	89
wait/synch/mutex/mysys/THR_LOCK::mutex	89
wait/synch/mutex/sql/LOCK_open	88

```
mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
-> FROM events_waits_summary_global_by_event_name
-> ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;
```

EVENT_NAME	SUM_TIMER_WAIT
wait/io/file/sql/MYSQL_LOG	1599816582
wait/synch/mutex/mysys/THR_LOCK_malloc	1530083250
wait/io/file/sql/binlog_index	1385291934
wait/io/file/sql/FRM	1292823243
wait/io/file/myisam/kfile	411193611
wait/io/file/myisam/dfile	322401645
wait/synch/mutex/mysys/LOCK_alarm	145126935
wait/io/file/sql/casetest	104324715
wait/synch/mutex/sql/LOCK_plugin	86027823
wait/io/file/sql/pid	72591750

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

#### Note

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```
mysql> SELECT * FROM file_instances\G
***** 1. row *****
```

```

FILE_NAME: /opt/mysql-log/60500/binlog.000007
EVENT_NAME: wait/io/file/sql/binlog
OPEN_COUNT: 0
***** 2. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/tables_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
***** 3. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/columns_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
...

```

Setup tables are used to configure and display monitoring characteristics. For example, to see which event timers are selected, query the `setup_timers` tables:

```

mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----+-----+

```

`setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```

mysql> SELECT * FROM setup_instruments;
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager | YES     | YES   |
...
| wait/synch/rwlock/sql/LOCK_grant | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave | YES     | YES   |
...
| wait/io/file/sql/binlog | YES     | YES   |
| wait/io/file/sql/binlog_index | YES     | YES   |
| wait/io/file/sql/casetest | YES     | YES   |
| wait/io/file/sql/dbopt | YES     | YES   |
...

```

To understand how to interpret instrument names, see [Section 20.4, “Performance Schema Instrument Naming Conventions”](#).

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:

```

mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';

```

The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and which are enabled:

```

mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_stages_current | NO      |
| events_stages_history | NO      |

```

events_stages_history_long	NO
events_statements_current	YES
events_statements_history	NO
events_statements_history_long	NO
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

To control whether the Performance Schema maintains a consumer as a destination for event information, set its `ENABLED` value.

For more information about the setup tables and how to use them to control event collection, see [Section 20.2.3.2, “Performance Schema Event Filtering”](#).

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see [Section 20.2.3.1, “Performance Schema Event Timing”](#).

## 20.2. Performance Schema Configuration

To use the MySQL Performance Schema, these configuration considerations apply:

- The Performance Schema must be configured into MySQL Server at build time to make it available. Performance Schema support is included in binary MySQL distributions. If you are building from source, you must ensure that it is configured into the build as described in [Section 20.2.1, “Performance Schema Build Configuration”](#).
- The Performance Schema must be enabled at server startup to enable event collection to occur. Specific Performance Schema features can be enabled at server startup or at runtime to control which types of event collection occur. See [Section 20.2.2, “Performance Schema Startup Configuration”](#), [Section 20.2.3, “Performance Schema Runtime Configuration”](#), and [Section 20.2.3.2, “Performance Schema Event Filtering”](#).

### 20.2.1. Performance Schema Build Configuration

For the Performance Schema to be available, it must be configured into the MySQL server at build time. Binary MySQL distributions provided by Oracle Corporation are configured to support the Performance Schema. If you use a binary MySQL distribution from another provider, check with the provider whether the distribution has been appropriately configured.

If you build MySQL from a source distribution, enable the Performance Schema by running `CMake` with the `WITH_PERFSCHEMA_STORAGE_ENGINE` option enabled:

```
shell> cmake . -DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Configuring MySQL with the `-DWITHOUT_PERFSCHEMA_STORAGE_ENGINE=1` option prevents inclusion of the Performance Schema, so if you want it included, do not use this option. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that may not have all the current tables), run `mysql_upgrade` after starting the server to ensure that the `performance_schema` database exists with all current tables. Then restart the server. One indication that you need to do this is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema`.`events_waits_history'
has the wrong structure
[ERROR] Native table 'performance_schema`.`events_waits_history_long'
```

```
has the wrong structure
...
```

To verify whether a server was built with Performance Schema support, check its help output. If the Performance Schema is available, the output will mention several variables with names that begin with `performance_schema`:

```
shell> mysql --verbose --help
...
--performance_schema
           Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
           Number of rows in events_waits_history_long.
...
```

You can also connect to the server and look for a line that names the `PERFORMANCE_SCHEMA` storage engine in the output from `SHOW ENGINES`:

```
mysql> SHOW ENGINES\G
...
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
  Transactions: NO
             XA: NO
  Savepoints: NO
...
```

If the Performance Schema was not configured into the server at build time, no row for `PERFORMANCE_SCHEMA` will appear in the output from `SHOW ENGINES`. You might see `performance_schema` listed in the output from `SHOW DATABASES`, but it will have no tables and you will not be able to use it.

A line for `PERFORMANCE_SCHEMA` in the `SHOW ENGINES` output means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

## 20.2.2. Performance Schema Startup Configuration

Assuming that the Performance Schema is available, it is enabled by default as of MySQL 5.6.6. Before 5.6.6, it is disabled by default. To enable or disable it explicitly, start the server with the `performance_schema` [2307] variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=on
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` [2307] to `OFF`, and the server runs without instrumentation.

As of MySQL 5.6.4, the Performance Schema permits instrument and consumer configuration at server startup, which previously was possible only at runtime using `UPDATE` statements for the `setup_instruments` and `setup_consumers` tables. This change was made because configuration at runtime is too late to disable instruments that have already been initialized during server startup. For example, the `wait/synch/mutex/sql/LOCK_open` mutex is initialized once during server startup, so attempts to disable the corresponding instrument at runtime have no effect.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, `instrument_name` is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and `value` is one of these values:

- `off`, `false`, or `0`: Disable the instrument
- `on`, `true`, or `1`: Enable and time the instrument
- `counted`: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` [2306] option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:

```
--performance-schema-instrument='wait/synch/cond/%=counted'
```

To disable all instruments, use this option:

```
--performance-schema-instrument='%=off'
```

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see [Section 20.2.3.2.2, “Naming Instruments or Consumers for Filtering Operations”](#).

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```
--performance-schema-consumer-consumer_name=value
```

Here, *consumer\_name* is a consumer name such as `events_waits_history`, and *value* is one of these values:

- `off`, `false`, or `0`: Do not collect events for the consumer
- `on`, `true`, or `1`: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```
--performance-schema-consumer-events-waits-history=on
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON |
| performance_schema_accounts_size | 100 |
| performance_schema_digests_size | 200 |
| performance_schema_events_stages_history_long_size | 10000 |
| performance_schema_events_stages_history_size | 10 |
| performance_schema_events_statements_history_long_size | 10000 |
| performance_schema_events_statements_history_size | 10 |
| performance_schema_events_waits_history_long_size | 10000 |
| performance_schema_events_waits_history_size | 10 |
| performance_schema_hosts_size | 100 |
| performance_schema_max_cond_classes | 80 |
| performance_schema_max_cond_instances | 1000 |
| ... |
```

The `performance_schema` [2307] variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

**Note**

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. It may be necessary to tune the values of Performance Schema system variables to find the number of instances that balances insufficient instrumentation against excessive memory consumption.

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables:

```
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

As of MySQL 5.6.6, the Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. To see which parameters are sized under this policy, use `mysqld --verbose --help` and look for those with a default value of `-1`, or see [Section 20.12, “Performance Schema System Variables”](#).

For each autosized parameter that is not set at server startup (or is set to `-1`), the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

```
max_connections
open_files_limit
table_definition_cache
table_open_cache
```

To override autosizing for a given parameter, set it a value other than `-1` at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, `SHOW VARIABLES` displays the actual values that autosized parameters were set to.

If the Performance Schema is disabled, its autosized parameters remain set to `-1` and `SHOW VARIABLES` displays `-1`.

### 20.2.3. Performance Schema Runtime Configuration

Performance Schema setup tables contain information about monitoring configuration:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
  -> WHERE TABLE_SCHEMA = 'performance_schema'
  -> AND TABLE_NAME LIKE 'setup%';
+-----+
| TABLE_NAME |
+-----+
| setup_actors |
| setup_consumers |
| setup_instruments |
| setup_objects |
| setup_timers |
+-----+
```

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` [756] privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see [Section 20.9.1, “Performance Schema Setup Tables”](#).

To see which event timers are selected, query the `setup_timers` tables:

```
mysql> SELECT * FROM setup_timers;
```

NAME	TIMER_NAME
idle	MICROSECOND
wait	CYCLE
stage	NANOSECOND
statement	NANOSECOND

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with a component matching the `NAME` value.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer for the `wait` timer:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'NANOSECOND'
-> WHERE NAME = 'wait';
mysql> SELECT * FROM setup_timers;
```

NAME	TIMER_NAME
idle	MICROSECOND
wait	NANOSECOND
stage	NANOSECOND
statement	NANOSECOND

For discussion of timers, see [Section 20.2.3.1, “Performance Schema Event Timing”](#).

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. [Section 20.2.3.2, “Performance Schema Event Filtering”](#), discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like to these changes take effect each time the server starts, put the statements in a file and start the server with the `--init-file=file_name` [424] option. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `--init-file` [424] argument when you start the server.

### 20.2.3.1. Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

Two tables provide timer information:

- `performance_timers` lists the available timers and their characteristics.
- `setup_timers` indicates which timers are used for which instruments.

Each timer row in `setup_timers` must refer to one of the timers listed in `performance_timers`.

Timers vary in precision and the amount of overhead they involve. To see what timers are available and their characteristics, check the `performance_timers` table:

```
mysql> SELECT * FROM performance_timers;
```

TIMER_NAME	TIMER_FREQUENCY	TIMER_RESOLUTION	TIMER_OVERHEAD
------------	-----------------	------------------	----------------

CYCLE	2389029850	1	72
NANOSECOND	NULL	NULL	NULL
MICROSECOND	1000000	1	585
MILLISECOND	1035	1	738
TICK	101	1	630

The `TIMER_NAME` column shows the names of the available timers. `CYCLE` refers to the timer that is based on the CPU (processor) cycle counter. If the values associated with a given timer name are `NULL`, that timer is not supported on your platform. The rows that do not have `NULL` indicate which timers you can use in `setup_timers`.

`TIMER_FREQUENCY` indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For `TICK`, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).

`TIMER_RESOLUTION` indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.

`TIMER_OVERHEAD` is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timer is in effect or to change the timer, access the `setup_timers` table:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| idle      | MICROSECOND |
| wait      | NANOSECOND  |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----+-----+

mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
-> WHERE NAME = 'wait';
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| idle      | MICROSECOND |
| wait      | MICROSECOND |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----+-----+
```

By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one.

To time waits, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the `CYCLE` timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is `NANOSECOND`. The extra “overhead” compared to the cycle timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the `CYCLE` timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using

the cycle counter is much cheaper than getting the actual time of day. For example, the standard `gettimeofday()` function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.
- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor's cycle rate fluctuates, conversion from cycles to real-time units is subject to error.
- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is `RDTSC` (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.
- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

Currently, MySQL works with cycle counters on x386 (Windows, Mac OS X, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

Within events, times are stored in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected. The timer used for an event is the one in effect when event timing begins. This timer is used to convert start and end values to picoseconds for storage in the event.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress use the original timer for the begin time and the new timer for the end time, which leads to unpredictable results. If you make timer changes, you may want to use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline (“time zero”) occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major

precision loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

### 20.2.3.2. Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The `setup_instruments` table lists the instruments for which events can be collected, whether they are enabled, and whether to collect timing information:

```
mysql> SELECT * FROM setup_instruments;
```

NAME	ENABLED	TIMED
wait/synch/mutex/sql/LOCK_global_read_lock	YES	YES
wait/synch/mutex/sql/LOCK_global_system_variables	YES	YES
wait/synch/mutex/sql/LOCK_lock_db	YES	YES
wait/synch/mutex/sql/LOCK_manager	YES	YES

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 20.2.3.2.1, “Event Pre-Filtering”](#).

- Performance Schema tables are the destinations for events and consume events. The `setup_consumers` table lists the types of consumers to which event information can be sent and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	NO
events_statements_history_long	NO
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

Filtering can be done at different stages of performance monitoring:

- Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. This type of filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- Pre-filtering reduces overhead. The overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.
- You can avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.

- You can avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining it. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.
- **Post-filtering.** This involves the use of [WHERE](#) clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. This type of filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.
- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see [Section 20.3, “Performance Schema Queries”](#).

### 20.2.3.2.1. Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To configure pre-filtering at the producer stage, several tables can be used:
  - The [setup\\_instruments](#) table indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables. An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.
  - The [setup\\_objects](#) table determines whether particular objects are monitored. Currently, the Performance Schema uses it to control monitoring of table objects.
  - The [threads](#) table indicates whether monitoring is enabled for each server thread.
  - The [setup\\_actors](#) table determines the initial monitoring state for new foreground threads.
- To configure pre-filtering at the consumer stage, modify the [setup\\_consumers](#) table. This determines the destinations to which events are sent.

The [setup\\_consumers](#) table also implicitly affects event production. If a given event will not be sent to any destination (that is, will not be consumed), the Performance Schema does not produce it.

Modifications to any of these tables affect monitoring immediately, with the exception of [setup\\_actors](#). Modifications to [setup\\_actors](#) affect only foreground threads created thereafter.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use [TRUNCATE TABLE](#) to empty the history tables.

After making instrumentation changes, you might want to truncate the summary tables as well to clear aggregate information for previously collected events. Except for [events\\_statements\\_summary\\_by\\_digest](#), the effect of [TRUNCATE TABLE](#) for summary tables is to reset the summary columns to 0 or [NULL](#), not to remove rows.

The following sections describe how to use specific tables to control how the Performance Schema performs pre-filtering.

### 20.2.3.2.1.1. Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```
mysql> SELECT * FROM setup_instruments;
```

NAME	ENABLED	TIMED
...		
wait/synch/mutex/sql/LOCK_global_read_lock	YES	YES
wait/synch/mutex/sql/LOCK_global_system_variables	YES	YES
wait/synch/mutex/sql/LOCK_lock_db	YES	YES
wait/synch/mutex/sql/LOCK_manager	YES	YES
...		
wait/synch/rwlock/sql/LOCK_grant	YES	YES
wait/synch/rwlock/sql/LOGGER::LOCK_logger	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_connect	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_slave	YES	YES
...		
wait/io/file/sql/binlog	YES	YES
wait/io/file/sql/binlog_index	YES	YES
wait/io/file/sql/casetest	YES	YES
wait/io/file/sql/dbopt	YES	YES
...		

To control whether an instrument is enabled, set its `ENABLED` column to `YES` or `NO`. To configure whether to collect timing information for an instrument, set its `TIMED` value to `YES` or `NO`. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 20.2.3.1, “Performance Schema Event Timing”](#).

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users.

- Disable all instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO';
```

Now no events will be collected.

- Disable all file instruments, adding them to the current set of disabled instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME LIKE 'wait/io/file/%';
```

- Disable only file instruments, enable all other instruments:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

The preceding queries use the `LIKE` [1190] operator and the pattern `'wait/io/file/%'` to match all instrument names that begin with `'wait/io/file/`. For additional information about specifying patterns to select instruments, see [Section 20.2.3.2.2, “Naming Instruments or Consumers for Filtering Operations”](#).

- Enable all but those instruments in the `mysys` library:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```

- Disable a specific instrument:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- To toggle the state of an instrument, “flip” its `ENABLED` value:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES');
```

```
-> WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- Disable timing for all events:

```
mysql> UPDATE setup_instruments SET TIMED = 'NO';
```

Modifications to the `setup_instruments` table affect monitoring immediately.

### 20.2.3.2.1.2. Pre-Filtering by Object

The `setup_objects` table controls whether particular objects are monitored. Currently, the Performance Schema uses it to control monitoring of table objects. The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM setup_objects;
+-----+-----+-----+-----+-----+
| OBJECT_TYPE | OBJECT_SCHEMA | OBJECT_NAME | ENABLED | TIMED |
+-----+-----+-----+-----+-----+
| TABLE     | mysql        | %           | NO      | NO    |
| TABLE     | performance_schema | %         | NO      | NO    |
| TABLE     | information_schema | %         | NO      | NO    |
| TABLE     | %            | %           | YES     | YES   |
+-----+-----+-----+-----+-----+
```

The `OBJECT_SCHEMA` and `OBJECT_NAME` columns should contain a literal schema or table name, or '%' to match any name.

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for 'db1' and 't1', then for 'db1' and '%', then for '%' and '%'. The order in which matching occurs matters because different `setup_objects` rows can have different `ENABLED` and `TIMED` values.

The effect of the default object configuration is to instrument all tables except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.

For table-related events, the Performance Schema combines the contents of `setup_objects` with `setup_instruments` to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in `setup_objects`, table instruments produce events only if they are enabled in both `setup_instruments` and `setup_objects`.
- The `TIMED` values in the two tables are combined, so that timing information is collected only with both values are `YES`.

Suppose that `setup_objects` contains the following rows:

```
+-----+-----+-----+-----+-----+
| OBJECT_TYPE | OBJECT_SCHEMA | OBJECT_NAME | ENABLED | TIMED |
+-----+-----+-----+-----+-----+
| TABLE     | db1          | t1          | YES     | YES   |
| TABLE     | db1          | t2          | YES     | NO    |
| TABLE     | db2          | %           | YES     | YES   |
| TABLE     | db3          | %           | YES     | NO    |
| TABLE     | %            | %           | YES     | YES   |
+-----+-----+-----+-----+-----+
```

If a table-related instrument in `setup_instruments` has a `TIMED` value of `NO`, no events for the instrument are timed. If the `TIMED` value is `YES`, event timing occurs as follows:

- `db1.t1` events are timed
- `db1.t2` events are not timed

- `db2.t3` events are timed
- `db3.t4` events are not timed
- `db4.t5` events are timed

If a persistent table and a temporary table have the same name, matching against `setup_objects` rows occurs the same way for both. It is not possible to enable monitoring for one table but not the other. However, each table is instrumented separately.

Modifications to the `setup_objects` table affect object monitoring immediately.

The `ENABLED` column was added in MySQL 5.6.3. For earlier versions that have no `ENABLED` column, `setup_objects` is used only to enable monitoring for objects that match some row in the table. There is no way to explicitly disable instrumentation with the table.

### 20.2.3.2.1.3. Pre-Filtering by Thread

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `thread.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that are enabled, as specified in the `setup_instruments` table.

The `INSTRUMENTED` column in the `threads` table indicates the monitoring state for each thread. For foreground threads (resulting from client connections), the initial `INSTRUMENTED` value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. For background threads, `INSTRUMENTED` is `YES` by default. `setup_actors` is not consulted because there is no associated user for background threads. For any thread, its `INSTRUMENTED` value can be changed during the life of the thread.

The initial `setup_actors` contents look like this:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+
| HOST | USER | ROLE |
+-----+-----+-----+
| %    | %    | %    |
+-----+-----+-----+
```

The Performance Schema uses the `HOST` and `USER` columns to match each new foreground thread. (`ROLE` is unused.) The `INSTRUMENTED` value for the thread becomes `YES` if any row matches. This enables instrumenting to be applied selectively per host, user, or combination of host and user.

The `HOST` and `USER` columns should contain a literal host or user name, or `'%'` to match any name. By default, monitoring is enabled for all new foreground threads because the `setup_actors` table initially contains a row with `'%'` for both `HOST` and `USER`. To perform more limited matching such as to enable monitoring only for some foreground threads, you must delete this row because it matches any connection.

Suppose that you modify `setup_actors` as follows:

```
DELETE FROM setup_actors;
```

Now `setup_actors` is empty and there are no rows that could match incoming connections. Consequently, the Performance Schema will set the `INSTRUMENTED` column for all new foreground threads to `NO`.

Suppose that you further modify `setup_actors`:

```
INSERT INTO setup_actors (HOST,USER,ROLE) VALUES('localhost','joe','%');
INSERT INTO setup_actors (HOST,USER,ROLE) VALUES('%','sam','%');
```

Now the Performance Schema determines how to set the `INSTRUMENTED` value for new connection threads as follows:

- If `joe` connects from the local host, the connection matches the first inserted row.
- If `joe` connects from any other host, there is no match.
- If `sam` connects from any host, the connection matches the second inserted row.
- For any other connection, there is no match.

Modifications to the `setup_actors` table do not affect existing threads.

#### 20.2.3.2.1.4. Pre-Filtering by Consumer

The `setup_consumers` table lists the available consumer types and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| events_stages_current               | NO      |
| events_stages_history               | NO      |
| events_stages_history_long          | NO      |
| events_statements_current           | YES     |
| events_statements_history           | NO      |
| events_statements_history_long      | NO      |
| events_waits_current                | NO      |
| events_waits_history                | NO      |
| events_waits_history_long           | NO      |
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| statements_digest                   | YES     |
+-----+-----+
```

Modify the `setup_consumers` table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its `ENABLED` value to `YES` or `NO`.

Modifications to the `setup_consumers` table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining it. For example, you can disable history consumers if you do not care about historical event information:

```
mysql> UPDATE setup_consumers
-> SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.
- A consumer is checked only if all consumers that it depends on (if any) are enabled.
- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.
- Dependent consumers may have their own dependent consumers.
- If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see [Section 20.2.3.2.1.5, “Example Consumer Configurations”](#).

### Global and Thread Consumers

- `global_instrumentation` is the highest level consumer. If `global_instrumentation` is `NO`, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If `global_instrumentation` is `YES`, the Performance Schema maintains information for global states and also checks the `thread_instrumentation` consumer.
- `thread_instrumentation` is checked only if `global_instrumentation` is `YES`. Otherwise, if `thread_instrumentation` is `NO`, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If `thread_instrumentation` is `YES`, the Performance Schema maintains thread-specific information and also checks `events_xxx_current` consumers.

### Statement Digest Consumer

This consumer requires `global_instrumentation` to be `YES` or it is not checked. There is no dependency on the Statement Event consumers. This means you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead.

### Wait Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked.

- `events_waits_current`, if `NO`, disables collection of individual wait events in the `events_waits_current` table. If `YES`, it enables wait event collection and the Performance Schema checks the `events_waits_history` and `events_waits_history_long` consumers.
- `events_waits_history` is not checked if `event_waits_current` is `NO`. Otherwise, a `events_waits_history` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history` table.
- `events_waits_history_long` is not checked if `event_waits_current` is `NO`. Otherwise, a `events_waits_history_long` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history_long` table.

### Stage Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked.

- `events_stages_current`, if `NO`, disables collection of individual stage events in the `events_stages_current` table. If `YES`, it enables stage event collection and the Performance Schema checks the `events_stages_history` and `events_stages_history_long` consumers.
- `events_stages_history` is not checked if `event_stages_current` is `NO`. Otherwise, a `events_stages_history` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history` table.
- `events_stages_history_long` is not checked if `event_stages_current` is `NO`. Otherwise, a `events_stages_history_long` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history_long` table.

## Statement Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked.

- `events_statements_current`, if `NO`, disables collection of individual statement events in the `events_statements_current` table. If `YES`, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.
- `events_statements_history` is not checked if `events_statements_current` is `NO`. Otherwise, a `events_statements_history` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history` table.
- `events_statements_history_long` is not checked if `events_statements_current` is `NO`. Otherwise, a `events_statements_history_long` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history_long` table.

### 20.2.3.2.1.5. Example Consumer Configurations

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema will execute less code on your behalf and you will have less information to sift through.

Suppose that the `setup_consumers` table contains the following hierarchy of values:

```
global_instrumentation
  thread_instrumentation
    events_waits_current
      events_waits_history
        events_waits_history_long
```

If a given consumer setting is `NO`, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is `YES`, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level.

Each configuration description indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

#### No Instrumentation

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | NO      |
| ...                                  |         |
+-----+-----+
```

In this configuration, nothing is instrumented.

Setup elements checked:

- Table `setup_consumers`, consumer `global_instrumentation`

Output tables maintained:

- None

### Global Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| global_instrumentation | YES     |
| thread_instrumentation | NO      |
| ...                  |         |
+-----+-----+
```

In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`
- Table `setup_timers`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`
- `cond_instances`
- `file_instances`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
- `events_waits_summary_by_instance`
- `events_waits_summary_global_by_event_name`

### Global and Thread Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| global_instrumentation | YES     |
| thread_instrumentation | YES     |
| events_waits_current   | NO      |
+-----+-----+
```

```
...
+-----+-----+
```

In this configuration, instrumentation is maintained globally and per thread. No individual wait events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `events_waits_current`
- Table `setup_actors`
- Column `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- `events_waits_summary_by_thread_by_event_name`

### Global, Thread, and Current-Event Instrumentation

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                 | YES     |
| events_waits_history                 | NO      |
| events_waits_history_long            | NO      |
...
+-----+-----+
```

In this configuration, instrumentation is maintained globally and per thread. Individual wait events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Consumer `events_waits_history`
- Consumer `events_waits_history_long`

Additional output tables maintained, relative to the preceding configuration:

- `events_waits_current`

### Global, Thread, Current-Event, and Event-History instrumentation

The preceding configuration collects no wait event history because the `events_waits_history` and `events_waits_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                 | YES     |
| events_waits_history                 | YES     |
| events_waits_history_long            | NO      |
...
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_waits_history`

This configuration collects event history globally, but not per thread:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| global_instrumentation | YES     |
| thread_instrumentation | YES     |
| events_waits_current   | YES     |
| events_waits_history   | NO      |
| events_waits_history_long | YES    |
| ...                   |         |
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_waits_history_long`

This configuration collects event history per thread and globally:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| global_instrumentation | YES     |
| thread_instrumentation | YES     |
| events_waits_current   | YES     |
| events_waits_history   | YES     |
| events_waits_history_long | YES    |
| ...                   |         |
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_waits_history`
- `events_waits_history_long`

### 20.2.3.2.2. Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```
mysql> UPDATE setup_instruments
  -> SET ENABLED = 'NO'
  -> WHERE NAME = 'wait/synch/mutex/myisamrg/MYRG_INFO::mutex';

mysql> UPDATE setup_consumers
  -> SET ENABLED = 'NO' WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```
mysql> UPDATE setup_instruments
  -> SET ENABLED = 'NO'
  -> WHERE NAME LIKE 'wait/synch/mutex/%';

mysql> UPDATE setup_consumers
  -> SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```
... WHERE NAME LIKE 'wait/io/file/%';
```

A pattern of `'%/file/%'` will match other instruments that have a component of `'/file/'` anywhere in the name. Even less suitable is the pattern `'%file%'` because it will match instruments with `'file'` anywhere in the name, such as `wait/synch/mutex/sql/LOCK_des_key_file`.

To check which instrument or consumer names a pattern matches, perform a simple test:

```
mysql> SELECT NAME FROM setup_instruments WHERE NAME LIKE 'pattern';
mysql> SELECT NAME FROM setup_consumers WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see [Section 20.4, “Performance Schema Instrument Naming Conventions”](#).

### 20.2.3.3. Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the InnoDB storage engine, use this query:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'wait/io/file/innodb/%';
```

NAME	ENABLED	TIMED
wait/io/file/innodb/innodb_data_file	YES	YES
wait/io/file/innodb/innodb_log_file	YES	YES
wait/io/file/innodb/innodb_temp_file	YES	YES

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.
- It is not practical to list all the instruments because there are hundreds of them.
- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

## 20.3. Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In [Section 20.2.3.2.1, “Event Pre-Filtering”](#), an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
-> FROM events_waits_history
-> WHERE EVENT_NAME LIKE 'wait/io/file/%'
-> AND NUMBER_OF_BYTES IS NOT NULL;
```

THREAD_ID	NUMBER_OF_BYTES
11	66
11	47
11	139
5	24
5	834

+-----+-----+-----+

## 20.4. Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of components separated by '/' characters. Example names:

```
wait/io/file/myisam/log
wait/io/file/mysys/charset
wait/lock/table/sql/handler
wait/synch/cond/mysys/COND_alarm
wait/synch/cond/sql/BINLOG::update_cond
wait/synch/mutex/mysys/BITMAP_mutex
wait/synch/mutex/sql/LOCK_delete
wait/synch/rwlock/sql/Query_cache_query::lock
stage/sql/closing_tables
stage/sql/Sorting_result
statement/com/Execute
statement/com/Query
statement/sql/create_table
statement/sql/lock_tables
```

The instrument name space has a tree-like structure. The components of an instrument name from left to right provide a progression from more general to more specific. The number of components a name has depends on the type of instrument.

The interpretation of a given component in a name depends on the components to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

```
wait/io/file/myisam/log
wait/synch/cond/myisam/MI_SORT_INFO::cond
```

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level component of an instrument prefix indicates the type of instrument. This component also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major component (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.

### Top-Level Instrument Components

- `idle`: An instrumented idle event. This instrument has no further components.
- `stage`: An instrumented stage event.
- `statement`: An instrumented statement event.
- `wait`: An instrumented wait event.

### Idle Instrument Components

- `idle`

The idle instrument. The Performance Schema generates idle events as discussed in the description of the `socket_instances.STATE` column in [Section 20.9.2.5, "The socket\\_instances Table"](#).

## Stage Instrument Components

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

## Statement Instrument Components

- `statement/com`: An instrumented command operation. These have names corresponding to `COM_xxx` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`). For example, the `statement/com/Connect` and `statement/com/Fetch` instruments correspond to the `COM_CONNECT` and `COM_FETCH` commands.
- `statement/sql`: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

## Wait Instrument Components

- `wait/io`

An instrumented I/O operation.

- `wait/io/file`

An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- `wait/io/socket`

An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

- `wait/io/table`

An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, `events_waits_current` for a table I/O wait usually has two rows. For more information, see [Section 20.6, “Performance Schema Atom and Molecule Events”](#).

Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

- `wait/lock`

An instrumented lock operation.

- `wait/lock/table`

An instrumented table lock operation.

- `wait/synch`

An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- `wait/synch/cond`

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- `wait/synch/mutex`

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- `wait/synch/rwlock`

A read/write lock object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

## 20.5. Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```
mysql> SHOW STATUS LIKE 'perf%';
```

Variable_name	Value
Performance_schema_cond_classes_lost	0
Performance_schema_cond_instances_lost	0
Performance_schema_file_classes_lost	0
Performance_schema_file_handles_lost	0
Performance_schema_file_instances_lost	0
Performance_schema_locker_lost	0
Performance_schema_mutex_classes_lost	0
Performance_schema_mutex_instances_lost	0
Performance_schema_rwlock_classes_lost	0
Performance_schema_rwlock_instances_lost	0
Performance_schema_table_handles_lost	0
Performance_schema_table_instances_lost	0
Performance_schema_thread_classes_lost	0
Performance_schema_thread_instances_lost	0

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- `Performance_schema_xxx_classes_lost` indicates how many instruments of type `xxx` could not be loaded.
- `Performance_schema_xxx_instances_lost` indicates how many instances of object type `xxx` could not be created.
- `Performance_schema_xxx_handles_lost` indicates how many instances of object type `xxx` could not be opened.
- `Performance_schema_locker_lost` indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments `Performance_schema_mutex_classes_lost` [2318]. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it will not be collected. If the instrument can be allocated, it can be used for

initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there will be only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers will increase the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost` [2318].

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` [2312] option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.
- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a
```

The server now has  $150+40 = 190$  mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for  $200-190 = 10$  instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` [2318] indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf%mutex_classes_lost";
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Performance_schema_mutex_classes_lost | 10 |
+-----+-----+
1 row in set (0.10 sec)
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` [2318] increases by 1.
- `Performance_schema_mutex_instances_lost` [2318] does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` [2318] greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `--performance_schema_max_mutex_classes=N` [2312], where *N* is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.
- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for `performance_schema_max_mutex_classes` [2312].

If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate more using `--performance_schema_max_mutex_classes=N` [2312], loading the plugin leads to starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` [2312] is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the `performance_schema` database will miss events. The `Performance_schema_mutex_classes_lost` [2318] status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in the `setup_instruments` table. This single instrument is used when creating a mutex in the code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server runs. In this case, `LOCK_delete` is a mutex that is per connection (`THD`), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances (`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments `Performance_schema_mutex_instances_lost` [2318] by 200 to indicate that instances could not be created.

A value of `Performance_schema_mutex_instances_lost` [2318] greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for `--performance_schema_max_mutex_instances=N` [2313].

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific `Performance_schema_xxx_lost` variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory will be allocated for file-related classes, instances, or handles, and all file events will be lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.row_size
  Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.row_count
```

```

Status: 10000
***** 5. row *****
Type: performance_schema
Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
Type: performance_schema
Name: performance_schema.memory
Status: 26459600
...

```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see [Section 13.7.5.16](#), “`SHOW ENGINE Syntax`”.

## 20.6. Performance Schema Atom and Molecule Events

For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

Row#	EVENT_NAME	TIMER_START	TIMER_END
1	wait/io/file/myisam/dfile	10001	10002
2	wait/io/table/sql/handler	10000	NULL

The row fetch causes a file read. In the example, the table I/O fetch event started before the file I/O event but has not finished (its `TIMER_END` value is `NULL`). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event
- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

## 20.7. Performance Schema Statement Digests

As of MySQL 5.6.5, the Performance Schema maintains statement digest information. Digesting converts a SQL statement to normalized form and computes a hash value for the result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. This section describes how statement normalizing occurs and how it can be useful.

Statement digesting involves these Performance Schema components:

- A `statement_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information.
- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have `DIGEST` and `DIGEST_TEXT` columns that contain digest MD5 values and the corresponding normalized statement text strings.
- A `events_statements_summary_by_digest` table provides aggregated statement digest information.

Normalizing a statement transforms the statement text to a more standardized string representation that preserves the general statement structure while removing information not essential to the

structure. Object identifiers such as database and table names are preserved. Values and comments are removed, and whitespace is adjusted. The Performance Schema does not retain information such as names, passwords, dates, and so forth.

Consider these statements:

```
SELECT * FROM orders WHERE customer_id=10 AND quantity>20
SELECT * FROM orders WHERE customer_id = 20 AND quantity > 100
```

To normalize these statements, the Performance Schema replaces data values by ? and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

```
SELECT * FROM orders WHERE customer_id = ? AND quantity > ?
```

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different comparison values have the same normalized form.

Now consider these statements:

```
SELECT * FROM customers WHERE customer_id = 1000
SELECT * FROM orders WHERE customer_id = 1000
```

In this case, the statements are not “the same.” The object identifiers differ, so the statements yield different normalized forms:

```
SELECT * FROM customers WHERE customer_id = ?
SELECT * FROM orders WHERE customer_id = ?
```

Normalized statements have a fixed length. The maximum length of a `DIGEST_TEXT` value is 1024 bytes. There is no option to change this maximum. If normalization produces a statement that exceeds this length, the text ends with “...”. Long statements that differ only in the part that occurs following the “...” are considered to be the same. Consider these statements:

```
SELECT * FROM mytable WHERE cola = 10 AND colb = 20
SELECT * FROM mytable WHERE cola = 10 AND colc = 20
```

If the cutoff happened to be right after the `AND`, both statements would have this normalized form:

```
SELECT * FROM mytable WHERE cola = ? AND ...
```

In this case, the difference in the second column name is lost and both statements are considered the same.

For each normalized statement, the Performance Schema computes a hash digest value and stores that value and the statement in the `DIGEST` and `DIGEST_TEXT` columns of the statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`). In addition, information for statements with the same `SCHEMA_NAME` and `DIGEST` values are aggregated in the `events_statements_summary_by_digest` summary table. The Performance Schema uses MD5 hash values because they are fast to compute and have a favorable statistical distribution that minimizes collisions.

The `events_statements_summary_by_digest` summary table has a fixed size, so when it becomes full, statements that have `SCHEMA_NAME` and `DIGEST` values not matching existing values in the table are grouped in a special row with `SCHEMA_NAME` and `DIGEST` set to `NULL`. This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the size of the summary table. To do this, set the `performance_schema_digests_size` [2308] system variable to a larger value at server startup. If no `performance_schema_digests_size` [2308] value is given, the server estimates the value to use at startup. (Before MySQL 5.6.9, there is no `SCHEMA_NAME` column and the special row has `DIGEST` set to `NULL`.)

The statement digest summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer

can use this information together with other information in the table to assess the application's performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

## 20.8. Performance Schema General Table Characteristics

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Most tables in the `performance_schema` database are read only and cannot be modified. Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so `TRUNCATE TABLE` can be used on tables containing those kinds of information, such as tables named with a prefix of `events_waits_`.

`TRUNCATE TABLE` can also be used with summary tables, but except for `events_statements_summary_by_digest`, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows.

Privileges are as for other databases and tables:

- To retrieve from `performance_schema` tables, you must have the `SELECT` [755] privilege.
- To change those columns that can be modified, you must have the `UPDATE` [756] privilege.
- To truncate tables that can be truncated, you must have the `DROP` [754] privilege.

## 20.9. Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

- Setup tables. These tables are used to configure and display monitoring characteristics.
- Current events table. The `events_waits_current` table contains the most recent event for each thread.
- History tables. These tables have the same structure as `events_waits_current` but contain more rows. The `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events.

To change the sizes of these tables, set the

`performance_schema_events_waits_history_size` [2310] and `performance_schema_events_waits_history_long_size` [2310] system variables at server startup.

- Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.
- Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.
- Miscellaneous tables. These do not fall into any of the other table groups.

### 20.9.1. Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` [756] privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- `setup_actors`: How to initialize monitoring for new foreground threads
- `setup_consumers`: The destinations to which event information can be sent and stored
- `setup_instruments`: The classes of instrumented objects for which events can be collected
- `setup_objects`: Which objects should be monitored
- `setup_timers`: The current event timer

### 20.9.1.1. The `setup_actors` Table

The `setup_actors` table contains information that determines whether to enable monitoring for new foreground server threads; that is, threads associated with client connections. This table has a maximum size of 100 rows by default. The size may be changed by modifying the `performance_schema_setup_actors_size` [2317] system variable at server startup.

The `setup_actors` table has these columns:

- `HOST`  
The host name. This should be a literal name, or `'%'` to mean “any host.”
- `USER`  
The user name. This should be a literal name, or `'%'` to mean “any user.”
- `ROLE`  
Unused.

For each new foreground thread, the Performance Schema matches the user and host for the thread against the rows of the `setup_actors` table. Based on whether any row matches, the `INSTRUMENTED` column of the `threads` table row for the thread is set to `YES` or `NO`. This enables instrumenting to be applied selectively per host, user, or combination of host and user.

The initial contents of the `setup_actors` table match any user and host combination, so monitoring for all foreground threads is enabled by default:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+
| HOST | USER | ROLE |
+-----+-----+-----+
| %    | %    | %    |
+-----+-----+-----+
```

Modifications to the `setup_actors` table do not affect existing threads.

For more information about the role of the `setup_actors` table in event monitoring, see [Section 20.2.3.2.1, “Event Pre-Filtering”](#).

### 20.9.1.2. The `setup_consumers` Table

The `setup_consumers` table lists the types of consumers for which event information can be stored and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME | ENABLED |
+-----+-----+
```

events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	NO
events_statements_history_long	NO
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO
global_instrumentation	YES
thread_instrumentation	YES

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see [Section 20.2.3.2.1.4, “Pre-Filtering by Consumer”](#).

The `setup_consumers` table has these columns:

- **NAME**

The consumer name.

- **ENABLED**

Whether the consumer is enabled. This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

Modifications to the `setup_consumers` table affect monitoring immediately.

### 20.9.1.3. The `setup_instruments` Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

```
mysql> SELECT * FROM setup_instruments;
```

NAME	ENABLED	TIMED
...		
wait/synch/mutex/sql/LOCK_global_read_lock	YES	YES
wait/synch/mutex/sql/LOCK_global_system_variables	YES	YES
wait/synch/mutex/sql/LOCK_lock_db	YES	YES
wait/synch/mutex/sql/LOCK_manager	YES	YES
...		
wait/synch/rwlock/sql/LOCK_grant	YES	YES
wait/synch/rwlock/sql/LOGGER::LOCK_logger	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_connect	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_slave	YES	YES
...		
wait/io/file/sql/binlog	YES	YES
wait/io/file/sql/binlog_index	YES	YES
wait/io/file/sql/casetest	YES	YES
wait/io/file/sql/dbopt	YES	YES
...		

Each instrument added to the source code provides a row for this table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `*_instances` tables.

The `setup_instruments` table has these columns:

- **NAME**

The instrument name. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 20.4, “Performance Schema Instrument Naming Conventions”](#). Events produced from

execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- `ENABLED`

Whether the instrument is enabled. This column can be modified. A disabled instrument produces no events.

- `TIMED`

Whether the instrument is timed. This column can be modified.

If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

Modifications to the `setup_instruments` table affect monitoring immediately.

For more information about the role of the `setup_instruments` table in event filtering, see [Section 20.2.3.2.1, “Event Pre-Filtering”](#).

#### 20.9.1.4. The `setup_objects` Table

The `setup_objects` table controls whether particular objects are monitored. This table has a maximum size of 100 rows by default. The size may be changed by modifying the `performance_schema_setup_objects_size` [2317] system variable at server startup.

The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM setup_objects;
+-----+-----+-----+-----+-----+
| OBJECT_TYPE | OBJECT_SCHEMA | OBJECT_NAME | ENABLED | TIMED |
+-----+-----+-----+-----+-----+
| TABLE     | mysql        | %           | NO      | NO    |
| TABLE     | performance_schema | %         | NO      | NO    |
| TABLE     | information_schema | %        | NO      | NO    |
| TABLE     | %           | %         | YES     | YES   |
+-----+-----+-----+-----+-----+
```

For object types listed in `setup_objects`, the Performance Schema uses the table to how to monitor them. Object matching is based on the `OBJECT_SCHEMA` and `OBJECT_NAME` columns. Objects for which there is no match are not monitored.

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different `setup_objects` rows can have different `ENABLED` and `TIMED` values.

The effect of the default object configuration is to instrument all tables except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.

The `setup_objects` table has these columns:

- `OBJECT_TYPE`

The type of object to instrument. Currently, this is always `'TABLE'` (base table).

- `OBJECT_SCHEMA`

The schema that contains the object. This should be a literal name, or `'%'` to mean “any schema.”

- `OBJECT_NAME`

The name of the instrumented object. This should be a literal name, or `'%'` to mean “any object.”

- `ENABLED`

Whether events for the object are instrumented. This column can be modified.

This column was added in MySQL 5.6.3. For earlier versions in which it is not present, the Performance Schema enables monitoring only for objects matched by some row in the table; monitoring is implicitly disabled for nonmatching objects.

- `TIMED`

Whether events for the object are timed. This column can be modified.

Rows can be inserted into or deleted from `setup_objects` by users with the [INSERT \[755\]](#) or [DELETE \[754\]](#) privilege on the table. For existing rows, only the `ENABLED` and `TIMED` columns can be modified, by users with the [UPDATE \[756\]](#) privilege on the table.

Modifications to the `setup_objects` table affect object monitoring immediately.

For more information about the role of the `setup_objects` table in event filtering, see [Section 20.2.3.2.1, “Event Pre-Filtering”](#).

### 20.9.1.5. The `setup_timers` Table

The `setup_timers` table shows the currently selected event timers:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----+-----+
```

The `setup_timers` table has these columns:

- `NAME`

The type of instrument the timer is used for.

- `TIMER_NAME`

The timer that applies to the instrument type. This column can be modified.

The `setup_timers.TIMER_NAME` value can be changed to select a different timer. The value can be any of the values in the `performance_timers.TIMER_NAME` column. For an explanation of how event timing occurs, see [Section 20.2.3.1, “Performance Schema Event Timing”](#).

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time, which may lead to unpredictable results. If you make timer changes, you may want to use `TRUNCATE TABLE` to reset Performance Schema statistics.

## 20.9.2. Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- `cond_instances`: Condition synchronization object instances

- `file_instances`: File instances
- `mutex_instances`: Mutex synchronization object instances
- `rwlock_instances`: Lock synchronization object instances
- `socket_instances`: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: `cond`, `mutex`, and `rwlock`. Each instance table has an `EVENT_NAME` or `NAME` column to indicate the instrument associated with each row. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 20.4, “Performance Schema Instrument Naming Conventions”](#).

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see [Section 20.15, “Using the Performance Schema to Diagnose Problems”](#)

### 20.9.2.1. The `cond_instances` Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other thread, or threads, will cause the condition to happen.

The `cond_instances` table has these columns:

- `NAME`  
The instrument name associated with the condition.
- `OBJECT_INSTANCE_BEGIN`  
The address in memory of the condition that was instrumented.

### 20.9.2.2. The `file_instances` Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it will not be in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- `FILE_NAME`  
The file name.
- `EVENT_NAME`  
The instrument name associated with the file.
- `OPEN_COUNT`  
The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` will be 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

### 20.9.2.3. The `mutex_instances` Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads will compete against each other, so that the first query to obtain a lock on the mutex will cause the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The `mutex_instances` table has these columns:

- `NAME`

The instrument name associated with the mutex.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the mutex that was instrumented.

- `LOCKED_BY_THREAD_ID`

When a thread currently has a mutex locked, `LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/synch/mutex/`.
- When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.
- When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).
- When a thread succeeds in locking a mutex:
  - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
  - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables
  - `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).
- When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is `NULL`).
- When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- `events_waits_current`, to see what mutex a thread is waiting for
- `mutex_instances`, to see which other thread currently owns a mutex

### 20.9.2.4. The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` instances (read write locks) seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time) or exclusive (only one thread can have a write lock at a given time).

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, granted in exclusive mode, or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- `NAME`

The instrument name associated with the lock.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the lock that was instrumented.

- `WRITE_LOCKED_BY_THREAD_ID`

When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- `READ_LOCKED_BY_COUNT`

When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

### 20.9.2.5. The `socket_instances` Table

The `socket_instances` table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table includes network activity such as socket instances, socket operations, and number of bytes transmitted and received.

```
mysql> SELECT * FROM socket_instances\G
***** 1. row *****
      EVENT_NAME: wait/io/socket/sql/server_unix_socket
OBJECT_INSTANCE_BEGIN: 4316619408
      THREAD_ID: 1
      SOCKET_ID: 16
        IP:
        PORT: 0
      STATE: ACTIVE
***** 2. row *****
      EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 4316644608
```

```

THREAD_ID: 21
SOCKET_ID: 39
  IP: 127.0.0.1
  PORT: 55233
  STATE: ACTIVE
***** 3. row *****
EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
OBJECT_INSTANCE_BEGIN: 4316699040
  THREAD_ID: 1
  SOCKET_ID: 14
  IP: 0.0.0.0
  PORT: 50603
  STATE: ACTIVE

```

Socket instruments have names of the form `wait/io/socket/sql/socket_type` and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively.
2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.
3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- `EVENT_NAME`

The name of the `wait/io/socket/*` instrument that produced the event. This is a `setup_instruments.NAME` value. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 20.4, “Performance Schema Instrument Naming Conventions”](#).

- `OBJECT_INSTANCE_BEGIN`

This column uniquely identifies the socket. The value is the address of an object in memory.

- `THREAD_ID`

The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- `SOCKET_ID`

The internal file handle assigned to the socket.

- `IP`

The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- `PORT`

The TCP/IP port number, in the range from 0 to 65535.

- `STATE`

The socket status, either `IDLE` or `ACTIVE`. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the `idle` instrument.

A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in `socket_instances` that is tracking the socket switches from a status of `ACTIVE` to `IDLE`.

The `EVENT_NAME` value remains `wait/io/socket/*`, but timing for the instrument is suspended. Instead, an event is generated in the `events_waits_current` table with an `EVENT_NAME` value of `idle`.

When the next request is received, the `idle` event terminates, the socket instance switches from `IDLE` to `ACTIVE`, and timing of the socket instrument resumes.

The `IP:PORT` column combination value identifies the connection. This combination value is used in the `OBJECT_NAME` column of the `events_waits_XXX` tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (`server_unix_socket`), the port is 0, and the IP is ''.
- For client connections via the Unix domain listener (`client_connection`), the port is 0, and the IP is ''.
- For the TCP/IP server listener socket (`server_tcpip_socket`), the port is always the master port (for example, 3306), and the IP is always `0.0.0.0`.
- For client connections via the TCP/IP listener (`client_connection`), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (`127.0.0.1` or `::1` for the local host)

The `socket_instances` table was added in MySQL 5.6.3.

## 20.9.3. Performance Schema Wait Event Tables

These tables store wait events:

- `events_waits_current`: Current wait events
- `events_waits_history`: The most recent wait events for each thread
- `events_waits_history_long`: The most recent wait events overall

### 20.9.3.1. The `events_waits_current` Table

The `events_waits_current` table contains current wait events, one row per thread showing the current status of the thread's most recent monitored wait event.

The `events_waits_current` table can be truncated with `TRUNCATE TABLE`.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events, up to a fixed number of rows.

The `events_waits_current` table has these columns:

- `THREAD_ID`

The thread associated with the event. The `THREAD_ID` and `EVENT_ID` values taken together form a primary key that uniquely identifies the row. No two rows will have the same pair of values.

- `EVENT_ID`

The thread current event number when the event starts.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts, and updated to the thread current event number when the event ends. This column was added in MySQL 5.6.4.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `setup_instruments.NAME` value. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 20.4, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL`.

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 20.2.3.1, “Performance Schema Event Timing”](#).

- `SPINS`

For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`, `OBJECT_INSTANCE_BEGIN`

These columns identify the object “being acted on.” What that means depends on the object type.

For a synchronization object (`cond`, `mutex`, `rwlock`):

- `OBJECT_SCHEMA`, `OBJECT_NAME`, and `OBJECT_TYPE` are `NULL`.
- `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.

For a file I/O object:

- `OBJECT_SCHEMA` is `NULL`.
- `OBJECT_NAME` is the file name.
- `OBJECT_TYPE` is `FILE`.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a socket object:

- `OBJECT_NAME` is the `IP:PORT` value for the socket.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a table I/O object:

- `OBJECT_SCHEMA` is the name of the schema that contains the table.
- `OBJECT_NAME` is the table name.

- `OBJECT_TYPE` is `TABLE` for a persistent base table or `TEMPORARY TABLE` for a temporary table.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

An `OBJECT_INSTANCE_BEGIN` value itself has no meaning, except that different values indicate different objects. `OBJECT_INSTANCE_BEGIN` can be used for debugging. For example, it can be used with `GROUP BY OBJECT_INSTANCE_BEGIN` to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

- `INDEX_NAME`

The name of the index used. `PRIMARY` indicates the table primary index. `NULL` means that no index was used.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested. Before MySQL 5.6.3, this column is always `NULL`.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `statement`, `stage`, or `wait`. This column was added in MySQL 5.6.3.

- `OPERATION`

The type of operation performed, such as `lock`, `read`, or `write`.

- `NUMBER_OF_BYTES`

The number of bytes read or written by the operation. For table I/O waits, `NUMBER_OF_BYTES` is `NULL`.

- `FLAGS`

Reserved for future use.

### 20.9.3.2. The `events_waits_history` Table

The `events_waits_history` table contains the most recent 10 wait events per thread. The table size may be changed by modifying the `performance_schema_events_waits_history_size` [2310] system variable at server startup. As new events are added to the table, older events are discarded if the table is full. Events are not added to the table until they have ended.

The `events_waits_history` table has the same structure as `events_waits_current`. See [Section 20.9.3.1, “The `events\_waits\_current` Table”](#).

The `events_waits_history` table can be truncated with `TRUNCATE TABLE`.

### 20.9.3.3. The `events_waits_history_long` Table

The `events_waits_history_long` table contains the most recent 10,000 wait events. The table size may be changed by modifying the `performance_schema_events_waits_history_long_size` [2310] system variable at server startup. As new events are added to the table, older events are discarded if the table is full. Events are not added to the table until they have ended.

The `events_waits_history_long` table has the same structure as `events_waits_current`. See [Section 20.9.3.1, “The `events\_waits\_current` Table”](#).

The `events_waits_history_long` table can be truncated with `TRUNCATE TABLE`.

## 20.9.4. Performance Schema Stage Event Tables

As of MySQL 5.6.3, the Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a `filesort` operation. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events.

These tables store stage events:

- `events_stages_current`: Current stage events
- `events_stages_history`: The most recent stage events for each thread
- `events_stages_history_long`: The most recent stage events overall

### 20.9.4.1. The `events_stages_current` Table

The `events_stages_current` table contains current stage events, one row per thread showing the current status of the thread's most recent monitored stage event.

The `events_stages_current` table can be truncated with `TRUNCATE TABLE`.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events, up to a fixed number of rows.

The `events_stages_current` table has these columns:

- `THREAD_ID`

The thread associated with the event. The `THREAD_ID` and `EVENT_ID` values taken together form a primary key that uniquely identifies the row. No two rows will have the same pair of values.

- `EVENT_ID`

The thread current event number when the event starts.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts, and updated to the thread current event number when the event ends. This column was added in MySQL 5.6.4.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `setup_instruments.NAME` value. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 20.4, "Performance Schema Instrument Naming Conventions"](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL`.

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 20.2.3.1, “Performance Schema Event Timing”](#).

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `statement`, `stage`, or `wait`.

The `events_stages_current` table was added in MySQL 5.6.3.

#### 20.9.4.2. The `events_stages_history` Table

The `events_stages_history` table contains the most recent 10 stage events per thread. The table size may be changed by modifying the `performance_schema_events_stages_history_size` [2309] system variable at server startup. As new events are added to the table, older events are discarded if the table is full. Events are not added to the table until they have ended.

The `events_stages_history` table has the same structure as `events_stages_current`. See [Section 20.9.4.1, “The `events\_stages\_current` Table”](#).

The `events_stages_history` table can be truncated with `TRUNCATE TABLE`.

The `events_stages_history` table was added in MySQL 5.6.3.

#### 20.9.4.3. The `events_stages_history_long` Table

The `events_stages_history_long` table contains the most recent 10,000 stage events. The table size may be changed by modifying the `performance_schema_events_stages_history_long_size` [2308] system variable at server startup. As new events are added to the table, older events are discarded if the table is full. Events are not added to the table until they have ended.

The `events_stages_history_long` table has the same structure as `events_stages_current`. See [Section 20.9.4.1, “The `events\_stages\_current` Table”](#).

The `events_stages_history_long` table can be truncated with `TRUNCATE TABLE`.

The `events_stages_history_long` table was added in MySQL 5.6.3.

### 20.9.5. Performance Schema Statement Event Tables

As of MySQL 5.6.3, the Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy. Wait events nest within stage events, which nest within statement events.

These tables store statement events:

- `events_statements_current`: Current statement events
- `events_statements_history`: The most recent statement events for each thread

- `events_statements_history_long`: The most recent statement events overall

Statement monitoring begins from the moment when the server sees that activity is requested on a thread, to the moment when all activity has ceased. Typically, this means from the time the server gets the first packet from the client to the time the server has finished sending the response. Monitoring occurs only for top-level statements. Statements within stored programs and subqueries are not seen separately.

A request from a client can be either a command or a SQL statement:

- Server commands correspond to the `COM_xxx` codes defined in the `mysql_com.h` header file and processed in `sql/sql_parse.cc`. Examples are `COM_PING`, `COM_QUERY`, and `COM_QUIT`. Instruments for commands have names that begin with `statement/com`, such as `statement/com/Ping`, `statement/com/Query`, and `statement/com/Quit`.
- SQL statements are expressed as text, such as `DELETE FROM t1` or `SELECT * FROM t2`. Instruments for SQL statements have names that begin with `statement/sql`, such as `statement/sql/delete` and `statement/sql/select`.

There are also special error-handling instruments:

- `statement/com/Error` accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.
- `statement/sql/error` accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the `statement/sql/error` instrument is used. By contrast, `SELECT *` parses but fails with a `No tables used` error. In this case, `statement/sql/select` is used and the statement event contains information to indicate the nature of the error.

Details for a request are not initially known. For example, because a SQL statement is sent as text inside a `COM_QUERY` packet, the proper `statement/sql/*` instrument is not known at the moment the request is received. The Performance Schema at first instruments such a request using an event with an `EVENT_NAME` of `statement/com/Query`. Then it changes the `EVENT_NAME` value to either a valid `statement/sql/*` name if the statement parses, or to `statement/sql/error` if it does not.

### 20.9.5.1. The `events_statements_current` Table

The `events_statements_current` table contains current statement events, one row per thread showing the current status of the thread's most recent monitored statement event.

The `events_statements_current` table can be truncated with `TRUNCATE TABLE`.

Of the tables that contain statement event rows, `events_statements_current` is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the `events_statements_history` and `events_statements_history_long` tables are collections of the most recent statement events, up to a fixed number of rows.

The `events_statements_current` table has these columns:

- `THREAD_ID`

The thread associated with the event. The `THREAD_ID` and `EVENT_ID` values taken together form a primary key that uniquely identifies the row. No two rows will have the same pair of values.

- `EVENT_ID`

The thread current event number when the event starts.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts, and updated to the thread current event number when the event ends. This column was added in MySQL 5.6.4.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `setup_instruments.NAME` value. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 20.4, “Performance Schema Instrument Naming Conventions”](#).

For SQL statements, the `EVENT_NAME` value initially is `statement/com/Query` until the statement is parsed, then changes to a more appropriate value, as described in [Section 20.9.5, “Performance Schema Statement Event Tables”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL`.

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 20.2.3.1, “Performance Schema Event Timing”](#).

- `LOCK_TIME`

The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

- `SQL_TEXT`

The text of the SQL statement. For a command not associated with a SQL statement, the value is `NULL`.

- `DIGEST`

The statement digest MD5 value as a string of 32 hexadecimal characters, or `NULL` if the `statement_digest` consumer is `no`. For more information about statement digesting, see [Section 20.7, “Performance Schema Statement Digests”](#). This column was added in MySQL 5.6.5.

- `DIGEST_TEXT`

The normalized statement digest text, or `NULL` if the `statement_digest` consumer is `no`. For more information about statement digesting, see [Section 20.7, “Performance Schema Statement Digests”](#). This column was added in MySQL 5.6.5.

- `CURRENT_SCHEMA`

The default database for the statement, `NULL` if there is none.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`

Reserved. Currently `NULL`.

- `OBJECT_INSTANCE_BEGIN`

This column identifies the statement. The value is the address of an object in memory.

- `MYSQL_ERRNO`

The statement error number, from the statement diagnostics area.

- `RETURNED_SQLSTATE`

The statement `SQLSTATE` value, from the statement diagnostics area.

- `MESSAGE_TEXT`

The statement error message, from the statement diagnostics area.

- `ERRORS`

Whether an error occurred for the statement. The value is 0 if the `SQLSTATE` value begins with 00 (completion) or 01 (warning). The value is 1 if the `SQLSTATE` value is anything else.

- `WARNINGS`

The number of warnings, from the statement diagnostics area.

- `ROWS_AFFECTED`

The number of rows affected by the statement. For a description of the meaning of “affected,” see [Section 21.8.6.1](#), “`mysql_affected_rows()`”.

- `ROWS_SENT`

The number of rows returned by the statement.

- `ROWS_EXAMINED`

The number of rows read from storage engines during statement execution.

- `CREATED_TMP_DISK_TABLES`

Like the `Created_tmp_disk_tables` [\[587\]](#) status variable, but specific to the statement.

- `CREATED_TMP_TABLES`

Like the `Created_tmp_tables` [\[588\]](#) status variable, but specific to the statement.

- `SELECT_FULL_JOIN`

Like the `Select_full_join` [\[598\]](#) status variable, but specific to the statement.

- `SELECT_FULL_RANGE_JOIN`

Like the `Select_full_range_join` [\[598\]](#) status variable, but specific to the statement.

- `SELECT_RANGE`

Like the `Select_range` [\[598\]](#) status variable, but specific to the statement.

- `SELECT_RANGE_CHECK`

Like the `Select_range_check` [\[598\]](#) status variable, but specific to the statement.

- `SELECT_SCAN`  
Like the `Select_scan` [598] status variable, but specific to the statement.
- `SORT_MERGE_PASSES`  
Like the `Sort_merge_passes` [599] status variable, but specific to the statement.
- `SORT_RANGE`  
Like the `Sort_range` [599] status variable, but specific to the statement.
- `SORT_ROWS`  
Like the `Sort_rows` [599] status variable, but specific to the statement.
- `SORT_SCAN`  
Like the `Sort_scan` [599] status variable, but specific to the statement.
- `NO_INDEX_USED`  
1 if the statement performed a table scan without using an index, 0 otherwise.
- `NO_GOOD_INDEX_USED`  
1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record` value in [Section 8.8.2, “EXPLAIN Output Format”](#).
- `NESTING_EVENT_ID`, `NESTING_EVENT_TYPE`  
Reserved. Currently `NULL`.

The `events_statements_current` table was added in MySQL 5.6.3.

### 20.9.5.2. The `events_statements_history` Table

The `events_statements_history` table contains the most recent 10 events per thread. The table size may be changed by modifying the `performance_schema_events_statements_history_size` [2309] system variable at server startup. As new events are added to the table, older events are discarded if the table is full. Events are not added to the table until they have ended.

The `events_statements_history` table has the same structure as `events_statements_current`. See [Section 20.9.5.1, “The `events\_statements\_current` Table”](#).

The `events_statements_history` table can be truncated with `TRUNCATE TABLE`.

The `events_statements_history` table was added in MySQL 5.6.3.

### 20.9.5.3. The `events_statements_history_long` Table

The `events_statements_history_long` table contains the most recent 10,000 events. The table size may be changed by modifying the `performance_schema_events_statements_history_long_size` [2309] system variable at server startup. As new events are added to the table, older events are discarded if the table is full. Events are not added to the table until they have ended.

The `events_statements_history_long` table has the same structure as `events_statements_current`. See [Section 20.9.5.1, “The `events\_statements\_current` Table”](#).

The `events_statements_history_long` table can be truncated with `TRUNCATE TABLE`.

The `events_statements_history_long` table was added in MySQL 5.6.3.

## 20.9.6. Performance Schema Connection Tables

As of MySQL 5.6.3, the Performance Schema provides statistics about connections to the server. When a client connects, it does so under a particular user name and from a particular host. The Performance Schema tracks connections per account (user name plus host name) and separately per user name and per host name, using these tables:

- `accounts`: Connection statistics per client account
- `hosts`: Connection statistics per client host name
- `users`: Connection statistics per client user name

The meaning of “account” in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` database, in the sense that the term refers to a combination of user and host values. Where they differ is that in the grant tables, the host part of an account can be a pattern, whereas in the connection tables the host value is always a specific nonpattern host name.

The connection tables all have `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per “tracking value” on which statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user name plus host name combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and per host name.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:

- The `accounts` table will have four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.
- The `users` table will have two rows, for `user1` and `user2`, each row counting two connections per user name.
- The `hosts` table will have two rows, for `hosta` and `hostb`, each row counting two connections per host name.

When a client connects, the Performance Schema determines which row in each connection table applies to the connection, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns in that row.

When a client disconnects, the Performance Schema decrements by one the `CURRENT_CONNECTIONS` column in the row and leaves the `TOTAL_CONNECTIONS` column unchanged.

Each connection table can be truncated with `TRUNCATE TABLE`, which has this effect:

- Rows with `CURRENT_CONNECTIONS = 0` are deleted.
- For rows with `CURRENT_CONNECTIONS > 0`, `TOTAL_CONNECTIONS` is reset to `CURRENT_CONNECTIONS`.
- Connection summary tables that depend on the connection table are truncated implicitly (summary values are set to 0). For more information about implicit truncation, see [Section 20.9.8.7, “Connection Summary Tables”](#).

### 20.9.6.1. The `accounts` Table

The `accounts` table contains a row for each account that has connected to the MySQL server. For each account, the table counts the current and total number of connections. The table size may be changed by modifying the `performance_schema_accounts_size` [2308] system variable at server startup. To disable account statistics, set this variable to 0.

The `accounts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 20.9.6, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection.

- `HOST`

The host name from which the client connected.

- `CURRENT_CONNECTIONS`

The current number of connections for the account.

- `TOTAL_CONNECTIONS`

The total number of connections for the account.

The `accounts` table was added in MySQL 5.6.3.

### 20.9.6.2. The `hosts` Table

The `hosts` table contains a row for each host from which clients have connected to the MySQL server. For each host name, the table counts the current and total number of connections. The table size may be changed by modifying the `performance_schema_hosts_size` [2310] system variable at server startup. To disable host statistics, set this variable to 0.

The `hosts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 20.9.6, “Performance Schema Connection Tables”](#).

- `HOST`

The host name from which the client connected.

- `CURRENT_CONNECTIONS`

The current number of connections for the host.

- `TOTAL_CONNECTIONS`

The total number of connections for the host.

The `hosts` table was added in MySQL 5.6.3.

### 20.9.6.3. The `users` Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size may be changed by modifying the `performance_schema_users_size` [2317] system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 20.9.6, “Performance Schema Connection Tables”](#).

- `USER`  
The client user name for the connection.
- `CURRENT_CONNECTIONS`  
The current number of connections for the user.
- `TOTAL_CONNECTIONS`  
The total number of connections for the user.

The `users` table was added in MySQL 5.6.3.

## 20.9.7. Performance Schema Connection Attribute Tables

As of MySQL 5.6.6, application programs can provide key/value connection attributes to be passed to the server at connect time, using the `mysql_options()` and `mysql_options4()` C API functions. The Performance Schema provides tables that expose this information through SQL statements:

- `session_account_connect_attrs`: Connection attributes per for the current session
- `session_connect_attrs`: Connection attributes for all sessions

Both tables have the same columns. The difference between them is that `session_connect_attrs` displays connection attributes for all sessions, whereas `session_account_connect_attrs` displays connections only for your own account.

- `PROCESSLIST_ID`  
The connection identifier for the session.
- `ATTR_NAME`  
The attribute name.
- `ATTR_VALUE`  
The attribute value.
- `ORDINAL_POSITION`  
The order in which the attribute was added to the set of connection attributes.

## 20.9.8. Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

### Event Wait Summaries:

- `events_waits_summary_global_by_event_name`: Wait events summarized per event name
- `events_waits_summary_by_instance`: Wait events summarized per instance
- `events_waits_summary_by_thread_by_event_name`: Wait events summarized per thread and event name

### Stage Summaries:

- `events_stages_summary_by_thread_by_event_name`: Stage waits summarized per thread and event name
- `events_stages_summary_global_by_event_name`: Stage waits summarized per event name

**Statement Summaries:**

- [events\\_statements\\_summary\\_by\\_thread\\_by\\_event\\_name](#): Statement events summarized per thread and event name
- [events\\_statements\\_summary\\_global\\_by\\_event\\_name](#): Statement events summarized per event name

**Object Wait Summaries:**

- [objects\\_summary\\_global\\_by\\_type](#): Object summaries

**File I/O Summaries:**

- [file\\_summary\\_by\\_event\\_name](#): File events summarized per event name
- [file\\_summary\\_by\\_instance](#): File events summarized per file instance

**Table I/O and Lock Wait Summaries:**

- [table\\_io\\_waits\\_summary\\_by\\_index\\_usage](#): Table I/O waits per index
- [table\\_io\\_waits\\_summary\\_by\\_table](#): Table I/O waits per table
- [table\\_lock\\_waits\\_summary\\_by\\_table](#): Table lock waits per table

**Connection Summaries:**

- [events\\_waits\\_summary\\_by\\_account\\_by\\_event\\_name](#): Wait events summarized per account and event name
- [events\\_waits\\_summary\\_by\\_user\\_by\\_event\\_name](#): Wait events summarized per user name and event name
- [events\\_waits\\_summary\\_by\\_host\\_by\\_event\\_name](#): Wait events summarized per host name and event name
- [events\\_stages\\_summary\\_by\\_account\\_by\\_event\\_name](#): Stage events summarized per account and event name
- [events\\_stages\\_summary\\_by\\_user\\_by\\_event\\_name](#): Stage events summarized per user name and event name
- [events\\_stages\\_summary\\_by\\_host\\_by\\_event\\_name](#): Stage events summarized per host name and event name
- [events\\_statements\\_summary\\_by\\_account\\_by\\_event\\_name](#): Statement events summarized per account and event name
- [events\\_statements\\_summary\\_by\\_user\\_by\\_event\\_name](#): Statement events summarized per user name and event name
- [events\\_statements\\_summary\\_by\\_host\\_by\\_event\\_name](#): Statement events summarized per host name and event name

**Socket Summaries:**

- [socket\\_summary\\_by\\_instance](#): Socket waits and I/O summarized per instance
- [socket\\_summary\\_by\\_event\\_name](#): Socket waits and I/O summarized per event name

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar

ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with `TRUNCATE TABLE`. Except for `events_statements_summary_by_digest`, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change.

### 20.9.8.1. Event Wait Summary Tables

The event waits summary tables aggregate general information about event waits:

- `events_waits_summary_global_by_event_name`: Wait events summarized per event name
- `events_waits_summary_by_instance`: Wait events summarized per instance
- `events_waits_summary_by_thread_by_event_name`: Wait events summarized per thread and event name

For example:

```
mysql> SELECT * FROM events_waits_summary_global_by_event_name\G
...
***** 6. row *****
EVENT_NAME: wait/synch/mutex/sql/BINARY_LOG::LOCK_index
COUNT_STAR: 8
SUM_TIMER_WAIT: 2119302
MIN_TIMER_WAIT: 196092
AVG_TIMER_WAIT: 264912
MAX_TIMER_WAIT: 569421
...
***** 9. row *****
EVENT_NAME: wait/synch/mutex/sql/hash_filo::lock
COUNT_STAR: 69
SUM_TIMER_WAIT: 16848828
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 244185
MAX_TIMER_WAIT: 735345
...
```

`TRUNCATE TABLE` is permitted for wait summary tables. It resets the counters to zero rather than removing rows.

The event wait summary tables have these grouping columns to indicate how events are aggregated:

- `events_waits_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given instrument. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.
- `events_waits_summary_by_instance` has `EVENT_NAME` and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given instrument instance. If an instrument is used to create multiple instances, each instance has a unique `OBJECT_INSTANCE_BEGIN` value, so these instances are summarized separately in this table.
- `events_waits_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and instrument.

The event waits summary tables have these summary columns containing aggregated values:

- `COUNT_STAR`

The number of summarized events. This value includes all events, whether timed or not.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of `NULL`. The same is true for the other `xxx_TIMER_WAIT` values.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed events.

## 20.9.8.2. Stage Summary Tables

The stage summary tables provide aggregated information about stage events:

- `events_stages_summary_by_thread_by_event_name`: Stage waits summarized per thread and event name
- `events_stages_summary_global_by_event_name`: Stage waits summarized per event name

For example:

```
mysql> SELECT * FROM events_stages_summary_global_by_event_name\G
...
***** 5. row *****
EVENT_NAME: stage/sql/checking permissions
COUNT_STAR: 57
SUM_TIMER_WAIT: 26501888880
MIN_TIMER_WAIT: 7317456
AVG_TIMER_WAIT: 464945295
MAX_TIMER_WAIT: 12858936792
...
***** 9. row *****
EVENT_NAME: stage/sql/closing tables
COUNT_STAR: 37
SUM_TIMER_WAIT: 662606568
MIN_TIMER_WAIT: 1593864
AVG_TIMER_WAIT: 17907891
MAX_TIMER_WAIT: 437977248
...
```

`TRUNCATE TABLE` is permitted for stage summary tables. It resets the counters to zero rather than removing rows.

The stage summary tables have these grouping columns to indicate how events are aggregated:

- `events_stages_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given instrument.
- `events_stages_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread instrument instance.

The stage summary tables have these summary columns containing aggregated values: `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, and `MAX_TIMER_WAIT`. These columns are analogous to the columns of the same names in the `events_waits_summary_global_by_event_name` and `events_waits_summary_by_thread_by_event_name` tables, except that the stage summary tables aggregate waits from `events_stages_current` rather than `events_waits_current`.

These tables were added in MySQL 5.6.3.

### 20.9.8.3. Statement Summary Tables

The statement summary tables aggregate information about statement events:

- `events_statements_summary_by_digest`: Statement events summarized per schema and digest value
- `events_statements_summary_by_thread_by_event_name`: Statement events summarized per thread and event name
- `events_statements_summary_global_by_event_name`: Statement events summarized per event name

For example:

```
mysql> SELECT * FROM events_statements_summary_global_by_event_name\G
***** 1. row *****
      EVENT_NAME: statement/sql/select
      COUNT_STAR: 25
      SUM_TIMER_WAIT: 1535983999000
      MIN_TIMER_WAIT: 209823000
      AVG_TIMER_WAIT: 61439359000
      MAX_TIMER_WAIT: 1363397650000
      SUM_LOCK_TIME: 20186000000
      SUM_ERRORS: 0
      SUM_WARNINGS: 0
      SUM_ROWS_AFFECTED: 0
      SUM_ROWS_SENT: 388
      SUM_ROWS_EXAMINED: 370
SUM_CREATED_TMP_DISK_TABLES: 0
      SUM_CREATED_TMP_TABLES: 0
      SUM_SELECT_FULL_JOIN: 0
      SUM_SELECT_FULL_RANGE_JOIN: 0
      SUM_SELECT_RANGE: 0
      SUM_SELECT_RANGE_CHECK: 0
      SUM_SELECT_SCAN: 6
      SUM_SORT_MERGE_PASSES: 0
      SUM_SORT_RANGE: 0
      SUM_SORT_ROWS: 0
      SUM_SORT_SCAN: 0
      SUM_NO_INDEX_USED: 6
      SUM_NO_GOOD_INDEX_USED: 0
      ...
```

`TRUNCATE TABLE` is permitted for statement summary tables. For `events_statements_summary_by_digest`, it empties the table. For the other statement summary tables, it resets the counters to zero rather than removing rows.

The statement summary tables have these grouping columns to indicate how events are aggregated:

- `events_statements_summary_by_digest` has `SCHEMA_NAME` and `DIGEST` column. Each row summarizes events for given schema/digest values. (The `DIGEST_TEXT` column contains the corresponding normalized statement digest text, but is neither a grouping nor summary column.)

Before MySQL 5.6.9, there is no `SCHEMA_NAME` column and grouping is based on `DIGEST` values only.

- `events_statements_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given instrument.
- `events_statements_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread instrument instance.

The statement summary tables have these summary columns containing aggregated values:

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns are analogous to the columns of the same names in the `events_waits_summary_global_by_event_name` and `events_waits_summary_by_thread_by_event_name` tables, except that the statement summary tables aggregate waits from `events_statements_current` rather than `events_waits_current`.

- `SUM_xxx`

The aggregate of the corresponding `xxx` column in the `events_statements_current` table. For example, the `SUM_LOCK_TIME` and `SUM_ERRORS` columns in statement summary tables are the aggregates of the `LOCK_TIME` and `ERRORS` columns in `events_statements_current` table.

The `events_statements_summary_by_digest` table has these additional summary columns:

- `FIRST_SEEN_TIMESTAMP`, `LAST_SEEN_TIMESTAMP`

The times at which a statement with the given digest value were first seen and most recently seen.

These tables were added in MySQL 5.6.3, except that `events_statements_summary_by_digest` was added in 5.6.5.

## Statement Digest Aggregation Rules

If the `statement_digest` consumer is enabled, aggregation into `events_statements_summary_by_digest` occurs as follows when a statement completes. Aggregation is based on the `DIGEST` value computed for the statement.

- If a `events_statements_summary_by_digest` row already exists with the digest value for the statement that just completed, statistics for the statement are aggregated to that row. The `LAST_SEEN` column is updated to the current time.
- If no row has the digest value for the statement that just completed, and the table is not full, a new row is created for the statement. The `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time.
- If no row has the statement digest value for the statement that just completed, and the table is full, the statistics for the statement that just completed are added to a special “catch-all” row with `DIGEST = NULL`, which is created if necessary. If the row is created, the `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time. Otherwise, the `LAST_SEEN` column is updated with the current time.

The row with `DIGEST = NULL` is maintained because Performance Schema tables have a maximum size due to memory constraints. The `DIGEST = NULL` row permits digests that do not match other rows to be counted even if the summary table is full, using a common “other” bucket. This row helps you estimate whether the digest summary is representative:

- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 5% of all digests shows that the digest summary table is very representative; the other rows cover 95% of the statements seen.
- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 50% of all digests shows that the digest summary table is not very representative; the other rows cover only half the statements seen. Most likely the DBA should increase the maximum table size so that more of the rows counted in the `DIGEST = NULL` row would be counted using more specific rows instead. To do this, set the `performance_schema_digests_size` [2308] system variable to a larger value at server startup. The default size is 200.

### 20.9.8.4. Object Wait Summary Table

The `objects_summary_global_by_type` aggregates object wait events. For example:

```
mysql> SELECT * FROM objects_summary_global_by_type\G
...
```

```

***** 3. row *****
OBJECT_TYPE: TABLE
OBJECT_SCHEMA: test
OBJECT_NAME: t
COUNT_STAR: 3
SUM_TIMER_WAIT: 263126976
MIN_TIMER_WAIT: 1522272
AVG_TIMER_WAIT: 87708678
MAX_TIMER_WAIT: 258428280
...
***** 10. row *****
OBJECT_TYPE: TABLE
OBJECT_SCHEMA: mysql
OBJECT_NAME: user
COUNT_STAR: 14
SUM_TIMER_WAIT: 365567592
MIN_TIMER_WAIT: 1141704
AVG_TIMER_WAIT: 26111769
MAX_TIMER_WAIT: 334783032
...

```

`TRUNCATE TABLE` is permitted for object summary tables. It resets the counters to zero rather than removing rows.

The `objects_summary_global_by_type` table has these grouping columns to indicate how events are aggregated: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. Each row summarizes events for the given object.

`objects_summary_global_by_type` has the same summary columns as the `events_waits_summary_by_xxx` tables. See [Section 20.9.8.1, “Event Wait Summary Tables”](#).

### 20.9.8.5. File I/O Summary Tables

The file I/O summary tables aggregate information about I/O operations:

- `file_summary_by_event_name`: File events summarized per event name
- `file_summary_by_instance`: File events summarized per file instance

For example:

```

mysql> SELECT * FROM file_summary_by_event_name\G
...
***** 2. row *****
EVENT_NAME: wait/io/file/sql/binlog
COUNT_STAR: 31
SUM_TIMER_WAIT: 8243784888
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 265928484
MAX_TIMER_WAIT: 6490658832
...
mysql> SELECT * FROM file_summary_by_instance\G
...
***** 2. row *****
FILE_NAME: /var/mysql/share/english/errmsg.sys
EVENT_NAME: wait/io/file/sql/ERRMSG
EVENT_NAME: wait/io/file/sql/ERRMSG
OBJECT_INSTANCE_BEGIN: 4686193384
COUNT_STAR: 5
SUM_TIMER_WAIT: 13990154448
MIN_TIMER_WAIT: 26349624
AVG_TIMER_WAIT: 2798030607
MAX_TIMER_WAIT: 8150662536
...

```

`TRUNCATE TABLE` is permitted for file I/O summary tables. It resets the counters to zero rather than removing rows.

The file I/O summary tables have these grouping columns to indicate how events are aggregated:

- `file_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given instrument.
- `file_summary_by_instance` has `FILE_NAME`, `EVENT_NAME`, and (as of MySQL 5.6.4) `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given file instrument instance.

The file I/O summary tables have the following summary columns containing aggregated values. (Before MySQL 5.6.4, the tables contain only the Only `COUNT_READ` `COUNT_WRITE` `SUM_NUMBER_OF_BYTES_READ`, and `SUM_NUMBER_OF_BYTES_WRITE` aggregation columns.) Some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ`

These columns aggregate all read operations, including `FGETS`, `FGETC`, `FREAD`, and `READ`.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all write operations, including `FPUTS`, `Fputc`, `FPRINTF`, `VFPRTF`, `FWRITE`, and `PWRITE`.

- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`

These columns aggregate all other I/O operations, including `CREATE`, `DELETE`, `OPEN`, `CLOSE`, `STREAM_OPEN`, `STREAM_CLOSE`, `SEEK`, `TELL`, `FLUSH`, `STAT`, `FSTAT`, `CHSIZE`, `RENAME`, and `SYNC`. There are no byte counts for these operations.

The MySQL server uses several techniques to avoid I/O operations by caching information read from files, so it is possible that statements you might expect to result in I/O events will not. You may be able to ensure that I/O does occur by flushing caches or restarting the server to reset its state.

### 20.9.8.6. Table I/O and Lock Wait Summary Tables

The following sections describe the table I/O and lock wait summary tables:

- `table_io_waits_summary_by_index_usage`: Table I/O waits per index
- `table_io_waits_summary_by_table`: Table I/O waits per table
- `table_lock_waits_summary_by_table`: Table lock waits per table

#### 20.9.8.6.1. The `table_io_waits_summary_by_table` Table

The `table_io_waits_summary_by_table` table aggregates all table I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table.

`TRUNCATE TABLE` is permitted for table I/O summary tables. It resets the counters to zero rather than removing rows. Truncating this table also truncates the `table_io_waits_summary_by_index_usage` table.

The `table_io_waits_summary_by_table` table has these grouping columns to indicate how events are aggregated: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_io_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all writes hold the sum of the corresponding columns that aggregate inserts, updates, and deletes. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`

These columns aggregate all read operations. They are the same as the sum of the corresponding `xxx_FETCH` columns.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`

These columns aggregate all write operations. They are the same as the sum of the corresponding `xxx_INSERT`, `xxx_UPDATE`, and `xxx_DELETE` columns.

- `COUNT_FETCH`, `SUM_TIMER_FETCH`, `MIN_TIMER_FETCH`, `AVG_TIMER_FETCH`, `MAX_TIMER_FETCH`

These columns aggregate all fetch operations.

- `COUNT_INSERT`, `SUM_TIMER_INSERT`, `MIN_TIMER_INSERT`, `AVG_TIMER_INSERT`, `MAX_TIMER_INSERT`

These columns aggregate all insert operations.

- `COUNT_UPDATE`, `SUM_TIMER_UPDATE`, `MIN_TIMER_UPDATE`, `AVG_TIMER_UPDATE`, `MAX_TIMER_UPDATE`

These columns aggregate all update operations.

- `COUNT_DELETE`, `SUM_TIMER_DELETE`, `MIN_TIMER_DELETE`, `AVG_TIMER_DELETE`, `MAX_TIMER_DELETE`

These columns aggregate all delete operations.

#### 20.9.8.6.2. The `table_io_waits_summary_by_index_usage` Table

The `table_io_waits_summary_by_index_usage` table aggregates all table index I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table index.

`TRUNCATE TABLE` is permitted for table I/O summary tables. It resets the counters to zero rather than removing rows. This table is also truncated by truncation of the `table_io_waits_summary_by_table` table. A DDL operation that changes the index structure of a table may cause the per-index statistics to be reset.

The structure of `table_io_waits_summary_by_index_usage` is nearly identical to `table_io_waits_summary_by_table`. The only difference is the additional group column, `INDEX_NAME`, which corresponds to the name of the index that was used when the table I/O wait event was recorded:

- A value of `PRIMARY` indicates that table I/O used the primary index.
- A value of `NULL` means that table I/O used no index.
- Inserts are counted against `INDEX_NAME = NULL`.

### 20.9.8.6.3. The `table_lock_waits_summary_by_table` Table

The `table_lock_waits_summary_by_table` table aggregates all table lock wait events, as generated by the `wait/lock/table/sql/handler` instrument. The grouping is by table.

`TRUNCATE TABLE` is permitted for table lock summary tables. It resets the counters to zero rather than removing rows.

This table contains information about internal and external locks:

- An internal lock corresponds to a lock in the SQL layer. This is currently implemented by a call to `thr_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which will have one of these values:

```
read normal
read with shared locks
read high priority
read no insert
write allow write
write concurrent insert
write delayed
write low priority
write normal
```

- An external lock corresponds to a lock in the storage engine layer. This is currently implemented by a call to `handler::external_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which will have one of these values:

```
read external
write external
```

The `table_lock_waits_summary_by_table` table has these grouping columns to indicate how events are aggregated: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_lock_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all writes hold the sum of the corresponding columns that aggregate inserts, updates, and deletes. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all lock operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`

These columns aggregate all read-lock operations. They are the same as the sum of the corresponding `xxx_READ_NORMAL`, `xxx_READ_WITH_SHARED_LOCKS`, `xxx_READ_HIGH_PRIORITY`, and `xxx_READ_NO_INSERT` columns.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`

These columns aggregate all write-lock operations. They are the same as the sum of the corresponding `xxx_WRITE_ALLOW_WRITE`, `xxx_WRITE_CONCURRENT_INSERT`, `xxx_WRITE_DELAYED`, `xxx_WRITE_LOW_PRIORITY`, and `xxx_WRITE_NORMAL` columns.

- `COUNT_READ_NORMAL`, `SUM_TIMER_READ_NORMAL`, `MIN_TIMER_READ_NORMAL`, `AVG_TIMER_READ_NORMAL`, `MAX_TIMER_READ_NORMAL`

These columns aggregate internal read locks.

- `COUNT_READ_WITH_SHARED_LOCKS`, `SUM_TIMER_READ_WITH_SHARED_LOCKS`, `MIN_TIMER_READ_WITH_SHARED_LOCKS`, `AVG_TIMER_READ_WITH_SHARED_LOCKS`, `MAX_TIMER_READ_WITH_SHARED_LOCKS`

These columns aggregate internal read locks.

- `COUNT_READ_HIGH_PRIORITY`, `SUM_TIMER_READ_HIGH_PRIORITY`, `MIN_TIMER_READ_HIGH_PRIORITY`, `AVG_TIMER_READ_HIGH_PRIORITY`, `MAX_TIMER_READ_HIGH_PRIORITY`

These columns aggregate internal read locks.

- `COUNT_READ_NO_INSERT`, `SUM_TIMER_READ_NO_INSERT`, `MIN_TIMER_READ_NO_INSERT`, `AVG_TIMER_READ_NO_INSERT`, `MAX_TIMER_READ_NO_INSERT`

These columns aggregate internal read locks.

- `COUNT_READ_EXTERNAL`, `SUM_TIMER_READ_EXTERNAL`, `MIN_TIMER_READ_EXTERNAL`, `AVG_TIMER_READ_EXTERNAL`, `MAX_TIMER_READ_EXTERNAL`

These columns aggregate external read locks.

- `COUNT_WRITE_ALLOW_WRITE`, `SUM_TIMER_WRITE_ALLOW_WRITE`, `MIN_TIMER_WRITE_ALLOW_WRITE`, `AVG_TIMER_WRITE_ALLOW_WRITE`, `MAX_TIMER_WRITE_ALLOW_WRITE`

These columns aggregate internal write locks.

- `COUNT_WRITE_CONCURRENT_INSERT`, `SUM_TIMER_WRITE_CONCURRENT_INSERT`, `MIN_TIMER_WRITE_CONCURRENT_INSERT`, `AVG_TIMER_WRITE_CONCURRENT_INSERT`, `MAX_TIMER_WRITE_CONCURRENT_INSERT`

These columns aggregate internal write locks.

- `COUNT_WRITE_DELAYED`, `SUM_TIMER_WRITE_DELAYED`, `MIN_TIMER_WRITE_DELAYED`, `AVG_TIMER_WRITE_DELAYED`, `MAX_TIMER_WRITE_DELAYED`

These columns aggregate internal write locks.

As of MySQL 5.6.6, `DELAYED` inserts are deprecated, so these columns will be removed in a future release.

- `COUNT_WRITE_LOW_PRIORITY`, `SUM_TIMER_WRITE_LOW_PRIORITY`, `MIN_TIMER_WRITE_LOW_PRIORITY`, `AVG_TIMER_WRITE_LOW_PRIORITY`, `MAX_TIMER_WRITE_LOW_PRIORITY`

These columns aggregate internal write locks.

- `COUNT_WRITE_NORMAL`, `SUM_TIMER_WRITE_NORMAL`, `MIN_TIMER_WRITE_NORMAL`, `AVG_TIMER_WRITE_NORMAL`, `MAX_TIMER_WRITE_NORMAL`

These columns aggregate internal write locks.

- `COUNT_WRITE_EXTERNAL`, `SUM_TIMER_WRITE_EXTERNAL`, `MIN_TIMER_WRITE_EXTERNAL`, `AVG_TIMER_WRITE_EXTERNAL`, `MAX_TIMER_WRITE_EXTERNAL`

These columns aggregate external write locks.

### 20.9.8.7. Connection Summary Tables

The connection summary tables are similar to the corresponding [events\\_xxx\\_summary\\_by\\_thread\\_by\\_event\\_name](#) tables, except that aggregation occurs per account, user, or host, rather than by thread.

The Performance Schema maintains summary tables that aggregate connection statistics by event name and account, user, or host. Separate groups of tables are available that aggregate wait, stage, and statement events, which results in this set of connection summary tables:

- [events\\_waits\\_summary\\_by\\_account\\_by\\_event\\_name](#): Wait events summarized per account and event name
- [events\\_waits\\_summary\\_by\\_user\\_by\\_event\\_name](#): Wait events summarized per user name and event name
- [events\\_waits\\_summary\\_by\\_host\\_by\\_event\\_name](#): Wait events summarized per host name and event name
- [events\\_stages\\_summary\\_by\\_account\\_by\\_event\\_name](#): Stage events summarized per account and event name
- [events\\_stages\\_summary\\_by\\_user\\_by\\_event\\_name](#): Stage events summarized per user name and event name
- [events\\_stages\\_summary\\_by\\_host\\_by\\_event\\_name](#): Stage events summarized per host name and event name
- [events\\_statements\\_summary\\_by\\_account\\_by\\_event\\_name](#): Statement events summarized per account and event name
- [events\\_statements\\_summary\\_by\\_user\\_by\\_event\\_name](#): Statement events summarized per user name and event name
- [events\\_statements\\_summary\\_by\\_host\\_by\\_event\\_name](#): Statement events summarized per host name and event name

In other words, the connection summary tables have names of the form [events\\_xxx\\_summary\\_yyy\\_by\\_event\\_name](#), where *xxx* is *waits*, *stages*, or *statements*, and *yyy* is *account*, *user*, or *host*.

The connection summary tables provide an intermediate aggregation level:

- [xxx\\_summary\\_by\\_thread\\_by\\_event\\_name](#) tables are more detailed than connection summary tables
- [xxx\\_summary\\_global\\_by\\_event\\_name](#) tables are less detailed than connection summary tables

`TRUNCATE TABLE` is permitted for connection summary tables. It resets the counters to zero rather than removing rows. In addition, connection summary tables are implicitly truncated if a connection table on which they depend is truncated. [Table 20.1, “Effect of Implicit Table Truncation”](#), describes the relationship between connection table truncation and implicitly truncated tables.

**Table 20.1. Effect of Implicit Table Truncation**

Truncated Table	Implicitly Truncated Summary Tables
<code>accounts</code>	Tables with names matching <code>_%_by_account%</code> , <code>_%_by_thread%</code>
<code>hosts</code>	Tables with names matching <code>_%_by_account%</code> , <code>_%_by_host%</code> , <code>_%_by_thread%</code>
<code>users</code>	Tables with names matching <code>_%_by_account%</code> , <code>_%_by_user%</code> , <code>_%_by_thread%</code>

The connection summary tables have these grouping columns to indicate how events are aggregated:

- For tables with `_by_account` in the name, the `USER`, `HOST`, and `EVENT_NAME` columns group events per account and event name.
- For tables with `_by_host` in the name, the `HOST` and `EVENT_NAME` columns group events per host name and event name.
- For tables with `_by_user` in the name, the `USER` and `EVENT_NAME` columns group events per user name and event name.

The connection summary tables have these summary columns containing aggregated values: `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, and `MAX_TIMER_WAIT`. These are similar to the columns of the same names in the `events_waits_summary_by_instance` table.

The connection summary tables were added in MySQL 5.6.3.

### 20.9.8.8. Socket Summary Tables

The socket summary tables aggregate timer and byte count information for socket operations:

- `socket_summary_by_instance`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instance. When a connection terminates, the row in `socket_summary_by_instance` corresponding to it is deleted.
- `socket_summary_by_event_name`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instrument.

The socket summary tables do not aggregate waits generated by `idle` events while sockets are waiting for the next request from the client. For `idle` event aggregations, use the wait-event summary tables; see [Section 20.9.8.1, “Event Wait Summary Tables”](#).

`TRUNCATE TABLE` is permitted for socket summary tables. Except for `events_statements_summary_by_digest`, it resets the counters to zero rather than removing rows.

The socket summary tables have these grouping columns to indicate how events are aggregated:

- `socket_summary_by_instance` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given object.
- `socket_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given instrument.

The socket summary tables have these summary columns containing aggregated values:

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all operations.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ`

These columns aggregate all receive operations (`RECV`, `RECVFROM`, and `RECVMSG`).

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all send operations (`SEND`, `SENDTO`, and `SENDMSG`).

- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`

These columns aggregate all other socket operations, such as `CONNECT`, `LISTEN`, `ACCEPT`, `CLOSE`, and `SHUTDOWN`. There are no byte counts for these operations.

The `socket_summary_by_instance` table also has an `EVENT_NAME` column that indicates the class of the socket: `client_connection`, `server_tcpip_socket`, `server_unix_socket`. This column can be grouped on to isolate, for example, client activity from that of the server listening sockets.

These tables were added in MySQL 5.6.3.

## 20.9.9. Performance Schema Miscellaneous Tables

The following sections describe tables that do not fall into the table categories discussed in the preceding sections:

- `host_cache`: Information from the internal host cache.
- `performance_timers`: Which event timers are available.
- `threads`: Information about server threads.

### 20.9.9.1. The `host_cache` Table

The `host_cache` table provides access to the contents of the host cache, which contains client host name and IP address information and is used to avoid DNS lookups. (See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).) The `host_cache` table exposes the contents of the host cache so that it can be examined using `SELECT` statements. The Performance Schema must be enabled or this table is empty.

`FLUSH HOSTS` and `TRUNCATE TABLE host_cache` have the same effect: They clear the host cache. This also empties the `host_cache` table (because it is the visible representation of the cache) and unblocks any blocked hosts (see [Section C.5.2.6, “Host ‘host\\_name’ is blocked”](#).) `FLUSH HOSTS` requires the `RELOAD [755]` privilege. `TRUNCATE TABLE` requires the `DROP [754]` privilege for the `host_cache` table.

The `host_cache` table has these columns:

- `IP`

The IP address of the client that connected to the server, expressed as a string.

- `HOST`

The resolved DNS host name for that client IP, or `NULL` if the name is unknown.

- `HOST_VALIDATED`

Whether the IP-to-host name-to-IP DNS resolution was performed successfully for the client IP. If `HOST_VALIDATED` is `YES`, the `HOST` column is used as the host name corresponding to the IP so that calls to DNS can be avoided. While `HOST_VALIDATED` is `NO`, DNS resolution is attempted again for each connect, until it eventually completes with either a valid result or a permanent error. This information enables the server to avoid caching bad or missing host names during temporary DNS failures, which would affect clients forever.

- `SUM_CONNECT_ERRORS`

The number of connection errors that are deemed “blocking” (assessed against the `max_connect_errors [502]` system variable). Currently, only protocol handshake errors are counted, and only for hosts that passed validation (`HOST_VALIDATED = YES`).

- `COUNT_HOST_BLOCKED_ERRORS`

The number of connections that were blocked because `SUM_CONNECT_ERRORS` exceeded the value of the `max_connect_errors [502]` system variable.

- `COUNT_NAMEINFO_TRANSIENT_ERRORS`

The number of transient errors during IP-to-host name DNS resolution.

- [COUNT\\_NAMEINFO\\_PERMANENT\\_ERRORS](#)

The number of permanent errors during IP-to-host name DNS resolution.

- [COUNT\\_FORMAT\\_ERRORS](#)

The number of host name format errors. MySQL does not perform matching of `Host` column values in the `mysql.user` table against host names for which one or more of the initial components of the name are entirely numeric, such as `1.2.example.com`. The client IP address is used instead. For the rationale why this type of matching does not occur, see [Section 6.2.3, “Specifying Account Names”](#).

- [COUNT\\_ADDRINFO\\_TRANSIENT\\_ERRORS](#)

The number of transient errors during host name-to-IP reverse DNS resolution.

- [COUNT\\_ADDRINFO\\_PERMANENT\\_ERRORS](#)

The number of permanent errors during host name-to-IP reverse DNS resolution.

- [COUNT\\_FCRDNS\\_ERRORS](#)

The number of forward-confirmed reverse DNS errors. These errors occur when IP-to-host name-to-IP DNS resolution produces an IP address that does not match the client originating IP address.

- [COUNT\\_HOST\\_ACL\\_ERRORS](#)

The number of errors that occur because no user from the client host can possibly log in. In such cases, the server returns `ER_HOST_NOT_PRIVILEGED [3669]` and does not even ask for a user name or password.

- [COUNT\\_NO\\_AUTH\\_PLUGIN\\_ERRORS](#)

The number of errors due to requests for an unavailable authentication plugin. A plugin can be unavailable if, for example, it was never loaded or a load attempt failed.

- [COUNT\\_AUTH\\_PLUGIN\\_ERRORS](#)

The number of errors reported by authentication plugins.

An authentication plugin can report different error codes to indicate the root cause of a failure. Depending on the type of error, one of these columns is incremented: [COUNT\\_AUTHENTICATION\\_ERRORS](#), [COUNT\\_AUTH\\_PLUGIN\\_ERRORS](#), [COUNT\\_HANDSHAKE\\_ERRORS](#). New return codes are an optional extension to the existing plugin API. Unknown or unexpected plugin errors are counted in the [COUNT\\_AUTH\\_PLUGIN\\_ERRORS](#) column.

- [COUNT\\_HANDSHAKE\\_ERRORS](#)

The number of errors detected at the wire protocol level.

- [COUNT\\_PROXY\\_USER\\_ERRORS](#)

The number of errors detected when a proxy user A is proxied to another user B who does not exist.

- [COUNT\\_PROXY\\_USER\\_ACL\\_ERRORS](#)

The number of errors detected when a proxy user A is proxied to another user B who does exist but for whom A does not have the `PROXY [755]` privilege.

- [COUNT\\_AUTHENTICATION\\_ERRORS](#)

The number of errors caused by failed authentication.

- `COUNT_SSL_ERRORS`

The number of errors due to SSL problems.

- `COUNT_MAX_USER_CONNECTIONS_ERRORS`

The number of errors caused by exceeding per-user connection quotas. See [Section 6.3.4, “Setting Account Resource Limits”](#).

- `COUNT_MAX_USER_CONNECTIONS_PER_HOUR_ERRORS`

The number of errors caused by exceeding per-user connections-per-hour quotas. See [Section 6.3.4, “Setting Account Resource Limits”](#).

- `COUNT_DEFAULT_DATABASE_ERRORS`

The number of errors related to the default database. For example, the database did not exist or the user had no privileges for accessing it.

- `COUNT_INIT_CONNECT_ERRORS`

The number of errors caused by execution failures of statements in the `init_connect` [489] system variable value.

- `COUNT_LOCAL_ERRORS`

The number of errors local to the server implementation and not related to the network, authentication, or authorization. For example, out-of-memory conditions fall into this category.

- `COUNT_UNKNOWN_ERRORS`

The number of other, unknown errors not accounted for by other columns in this table. This column is reserved for future use, in case new error conditions must be reported, and if preserving the backward compatibility and table structure of the `host_cache` table is required.

- `FIRST_SEEN`

The timestamp of the first connection attempt seen from the client in the `IP` column.

- `LAST_SEEN`

The timestamp of the last connection attempt seen from the client in the `IP` column.

- `FIRST_ERROR_SEEN`

The timestamp of the first error seen from the client in the `IP` column.

- `LAST_ERROR_SEEN`

The timestamp of the last error seen from the client in the `IP` column.

The `host_cache` table was added in MySQL 5.6.5.

### 20.9.9.2. The `performance_timers` Table

The `performance_timers` table shows which event timers are available:

```
mysql> SELECT * FROM performance_timers;
```

TIMER_NAME	TIMER_FREQUENCY	TIMER_RESOLUTION	TIMER_OVERHEAD
CYCLE	2389029850	1	72

NANOSECOND	NULL	NULL	NULL
MICROSECOND	1000000	1	585
MILLISECOND	1035	1	738
TICK	101	1	630

If the values associated with a given timer name are `NULL`, that timer is not supported on your platform. The rows that do not contain `NULL` indicate which timers you can use in `setup_timers`.

The `performance_timers` table has these columns:

- `TIMER_NAME`

The name by which to refer to the timer when configuring the `setup_timers` table.

- `TIMER_FREQUENCY`

The number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. For example, on a system with a 2.4GHz processor, the `CYCLE` may be close to 2400000000.

- `TIMER_RESOLUTION`

Indicates the number of timer units by which timer values increase. If a timer has a resolution of 10, its value increases by 10 each time.

- `TIMER_OVERHEAD`

The minimal number of cycles of overhead to obtain one timing with the given timer. The Performance Schema determines this value by invoking the timer 20 times during initialization and picking the smallest value. The total overhead really is twice this amount because the instrumentation invokes the timer at the start and end of each event. The timer code is called only for timed events, so this overhead does not apply for nontimed events.

### 20.9.9.3. The `threads` Table

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it:

```
mysql> SELECT * FROM threads\G
***** 1. row *****
      THREAD_ID: 1
        NAME: thread/sql/main
         TYPE: BACKGROUND
    PROCESSLIST_ID: NULL
    PROCESSLIST_USER: NULL
    PROCESSLIST_HOST: NULL
    PROCESSLIST_DB: NULL
    PROCESSLIST_COMMAND: NULL
    PROCESSLIST_TIME: 80284
    PROCESSLIST_STATE: NULL
    PROCESSLIST_INFO: NULL
    PARENT_THREAD_ID: NULL
         ROLE: NULL
    INSTRUMENTED: YES
...
***** 4. row *****
      THREAD_ID: 51
        NAME: thread/sql/one_connection
         TYPE: FOREGROUND
    PROCESSLIST_ID: 34
    PROCESSLIST_USER: paul
    PROCESSLIST_HOST: localhost
    PROCESSLIST_DB: performance_schema
    PROCESSLIST_COMMAND: Query
    PROCESSLIST_TIME: 0
    PROCESSLIST_STATE: Sending data
    PROCESSLIST_INFO: SELECT * FROM threads
```

```
PARENT_THREAD_ID: 1
          ROLE: NULL
          INSTRUMENTED: YES
...

```

If you have the [PROCESS \[755\]](#) privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using).

The `threads` table has these columns:

- `THREAD_ID`

A unique thread identifier.

- `NAME`

The name associated with the thread instrumentation code in the server. For example, `thread/sql/one_connection` corresponds to the thread function in the code responsible for handling a user connection, and `thread/sql/main` stands for the `main()` function of the server.

- `TYPE`

The thread type, either `FOREGROUND` or `BACKGROUND`. User connection threads are foreground threads. Threads associated with internal server activity are background threads. Examples are internal `InnoDB` threads, “binlog dump” threads sending information to slaves, and slave I/O and SQL threads.

- `PROCESSLIST_ID`

For threads that are displayed in the `INFORMATION_SCHEMA.PROCESSLIST` table, this is the `PROCESSLIST.ID` value, which is also the value that `CONNECTION_ID()` [1267] would return within that thread. For background threads (threads not associated with a user connection), `PROCESSLIST_ID` is 0, so the values are not unique.

- `PROCESSLIST_USER`

The user associated with a foreground thread, `NULL` for a background thread.

- `PROCESSLIST_HOST`

The host name of the client associated with a foreground thread, `NULL` for a background thread.

- `PROCESSLIST_DB`

The default database for the thread, or `NULL` if there is none.

- `PROCESSLIST_COMMAND`

The type of command the thread is executing. For descriptions for thread commands, see [Section 8.12.5, “Examining Thread Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See [Section 5.1.6, “Server Status Variables”](#)

- `PROCESSLIST_TIME`

The time in seconds that the thread has been in its current state.

- `PROCESSLIST_STATE`

An action, event, or state that indicates what the thread is doing. For descriptions of `PROCESSLIST_STATE` values, see [Section 8.12.5, “Examining Thread Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- `PROCESSLIST_INFO`

The statement the thread is executing, or `NULL` if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `PROCESSLIST_INFO` value shows the `SELECT` statement.

- `PARENT_THREAD_ID`

If this thread is a subthread (spawned by another thread), this is the `THREAD_ID` value of the spawning thread. Thread spawning occurs, for example, to handle insertion of rows from `INSERT DELAYED` statements.

- `ROLE`

Unused.

- `INSTRUMENTED`

Whether the thread is instrumented:

- For foreground threads, the initial `INSTRUMENTED` value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. Matching is based on the values of the `PROCESSLIST_USER` and `PROCESSLIST_HOST` columns.

If the thread spawns a subthread, matching occurs again for the subthread.

- For background threads, `INSTRUMENTED` is `YES` by default. `setup_actors` is not consulted because there is no associated user for background threads.
- For any thread, its `INSTRUMENTED` value can be changed during the lifetime of the thread. This is the only `threads` table column that can be modified.

For thread monitoring to occur, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `thread.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that are enabled, as specified in the `setup_instruments` table.

The initial contents of the `threads` table are based on the threads in existence when Performance Schema initialization occurs. Thereafter, a new row is added each time the server creates a thread.

Removal of rows from the `threads` table occurs when threads end. For a thread associated with a client session, removal occurs when the session ends. If a client has auto-reconnect enabled and the session reconnects after a disconnect, the session will be associated with a new row in the `threads` table (one that has a different `PROCESSLIST_ID` value). The initial `INSTRUMENTED` value for the new thread may be different from that of the original thread: The `setup_actors` table may have changed in the meantime, and if the `INSTRUMENTED` value for the original thread was changed after it was initialized, that change does not carry over to the new thread.

The `threads` table columns with names having a prefix of `PROCESS_` provide information similar to that available from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `SHOW PROCESSLIST` statement. Thus, all three sources provide thread-monitoring information. Use of `threads` differs from use of the other two sources in these ways:

- Access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex.

- `threads` provides additional information for each thread, such as whether it is a foreground or background thread, and the location within the server associated with the thread.
- `threads` provides information about background threads, so it can be used to monitor activity the other thread information sources cannot.
- You can turn thread monitoring on or off. To control monitoring of existing threads, set the `INSTRUMENTED` column of the `threads` table. To control the initial `INSTRUMENTED` value for new foreground threads, use the `setup_actors` table.

For these reasons, DBAs who perform server monitoring using `INFORMATION_SCHEMA.PROCESSLIST` or `SHOW PROCESSLIST` may wish to monitor using `threads` instead.

## 20.10. Performance Schema Option and Variable Reference

Table 20.2. Performance Schema Variable Reference

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">performance_schema</a> [2307]	Yes	Yes	Yes		Global	No
<a href="#">Performance_schema_accounts_lost</a> [2318]				Yes	Global	No
<a href="#">performance_schema_accounts_lost</a> [2308]	Yes	Yes	Yes		Global	No
<a href="#">Performance_schema_cond_classes_lost</a> [2318]				Yes	Global	No
<a href="#">Performance_schema_cond_instances_lost</a> [2318]				Yes	Global	No
<a href="#">performance_schema_events_statements_history_size</a> [2308]	Yes	Yes	Yes		Global	No
<a href="#">performance_schema_events_statements_history_size</a> [2309]	Yes	Yes	Yes		Global	No
<a href="#">performance_schema_events_statements_history_long_size</a> [2309]	Yes	Yes	Yes		Global	No
<a href="#">performance_schema_events_statements_history_size</a> [2309]	Yes	Yes	Yes		Global	No
<a href="#">performance_schema_events_waits_history_long_size</a> [2310]	Yes	Yes	Yes		Global	No
<a href="#">performance_schema_events_waits_history_size</a> [2310]	Yes	Yes	Yes		Global	No
<a href="#">Performance_schema_file_classes_lost</a> [2318]				Yes	Global	No
<a href="#">Performance_schema_file_handles_lost</a> [2318]				Yes	Global	No
<a href="#">Performance_schema_file_instances_lost</a> [2318]				Yes	Global	No

<a href="#">performance_schema_users_size</a> [2317]	Yes	Yes	Yes		Global	No

## 20.11. Performance Schema Command Options

Performance Schema parameters can be specified at server startup on the command line or in option files to configure Performance Schema instruments and consumers. Runtime configuration is also possible in many cases (see [Section 20.2.3, “Performance Schema Runtime Configuration”](#)), but startup configuration must be used when runtime configuration is too late to affect instruments that have already been initialized during the startup process.

Performance Schema consumers and instruments can be configured at startup using the following syntax. For additional details, see [Section 20.2.2, “Performance Schema Startup Configuration”](#).

- `--performance-schema-consumer=consumer_name=value` [2306]

Configure a Performance Schema consumer. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

- `--performance-schema-instrument=instrument_name=value` [2306]

Configure a Performance Schema instrument. The name may be given as a pattern to configure instruments that match the pattern.

## 20.12. Performance Schema System Variables

The Performance Schema implements several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
```

Variable_name	Value
performance_schema	ON
performance_schema_accounts_size	100
performance_schema_digests_size	200
performance_schema_events_stages_history_long_size	10000
performance_schema_events_stages_history_size	10
performance_schema_events_statements_history_long_size	10000
performance_schema_events_statements_history_size	10
performance_schema_events_waits_history_long_size	10000
performance_schema_events_waits_history_size	10
performance_schema_hosts_size	100
performance_schema_max_cond_classes	80
performance_schema_max_cond_instances	1000
performance_schema_max_file_classes	50
performance_schema_max_file_handles	32768
performance_schema_max_file_instances	10000
performance_schema_max_mutex_classes	200
performance_schema_max_mutex_instances	1000000
performance_schema_max_rwlock_classes	30
performance_schema_max_rwlock_instances	1000000
performance_schema_max_socket_classes	10
performance_schema_max_socket_instances	1000
performance_schema_max_stage_classes	150
performance_schema_max_statement_classes	165
performance_schema_max_table_handles	10000
performance_schema_max_table_instances	1000
performance_schema_max_thread_classes	50
performance_schema_max_thread_instances	1000
performance_schema_session_connect_attrs_size	512
performance_schema_setup_actors_size	100
performance_schema_setup_objects_size	100
performance_schema_users_size	100

Performance Schema system variables can be set at server startup on the command line or in option files, and many can be set at runtime. See [Section 20.10, “Performance Schema Option and Variable Reference”](#).

As of MySQL 5.6.6, the Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For more information, see [Section 20.2.2, “Performance Schema Startup Configuration”](#).

Performance Schema variables have the following meanings:

- [performance\\_schema \[2307\]](#)

<b>Command-Line Format</b>	<code>--performance_schema=#</code>
<b>Option-File Format</b>	<code>performance_schema=#</code>
<b>Variable Name</b>	<code>performance_schema</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values (&lt;= 5.6.5)</b>
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>OFF</code>
	<b>Permitted Values (&gt;= 5.6.6)</b>
<b>Type</b>	<code>boolean</code>

	<b>Default</b>	ON
--	----------------	----

The value of this variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled. By default, the value is `ON` by default as of MySQL 5.6.6 and `OFF` before that. At server startup, you can specify this variable with no value or a value of `ON` or `1` to enable it, or with a value of `OFF` or `0` to disable it.

- [performance\\_schema\\_accounts\\_size \[2308\]](#)

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--performance_schema_accounts_size=#</code>	
<b>Option-File Format</b>	<code>performance_schema_accounts_size=#</code>	
<b>Variable Name</b>	<code>performance_schema_accounts_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	0 .. 1048576
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)
	<b>Range</b>	-1 .. 1048576

The number of rows in the `accounts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `accounts` table. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_digests\\_size \[2308\]](#)

The maximum number of rows in the `events_statements_summary_by_digest` table. This variable was added in MySQL 5.6.5.

- [performance\\_schema\\_events\\_stages\\_history\\_long\\_size \[2308\]](#)

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--performance_schema_events_stages_history_long_size=#</code>	
<b>Option-File Format</b>	<code>performance_schema_events_stages_history_long_size=#</code>	
<b>Variable Name</b>	<code>performance_schema_events_stages_history_long_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10000
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)

The number of rows in the `events_stages_history_long` table. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_events\\_stages\\_history\\_size \[2309\]](#)

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	--performance_schema_events_stages_history_size=#	
<b>Option-File Format</b>	performance_schema_events_stages_history_size=#	
<b>Variable Name</b>	performance_schema_events_stages_history_size	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)

The number of rows per thread in the `events_stages_history` table. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_events\\_statements\\_history\\_long\\_size \[2309\]](#)

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	--performance_schema_events_statements_history_long_size=#	
<b>Option-File Format</b>	performance_schema_events_statements_history_long_size=#	
<b>Variable Name</b>	performance_schema_events_statements_history_long_size	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10000
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)

The number of rows in the `events_statements_history_long` table. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_events\\_statements\\_history\\_size \[2309\]](#)

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	--performance_schema_events_statements_history_size=#	
<b>Option-File Format</b>	performance_schema_events_statements_history_size=#	
<b>Variable Name</b>	performance_schema_events_statements_history_size	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric

	<b>Default</b>	10
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)

The number of rows per thread in the `events_statements_history` table. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_events\\_waits\\_history\\_long\\_size \[2310\]](#)

<b>Command-Line Format</b>	<code>--performance_schema_events_waits_history_long_size=#</code>	
<b>Option-File Format</b>	<code>performance_schema_events_waits_history_long_size=#</code>	
<b>Variable Name</b>	<code>performance_schema_events_waits_history_long_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10000
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)

The number of rows in the `events_waits_history_long` table.

- [performance\\_schema\\_events\\_waits\\_history\\_size \[2310\]](#)

<b>Command-Line Format</b>	<code>--performance_schema_events_waits_history_size=#</code>	
<b>Option-File Format</b>	<code>performance_schema_events_waits_history_size=#</code>	
<b>Variable Name</b>	<code>performance_schema_events_waits_history_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)

The number of rows per thread in the `events_waits_history` table.

- [performance\\_schema\\_hosts\\_size \[2310\]](#)

<b>Version Introduced</b>	5.6.3
<b>Command-Line Format</b>	<code>--performance_schema_hosts_size=#</code>
<b>Option-File Format</b>	<code>performance_schema_hosts_size=#</code>
<b>Variable Name</b>	<code>performance_schema_hosts_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

	<b>Permitted Values (&lt;= 5.6.5)</b>	
<b>Type</b>	numeric	
<b>Default</b>	10	
<b>Range</b>	0 .. 1048576	
	<b>Permitted Values (&gt;= 5.6.6)</b>	
<b>Type</b>	numeric	
<b>Default</b>	-1 (autosized)	
<b>Range</b>	-1 .. 1048576	

The number of rows in the `hosts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `hosts` table. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_max\\_cond\\_classes \[2311\]](#)

<b>Command-Line Format</b>	<code>--performance_schema_max_cond_classes=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_cond_classes=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_cond_classes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
<b>Type</b>	numeric	
<b>Default</b>	80	

The maximum number of condition instruments.

- [performance\\_schema\\_max\\_cond\\_instances \[2311\]](#)

<b>Command-Line Format</b>	<code>--performance_schema_max_cond_instances=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_cond_instances=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_cond_instances</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
<b>Type</b>	numeric	
<b>Default</b>	1000	
	<b>Permitted Values (&gt;= 5.6.6)</b>	
<b>Type</b>	numeric	
<b>Default</b>	-1 (autosized)	

The maximum number of instrumented condition objects.

- [performance\\_schema\\_max\\_file\\_classes \[2311\]](#)

<b>Command-Line Format</b>	<code>--performance_schema_max_file_classes=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_file_classes=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_file_classes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	

	<b>Permitted Values</b>	
<b>Type</b>	numeric	
<b>Default</b>	50	

The maximum number of file instruments.

- [performance\\_schema\\_max\\_file\\_handles \[2312\]](#)

<b>Command-Line Format</b>	--performance_schema_max_file_handles=#	
<b>Option-File Format</b>	performance_schema_max_file_handles=#	
<b>Variable Name</b>	performance_schema_max_file_handles	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
<b>Type</b>	numeric	
<b>Default</b>	32768	

The maximum number of opened file objects.

The value of [performance\\_schema\\_max\\_file\\_handles \[2312\]](#) should be greater than the value of [open\\_files\\_limit \[518\]](#); [open\\_files\\_limit \[518\]](#) affects the maximum number of open file handles the server can support and [performance\\_schema\\_max\\_file\\_handles \[2312\]](#) affects how many of these file handles can be instrumented.

- [performance\\_schema\\_max\\_file\\_instances \[2312\]](#)

<b>Command-Line Format</b>	--performance_schema_max_file_instances=#	
<b>Option-File Format</b>	performance_schema_max_file_instances=#	
<b>Variable Name</b>	performance_schema_max_file_instances	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
<b>Type</b>	numeric	
<b>Default</b>	10000	
	<b>Permitted Values (&gt;= 5.6.6)</b>	
<b>Type</b>	numeric

	<b>Default</b>	1000
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)

The maximum number of instrumented rwlock objects.

- [performance\\_schema\\_max\\_socket\\_classes](#) [2314]

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--performance_schema_max_socket_classes=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_socket_classes=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_socket_classes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>10</code>

The maximum number of socket instruments. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_max\\_socket\\_instances](#) [2314]

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--performance_schema_max_socket_instances=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_socket_instances=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_socket_instances</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1000</code>
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>-1 (autosized)</code>

The maximum number of instrumented socket objects. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_max\\_stage\\_classes](#) [2314]

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	<code>--performance_schema_max_stage_classes=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_stage_classes=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_stage_classes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>100</code>

The maximum number of stage instruments. This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_max\\_statement\\_classes](#) [2314]

<b>Version Introduced</b>	5.6.3	2314
---------------------------	-------	------

<b>Command-Line Format</b>	<code>--performance_schema_max_statement_classes=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_statement_classes=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_statement_classes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>autosized</code>

The maximum number of statement instruments. The default value is calculated at server build time based on the number of commands in the client/server protocol and the number of SQL statement types supported by the server.

This variable should not be changed, unless to set it to 0 to disable all statement instrumentation and save all memory associated with it. Setting the variable to nonzero values other than the default has no benefit; in particular, values larger than the default cause more memory to be allocated than is needed.

This variable was added in MySQL 5.6.3.

- [performance\\_schema\\_max\\_table\\_handles \[2315\]](#)

<b>Command-Line Format</b>	<code>--performance_schema_max_table_handles=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_table_handles=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_table_handles</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>100000</code>
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>-1 (autosized)</code>

The maximum number of opened table objects.

- [performance\\_schema\\_max\\_table\\_instances \[2315\]](#)

<b>Command-Line Format</b>	<code>--performance_schema_max_table_instances=#</code>	
<b>Option-File Format</b>	<code>performance_schema_max_table_instances=#</code>	
<b>Variable Name</b>	<code>performance_schema_max_table_instances</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>50000</code>
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	<code>numeric</code>

	<b>Default</b>	-1 (autosized)
--	----------------	----------------

The maximum number of instrumented table objects.

- [performance\\_schema\\_max\\_thread\\_classes](#) [2316]

<b>Command-Line Format</b>	--performance_schema_max_thread_classes=#	
<b>Option-File Format</b>	performance_schema_max_thread_classes=#	
<b>Variable Name</b>	performance_schema_max_thread_classes	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	50

The maximum number of thread instruments.

- [performance\\_schema\\_max\\_thread\\_instances](#) [2316]

<b>Command-Line Format</b>	--performance_schema_max_thread_instances=#	
<b>Option-File Format</b>	performance_schema_max_thread_instances=#	
<b>Variable Name</b>	performance_schema_max_thread_instances	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	1000
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)

The maximum number of instrumented thread objects.

The [max\\_connections](#) [503] and [max\\_delayed\\_threads](#) [504] system variables affect how many threads are run in the server. [performance\\_schema\\_max\\_thread\\_instances](#) [2316] affects how many of these running threads can be instrumented. If you increase [max\\_connections](#) [503] or [max\\_delayed\\_threads](#) [504], you should consider increasing [performance\\_schema\\_max\\_thread\\_instances](#) [2316] so that [performance\\_schema\\_max\\_thread\\_instances](#) [2316] is greater than the sum of [max\\_connections](#) [503] and [max\\_delayed\\_threads](#) [504].

- [performance\\_schema\\_session\\_connect\\_attrs\\_size](#) [2316]

<b>Version Introduced</b>	5.6.6
<b>Command-Line Format</b>	--performance_schema_session_connect_attrs_size=#
<b>Option-File Format</b>	performance_schema_session_connect_attrs_size=#
<b>Variable Name</b>	performance_schema_session_connect_attrs_size
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>

	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)
	<b>Range</b>	-1 .. 1048576

The amount of preallocated memory per thread used to hold connection attribute strings. If the connection attribute strings are larger than the reserved storage, the [Performance\\_schema\\_session\\_connect\\_attrs\\_lost \[2319\]](#) status variable is incremented. This variable was added in MySQL 5.6.7.

- [performance\\_schema\\_setup\\_actors\\_size \[2317\]](#)

<b>Version Introduced</b>	5.6.1	
<b>Command-Line Format</b>	--performance_schema_setup_actors_size=#	
<b>Option-File Format</b>	performance_schema_setup_actors_size=#	
<b>Variable Name</b>	performance_schema_setup_actors_size	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	100

The number of rows in the [setup\\_actors](#) table.

- [performance\\_schema\\_setup\\_objects\\_size \[2317\]](#)

<b>Version Introduced</b>	5.6.1	
<b>Command-Line Format</b>	--performance_schema_setup_objects_size=#	
<b>Option-File Format</b>	performance_schema_setup_objects_size=#	
<b>Variable Name</b>	performance_schema_setup_objects_size	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	numeric
	<b>Default</b>	100

The number of rows in the [setup\\_objects](#) table.

- [performance\\_schema\\_users\\_size \[2317\]](#)

<b>Version Introduced</b>	5.6.3	
<b>Command-Line Format</b>	--performance_schema_users_size=#	
<b>Option-File Format</b>	performance_schema_users_size=#	
<b>Variable Name</b>	performance_schema_users_size	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values (&lt;= 5.6.5)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	10

	<b>Range</b>	0 .. 1048576
	<b>Permitted Values (&gt;= 5.6.6)</b>	
	<b>Type</b>	numeric
	<b>Default</b>	-1 (autosized)
	<b>Range</b>	-1 .. 1048576

The number of rows in the `users` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `users` table. This variable was added in MySQL 5.6.3.

## 20.13. Performance Schema Status Variables

The Performance Schema implements several status variables that provide information about instrumentation that could not be loaded or created due to memory constraints:

```
mysql> SHOW STATUS LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Performance_schema_accounts_lost | 0 |
| Performance_schema_cond_classes_lost | 0 |
| Performance_schema_cond_instances_lost | 0 |
| Performance_schema_file_classes_lost | 0 |
| Performance_schema_file_handles_lost | 0 |
| Performance_schema_file_instances_lost | 0 |
| Performance_schema_hosts_lost | 0 |
| Performance_schema_locker_lost | 0 |
| Performance_schema_mutex_classes_lost | 0 |
| Performance_schema_mutex_instances_lost | 0 |
| Performance_schema_rwlock_classes_lost | 0 |
| Performance_schema_rwlock_instances_lost | 0 |
| Performance_schema_socket_classes_lost | 0 |
| Performance_schema_socket_instances_lost | 0 |
| Performance_schema_stage_classes_lost | 0 |
| Performance_schema_statement_classes_lost | 0 |
| Performance_schema_table_handles_lost | 0 |
| Performance_schema_table_instances_lost | 0 |
| Performance_schema_thread_classes_lost | 0 |
| Performance_schema_thread_instances_lost | 0 |
| Performance_schema_users_lost | 0 |
+-----+-----+
```

Names for these variables have several forms:

- `Performance_schema_accounts_lost`

The number of times a row could not be added to the `accounts` table because it was full. This variable was added in MySQL 5.6.3.

- `Performance_schema_xxx_classes_lost`

How many instruments of type `xxx` could not be loaded.

- `Performance_schema_hosts_lost`

The number of times a row could not be added to the `hosts` table because it was full. This variable was added in MySQL 5.6.3.

- `Performance_schema_xxx_instances_lost`

How many instances of object type `xxx` could not be created.

- `Performance_schema_xxx_handles_lost`

How many instances of object type `xxx` could not be opened.

- `Performance_schema_locker_lost`

How many events are “lost” or not recorded, due to the following conditions:

- Events are recursive (for example, waiting for A caused a wait on B, which caused a wait on C).
- The depth of the nested events stack is greater than the limit imposed by the implementation.

Currently, events recorded by the Performance Schema are not recursive, so this variable should always be 0.

- `Performance_schema_session_connect_attrs_lost`

The number of times a connection attribute string was larger than the reserved storage. This variable was added in MySQL 5.6.7.

- `Performance_schema_users_lost`

The number of times a row could not be added to the `users` table because it was full. This variable was added in MySQL 5.6.3.

For information on using these variables to check Performance Schema status, see [Section 20.5, “Performance Schema Status Monitoring”](#).

## 20.14. Performance Schema and Plugins

Removing a plugin with `UNINSTALL PLUGIN` does not affect information already collected for code in that plugin. Time spent executing the code while the plugin was loaded was still spent even if the plugin is unloaded later. The associated event information, including aggregate information, remains readable in `performance_schema` database tables. For additional information about the effect of plugin installation and removal, see [Section 20.5, “Performance Schema Status Monitoring”](#).

A plugin implementor who instruments plugin code should document its instrumentation characteristics to enable those who load the plugin to account for its requirements. For example, a third-party storage engine should include in its documentation how much memory the engine needs for mutex and other instruments.

## 20.15. Using the Performance Schema to Diagnose Problems

The Performance Schema is a tool to help a DBA do performance tuning by taking real measurements instead of “wild guesses.” This section demonstrates some ways to use the Performance Schema for this purpose. The discussion here relies on the use of event filtering, which is described in [Section 20.2.3.2, “Performance Schema Event Filtering”](#).

The following example provides one methodology that you can use to analyze a repeatable problem, such as investigating a performance bottleneck. To begin, you should have a repeatable use case where performance is deemed “too slow” and needs optimization, and you should enable all instrumentation (no pre-filtering at all).

1. Run the use case.
2. Using the Performance Schema tables, analyze the root cause of the performance problem. This analysis will rely heavily on post-filtering.
3. For problem areas that are ruled out, disable the corresponding instruments. For example, if analysis shows that the issue is not related to file I/O in a particular storage engine, disable the file I/O instruments for that engine. Then truncate the history and summary tables to remove previously collected events.
4. Repeat the process at step 1.

At each iteration, the Performance Schema output, particularly the `events_waits_history_long` table, will contain less and less “noise” caused by nonsignificant instruments, and given that this table has a fixed size, will contain more and more data relevant to the analysis of the problem at hand.

At each iteration, investigation should lead closer and closer to the root cause of the problem, as the “signal/noise” ratio will improve, making analysis easier.

5. Once a root cause of performance bottleneck is identified, take the appropriate corrective action, such as:
  - Tune the server parameters (cache sizes, memory, and so forth).
  - Tune a query by writing it differently,
  - Tune the database schema (tables, indexes, and so forth).
  - Tune the code (this applies to storage engine or server developers only).
6. Start again at step 1, to see the effects of the changes on performance.

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. This is made possible by Performance Schema instrumentation as follows:

1. Suppose that thread 1 is stuck waiting for a mutex.
2. You can determine what the thread is waiting for:

```
SELECT * FROM events_waits_current WHERE THREAD_ID = thread_1;
```

Say the query result identifies that the thread is waiting for mutex A, found in `events_waits_current.OBJECT_INSTANCE_BEGIN`.

3. You can determine which thread is holding mutex A:

```
SELECT * FROM mutex_instances WHERE OBJECT_INSTANCE_BEGIN = mutex_A;
```

Say the query result identifies that it is thread 2 holding mutex A, as found in `mutex_instances.LOCKED_BY_THREAD_ID`.

4. You can see what thread 2 is doing:

```
SELECT * FROM events_waits_current WHERE THREAD_ID = thread_2;
```

---

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including ODBC, Java (JDBC), Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

#### Note

Connector version numbers do not correlate with MySQL Server version numbers. See [Table 21.2, “MySQL Connector Versions and MySQL Server Versions”](#).

## MySQL Connectors

Oracle develops a number of connectors:

- [Connector/ODBC](#) provides driver support for connecting to MySQL using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix, and Mac OS X platforms.
- [Connector/Net](#) enables developers to create .NET applications that connect to MySQL. Connector/Net implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that use Connector/Net can be written in any supported .NET language.

The MySQL [Visual Studio Plugin](#) works with Connector/Net and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools available in Visual Studio to create and edit objects within a MySQL database.

- [Connector/J](#) provides driver support for connecting to MySQL from Java applications using the standard Java Database Connectivity (JDBC) API.
- [Connector/Python](#) provides driver support for connecting to MySQL from Python applications using an API that is compliant with the [Python DB API version 2.0](#). No additional Python modules or MySQL client libraries are required.
- [Connector/C++](#) enables C++ applications to connect to MySQL.
- [Connector/C](#) is a standalone replacement for the MySQL Client Library (`libmysqlclient`), to be used for C applications.

## The MySQL C API

For direct access to using MySQL natively within a C application, there are two methods:

- The [C API](#) provides low-level access to the MySQL client/server protocol through the `libmysqlclient` client library. This is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command-line clients and many of the MySQL Connectors and third-party APIs detailed here.

`libmysqlclient` is included in MySQL distributions and in MySQL Connector/C distributions.

- `libmysqld` is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

`libmysqld` is included in MySQL distributions, but not in MySQL Connector/C distributions.

See also [Section 21.8.1, “MySQL C API Implementations”](#).

To access MySQL from a C application, or to build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the [C API](#) is where to start. A number of programmer's

utilities are available to help with the process; see [Section 4.7, “MySQL Program Development Utilities”](#).

## Third-Party MySQL APIs

The remaining APIs described in this chapter provide an interface to MySQL from specific application languages. These third-party solutions are not developed or supported by Oracle. Basic information on their usage and abilities is provided here for reference purposes only.

All the third-party language APIs are developed using one of two methods, using `libmysqlclient` or by implementing a *native driver*. The two solutions offer different benefits:

- Using `libmysqlclient` offers complete compatibility with MySQL because it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through `libmysqlclient` and the performance may be lower as data is copied between the native language, and the MySQL API components.
- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier for end users to build and deploy because no copy of the MySQL client libraries is needed to build the native driver components.

[Table 21.1, “MySQL APIs and Interfaces”](#) lists many of the libraries and interfaces available for MySQL. [Table 21.2, “MySQL Connector Versions and MySQL Server Versions”](#) shows which MySQL Server versions each connector supports.

**Table 21.1. MySQL APIs and Interfaces**

Environment	API	Type	Notes
Ada	GNU Ada MySQL Bindings	<code>libmysqlclient</code>	See <a href="#">MySQL Bindings for GNU Ada</a>
C	C API	<code>libmysqlclient</code>	See <a href="#">Section 21.8, “MySQL C API”</a> .
C	Connector/C	Replacement for <code>libmysqlclient</code>	See <a href="#">Section 21.5, “MySQL Connector/C”</a> .
C++	Connector/C++	<code>libmysqlclient</code>	See <a href="#">Section 21.4, “MySQL Connector/C++”</a> .
	MySQL++	<code>libmysqlclient</code>	See <a href="#">MySQL++ Web site</a> .
	MySQL wrapped	<code>libmysqlclient</code>	See <a href="#">MySQL wrapped</a> .
Cocoa	MySQL-Cocoa	<code>libmysqlclient</code>	Compatible with the Objective-C Cocoa environment. See <a href="http://mysql-cocoa.sourceforge.net/">http://mysql-cocoa.sourceforge.net/</a>
D	MySQL for D	<code>libmysqlclient</code>	See <a href="#">MySQL for D</a> .
Eiffel	Eiffel MySQL	<code>libmysqlclient</code>	See <a href="#">Section 21.14, “MySQL Eiffel Wrapper”</a> .
Erlang	<code>erlang-mysql-driver</code>	<code>libmysqlclient</code>	See <a href="#">erlang-mysql-driver</a> .
Haskell	Haskell MySQL Bindings	Native Driver	See <a href="#">Brian O’Sullivan’s pure Haskell MySQL bindings</a> .
	<code>hsqldb-mysql</code>	<code>libmysqlclient</code>	See <a href="#">MySQL driver for Haskell</a> .
Java/JDBC	Connector/J	Native Driver	See <a href="#">Section 21.3, “MySQL Connector/J”</a> .

	<code>Net::MySQL</code>	Native Driver	See <a href="#">Net::MySQL at CPAN</a>
PHP	<code>mysql</code> , <code>ext/mysql</code> interface (deprecated)	<code>libmysqlclient</code>	See <a href="#">Section 21.9.2, “Original MySQL API (mysql)”</a> .
	<code>mysqli</code> , <code>ext/mysqli</code> interface	<code>libmysqlclient</code>	See <a href="#">Section 21.9.3, “MySQL Improved Extension (mysqli)”</a> .
	<code>PDO_MYSQL</code>	<code>libmysqlclient</code>	See <a href="#">Section 21.9.4, “MySQL Functions (PDO_MYSQL) (MySQL (PDO))”</a> .
	PDO <code>mysqlnd</code>	Native Driver	
Python	Connector/Python	Native Driver	See <a href="#">Section 21.6, “MySQL Connector/Python”</a> .
	MySQLdb	<code>libmysqlclient</code>	See <a href="#">Section 21.11, “MySQL Python API”</a> .
Ruby	MySQL/Ruby	<code>libmysqlclient</code>	Uses <code>libmysqlclient</code> . See <a href="#">Section 21.12.1, “The MySQL/Ruby API”</a> .
	Ruby/MySQL	Native Driver	See <a href="#">Section 21.12.2, “The Ruby/MySQL API”</a> .
Scheme	<code>Myscsh</code>	<code>libmysqlclient</code>	See <a href="#">Myscsh</a> .
SPL	<code>sql_mysql</code>	<code>libmysqlclient</code>	See <a href="#">sql_mysql</a> for SPL.
Tcl	MySQLtcl	<code>libmysqlclient</code>	See <a href="#">Section 21.13, “MySQL Tcl API”</a> .

Table 21.2. MySQL Connector Versions and MySQL Server Versions

Connector	Connector version	MySQL Server version
Connector/C++	1.0.5 GA	5.6, 5.5, 5.4, 5.1
Connector/J	5.1.8	5.6, 5.5, 5.4, 5.1, 5.0, 4.1
Connector/Net	6.5	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.4	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.3	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.2 (No longer supported)	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.1 (No longer supported)	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.0 (No longer supported)	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	5.2 (No longer supported)	5.6, 5.5, 5.4, 5.1, 5.0

Connector	Connector version	MySQL Server version
Connector/Net	1.0 (No longer supported)	5.0, 4.0
Connector/ODBC	5.1	5.6, 5.5, 5.4, 5.1, 5.0, 4.1.1+
Connector/ODBC	3.51 (Unicode not supported)	5.6, 5.5, 5.4, 5.1, 5.0, 4.1

## 21.1. MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (previously called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 5.2, which includes the functionality of the Unicode driver and the ANSI driver, which formerly were split between Connector/ODBC 5.1 and Connector/ODBC 3.51.

MySQL Connector/ODBC provides both driver-manager based and native interfaces to the MySQL database, with full support for MySQL functionality, including stored procedures, [transactions](#) and, with Connector/ODBC 5.1 and higher, full Unicode compliance.

For more information on the ODBC API standard and how to use it, refer to <http://support.microsoft.com/kb/110093>.

The application development section of the ODBC API reference assumes a good working knowledge of C, general DBMS, and a familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to <http://dev.mysql.com/doc/>.

Typically, you need to install Connector/ODBC only on Windows machines. For Unix and Mac OS X, you can use the native MySQL network or named pipes to communicate with your MySQL database. You may need Connector/ODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with the database. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

For release notes detailing the changes in each release of Connector/ODBC, see [MySQL Connector/ODBC Release Notes](#).

### Key connector/ODBC topics include:

- Installing Connector/ODBC: [Section 21.1.3, “Connector/ODBC Installation”](#).
- The configuration options: [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).
- An example that connects to a MySQL database from a Windows host: [Section 21.1.5.2, “Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC”](#).
- An example that uses Microsoft Access as an interface to a MySQL database: [Section 21.1.5.4, “Using Connector/ODBC with Microsoft Access”](#).
- General tips and notes, including how to obtain the last auto-increment ID: [Section 21.1.7.1, “Connector/ODBC General Functionality”](#).
- Application-specific usage tips and notes: [Section 21.1.7.2, “Connector/ODBC Application-Specific Tips”](#).
- A FAQ (Frequently Asked Questions) list: [Section 21.1.7.3, “Connector/ODBC Errors and Resolutions \(FAQ\)”](#).
- Additional Connector/ODBC support options: [Section 21.1.8, “Connector/ODBC Support”](#).

## 21.1.1. Connector/ODBC Versions

These are the versions of Connector/ODBC that are currently available:

- Connector/ODBC 5.2, currently in GA status, upgrades the ANSI driver of Connector/ODBC 3.51 to the 5.x code base. It also includes new features, such as enabling server-side prepared statements by default. At installation time, you can choose the Unicode driver for the broadest compatibility with data sources using various character sets, or the ANSI driver for optimal performance with a more limited range of character sets. It works with MySQL versions 4.1.1 and higher.
- Connector/ODBC 5.1, now superseded by 5.2, is a partial rewrite of the of the 3.51 code base, and is designed to work with MySQL versions 4.1.1 and newer.

Connector/ODBC 5.1 also includes the following changes and improvements over the 3.51 release:

- Improved support on Windows 64-bit platforms.
- Full Unicode support at the driver level. This includes support for the `SQL_WCHAR` data type, and support for Unicode login, password and DSN configurations. For more information, see [Microsoft Knowledgebase Article #716246](#).
- Support for the `SQL_NUMERIC_STRUCT` data type, which provides easier access to the precise definition of numeric values. For more information, see [Microsoft Knowledgebase Article #714556](#).
- Native Windows setup library. This replaces the Qt library based interface for configuring DSN information within the ODBC Data Sources application.
- Support for the ODBC descriptor, which improves the handling and metadata of columns and parameter data. For more information, see [Microsoft Knowledgebase Article #716339](#).
- Connector/ODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. Connector/ODBC 3.51 has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) to continue to provide all functionality of ODBC for accessing MySQL.

With MySQL Connector/ODBC 5.2 now offering both ANSI and Unicode drivers, you should expect to upgrade relatively soon.

The manual for versions of Connector/ODBC older than 5.2 can be located in the corresponding binary or source distribution. Please note that versions of Connector/ODBC earlier than the 3.51 revision were not fully compliant with the ODBC specification.

### Note

From this section onward, the primary focus of this guide is the Connector/ODBC 5.2 driver.

### Note

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

## 21.1.2. Connector/ODBC Introduction

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that enables connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent

applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://support.microsoft.com/kb/110093>.

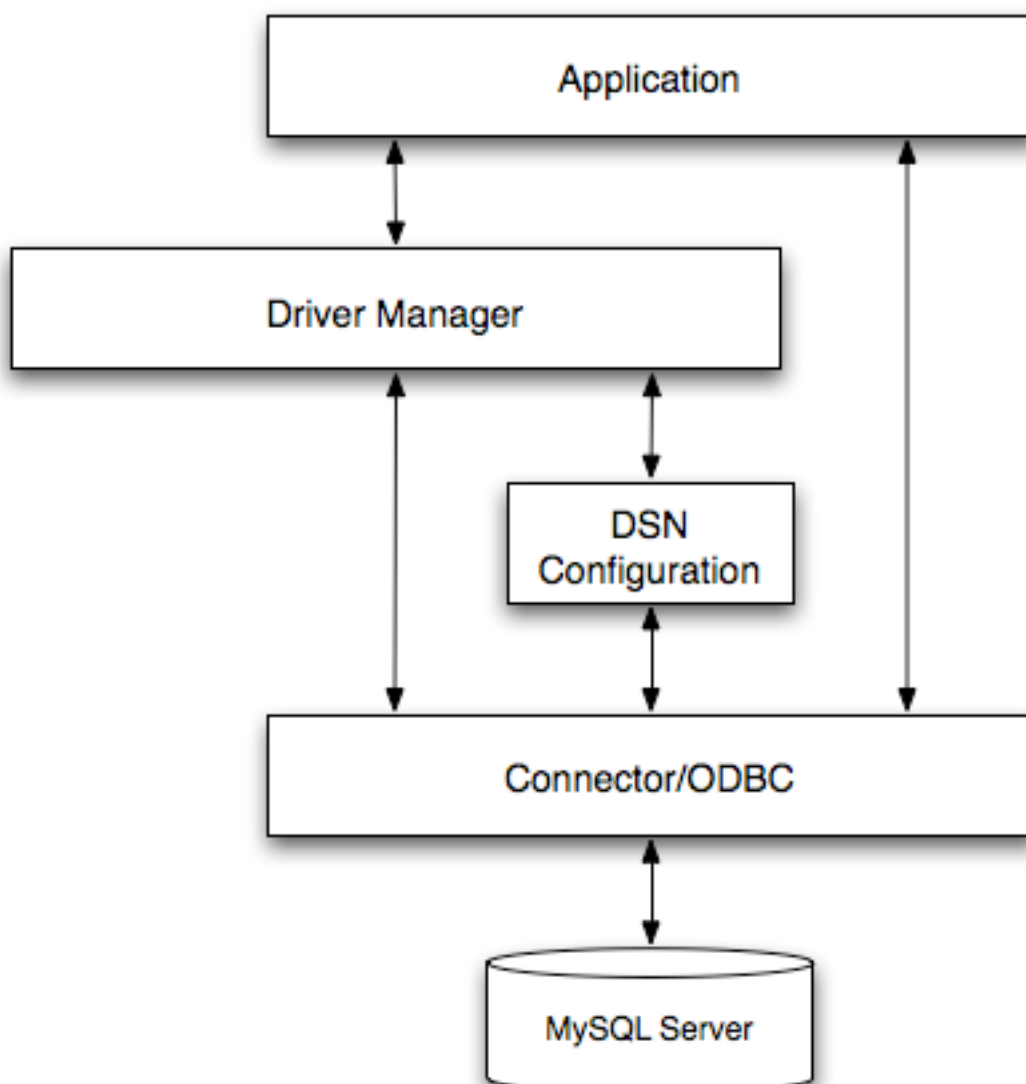

### 21.1.2.1. General Information About ODBC and Connector/ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by Connector/ODBC is given at [Section 21.1.6.1, "Connector/ODBC API Reference"](#). For general information about ODBC, see <http://support.microsoft.com/kb/110093>.

#### 21.1.2.1.1. Connector/ODBC Architecture

The Connector/ODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn communicates with the Driver Manager. The Application communicates with the Driver Manager

using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it.
- Submitting SQL statements for execution.
- Retrieving results (if any).
- Processing errors.
- [Committing](#) or [rolling back](#) the [transaction](#) enclosing the SQL statement.
- Disconnecting from the MySQL server.

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

- Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the Connector/ODBC driver to enable the ODBC API to communicate with the MySQL host.
- Processes ODBC function calls or passes them to the driver for processing.

- **Connector/ODBC Driver:**

The Connector/ODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, [Section 21.1.4, "Configuring Connector/ODBC"](#).

- **MySQL Server:**

The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

### 21.1.2.1.2. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.
- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers, are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://support.microsoft.com/kb/110093>.
- Mac OS X includes `ODBC Administrator`, a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. <http://www.apple.com>.
- `unixODBC` Driver Manager for Unix (`libodbc.so`). See <http://www.unixodbc.org>, for more information. The `unixODBC` Driver Manager includes the Connector/ODBC driver 3.51 in the installation package, starting with version `unixODBC 2.1.2`.
- `iODBC` ODBC Driver Manager for Unix (`libiodbc.so`), see <http://www.iodbc.org>, for more information.

### 21.1.3. Connector/ODBC Installation

This section explains where to download Connector/ODBC, and how to run the installer, copy the files manually, or build from source.

#### Where to Get Connector/ODBC

You can get a copy of the latest version of Connector/ODBC binaries and sources from our Web site at <http://dev.mysql.com/downloads/connector/odbc/>.

For more information about Connector/ODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

#### Choosing Unicode or ANSI Driver

Connector/ODBC offers the flexibility to handle data using any character set through its **Unicode-enabled** driver, or the maximum raw speed for a more limited range of character sets through its **ANSI** driver. Some users postponed their upgrade to Connector/ODBC 5.1, remaining with the older 3.51 version to keep this performance edge. As of Connector/ODBC 5.2, both kinds of drivers are available based on the 5.x code base: you can choose either a Unicode-enabled driver or an ANSI driver on the download page. The Unicode-enabled driver, recommended for most users, has no special qualifier in the download filename. The ANSI driver includes `-ansi-` in the download filename.

#### Note

You can install either the Unicode driver on a Windows system, or the ANSI driver, or both. The drivers are distinguished in the list of installed software and

in the names of libraries and directories by a `w` (for “wide characters”) for the Unicode driver, and `a` in the ANSI driver.

## Choosing Binary or Source Installation Method

You can install the Connector/ODBC drivers using two different methods:

- The **binary installation** is the easiest and most straightforward method of installation. You receive all the necessary libraries and other files pre-built, with an installer program or batch script to perform all necessary copying and configuration.
- The **source installation** method is intended for platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or Connector/ODBC drivers before installation.

If a binary distribution is not available for a particular platform, and you build the driver from the original source code, you can contribute the binaries you create to MySQL by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com), so that it becomes available for other users.

## Supported Platforms

Connector/ODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, 2003, Vista and 7.
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix.
- Mac OS X and Mac OS X Server.

### Note

On all non-Windows platforms except Mac OS X, the driver is built against `unixODBC` and is expecting a 2-byte `SQLWCHAR`, not 4 bytes as `iODBC` is using. For this reason, the binaries are **only** compatible with `unixODBC`; recompile the driver against `iODBC` to use them together. For further information, see [Section 21.1.2.1.2, “ODBC Driver Managers”](#).

For further instructions, consult the documentation corresponding to the platform where you are installing and whether you are running a binary installer or building from source:

Platform	Binary Installer	Build from Source
Windows	<a href="#">Installation Instructions</a>	<a href="#">Build Instructions</a>
Unix/Linux	<a href="#">Installation Instructions</a>	<a href="#">Build Instructions</a>
Mac OS X	<a href="#">Installation Instructions</a>	

### 21.1.3.1. Installing Connector/ODBC on Windows

Before installing the Connector/ODBC drivers on Windows, ensure that your Microsoft Data Access Components (MDAC) are up to date. You can obtain the latest version from the [Microsoft Data Access and Storage](#) Web site.

There are different distribution types to use when installing for Windows. The software that is installed is identical in each case, only the installation method is different.

- The **zipped installer** consists of a zipped package containing a standalone installation application. To install from this package, unzip the installer, and then run the installation application.

The **MSI installer** is an installation file that can be used with the installer included in Windows 2000, Windows XP and Windows Server 2003.

See [Section 21.1.3.1.1, “Installing the Windows Connector/ODBC Driver Using an Installer”](#) for the steps to complete the installation with either of these installers.

- The **zipped DLL** package contains DLL files that must be manually installed. See [Section 21.1.3.1.2, “Installing the Windows Connector/ODBC Driver using the Zipped DLL Package”](#) for the steps to complete this type of installation.

**Note**

An OLEDB/ODBC driver for Windows 64-bit is available from [Microsoft Downloads](#).

### 21.1.3.1.1. Installing the Windows Connector/ODBC Driver Using an Installer

The zipped or MSI installer packages offer a very simple method for installing the Connector/ODBC drivers. If you have downloaded the zipped installer, extract the installer application. The basic installation process is identical for both installers.

Follow these steps to complete the installation:

1. Double-click the standalone installer that you extracted, or the MSI file you downloaded.
2. The MySQL Connector/ODBC Setup Wizard starts. Click the **Next** button to begin the installation process.
3. Choose the installation type. The **Typical** installation provides the standard files needed to connect to a MySQL database using ODBC. The **Complete** option installs all the available files, including debug and utility components. Oracle recommends choosing one of these two options to complete the installation. If you choose one of these methods, click **Next**, then proceed to step 5.

You can also choose a **Custom** installation, where you select the individual components to install. If you choose this method, click **Next**, then proceed to step 4.

4. If you have chosen a custom installation, use the pop-ups to select which components to install, then click **Next** to install the necessary files.
5. Once the files are copied to their final locations, the installation is complete. Click **Finish** to exit the installer.

Now that the installation is complete, configure your ODBC connections using [Section 21.1.4, “Configuring Connector/ODBC”](#).

### 21.1.3.1.2. Installing the Windows Connector/ODBC Driver using the Zipped DLL Package

If you have downloaded the zipped DLL package:

1. Unzip the installation files.
2. Run the included batch file to perform an installation to the default locations.
3. Alternatively, install the individual files required for Connector/ODBC operation manually.

**Note**

The following instructions only work for 32-bit Windows systems. If you have a 64-bit Windows system, use the MSI installer, which installs both the 32-bit and 64-bit drivers to the correct locations.

To install using the **batch file**:

1. Unzip the Connector/ODBC zipped DLL package.
2. Open a command prompt.
3. Change to the directory created when you unzipped the Connector/ODBC zipped DLL package.
4. Run `Install.bat`:

```
C:\> Install.bat
```

This copies the necessary files into the default location, and then registers the Connector/ODBC driver with the Windows ODBC manager.

#### Note

Changing or adding a new DSN (data source name) may be accomplished using either the GUI, or from the command-line using `myodbc-installer.exe` with Connector/ODBC 5.x, or `myodbc3i.exe` with Connector/ODBC 3.51,

Although Oracle recommends installing these files in the standard location, you can also copy the files by hand to an alternative location - for example, to run or test different versions of the Connector/ODBC driver on the same machine. To **copy the files** to a location of your choice, use the following steps:

1. Unzip the Connector/ODBC zipped DLL package.
2. Open a command prompt.
3. Change to the directory created when you unzipped the Connector/ODBC zipped DLL package.
4. Copy the library files to a suitable directory. The default location is the default Windows system directory `\Windows\System32`:

```
C:\> copy lib\myodbc5S.dll \Windows\System32
C:\> copy lib\myodbc5S.lib \Windows\System32

If installing the Unicode-enabled driver:
C:\> copy lib\myodbc5w.dll \Windows\System32
C:\> copy lib\myodbc5w.lib \Windows\System32

If installing the ANSI driver:
C:\> copy lib\myodbc5a.dll \Windows\System32
C:\> copy lib\myodbc5a.lib \Windows\System32
```

5. Copy the Connector/ODBC tools. These must be placed in a directory that is in the system `%PATH%`. The default is to install these into the Windows system directory `\Windows\System32`:

```
C:\> copy bin\myodbc3i.exe \Windows\System32
C:\> copy bin\myodbc3m.exe \Windows\System32
C:\> copy bin\myodbc3c.exe \Windows\System32
```

6. Optionally, copy the help files. For these files to be accessible through the help system, they must be installed in the Windows system directory:

```
C:\> copy doc\*.hlp \Windows\System32
```

7. Finally, register the Connector/ODBC driver with the ODBC manager:

```
For Unicode-enabled driver:
C:\> myodbc3i -a -d -t"MySQL ODBC 5.2 Driver;\
    DRIVER=myodbc5w.dll;SETUP=myodbc5S.dll"

For ANSI driver:
C:\> myodbc3i -a -d -t"MySQL ODBC 5.2 Driver;\
```

```
DRIVER=myodbc5a.dll;SETUP=myodbc5S.dll"
```

If you installed these files into a non-default location, change the references to the DLL files and command location in the above statement

### 21.1.3.2. Installing Connector/ODBC on Unix

There are two methods available for installing Connector/ODBC on Unix from a binary distribution. For most Unix environments, you will use the **tarball** distribution. For Linux systems, there is also an **RPM** distribution available.

#### Note

To install Connector/ODBC 5.x on Unix requires unixODBC 2.2.12 or later to be installed.

#### 21.1.3.2.1. Installing Connector/ODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps that demonstrate the process using the Linux version of the tarball, substituting the appropriate file and directory names based on the package you download:

```
shell> su root
shell> gunzip mysql-connector-odbc-5.2.2-i686-pc-linux.tar.gz
shell> tar xvf mysql-connector-odbc-5.2.2-i686-pc-linux.tar
shell> cd mysql-connector-odbc-5.2.2-i686-pc-linux
```

Read the installation instructions in the `INSTALL` file and execute these commands.

Then see [Section 21.1.4.5, "Configuring a Connector/ODBC DSN on Unix"](#) to configure the DSN for Connector/ODBC. For more information, refer to the `INSTALL` file that comes with your distribution.

#### 21.1.3.2.2. Installing Connector/ODBC from an RPM Distribution

To install or upgrade Connector/ODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of Connector/ODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh mysql-connector-odbc-5.2.2.i386.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh mysql-connector-odbc-5.2.2.i386.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC`, respectively. See [Section 21.1.4.5, "Configuring a Connector/ODBC DSN on Unix"](#) for the post-installation configuration steps.

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e mysql-connector-odbc
```

### 21.1.3.3. Installing Connector/ODBC on Mac OS X

Mac OS X is based on the FreeBSD operating system, and you can normally use the MySQL network port for connecting to MySQL servers on other hosts. Installing the Connector/ODBC driver lets you connect to MySQL databases on any platform through the ODBC interface. If your application requires an ODBC interface, install the Connector/ODBC driver. Applications that require or can use ODBC (and therefore the Connector/ODBC driver) include ColdFusion, Filemaker Pro, 4th Dimension and many other applications.

Mac OS X includes its own ODBC manager, based on the [iODBC](#) manager. Mac OS X includes an administration tool that provides easier administration of ODBC drivers and configuration, updating the underlying [iODBC](#) configuration files.

For Connector/ODBC 5.x, the package is provided as a compressed tar archive that you manually install.

In either case, the driver is designed to work with the iODBC driver manager included with Mac OS X.

To install Connector/ODBC 5.x:

1. Download the installation file for the appropriate level of Mac OS X (10.5 or higher).
2. Extract the archive:

```
shell> tar xvzf mysql-connector-odbc-5.x.y-osx10.z-x86-(32/64)bit.tar.gz
```

3. The directory created contains the subdirectories, [lib](#), [bin](#), and [test](#). Copy the contents of [lib](#) and [bin](#) to a suitable location such as [/usr/local](#):

```
shell> sudo cp bin/* /usr/local/bin
shell> sudo cp lib/* /usr/local/lib
```

4. Finally, register the driver with iODBC using the [myodbc3i](#) tool you just installed:

```
shell> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;Driver=/usr/local/lib/libmyodbc3.so;Setup=/usr/local/
```

To verify the installed drivers, either use the ODBC Administrator application or the [myodbc3i](#) utility:

```
shell> myodbc3i -q -d
```

### 21.1.3.4. Building Connector/ODBC from a Source Distribution on Windows

You only need to build Connector/ODBC from source on Windows to modify the source or installation location. If you are unsure whether to install from source, please use the binary installation detailed in [Section 21.1.3.1, "Installing Connector/ODBC on Windows"](#).

Building Connector/ODBC from source on Windows requires a number of different tools and packages:

- MDAC, Microsoft Data Access SDK from <http://support.microsoft.com/kb/110093>.
- Suitable C compiler, such as Microsoft Visual C++ or the C compiler included with Microsoft Visual Studio.

Microsoft Visual Studio 7 and 8 are preferred, and well-tested.

- Connector/ODBC 5.2: [cmake](#).
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

## Build Steps

Set the environment variables for the Visual Studio toolchain. Visual Studio includes a batch file to set these for you, and installs a **Start** menu shortcut that opens a command prompt with these variables set.

Set `MYSQL_DIR` to the MySQL server installation path, while using the short-style file names. For example:

```
C:\> set MYSQL_DIR=C:\PROGRA~1\MySQL\MYSQLS~1.0
```

Build Connector/ODBC using the `cmake` command-line tool by executing the following from the source root directory (in a command prompt window):

```
C:\> cmake -G "Visual Studio 8 2005"
```

This produces a project file that you can open with Visual Studio, or build from the command line with either of the following commands:

```
C:\> devenv.com MySQL_Connector_ODBC.sln /build Release
C:\> devenv.com MySQL_Connector_ODBC.sln /build RelWithDebInfo
```

To compile a debug build, set the `cmake` build type so that the correct versions of the MySQL client libraries are used:

```
C:\> cmake -G "Visual Studio 8 2005" -DCMAKE_BUILD_TYPE=Debug
C:\> devenv.com MySQL_Connector_ODBC.sln /build Debug
```

Upon completion, the executables are in the `bin/` and `lib/` subdirectories.

See [Section 21.1.3.1.2, "Installing the Windows Connector/ODBC Driver using the Zipped DLL Package"](#) for the `copy` commands to complete the installation.

### 21.1.3.5. Building Connector/ODBC from a Source Distribution on Unix

#### Note

Connector/5.2 uses `cmake` for build, rather than `autoconf` and its `configure` command.

You need the following tools to build MySQL from source on Unix:

- A working ANSI C++ compiler. GCC 4.2.1 or later, Sun Studio 10 or later, Visual Studio 2008 or later, and many current vendor-supplied compilers are known to work.
- `cmake`.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

If you have built your own MySQL server or client libraries from source using the GNU autotools, use the `--enable-thread-safe-client` option to `configure` when the libraries were built. No special option is needed if you configure with `cmake`.

Also, ensure that the `libmysqlclient` library was built and installed as a shared library.

- A compatible ODBC manager must be installed. Connector/ODBC is known to work with the `iODBC` and `unixODBC` managers. See [Section 21.1.2.1.2, "ODBC Driver Managers"](#) for more information.
- If you are using a character set that is not compiled into the MySQL client library, install the MySQL character definitions from the `charsets` directory into `SHAREDIR` (by default, `/usr/local/`

`mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine. See [Section 10.1, “Character Set Support”](#) for more information on character set support.

Once you have all the required files, unpack the source files to a separate directory, then run `configure` and build the library using `make`.

## Typical `cmake` Options

`iODBC` is the default ODBC library used by Connector/ODBC. Alternatively, `unixODBC` may be used by passing in the appropriate option to `cmake`. For example:

```
shell> cmake -G "Unix Makefiles" -DWITH_UNIXODBC=1
```

When you run `cmake`, you might add options to the command line. Here are some examples:

- `-DODBC_INCLUDES=dir_name [133]`: Used when the ODBC include directory is not found within the system `$PATH`.
- `-DODBC_LIB_DIR=dir_name [133]`: Used when the ODBC library directory is not found within the system `$PATH`.
- `-DWITH_UNIXODBC=1 [137]`: Enables `unixODBC` support.

## Additional `configure` Options

There are a number of other options that you need, or want, to set when configuring the Connector/ODBC driver before it is built.

- To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled (default) using

```
--disable-thread-safe
```

This option enables the building of the driver thread-safe library `libmyodbc3_r.so` from by linking with MySQL thread-safe client library `libmysqlclient_r.so`. (The extensions are OS-dependent.)

If the compilation with the thread-safe option fails, it may be because the correct thread-libraries on the system could not be located. Set the value of `LIBS` to point to the correct thread library for your system.

```
LIBS="-lpthread" ./configure ..
```

- You can enable or disable the shared and static versions of Connector/ODBC using these options:

```
--enable-shared[=yes|no]
--disable-shared
--enable-static[=yes|no]
--disable-static
```

- By default, all the binary distributions are built as non-debug versions (configured with `--without-debug`).

To enable debugging information, build the driver from a source distribution with the proper configuration option to enable debugging support. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- This option is available only for source trees that have been obtained from the Subversion repository. This option does not apply to the packaged source distributions.

By default, the driver is built with the `--without-docs` option. If you would like the documentation to be built, then execute `configure` with:

```
--with-docs
```

## Build Steps for Unix

To build the driver libraries, execute `make`:

```
shell> make
```

If any errors occur, correct them and continue the build process. If you are not able to build, then send a detailed email to [myodbc@lists.mysql.com](mailto:myodbc@lists.mysql.com) for further assistance.

## Building Shared Libraries

On most platforms, MySQL does not build or support `.so` (shared) client libraries by default. This is based on our experience of problems when building shared libraries.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd mysql-connector-odbc-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error \
    -o .libs/libmyodbc3-3.51.01.so \
    catalog.o connect.o cursor.o dll.o error.o execute.o \
    handle.o info.o misc.o myodbc3.o options.o prepare.o \
    results.o transact.o utility.o \
    -L/usr/local/mysql/lib/mysql/ \
    -L/usr/local/iodbc/lib/ \
    -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iODBC`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to the Connector/ODBC library installation directory (`/usr/local/lib`, or the `lib` directory under the installation directory that you supplied with the `--prefix` option).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3_r-3.51.01.so
    catalog.o connect.o cursor.o dll.o error.o execute.o
    handle.o info.o misc.o myodbc3.o options.o prepare.o
    results.o transact.o utility.o
    -L/usr/local/mysql/lib/mysql/
    -L/usr/local/iodbc/lib/
    -lz -lc -lmysqlclient_r -liodbcinst
```

## Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For Connector/ODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe Connector/ODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

## Testing Connector/ODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, use the following command:

```
shell> make test
```

Before running the tests, create the DSN 'myodbc3' in `odbc.ini` and set the environment variable `ODBCINI` to the correct `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command-line arguments to each sample.

### 21.1.3.6. Building Connector/ODBC from a Source Distribution on Mac OS X

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
--with-unixODBC=/usr/local
--with-mysql-path=/usr/local/mysql
--disable-shared
--enable-gui=no
--host=powerpc-apple
```

The command assumes that the `unixODBC` and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
  $CC -bundle -flat_namespace -undefined error
-o .libs/libmyodbc3-3.51.01.so *.o
-L/usr/local/mysql/lib/
-L/usr/local/iodbc/lib
-liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
      $CC -bundle -flat_namespace -undefined error
      -o .libs/libmyodbc3-3.51.01.so *.o
      -L/usr/local/mysql/lib/
      -L/usr/local/iodbc/lib
      -liodbcinst -lmysqlclient_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using `unixODBC` instead of `iODBC` and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

### 21.1.3.7. Installing Connector/ODBC from the Development Source Tree

#### Caution

Read this section only if you are interested in helping us test our new code. To just get MySQL Connector/ODBC up and running on your system, use a standard release distribution.

To obtain the most recent development source tree, first download and install Bazaar from the [Bazaar VCS Web site](#). Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

Building from the source trees requires the following tools:

- `autoconf` 2.52 (or newer).
- `automake` 1.4 (or newer).
- `libtool` 1.4 (or newer).
- `m4`.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To check out the Connector/ODBC sources, change to the directory where you want the copy of the Connector/ODBC tree to be stored, then use the following command:

```
shell> bzr branch lp:mysqlbc
```

You should now have a copy of the entire Connector/ODBC source tree in the directory `connector-odbc3`. To build from this source tree on Unix or Linux, follow these steps:

```
shell> cd myodbc
shell> aclocal
shell> autoheader
shell> libtoolize -c -f
shell> autoconf
shell> automake;
shell> ./configure # Add your favorite options here
shell> make
```

When the build is done, run `make install` to install the Connector/ODBC driver on your system.

If you have gotten to the `make` stage and the distribution does not compile, please report it to [myodbc@lists.mysql.com](mailto:myodbc@lists.mysql.com).

On Windows, make use of Windows Makefiles [WIN-Makefile](#) and [WIN-Makefile\\_debug](#) in building the driver. For more information, see [Section 21.1.3.4, “Building Connector/ODBC from a Source Distribution on Windows”](#).

After the initial checkout operation to get the source tree, run `bzr pull` periodically to update your source according to the latest version.

## 21.1.4. Configuring Connector/ODBC

Before you connect to a MySQL database using the Connector/ODBC driver, you configure an ODBC Data Source Name (DSN). The DSN associates the various configuration parameters required to communicate with a database to a specific name. You use the DSN in an application to communicate with the database, rather than specifying individual parameters within the application itself. DSN information can be user-specific, system-specific, or provided in a special file. ODBC data source names are configured in different ways, depending on your platform and ODBC driver.

### 21.1.4.1. Overview of Connector/ODBC Data Source Names

A Data Source Name associates the configuration parameters for communicating with a specific database. Generally, a DSN consists of the following parameters:

- Name
- Host Name
- Database Name
- Login
- Password

In addition, different ODBC drivers, including Connector/ODBC, may accept additional driver-specific options and parameters.

There are three types of DSN:

- A *System DSN* is a global DSN definition that is available to any user and application on a particular system. A System DSN can normally only be configured by a systems administrator, or by a user who has specific permissions that let them create System DSNs.
- A *User DSN* is specific to an individual user, and can be used to store database connectivity information that the user regularly uses.
- A *File DSN* uses a simple file to define the DSN configuration. File DSNs can be shared between users and machines and are therefore more practical when installing or deploying DSN information as part of an application across many machines.

DSN information is stored in different locations depending on your platform and environment.

### 21.1.4.2. Connector/ODBC Connection Parameters

You can specify the parameters in the following tables for Connector/ODBC when configuring a DSN:

- [Table 21.3, “Connector/ODBC DSN Configuration Options”](#)
- [Table 21.4, “Connector/ODBC Option Flags”](#)

Users on Windows can use the Options and Advanced panels when configuring a DSN to set these parameters; see the table for information on which options relate to which fields and check boxes. On Unix and Mac OS X, use the parameter name and value as the keyword/value pair in the DSN configuration. Alternatively, you can set these parameters within the `InConnectionString` argument in the `SQLDriverConnect()` call.

**Table 21.3. Connector/ODBC DSN Configuration Options**

Parameter	Default Value	Comment
<code>user</code>	ODBC	The user name used to connect to MySQL.
<code>uid</code>	ODBC	Synonymous with <code>user</code> . Added in 3.51.16.
<code>server</code>	<code>localhost</code>	The host name of the MySQL server.
<code>database</code>		The default database.
<code>option</code>	0	Options that specify how Connector/ODBC works. See <a href="#">Table 21.4, “Connector/ODBC Option Flags”</a> and <a href="#">Table 21.5, “Recommended Connector/ODBC option Values for Different Configurations”</a> .
<code>port</code>	3306	The TCP/IP port to use if <code>server</code> is not <code>localhost</code> .
<code>initstmt</code>		Initial statement. A statement to execute when connecting to MySQL. In version 3.51 the parameter is called <code>stmt</code> . Note, the driver supports the initial statement being executed only at the time of the initial connection.
<code>password</code>		The password for the <code>user</code> account on <code>server</code> .
<code>pwd</code>		Synonymous with <code>password</code> . Added in 3.51.16.
<code>socket</code> [542]		The Unix socket file or Windows named pipe to connect to if <code>server</code> is <code>localhost</code> .
<code>sslca</code>		The path to a file with a list of trust SSL CAs. Added in 3.51.16.
<code>sslcapath</code>		The path to a directory that contains trusted SSL CA certificates in PEM format. Added in 3.51.16.
<code>sslcert</code>		The name of the SSL certificate file to use for establishing a secure connection. Added in 3.51.16.
<code>sslcipher</code>		A list of permissible ciphers to use for SSL encryption. The cipher list has the same format as the <code>openssl ciphers</code> command. Added in 3.51.16.
<code>sslkey</code>		The name of the SSL key file to use for establishing a secure connection. Added in 3.51.16.
<code>charset</code>		The character set to use for the connection. Added in 3.51.17.
<code>sslverify</code>		If set to 1, the SSL certificate will be verified when used with the MySQL connection. If not set, then the default behavior is to ignore SSL certificate verification.
<code>readtimeout</code>		The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP <code>Close_Wait_Timeout</code> value of 10 minutes. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the <code>MYSQL_OPT_READ_TIMEOUT</code> option of the MySQL Client Library. Added in 3.51.27.
<code>writetimeout</code>		The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are <code>net_retry_count</code> retries if necessary, so the total effective timeout value is <code>net_retry_count</code> times the option value. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the <code>MYSQL_OPT_WRITE_TIMEOUT</code> option of the MySQL Client Library. Added in 3.51.27.

Parameter	Default Value	Comment
<code>interactive</code>		Enables the <code>CLIENT_INTERACTIVE</code> connection option of <code>mysql_real_connect</code> .
<code>prefetch</code>	0	When set to a non-zero value <i>N</i> , causes all queries in the connection to return <i>N</i> rows at a time rather than the entire result set. Useful for queries against very large tables where it is not practical to retrieve the whole result set at once. You can scroll through the result set, <i>N</i> records at a time.  This option works only with forward-only cursors. It does not work when the <code>FLAG_MULTI_STATEMENTS</code> flag is set. It can be used in combination with the <code>FLAG_NO_CACHE</code> option. Its behavior in ADO applications is undefined: the prefetching might or might not occur.
<code>no_ssps</code>	0	In Connector/ODBC 5.2, by default, server-side prepared statements are used. When this option is set to a non-zero value, prepared statements are emulated on the client side, which is the same behavior as in 5.1 and 3.51. Added in 5.2.
<code>can_handle_expired_pwd</code>		Indicates that the application can deal with an expired password, which is signalled by an SQL state of <code>08004</code> ("Server rejected the connection") and a native error code <code>ER_MUST_CHANGE_PASSWORD_LOGIN</code> (1862). The connection is "sandboxed", and can do nothing other than issue a <code>SET PASSWORD</code> statement. To establish a connection in this case, your application must either use the <code>initstmt</code> connection option to set a new password at the start, or issue a <code>SET PASSWORD</code> statement immediately after connecting. Once the expired password is reset, the restrictions on the connection are lifted. See <a href="#">Section 13.7.1.1, "ALTER USER Syntax"</a> for details about password expiration for MySQL server accounts. Added in 5.2.4.

**Note**

The SSL configuration parameters can also be automatically loaded from a `my.ini` or `my.cnf` file. See [Section 4.2.3.3, "Using Option Files"](#).

The `option` argument is used to tell Connector/ODBC that the client is not 100% ODBC-compliant. On Windows, you normally select options by toggling the check boxes in the connection screen, but you can also select them in the `option` argument. The following options are listed in the order in which they appear in the Connector/ODBC connect screen.

**Table 21.4. Connector/ODBC Option Flags**

Flag Name	GUI Option	Constant Value	Description
<code>FLAG_FIELD_LENGTH</code>	Do not Optimize Column Width		The client cannot handle that Connector/ODBC returns the real width of a column. This option was removed in 3.51.18.
<code>FLAG_FOUND_ROWS</code>	Return Matching Rows	2	The client cannot handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns "found rows" instead. You must have MySQL 3.21.14 or newer for this to work.
<code>FLAG_DEBUG</code>	Trace Driver Calls To myodbc.log		Make a debug log in <code>C:\myodbc.log</code> on Windows,

## Configuring Connector/ODBC

Flag Name	GUI Option	Constant Value	Description
			or <code>/tmp/myodbc.log</code> on Unix variants. This option was removed in Connector/ODBC 3.51.18.
<code>FLAG_BIG_PACKETS</code>	Allow Big Results	8	Do not set any packet limit for results and bind parameters. Without this option, parameter binding will be truncated to 255 characters.
<code>FLAG_NO_PROMPT</code>	Do not Prompt Upon Connect	16	Do not prompt for questions even if driver would like to prompt.
<code>FLAG_DYNAMIC_CURSOR</code>	Enable Dynamic Cursor	32	Enable or disable the dynamic cursor support.
<code>FLAG_NO_SCHEMA</code>	Ignore # in Table Name	64	Ignore use of database name in <code>db_name.tbl_name.col_name</code> .
<code>FLAG_NO_DEFAULT_CURSOR</code>	User Manager Cursors	128	Force use of ODBC manager cursors (experimental).
<code>FLAG_NO_LOCALE</code>	Do not Use Set Locale	256	Disable the use of extended fetch (experimental).
<code>FLAG_PAD_SPACE</code>	Pad Char To Full Length	512	Pad <code>CHAR</code> columns to full column length.
<code>FLAG_FULL_COLUMN_NAMES</code>	Return Table Names for SQLDescribeCol	1024	<code>SQLDescribeCol()</code> returns fully qualified column names.
<code>FLAG_COMPRESSED_PROTO</code>	Use Compressed Protocol	2048	Use the compressed client/server protocol.
<code>FLAG_IGNORE_SPACE</code>	Ignore Space After Function Names	4096	Tell server to ignore space after function name and before "(" (needed by PowerBuilder). This makes all function names keywords.
<code>FLAG_NAMED_PIPE</code>	Force Use of Named Pipes	8192	Connect with named pipes to a <code>mysqld</code> server running on NT.
<code>FLAG_NO_BIGINT</code>	Change BIGINT Columns to Int	16384	Change <code>BIGINT</code> columns to <code>INT</code> columns (some applications cannot handle <code>BIGINT</code> ).
<code>FLAG_NO_CATALOG</code>	No Catalog	32768	Forces results from the catalog functions, such as <code>SQLTables</code> , to always return <code>NULL</code> and the driver to report that catalogs are not supported.
<code>FLAG_USE_MYCNF</code>	Read Options From <code>my.cnf</code>	65536	Read parameters from the <code>[client]</code> and <code>[odbc]</code> groups from <code>my.cnf</code> .
<code>FLAG_SAFE</code>	Safe	131072	Add some extra safety checks.
<code>FLAG_NO_TRANSACTIONS</code>	Disable transactions	262144	Disable transactions.
<code>FLAG_LOG_QUERY</code>	Save queries to <code>myodbc.sql</code>	524288	Enable query logging to <code>c:\myodbc.sql(/tmp/</code>

Flag Name	GUI Option	Constant Value	Description
			<code>myodbc.sql</code> ) file. (Enabled only in debug mode.)
<code>FLAG_NO_CACHE</code>	Do not Cache Result (forward only cursors)	1048576	Do not cache the results locally in the driver, instead read from server ( <code>mysql_use_result()</code> ). This works only for forward-only cursors. This option is very important in dealing with large tables when you do not want the driver to cache the entire result set.
<code>FLAG_FORWARD_CURSOR</code>	Force Use Of Forward Only Cursors	2097152	Force the use of <code>Forward-only</code> cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use noncache result sets, then this option ensures the forward-only cursor behavior.
<code>FLAG_AUTO_RECONNECT</code>	Enable auto-reconnect.	4194304	Enables auto-reconnection functionality. Do not use this option with <code>transactions</code> , since an auto-reconnection during a incomplete transaction may cause corruption. Note that an auto-reconnected connection will not inherit the same settings and environment as the original. Added in 3.51.13.
<code>FLAG_AUTO_IS_NULL</code>	Flag Auto Is Null	8388608	<p>When <code>FLAG_AUTO_IS_NULL</code> is set, the driver does not change the default value of <code>sql_auto_is_null</code> [543], leaving it at 1, so you get the MySQL default, not the SQL standard behavior.</p> <p>When <code>FLAG_AUTO_IS_NULL</code> is not set, the driver changes the default value of <code>SQL_AUTO_IS_NULL</code> to 0 after connecting, so you get the SQL standard, not the MySQL default behavior.</p> <p>Thus, omitting the flag disables the compatibility option and forces SQL standard behavior.</p> <p>See <code>IS NULL</code> [1168]. Added in 3.51.13.</p>

Flag Name	GUI Option	Constant Value	Description
<a href="#">FLAG_ZERO_DATE_TO_MIN</a>	Return SQL_NULL_DATA for zero date	16777216	Translates zero dates ( <a href="#">XXXX-00-00</a> ) into the minimum date values supported by ODBC, <a href="#">XXXX-01-01</a> . This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. Added in 3.51.17.
<a href="#">FLAG_MIN_DATE_TO_ZERO</a>	Bind minimal date as zero date	33554432	Translates the minimum ODBC date value ( <a href="#">XXXX-01-01</a> ) to the zero date format supported by MySQL ( <a href="#">XXXX-00-00</a> ). This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. Added in 3.51.17.
<a href="#">FLAG_MULTI_STATEMENTS</a>	Allow multiple statements	67108864	Enables support for batched statements. Added in 3.51.18.
<a href="#">FLAG_COLUMN_SIZE_S32</a>	Limit column size to 32-bit value	134217728	Limits the column size to a signed 32-bit value to prevent problems with larger column sizes in applications that do not support them. This option is automatically enabled when working with ADO applications. Added in 3.51.22.
<a href="#">FLAG_NO_BINARY_RESULT</a>	Always handle binary function results as character data	268435456	When set this option disables charset 63 for columns with an empty <a href="#">org_table</a> . Added in 3.51.26.
<a href="#">FLAG_DFLT_BIGINT_BIND_STR</a>		536870912	Causes <a href="#">BIGINT</a> parameters to be bound as strings. Microsoft Access treats <a href="#">BIGINT</a> as a string on linked tables. The value is read correctly, but bound as a string. This option is used automatically if the driver is used by Microsoft Access.
<a href="#">FLAG_NO_INFORMATION_SCHEMA</a>		1073741824	Tells catalog functions not to use <a href="#">INFORMATION_SCHEMA</a> , but rather use legacy algorithms. The trade-off here is usually speed for information quality. Using <a href="#">INFORMATION_SCHEMA</a> is often slow, but the information obtained is more complete.

To select multiple options, add together their values, using the numbers from the [Constant Value](#) column in the table.

**Note**

In MySQL Connector/ODBC 5.2, you can use the flag name directly as a parameter in the connection string, by specifying the flag name without the FLAG\_ prefix. So, in addition to using the `options` parameter with various flags set, you can use the flags directly as parameters. For example, `FIELD_LENGTH`, `FOUND_ROWS` and `DEBUG` could all be used as parameters.

The following table shows some recommended `option` values for various configurations:

**Table 21.5. Recommended Connector/ODBC option Values for Different Configurations**

Configuration	Option Value
Microsoft Access, Visual Basic	3
Driver trace generation (Debug mode)	4
Microsoft Access (with improved DELETE queries)	35
Large tables with too many rows	2049
Sybase PowerBuilder	135168
Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

### 21.1.4.3. Configuring a Connector/ODBC DSN on Windows

The `ODBC Data Source Administrator` within Windows lets you create DSNs, check driver installation and configure ODBC systems such as tracing (used for debugging) and connection pooling.

Different editions and versions of Windows store the `ODBC Data Source Administrator` in different locations depending on the version of Windows that you are using.

To open the `ODBC Data Source Administrator` in Windows Server 2003:

**Tip**

To identify whether a DSN was created using the 32-bit or the 64-bit driver, include the driver being used within the DSN identifier. This will help you to identify the right DSN to use with applications such as Excel that are only compatible with the 32-bit driver. For example, you might add `Using32bitCODBC` to the DSN identifier for the 32-bit interface and `Using64bitCODBC` for those using the 64-bit Connector/ODBC driver.

1. On the `Start` menu, choose `Administrative Tools`, and then click `Data Sources (ODBC)`.

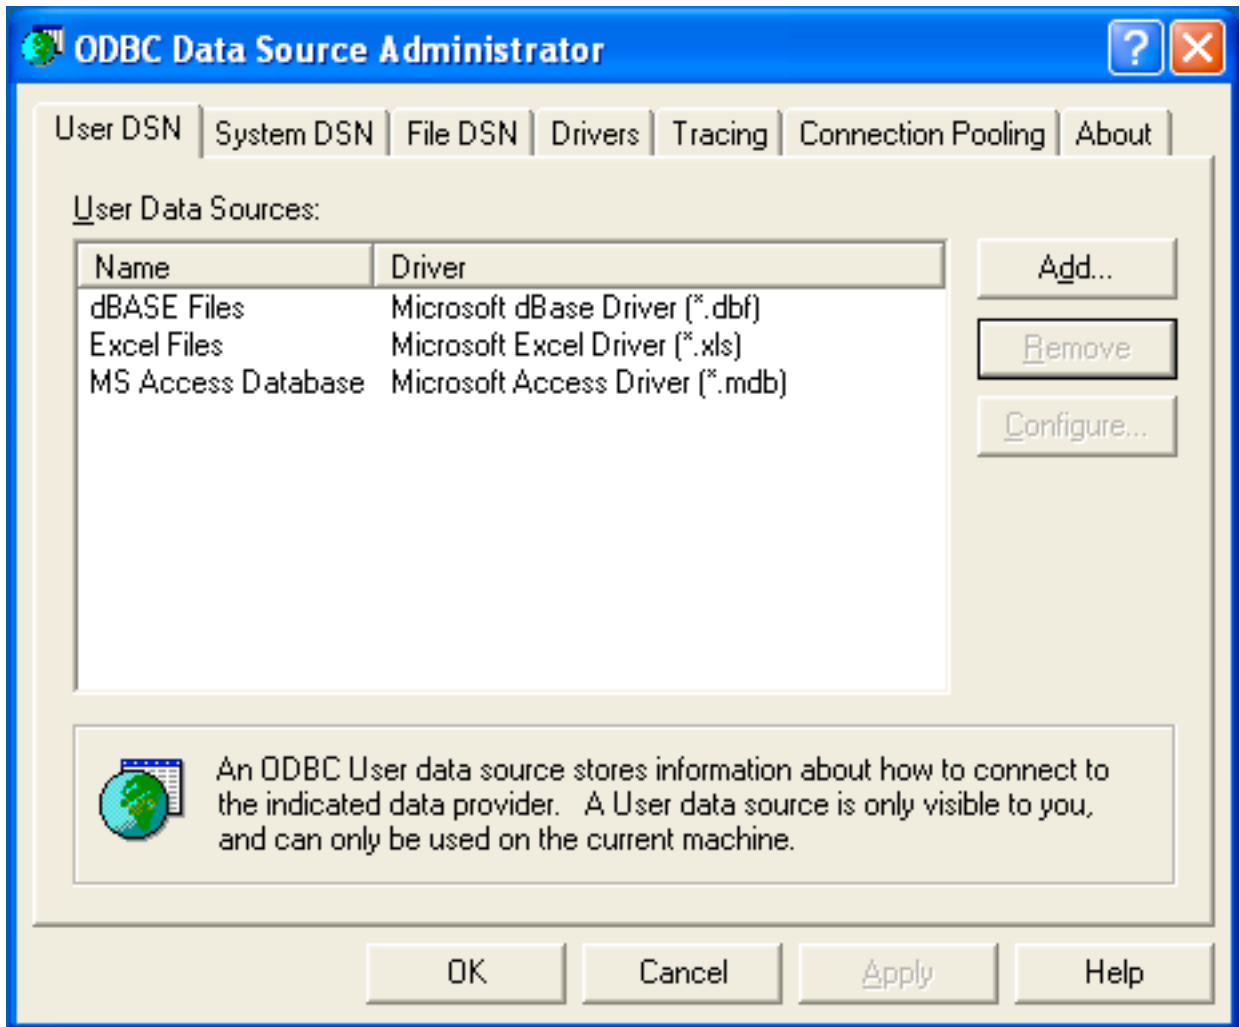

To open the `ODBC Data Source Administrator` in Windows 2000 Server or Windows 2000 Professional:

1. On the `Start` menu, choose `Settings`, and then click `Control Panel`.
2. In `Control Panel`, click `Administrative Tools`.
3. In `Administrative Tools`, click `Data Sources (ODBC)`.

To open the `ODBC Data Source Administrator` on Windows XP:

1. On the `Start` menu, click `Control Panel`.
2. In the `Control Panel` when in `Category View` click `Performance and Maintenance` and then click `Administrative Tools..` If you are viewing the `Control Panel` in `Classic View`, click `Administrative Tools`.
3. In `Administrative Tools`, click `Data Sources (ODBC)`.

Irrespective of your Windows version, you should be presented the [ODBC Data Source Administrator](#) window:

Within Windows XP, you can add the [Administrative Tools](#) folder to your **Start** menu to make it easier to locate the ODBC Data Source Administrator. To do this:

1. Right-click the **Start** menu.
2. Select [Properties](#).
3. Click [Customize...](#)
4. Select the [Advanced](#) tab.
5. Within [Start menu items](#), within the [System Administrative Tools](#) section, select [Display on the All Programs menu](#).

Within both Windows Server 2003 and Windows XP, consider permanently adding the [ODBC Data Source Administrator](#) to your **Start** menu. To do this, locate the [Data Sources \(ODBC\)](#) icon using the methods shown, then right-click on the icon and then choose [Pin to Start Menu](#).

The interfaces for the 3.51 and 5.x versions of the Connector/ODBC driver are different, although the fields and information that you need to enter remain the same.

To configure a DSN using Connector/ODBC 5.2, see [Section 21.1.4.3.1, "Configuring a Connector/ODBC 5.x DSN on Windows"](#).

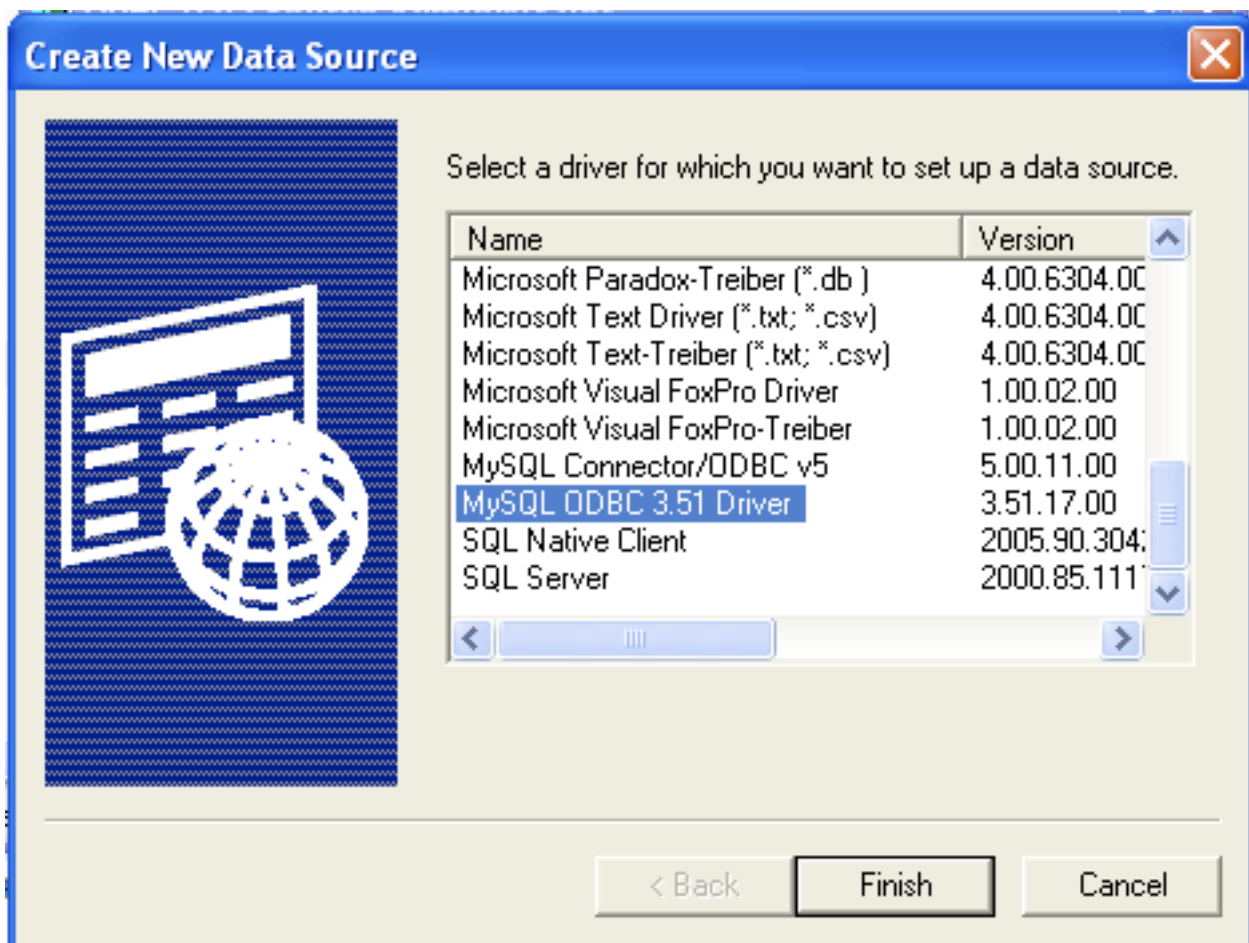

### 21.1.4.3.1. Configuring a Connector/ODBC 5.x DSN on Windows

Due to the native Unicode support within Connector/ODBC, you do not need to specify the initial character set to be used with your connection.

To add or configure a Connector/ODBC 5.x DSN on Windows, use either the command-line, or the [ODBC Data Source Administrator](#) GUI.

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users), select the **System DSN** tab. To create a User DSN, which will be unique only to the current user, click the **Add...** button.
3. Select the ODBC driver for this DSN.

Select [MySQL ODBC 5.x Driver](#) for the appropriate level of Connector/ODBC, then click **Finish**.

4. You now need to configure the specific fields for the DSN you are creating through the [Connection Parameters](#) dialog.

In the **Data Source Name** box, enter the name of the data source to access. It can be any valid name that you choose.

5. In the **Description** box, enter some text to help identify the connection.
6. In the **Server** field, enter the name of the MySQL server host to access. By default, it is `localhost`.
7. In the **User** field, enter the user name to use for this connection.
8. In the **Password** field, enter the corresponding password for this connection.
9. The **Database** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. To communicate over a different TCP/IP port than the default (3306), change the value of the **Port**.
11. Click **OK** to save the DSN.

To verify the connection using the parameters you have entered, click the **Test** button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

You can configure a number of options for a specific DSN by using the **Details** button.

**MySQL Connector/ODBC Data Source Configuration**

MySQL Connector/ODBC

**Connection Parameters**

Data Source Name:

Description:

Server:  Port:

User:

Password:

Database:

Flags 1 | Flags 2 | Flags 3 | Debug | SSL Settings

Return matched rows instead of affected rows

Allow big result sets

Use compression

Treat BIGINT columns as INT columns

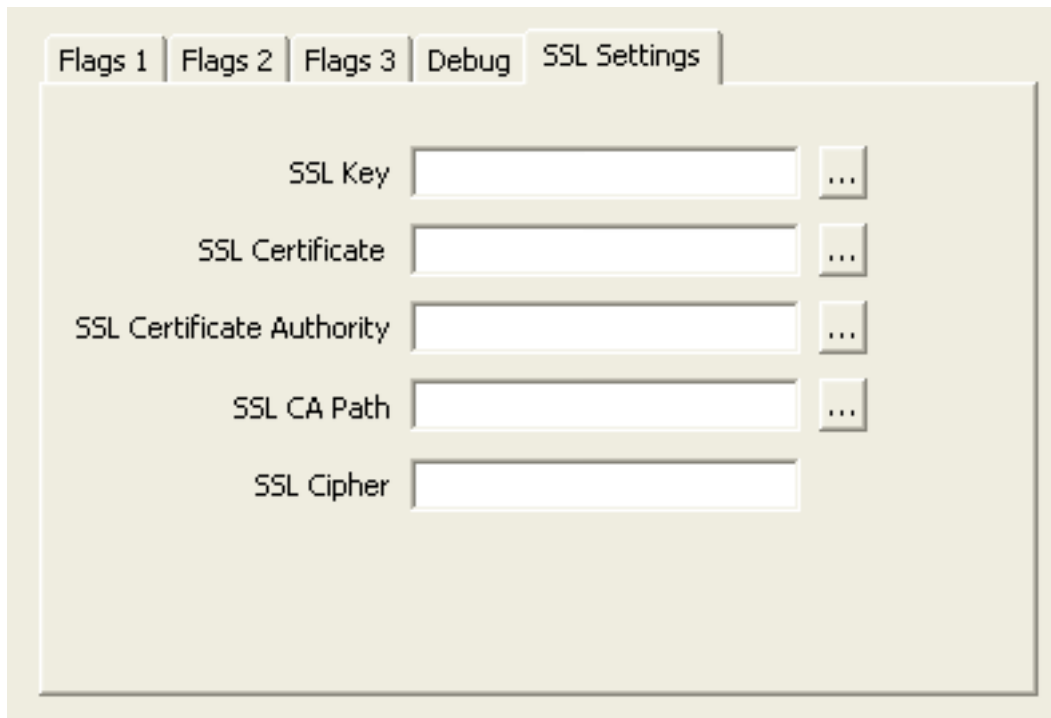

Enable safe options (see documentation)

Enable automatic reconnect

Enable SQL\_AUTO\_IS\_NULL

The **Details** button opens a tabbed display where you set additional options:

- **Flags 1**, **Flags 2**, and **Flags 3** enable you to select the additional flags for the DSN connection. For more information on these flags, see [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).
- **Debug** lets you turn on ODBC debugging to record the queries you execute through the DSN to the `myodbc.sql` file. For more information, see [Section 21.1.4.8, “Getting an ODBC Trace File”](#).
- **SSL Settings** configures the additional options required for using the Secure Sockets Layer (SSL) when communicating with MySQL server. Note that you must also enable SSL and configure the MySQL server with suitable certificates to communicate over SSL.

The **Advanced** tab lets you configure Connector/ODBC connection parameters. Refer to [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#), for information about the meaning of these options.

#### 21.1.4.3.2. Configuring a Connector/ODBC 5.x DSN on Windows, Using the Command Line

Use `myodbc-installer.exe` when configuring Connector/ODBC 5.1 or later from the command-line.

Execute `myodbc-installer.exe` without arguments to view a list of available options.

#### 21.1.4.3.3. Troubleshooting ODBC Connection Problems

This section answers Connector/ODBC connection-related questions.

- **While configuring a Connector/ODBC DSN, a `Could Not Load Translator or Setup Library` error occurs**

For more information, refer to [MS KnowledgeBase Article\(Q260558\)](#). Also, make sure you have the latest valid `ct13d32.dll` in your system directory.

- On Windows, the default `myodbc5w.dll` (Unicode) or `myodbc5a.dll` (ANSI) is compiled for optimal performance. To debug Connector/ODBC (for example, to enable tracing), instead use `myodbc5d.dll`. To install this file, copy `myodbc5d.dll` over the installed `myodbc5w.dll` or `myodbc5a.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging, because the debug version may cause performance issues.

#### 21.1.4.4. Configuring a Connector/ODBC DSN on Mac OS X

To configure a DSN on Mac OS X, you can either use the command-line utility (`myodbc-installer` with connector/ODBC 5.1, or `myodbc3i` with connector/OCBC 3.51), edit the `odbc.ini` file within the `Library/ODBC` directory of the user, or use the ODBC Administrator GUI. If you have Mac OS X 10.2 or earlier, refer to [Section 21.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#). Select whether to create a User DSN or a System DSN. When adding a System DSN, you might need to authenticate with the system. Click the padlock and enter a user and password with administrator privileges.

For correct operation of ODBC Administrator, ensure that the `/Library/ODBC/odbc.ini` file used to set up ODBC connectivity and DSNs are writable by the `admin` group. If this file is not writable by this group, then the ODBC Administrator may fail, or may appear to work but not generate the correct entry.

#### Warning

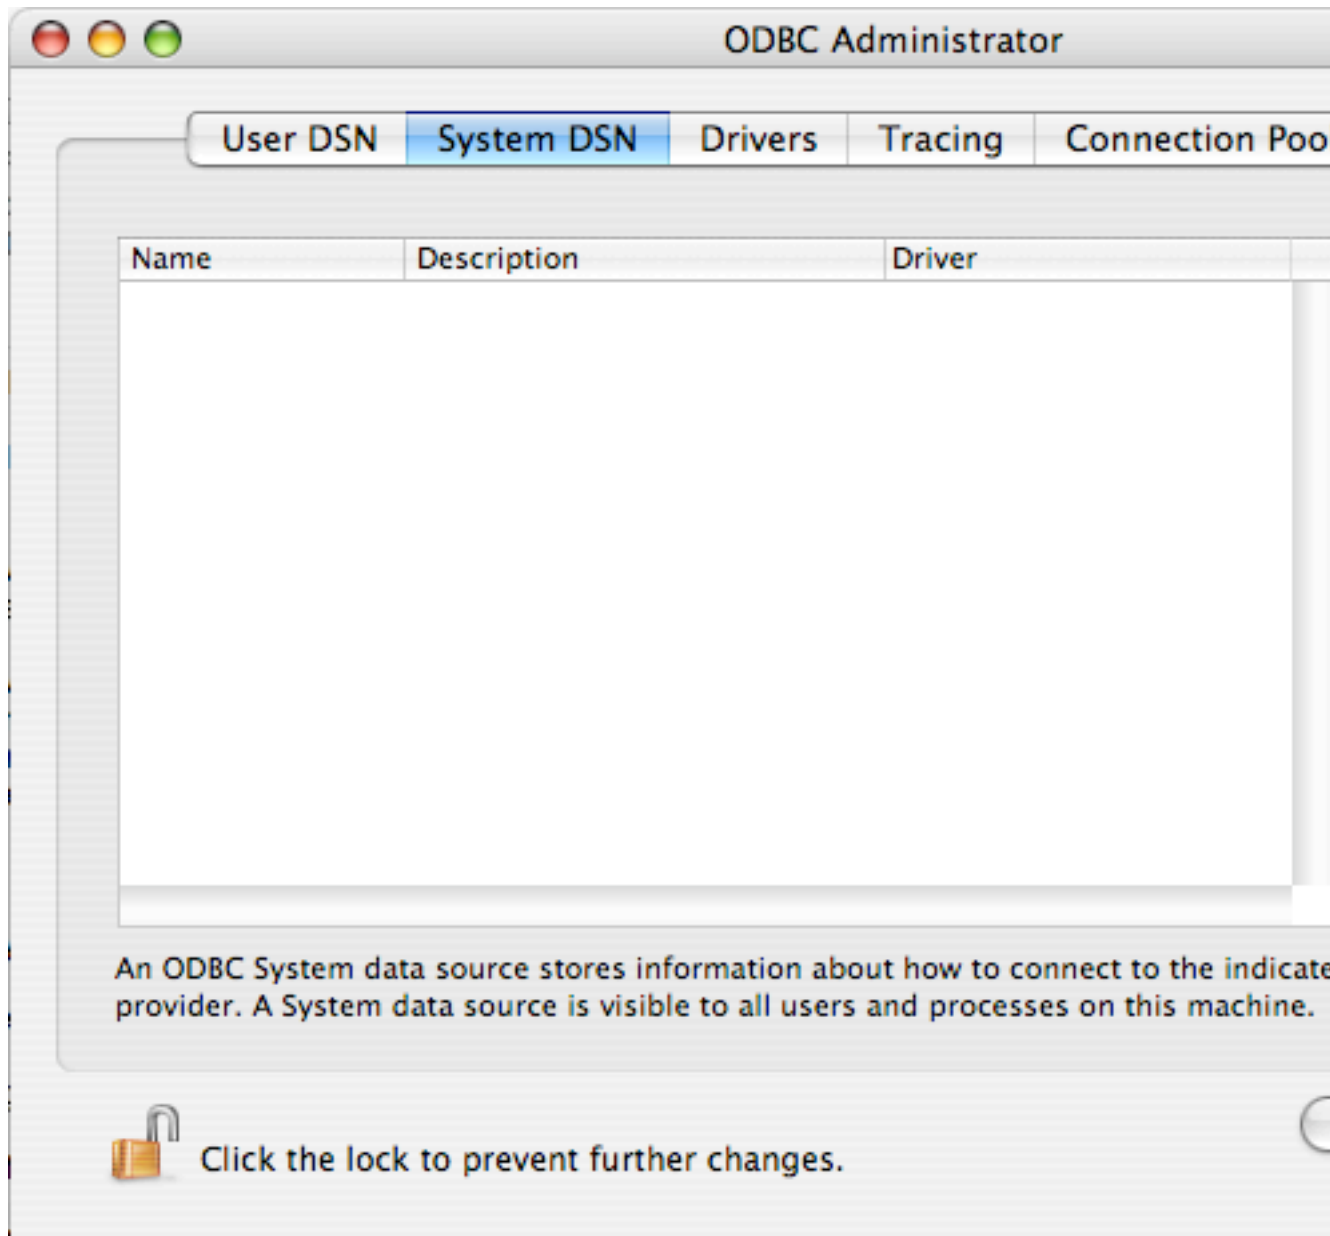

There are known issues with the Mac OS X ODBC Administrator and Connector/ODBC that may prevent you from creating a DSN using this method. In this case, use the command line or edit the `odbc.ini` file directly. Note that existing DSNs or those that you create using the `myodbc3i` or `myodbc-installer` tool can still be checked and edited using ODBC Administrator.

To create a DSN using the `myodbc3i` utility, you need only specify the DSN type and the DSN connection string. For example:

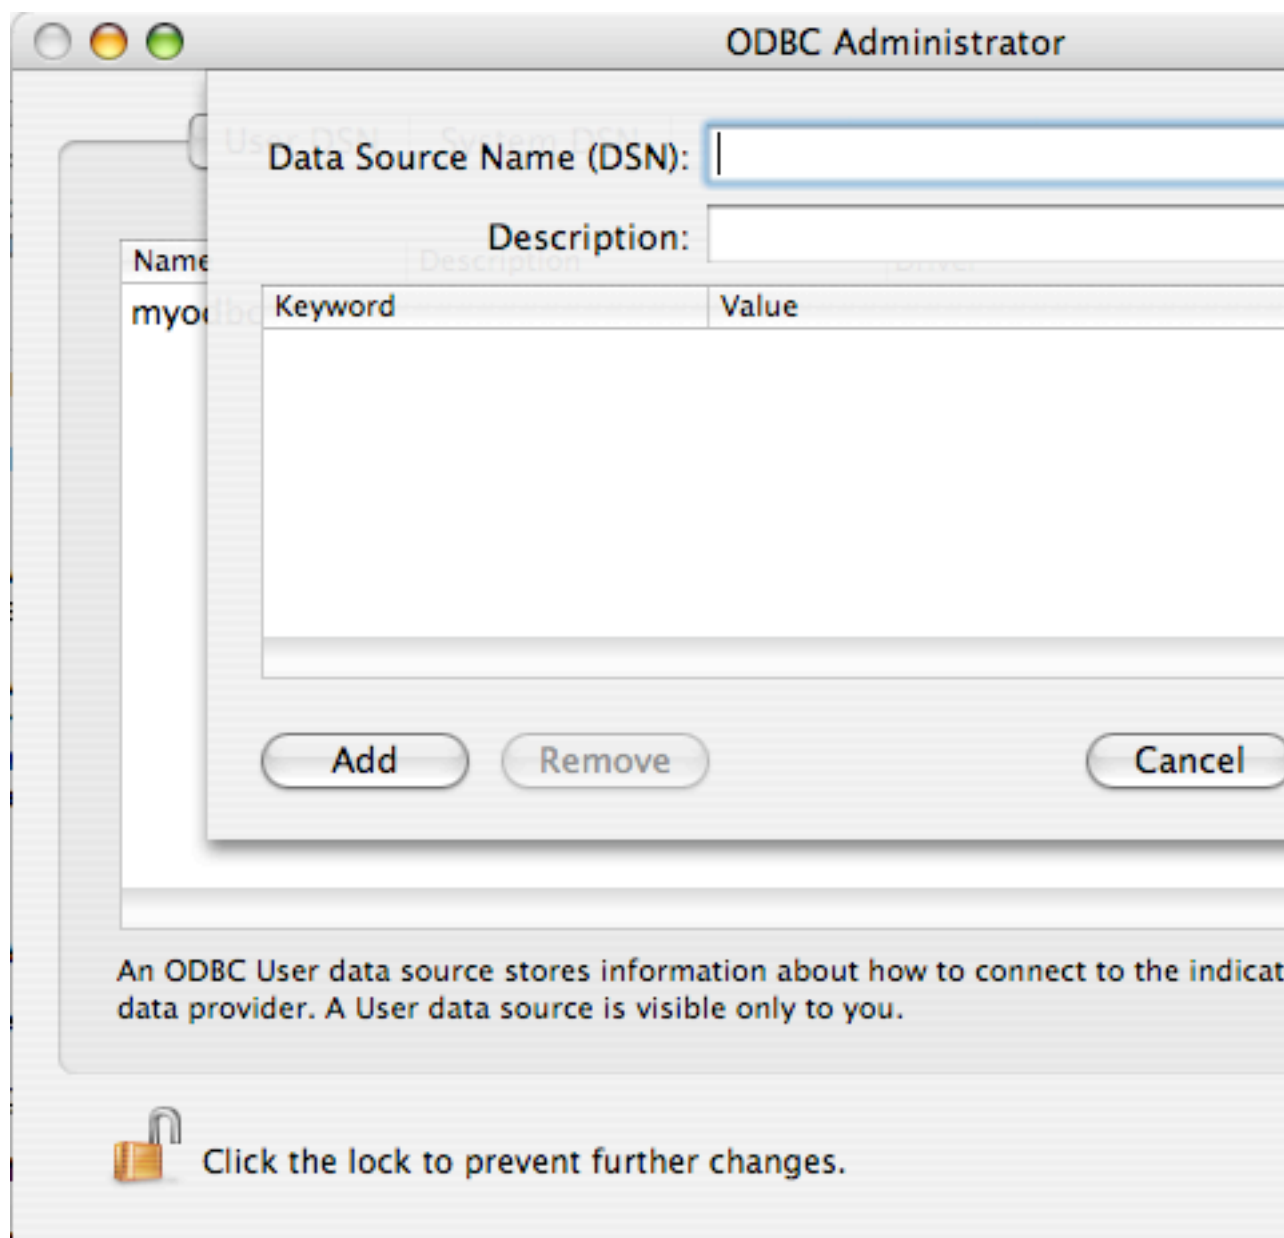

```
shell> myodbc3i -a -s -t"DSN=mydb;DRIVER=MySQL ODBC 3.51 Driver;SERVER=mysql;USER=username;PASSWORD=pa
```

To use ODBC Administrator:

1. Open the ODBC Administrator from the [Utilities](#) folder in the [Applications](#) folder.

2. On the User DSN or System DSN panel, click **Add**.
3. Select the Connector/ODBC driver and click **OK**.
4. You will be presented with the **Data Source Name** dialog. Enter the **Data Source Name** and an optional **Description** for the DSN.

5. Click **Add** to add a new keyword/value pair to the panel. Configure at least four pairs to specify the [server](#), [username](#), [password](#) and [database](#) connection parameters. See [Section 21.1.4.2, "Connector/ODBC Connection Parameters"](#).
6. Click **OK** to add the DSN to the list of configured data source names.

A completed DSN configuration may look like this:

Data Source Name (DSN): **WorldSample**

Description: **Connection to sample World database**

Keyword	Value
server	mysql
user	sakila
password	Sample
database	test_world

Buttons: Add, Remove, Cancel, OK

You can configure other ODBC options in your DSN by adding further keyword/value pairs and setting the corresponding values. See [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).

#### 21.1.4.5. Configuring a Connector/ODBC DSN on Unix

On [Unix](#), you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc3` as the DSN name for Connector/ODBC 3.51:

```

;
; odbc.ini configuration for Connector/ODBC and Connector/ODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc3      = MyODBC 3.51 Driver DSN

[myodbc3]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = Connector/ODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION      = 3
SOCKET      =

[Default]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = Connector/ODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION      = 3
SOCKET      =

```

Refer to the [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

**Note**

If you are using `unixODBC`, you can use the following tools to set up the DSN:

- `ODBCConfig` GUI tool ([HOWTO: ODBCConfig](#))
- `odbcinst`

In some cases when using `unixODBC`, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

### 21.1.4.6. Connecting Without a Predefined DSN

You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for Connector/ODBC using DSN-Less connections:

#### For Connector/ODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
SERVER=localhost;\
DATABASE=test;\
USER=venu;\
PASSWORD=venu;\
OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
"SERVER=localhost;"
"DATABASE=test;"
"USER=venu;"
"PASSWORD=venu;"
"OPTION=3;"
```

**Note.** On Mac OS X, you might need to specify the full path to the Connector/ODBC driver library.

Refer to [Section 21.1.4.2, "Connector/ODBC Connection Parameters"](#) for the list of connection parameters that can be supplied.

### 21.1.4.7. ODBC Connection Pooling

Connection pooling enables the ODBC driver to re-use existing connections to a given database from a pool of connections, instead of opening a new connection each time the database is accessed. By enabling connection pooling you can improve the overall performance of your application by lowering the time taken to open a connection to a database in the connection pool.

For more information about connection pooling: <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470>.

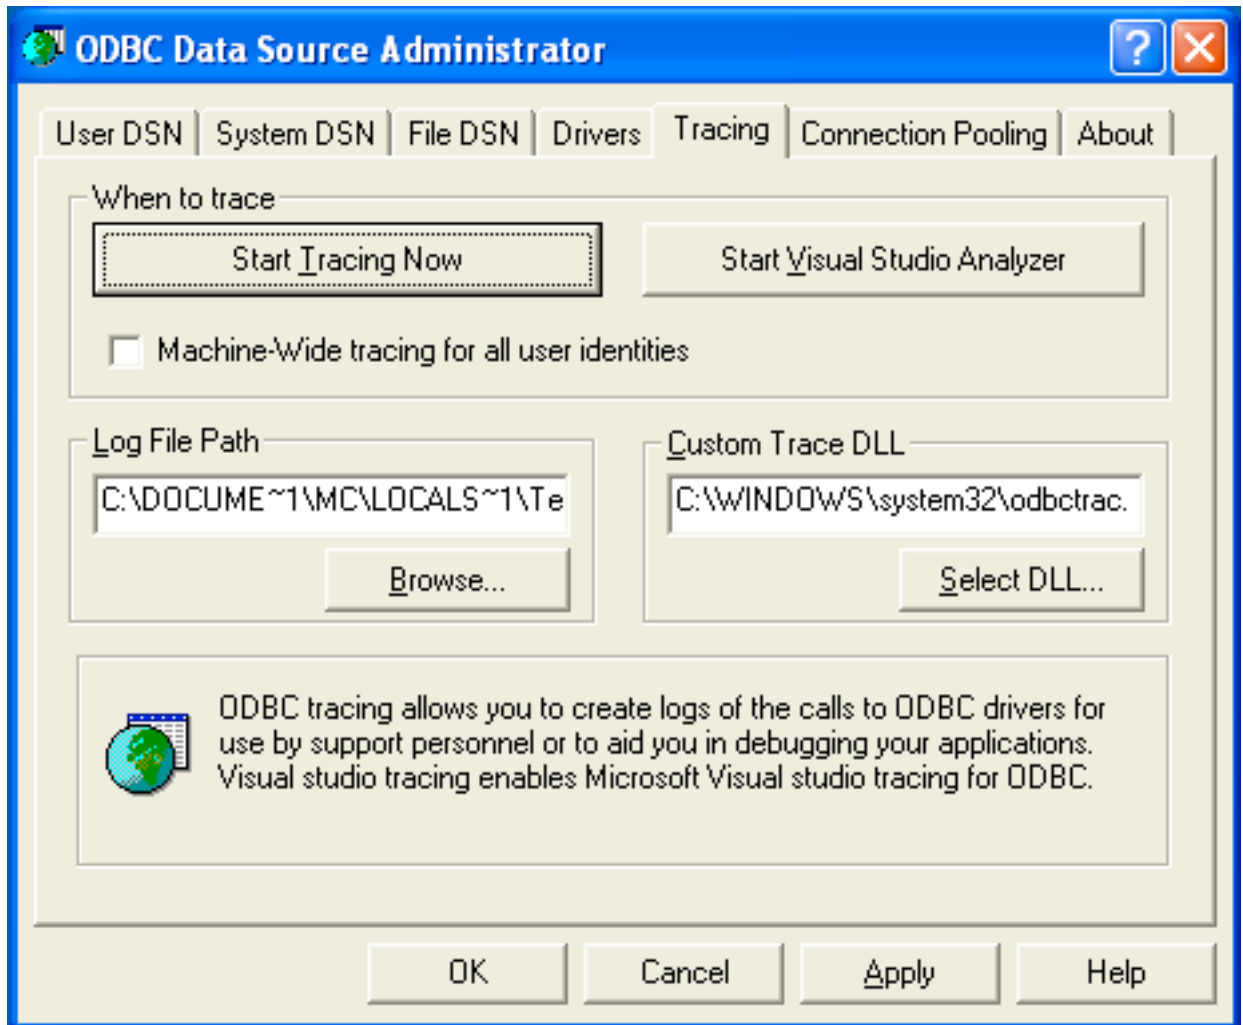

### 21.1.4.8. Getting an ODBC Trace File

If you encounter difficulties or problems with Connector/ODBC, start by making a log file from the `ODBC Manager` and Connector/ODBC. This is called *tracing*, and is enabled through the ODBC Manager. The procedure for this differs for Windows, Mac OS X and Unix.

### 21.1.4.8.1. Enabling ODBC Tracing on Windows

To enable the trace option on Windows:

1. The [Tracing](#) tab of the ODBC Data Source Administrator dialog box lets you configure the way ODBC function calls are traced.

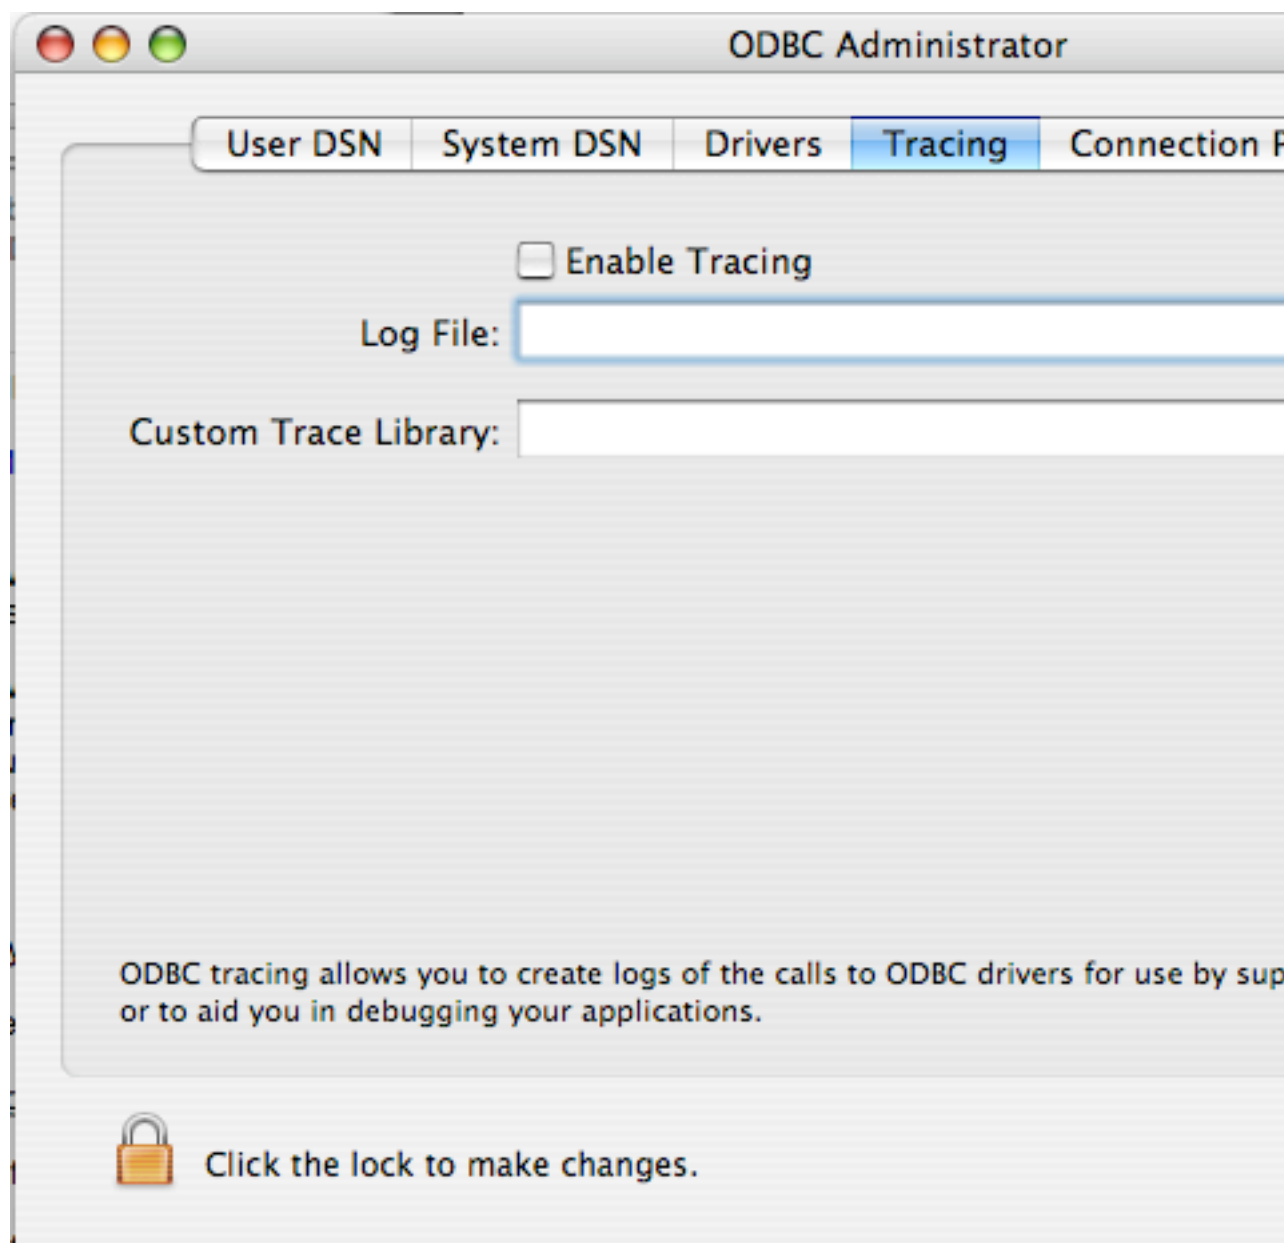

2. When you activate tracing from the [Tracing](#) tab, the [Driver Manager](#) logs all ODBC function calls for all subsequently run applications.
3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.
4. Tracing ceases only after you click [Stop Tracing Now](#). Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

### 21.1.4.8.2. Enabling ODBC Tracing on Mac OS X

To enable the trace option on Mac OS X 10.3 or later, use the [Tracing](#) tab within ODBC Administrator .

1. Open the ODBC Administrator.
2. Select the [Tracing](#) tab.

3. Select the `Enable Tracing` check box.
4. Enter the location to save the Tracing log. To append information to an existing log file, click the `Choose...` button.

#### 21.1.4.8.3. Enabling ODBC Tracing on Unix

To enable the trace option on Mac OS X 10.2 (or earlier) or Unix, add the `trace` option to the ODBC configuration:

1. On Unix, explicitly set the `Trace` option in the `ODBC.INI` file.

Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

```
TraceFile = /tmp/odbc.trace
Trace     = 1
```

`TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at [HOWTO-ODBCConfig](#).

#### 21.1.4.8.4. Enabling a Connector/ODBC Log

To generate a Connector/ODBC log, do the following:

1. Within Windows, enable the `Trace Connector/ODBC` option flag in the Connector/ODBC connect/configure screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the `myodbcd.dll` driver, see [Section 21.1.4.3.3, "Troubleshooting ODBC Connection Problems"](#).

On Mac OS X, Unix, or if you are using a DSN-less connection, either supply `OPTION=4` in the connection string, or set the corresponding keyword/value pair in the DSN.

2. Start your application and try to get it to fail. Then check the Connector/ODBC trace file to find out what could be wrong.

If you need help determining what is wrong, see [Section 21.1.8.1, "Connector/ODBC Community Support"](#).

### 21.1.5. Connector/ODBC Examples

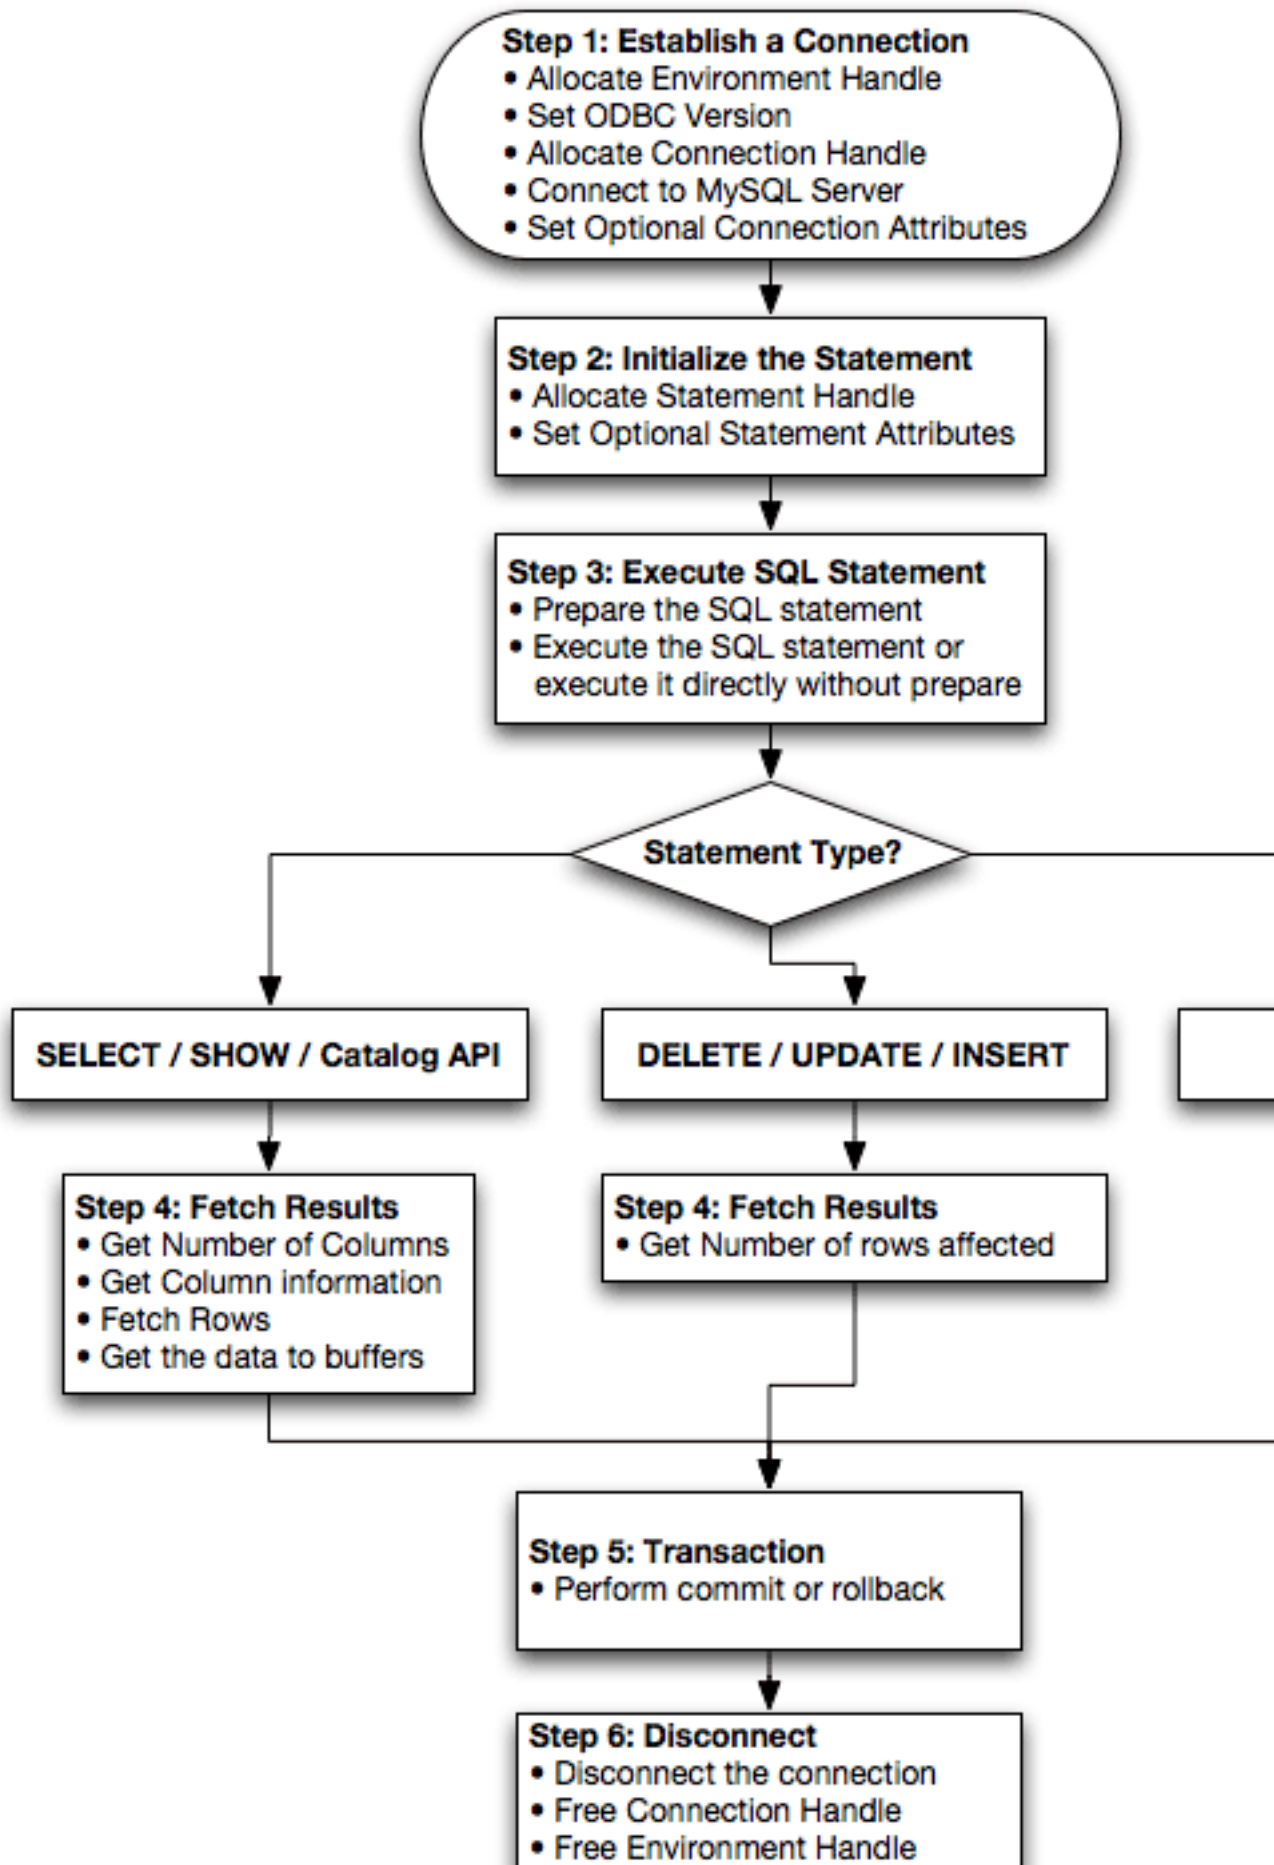

Once you have configured a DSN to provide access to a database, how you access and use that connection is dependent on the application or programming language. As ODBC is a standardized interface, any application or language that supports ODBC can use the DSN and connect to the configured database.

#### 21.1.5.1. Basic Connector/ODBC Application Steps

Interacting with a MySQL server from an applications using the Connector/ODBC typically involves the following operations:

- Configure the Connector/ODBC DSN.
- Connect to MySQL server.
- Initialization operations.
- Execute SQL statements.
- Retrieve results.
- Perform [transactions](#).
- Disconnect from the server.

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

### 21.1.5.2. Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC

A typical situation where you would install Connector/ODBC is to access a database on a Linux or Unix host from a Windows machine.

As an example of the process required to set up access between two machines, the steps below take you through the basic steps. These instructions assume that you connect to system ALPHA from system BETA with a user name and password of `myuser` and `mypassword`.

On system ALPHA (the MySQL server) follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a user name of `myuser` that can connect from system BETA using a password of `myuser` to the database `test`:

```
GRANT ALL ON test.* to 'myuser'@'BETA' IDENTIFIED BY 'mypassword';
```

For more information about MySQL privileges, refer to [Section 6.3, "MySQL User Account Management"](#).

On system BETA (the Connector/ODBC client), follow these steps:

1. Configure a Connector/ODBC DSN using parameters that match the server, database and authentication information that you have just configured on system ALPHA.

Parameter	Value	Comment
DSN	remote_test	A name to identify the connection.
SERVER	ALPHA	The address of the remote server.
DATABASE	test	The name of the default database.
USER	myuser	The user name configured for access to this database.
PASSWORD	mypassword	The password for <code>myuser</code> .

2. Using an ODBC-capable application, such as Microsoft Office, connect to the MySQL server using the DSN you have just created. If the connection fails, use tracing to examine the connection process. See [Section 21.1.4.8, "Getting an ODBC Trace File"](#), for more information.

### 21.1.5.3. Connector/ODBC and Third-Party ODBC Tools

Once you have configured your Connector/ODBC DSN, you can access your MySQL database through any application that supports the ODBC interface, including programming languages and third-party applications. This section contains guides and help on using Connector/ODBC with various ODBC-compatible tools and applications, including Microsoft Word, Microsoft Excel and Adobe/Macromedia ColdFusion.

Connector/ODBC has been tested with the following applications:

Publisher	Application	Notes
Adobe	ColdFusion	Formerly Macromedia ColdFusion
Borland	C++ Builder	
	Builder 4	
	Delphi	
Business Objects	Crystal Reports	
Claris	Filemaker Pro	

Publisher	Application	Notes
Corel	Paradox	
Computer Associates	Visual Objects	Also known as CAVO
	AllFusion ERwin Data Modeler	
Gupta	Team Developer	Previously known as Centura Team Developer; Gupta SQL/Windows
Gensym	G2-ODBC Bridge	
Inline	iHTML	
Lotus	Notes	Versions 4.5 and 4.6
Microsoft	Access	
	Excel	
	Visio Enterprise	
	Visual C++	
	Visual Basic	
	ODBC.NET	Using C#, Visual Basic, C++
	FoxPro	
	Visual Interdev	
OpenOffice.org	OpenOffice.org	
Perl	DBD::ODBC	
Pervasive Software	DataJunction	
Sambar Technologies	Sambar Server	
SPSS	SPSS	
SoftVelocity	Clarion	
SQLExpress	SQLExpress for Xbase+ +	
Sun	StarOffice	
SunSystems	Vision	
Sybase	PowerBuilder	
	PowerDesigner	
theKompany.com	Data Architect	

If you know of any other applications that work with Connector/ODBC, please send mail to [myodbc@lists.mysql.com](mailto:myodbc@lists.mysql.com) about them.

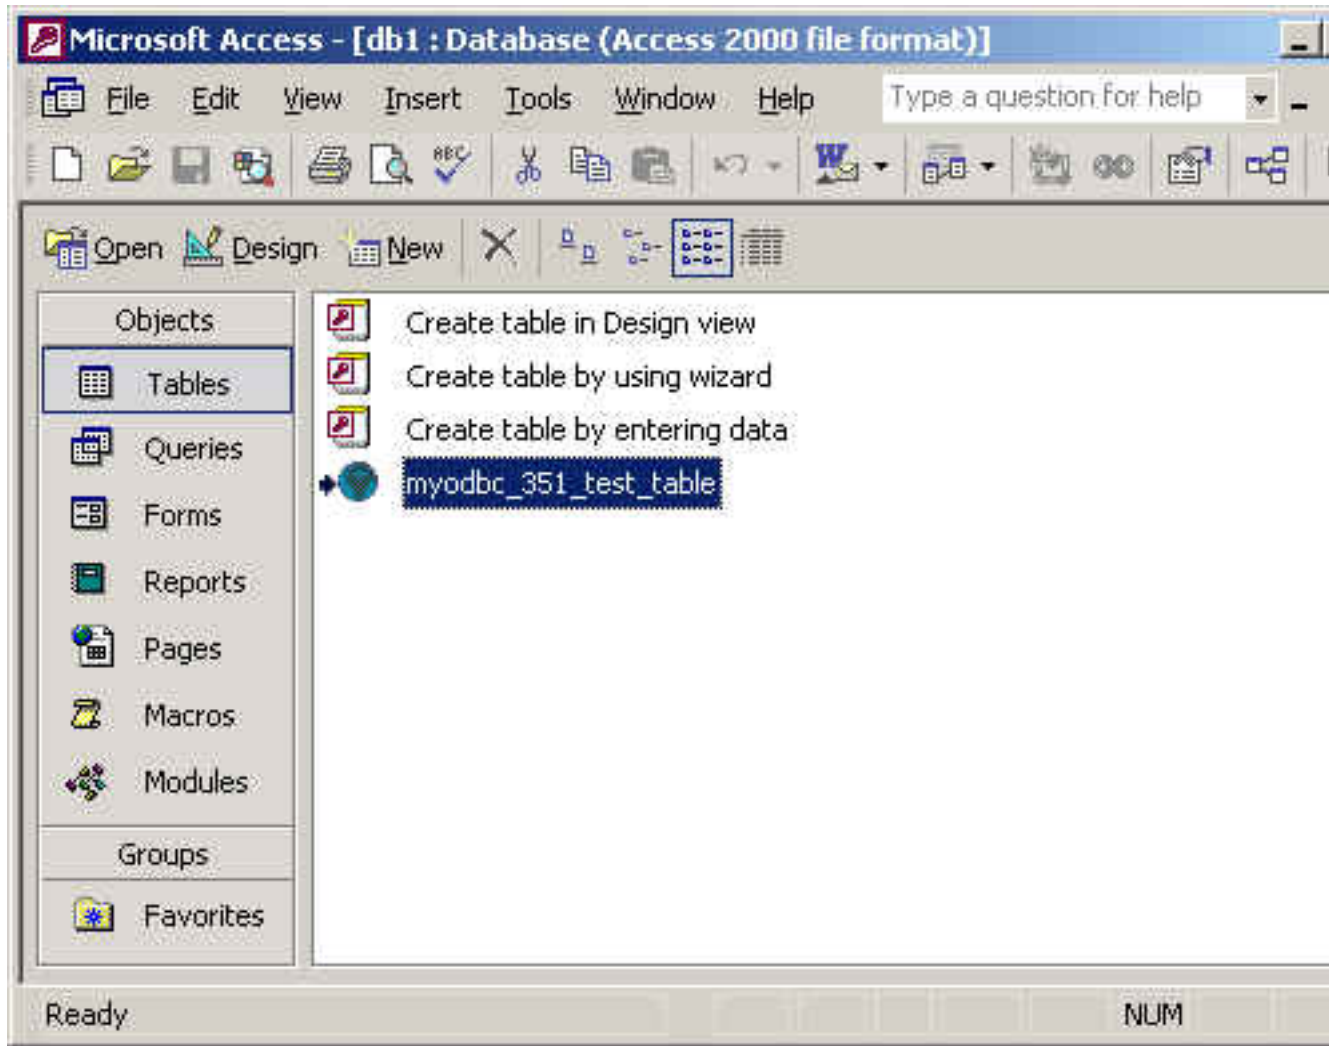

#### 21.1.5.4. Using Connector/ODBC with Microsoft Access

You can use MySQL database with Microsoft Access using Connector/ODBC. The MySQL database can be used as an import source, an export source, or as a linked table for direct use within an Access application, so you can use Access as the front-end interface to a MySQL database.

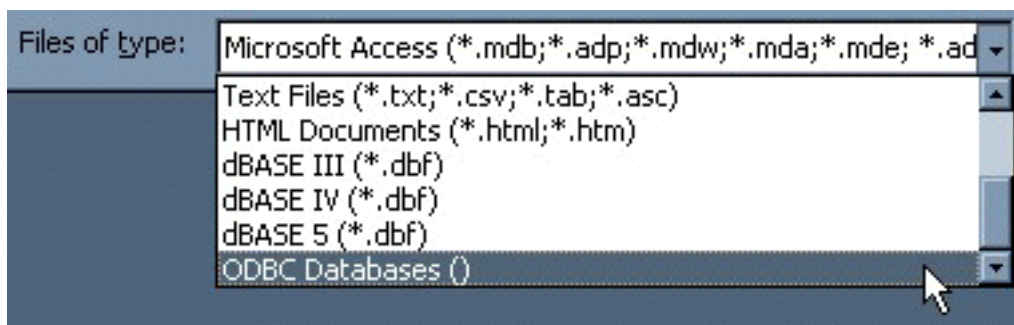

##### 21.1.5.4.1. Exporting Access Data to MySQL

To export a table of data from an Access database to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the [table](#) or [query](#) to export, and then in the [File](#) menu, select [Export](#).
3. In the [Export Object Type Object name To](#) dialog box, in the [Save As Type](#) box, select [ODBC Databases \(\)](#) as shown here:

4. In the [Export](#) dialog box, enter a name for the file (or use the suggested name), and then select [OK](#).
5. The [Select Data Source](#) dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the [File Data Source](#) or [Machine Data Source](#) tab, and then double-click the [Connector/ODBC](#) or [Connector/ODBC 3.51](#) data source to export to. To define a new data source for [Connector/ODBC](#), please [Section 21.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

**Note**

Ensure that the information that you are exporting to the MySQL table is valid for the corresponding MySQL data types. Values that are outside of the supported range of the MySQL data type but valid within Access may trigger an “overflow” error during the export.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

#### 21.1.5.4.2. Importing MySQL Data to Access

To import a table or tables from MySQL to Access, follow these instructions:

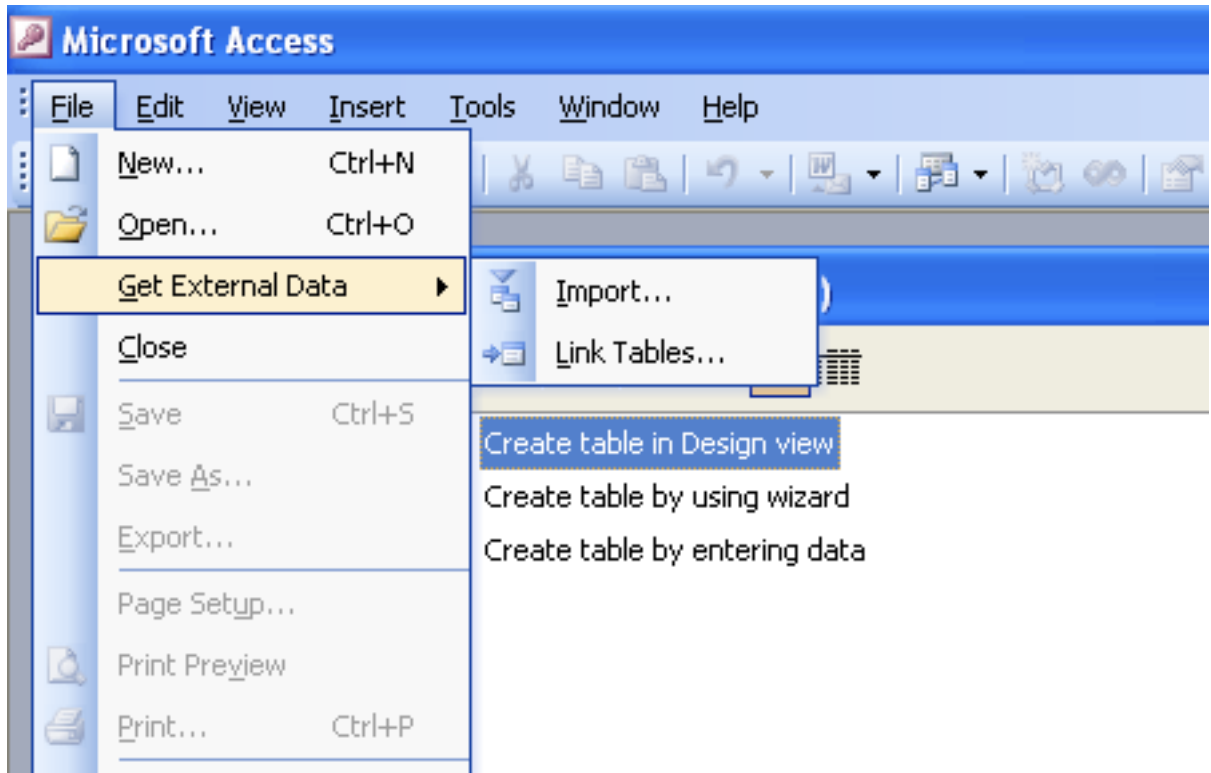

1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the **File** menu, point to **Get External Data**, and then click **Import**.
3. In the **Import** dialog box, in the Files Of Type box, select **ODBC Databases (J)**. The Select Data Source dialog box lists the defined data sources **The Select Data Source** dialog box is displayed; it lists the defined data source names.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click **OK**.
5. Microsoft Access connects to the MySQL server through **ODBC data source** and displays the list of tables that you can **import**.
6. Click each table to **import**, and then click **OK**.

#### 21.1.5.4.3. Using Microsoft Access as a Front-end to MySQL

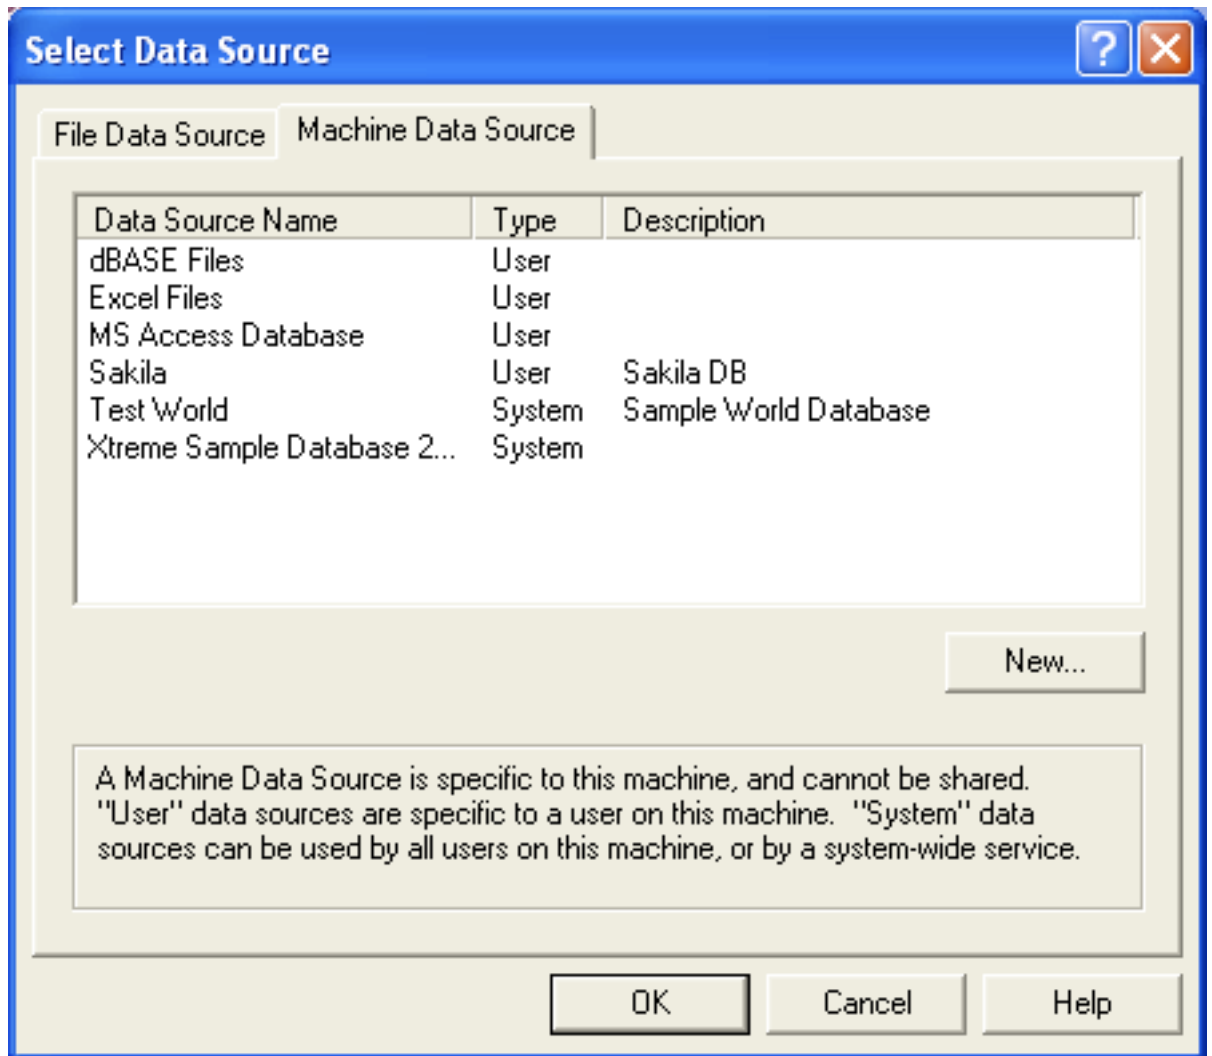

You can use Microsoft Access as a front end to a MySQL database by linking tables within your Microsoft Access database to tables that exist within your MySQL database. When a query is requested on a table within Access, ODBC is used to execute the queries on the MySQL database instead.

**To create a linked table:**

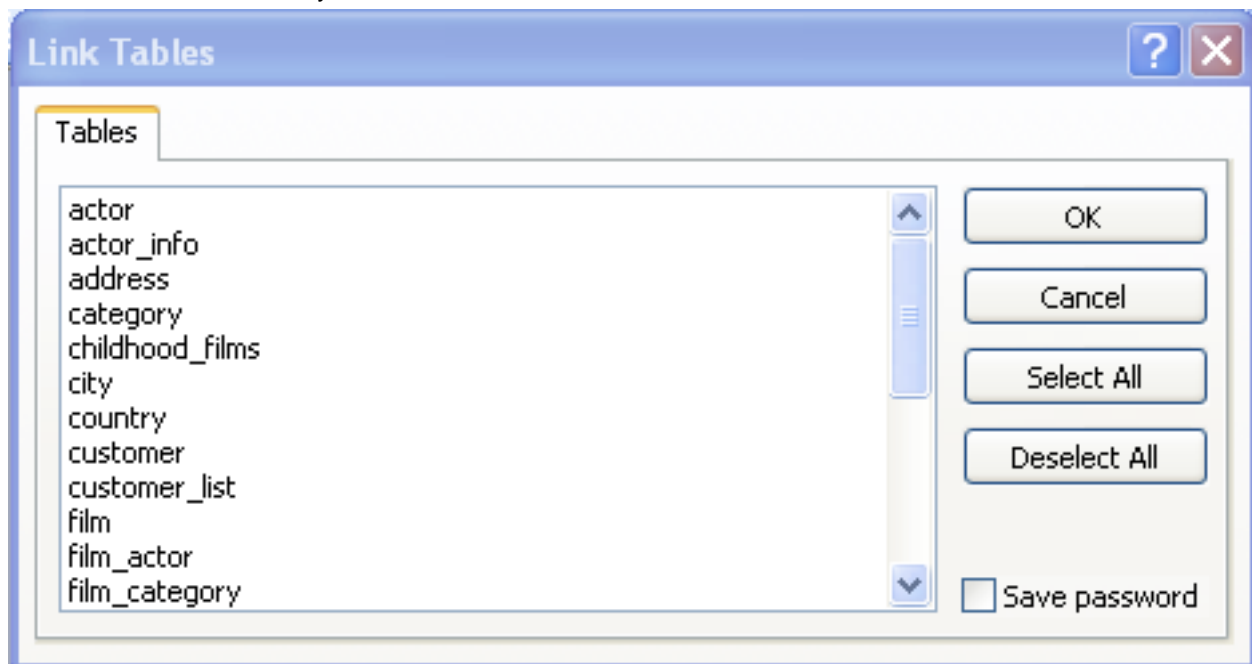

1. Open the Access database that you want to link to MySQL.
2. From the **File**, choose **Get External Data->Link Tables**.

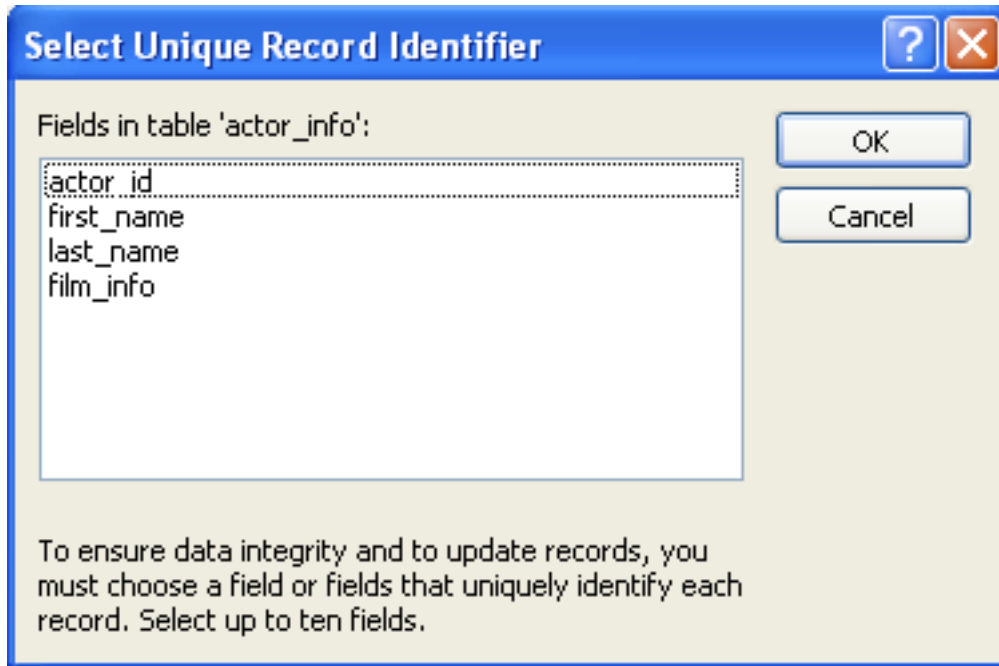

3. From the browser, choose **ODBC Databases ()** from the **Files of type** pop-up.
4. In the **Select Data Source** window, choose an existing DSN, either from a **File Data Source** or **Machine Data Source**. You can also create a new DSN using the **New...** button. For more information on creating a DSN see [Section 21.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

- In the **Link Tables** dialog, select one or more tables from the MySQL database. A link will be created to each table that you select from this list.

6. If Microsoft Access is unable to determine the unique record identifier for a table automatically then it may ask you to confirm the column, or combination of columns, to be used to uniquely identify each row from the source table. Select the columns to use and click **OK**.

Once the process has been completed, you can now build interfaces and queries to the linked tables just as you would for any Access database.

Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

**To view or refresh links:**

1. Open the database that contains links to MySQL tables.
2. On the **Tools** menu, point to **Add-ins** (**Database Utilities** in Access 2000 or newer), and then click **Linked Table Manager**.
3. Select the check box for the tables whose links you want to refresh.
4. Click **OK** to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the **Select New Location of <table name>** dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

**To change the path for a set of linked tables:**

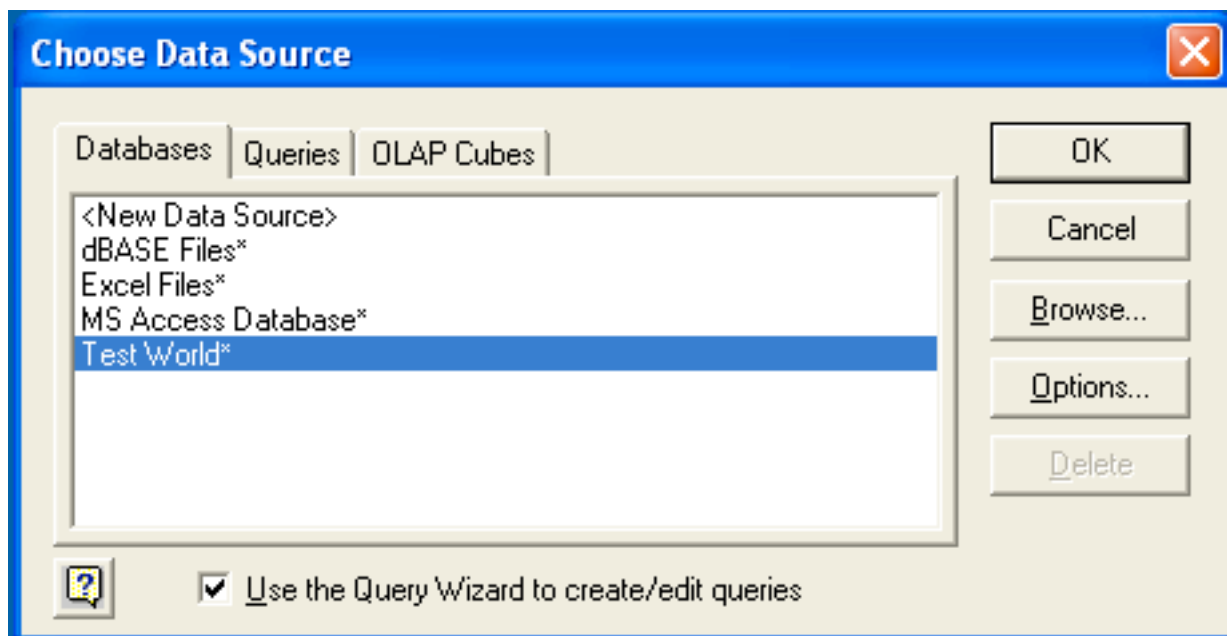

1. Open the database that contains links to tables.
2. On the **Tools** menu, point to **Add-ins** (**Database Utilities** in Access 2000 or newer), and then click **Linked Table Manager**.
3. Select the **Always Prompt For A New Location** check box.
4. Select the check box for the tables whose links you want to change, and then click **OK**.
5. In the **Select New Location of <table name>** dialog box, specify the new location, click **Open**, and then click **OK**.

### 21.1.5.5. Using Connector/ODBC with Microsoft Word or Excel

You can use Microsoft Word and Microsoft Excel to access information from a MySQL database using Connector/ODBC. Within Microsoft Word, this facility is most useful when importing data for mailmerge, or for tables and data to be included in reports. Within Microsoft Excel, you can execute queries on your MySQL server and import the data directly into an Excel Worksheet, presenting the data as a series of rows and columns.

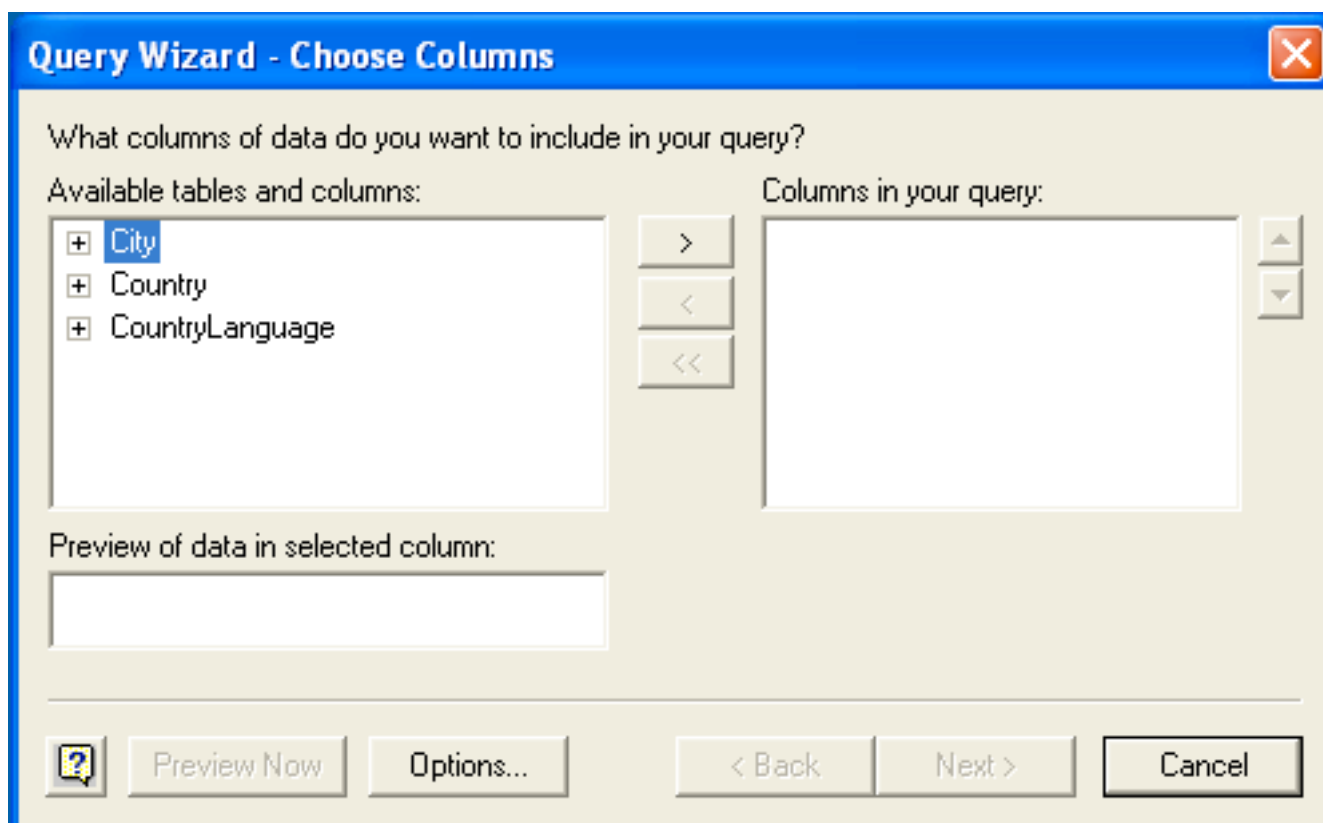

With both applications, data is accessed and imported into the application using Microsoft Query, which lets you execute a query through an ODBC source. You use Microsoft Query to build the SQL statement to be executed, selecting the tables, fields, selection criteria and sort order. For example, to insert information from a table in the World test database into an Excel spreadsheet, using the DSN samples shown in [Section 21.1.4, "Configuring Connector/ODBC"](#):

1. Create a new Worksheet.
2. From the **Data** menu, choose **Import External Data**, and then select **New Database Query**.
3. Microsoft Query will start. First, you need to choose the data source, by selecting an existing Data Source Name.

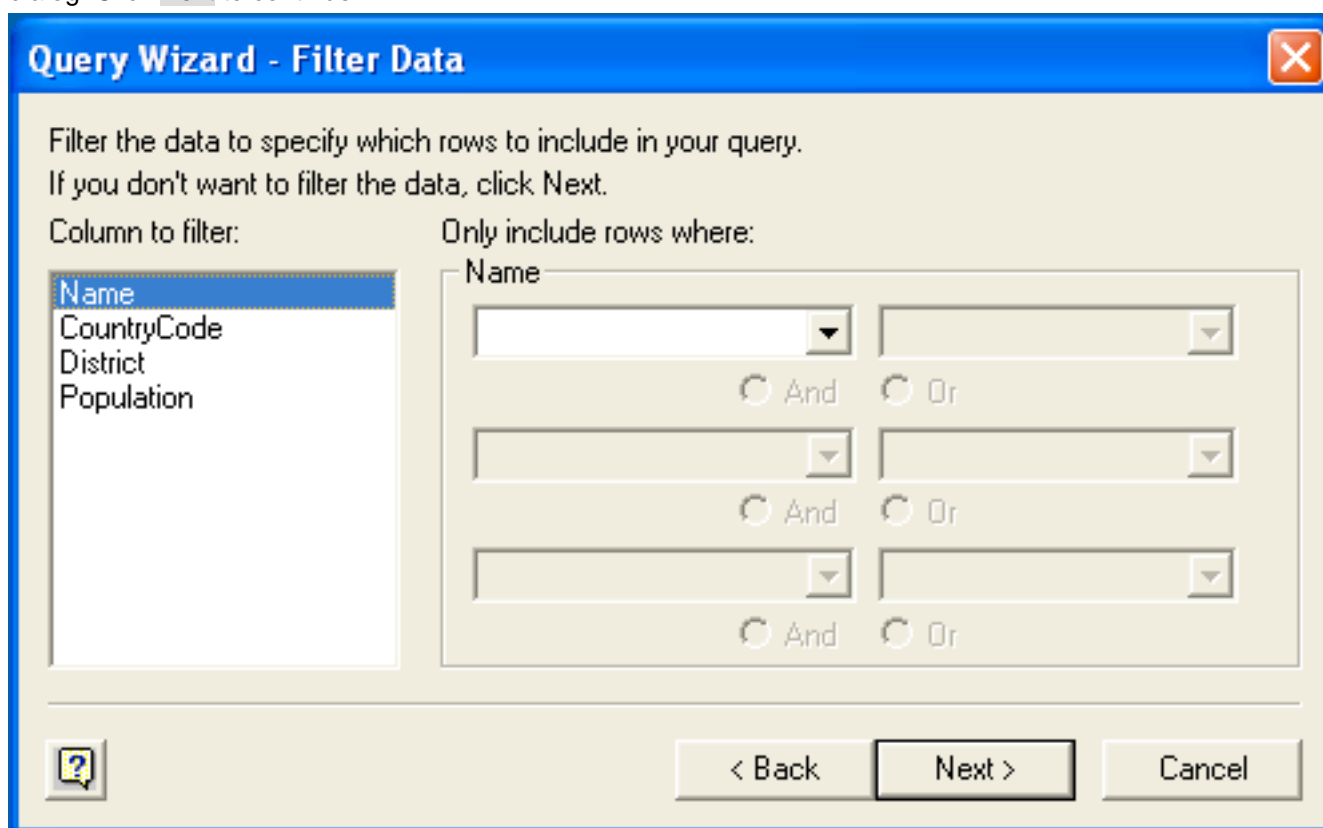

4. Within the **Query Wizard**, choose the columns to import. The list of tables available to the user configured through the DSN is shown on the left, the columns that will be added to your query are shown on the right. The columns you choose are equivalent to those in the first section of a **SELECT** query. Click **Next** to continue.

5. You can filter rows from the query (the equivalent of a `WHERE` clause) using the [Filter Data](#) dialog. Click **Next** to continue.

6. Select an (optional) sort order for the data. This is equivalent to using a `ORDER BY` clause in your SQL query. You can select up to three fields for sorting the information returned by the query. Click **Next** to continue.

**Query Wizard - Sort Order**

Specify how you want your data sorted.  
If you don't want to sort the data, click **Next**.

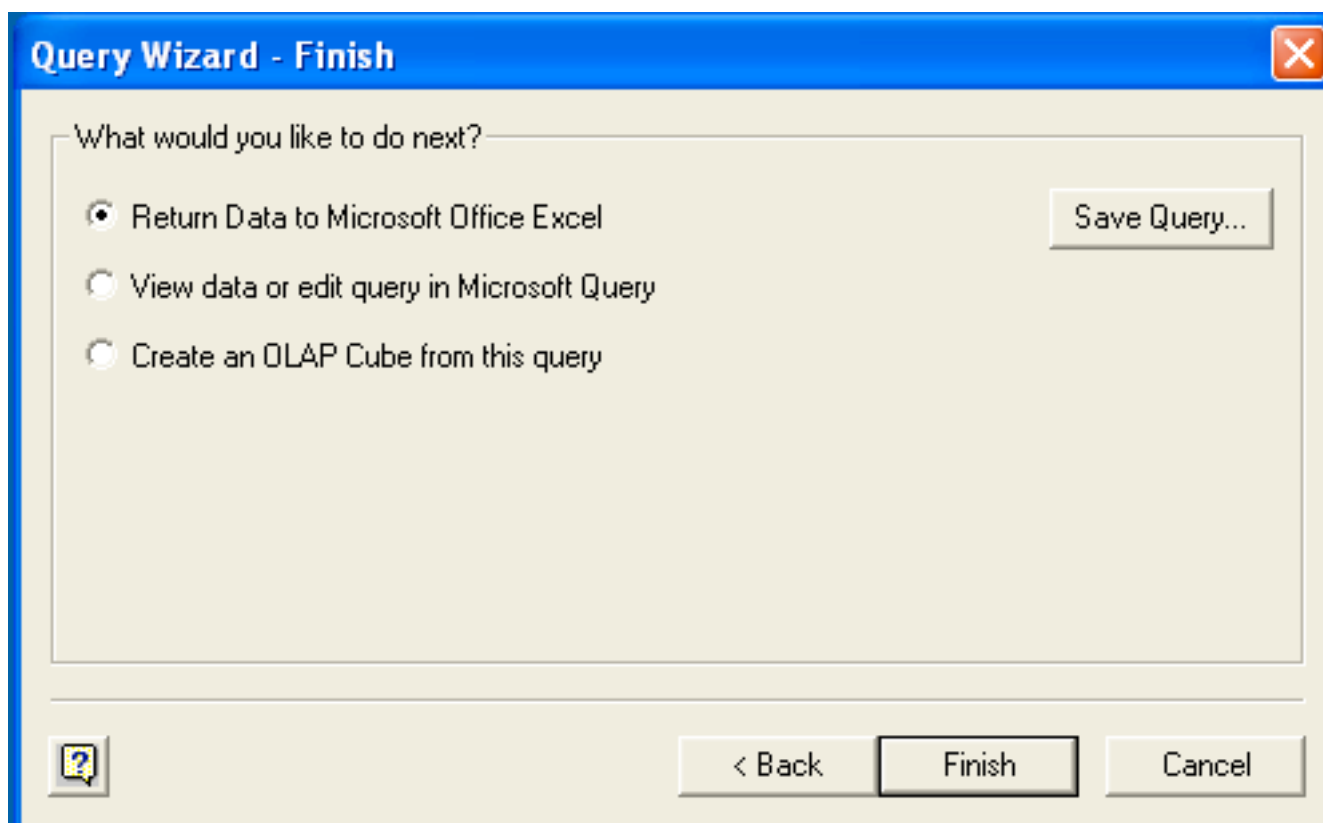

Sort by  
Name  Ascending  Descending

Then by  
 Ascending  Descending

Then by  
 Ascending  Descending

 < Back Next > Cancel

7. Select the destination for your query. You can select to return the data Microsoft Excel, where you can choose a worksheet and cell where the data will be inserted; you can continue to view the query and results within Microsoft Query, where you can edit the SQL query and further filter and sort the information returned; or you can create an OLAP Cube from the query, which can then be used directly within Microsoft Excel. Click **Finish**.

The same process can be used to import data into a Word document, where the data will be inserted as a table. This can be used for mail merge purposes (where the field data is read from a Word table), or where you want to include data and reports within a report or other document.

### 21.1.5.6. Using Connector/ODBC with Crystal Reports

Crystal Reports can use an ODBC DSN to connect to a database from which you to extract data and information for reporting purposes.

#### Note

There is a known issue with certain versions of Crystal Reports where the application is unable to open and browse tables and fields through an ODBC connection. Before using Crystal Reports with MySQL, please ensure that you have update to the latest version, including any outstanding service packs and hotfixes. For more information on this issue, see the [Business\) Objects Knowledgebase](#) for more information.

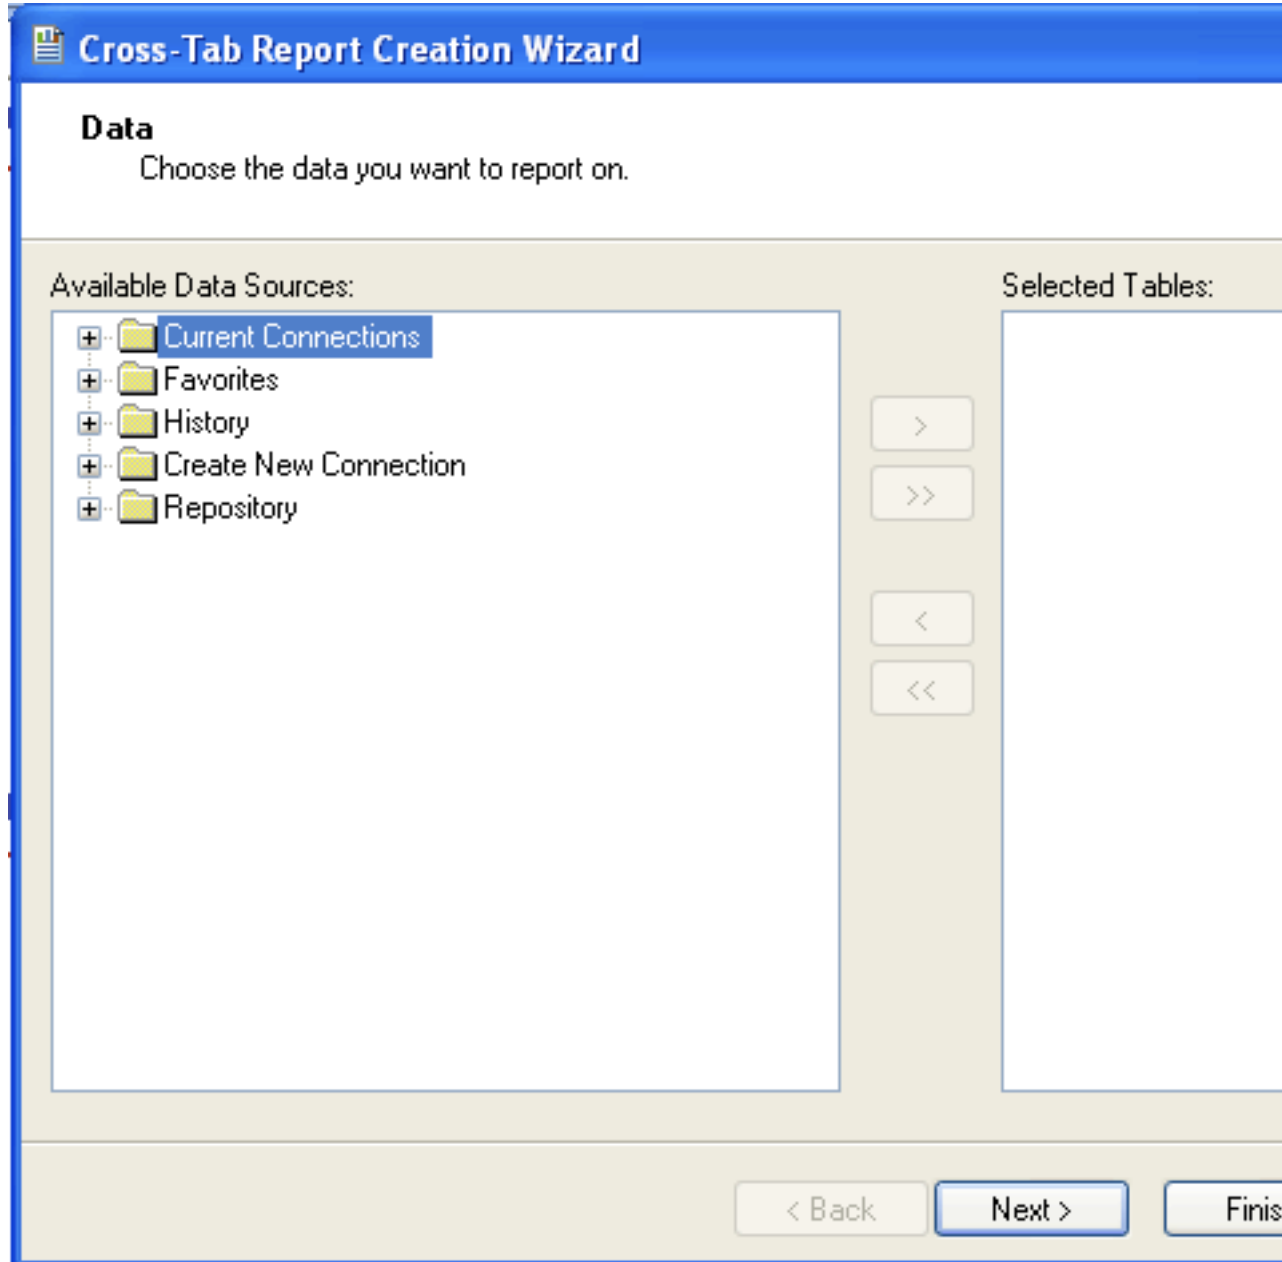

For example, to create a simple crosstab report within Crystal Reports XI, follow these steps:

1. Create a DSN using the [Data Sources \(ODBC\)](#) tool. You can either specify a complete database, including user name and password, or you can build a basic DSN and use Crystal Reports to set the user name and password.

For the purposes of this example, a DSN that provides a connection to an instance of the MySQL Sakila sample database has been created.

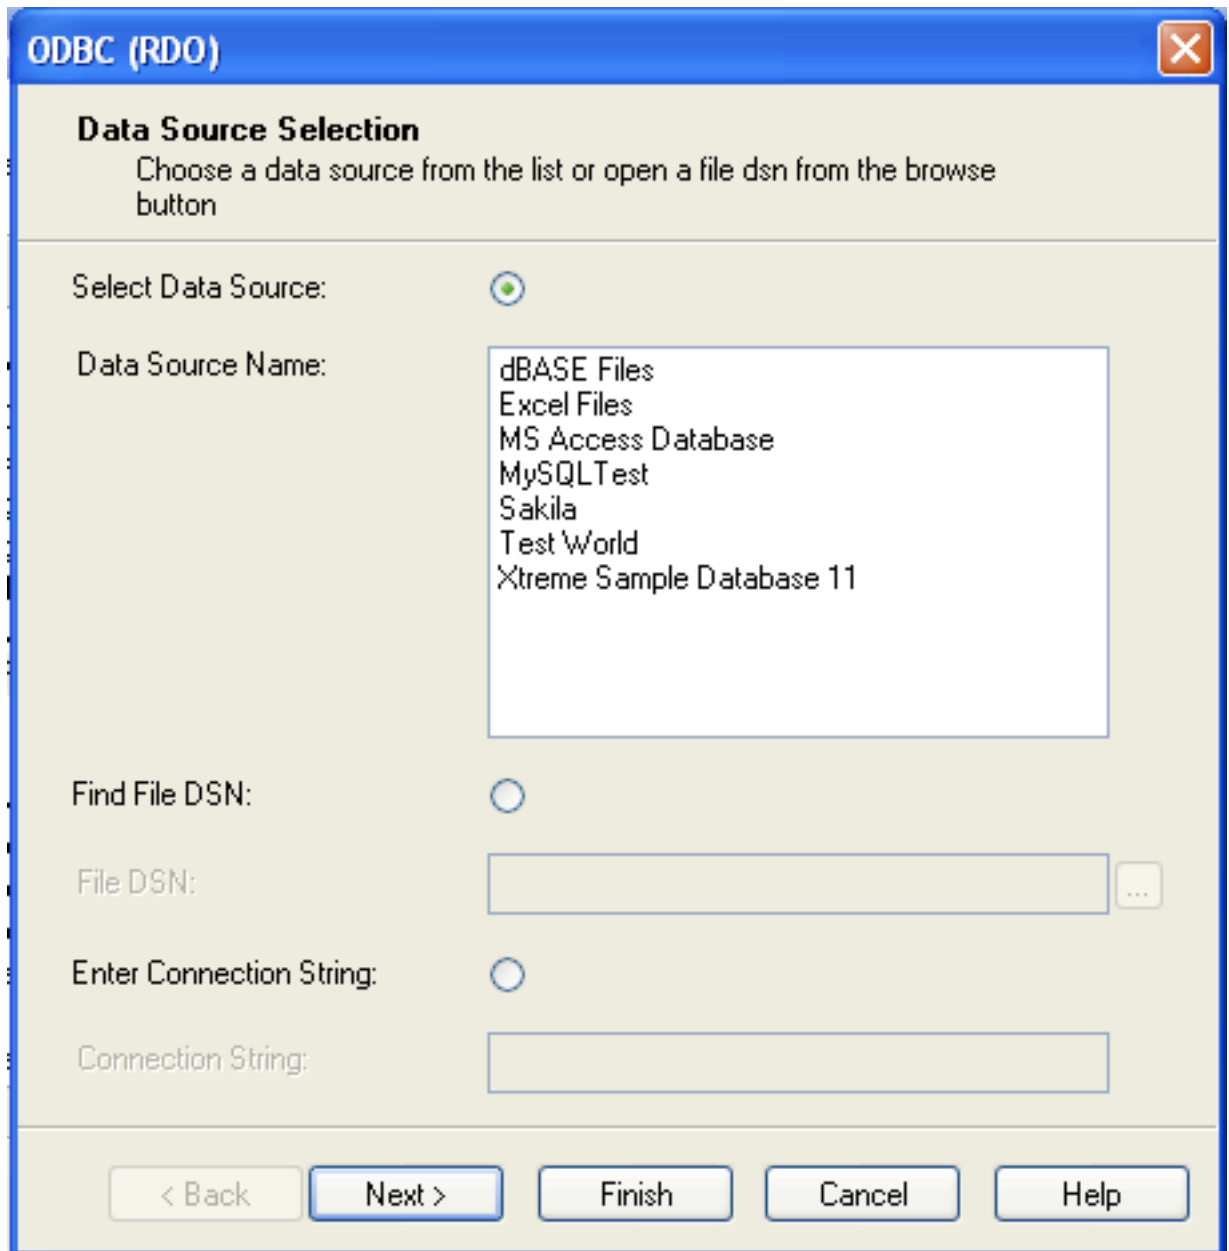

2. Open Crystal Reports and create a new project, or an open an existing reporting project into which you want to insert data from your MySQL data source.
3. Start the Cross-Tab Report Wizard, either by clicking the option on the Start Page. Expand the **Create New Connection** folder, then expand the **ODBC (RDO)** folder to obtain a list of ODBC data sources.

You will be asked to select a data source.

4. When you first expand the **ODBC (RDO)** folder you will be presented the Data Source Selection screen. From here you can select either a pre-configured DSN, open a file-based DSN or enter and manual connection string. For this example, the **Sakila** DSN will be used.

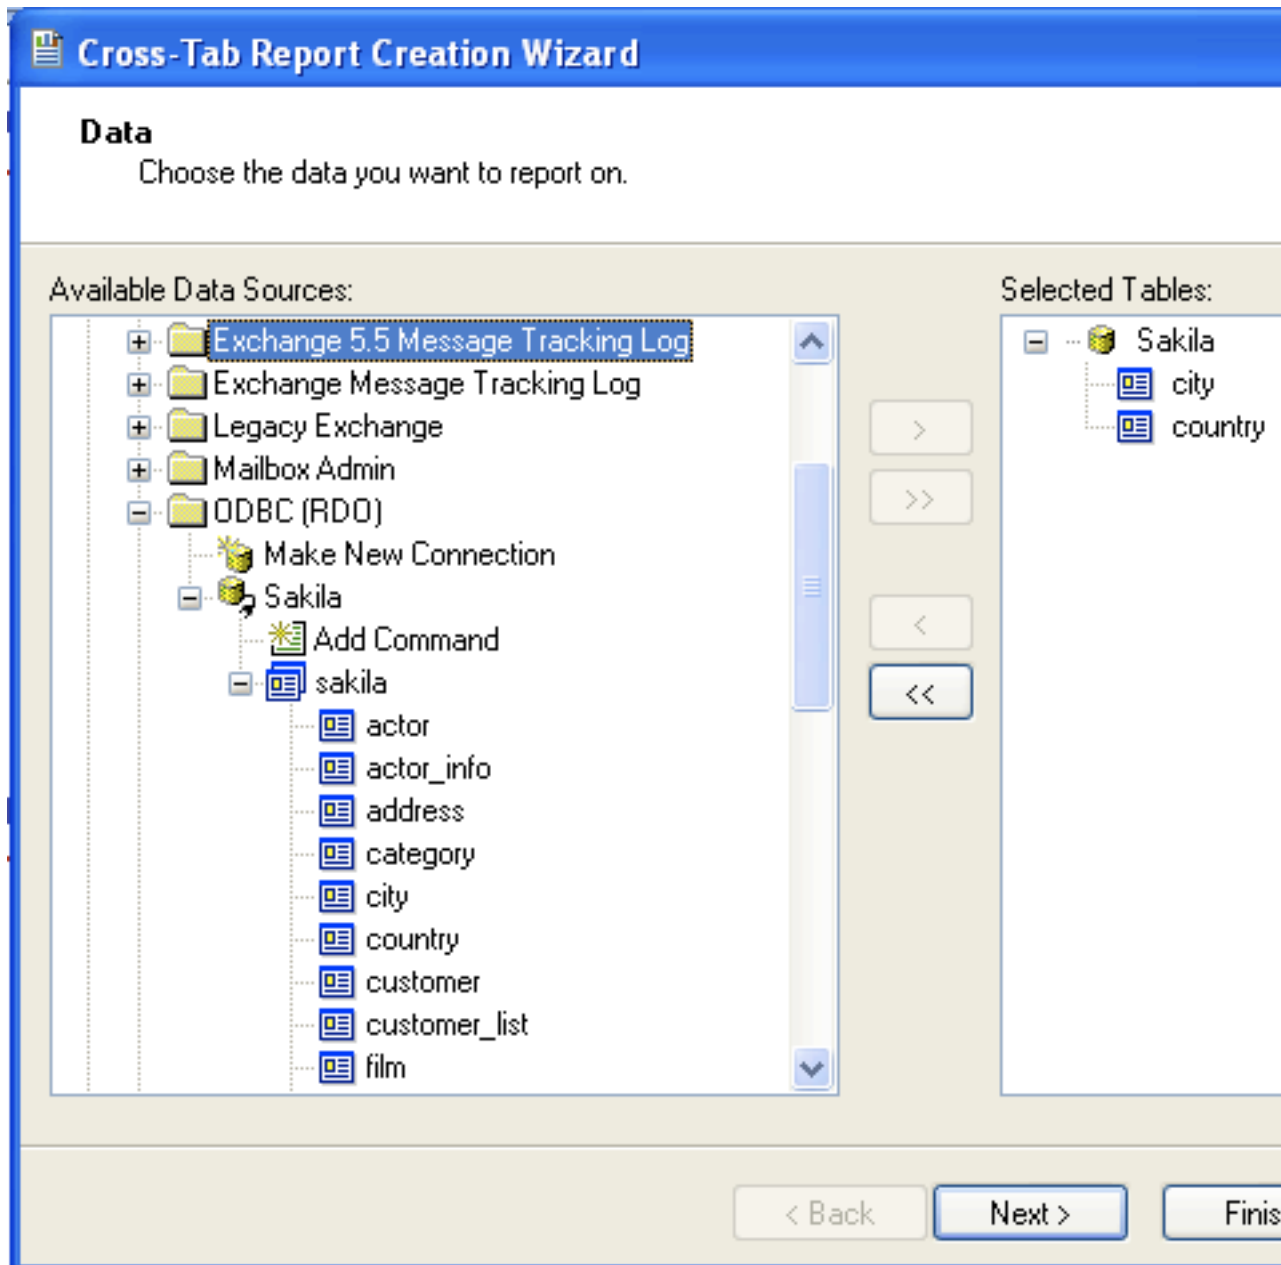

If the DSN contains a user name/password combination, or you want to use different authentication credentials, click **Next** to enter the user name and password that you want to use. Otherwise, click **Finish** to continue the data source selection wizard.

5. You will be returned the Cross-Tab Report Creation Wizard. You now need to select the database and tables that you want to include in your report. For our example, we will expand the selected Sakila database. Click the `city` table and use the `>` button to add the table to the report. Then repeat the action with the `country` table. Alternatively you can select multiple tables and add them to the report.

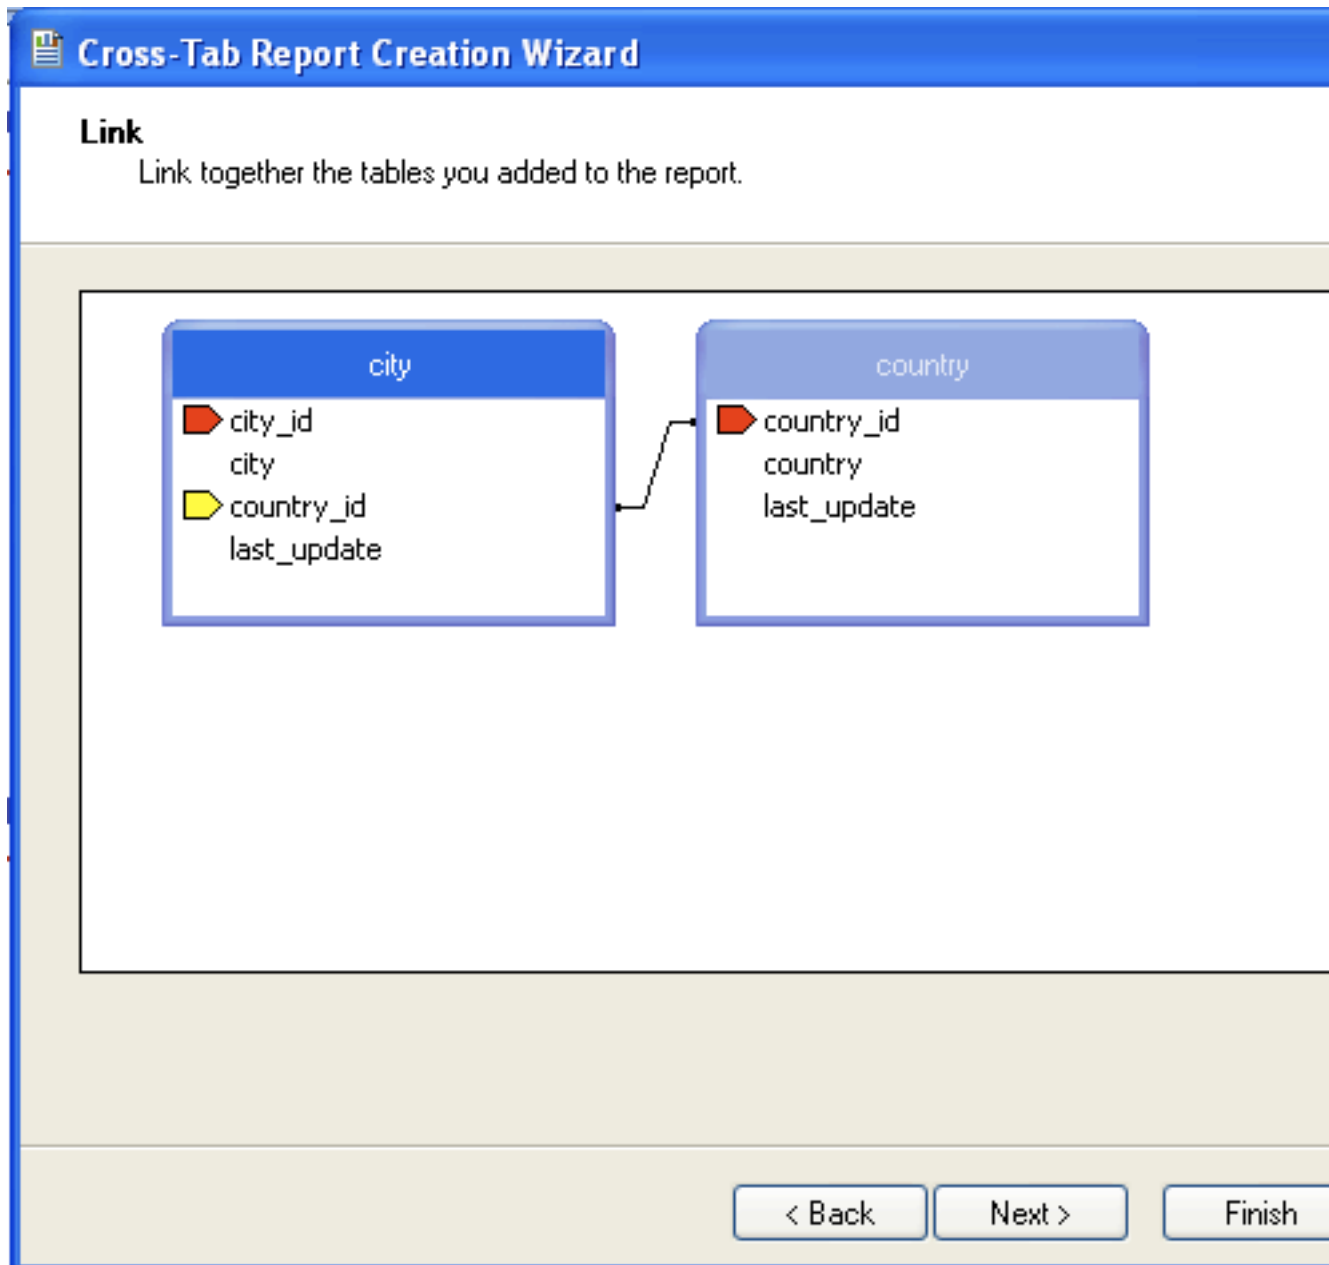

Finally, you can select the parent **Sakila** resource and add of the tables to the report.

Once you have selected the tables you want to include, click **Next** to continue.

6. Crystal Reports will now read the table definitions and automatically identify the links between the tables. The identification of links between tables enables Crystal Reports to automatically lookup and summarize information based on all the tables in the database according to your query. If Crystal Reports is unable to perform the linking itself, you can manually create the links between fields in the tables you have selected.

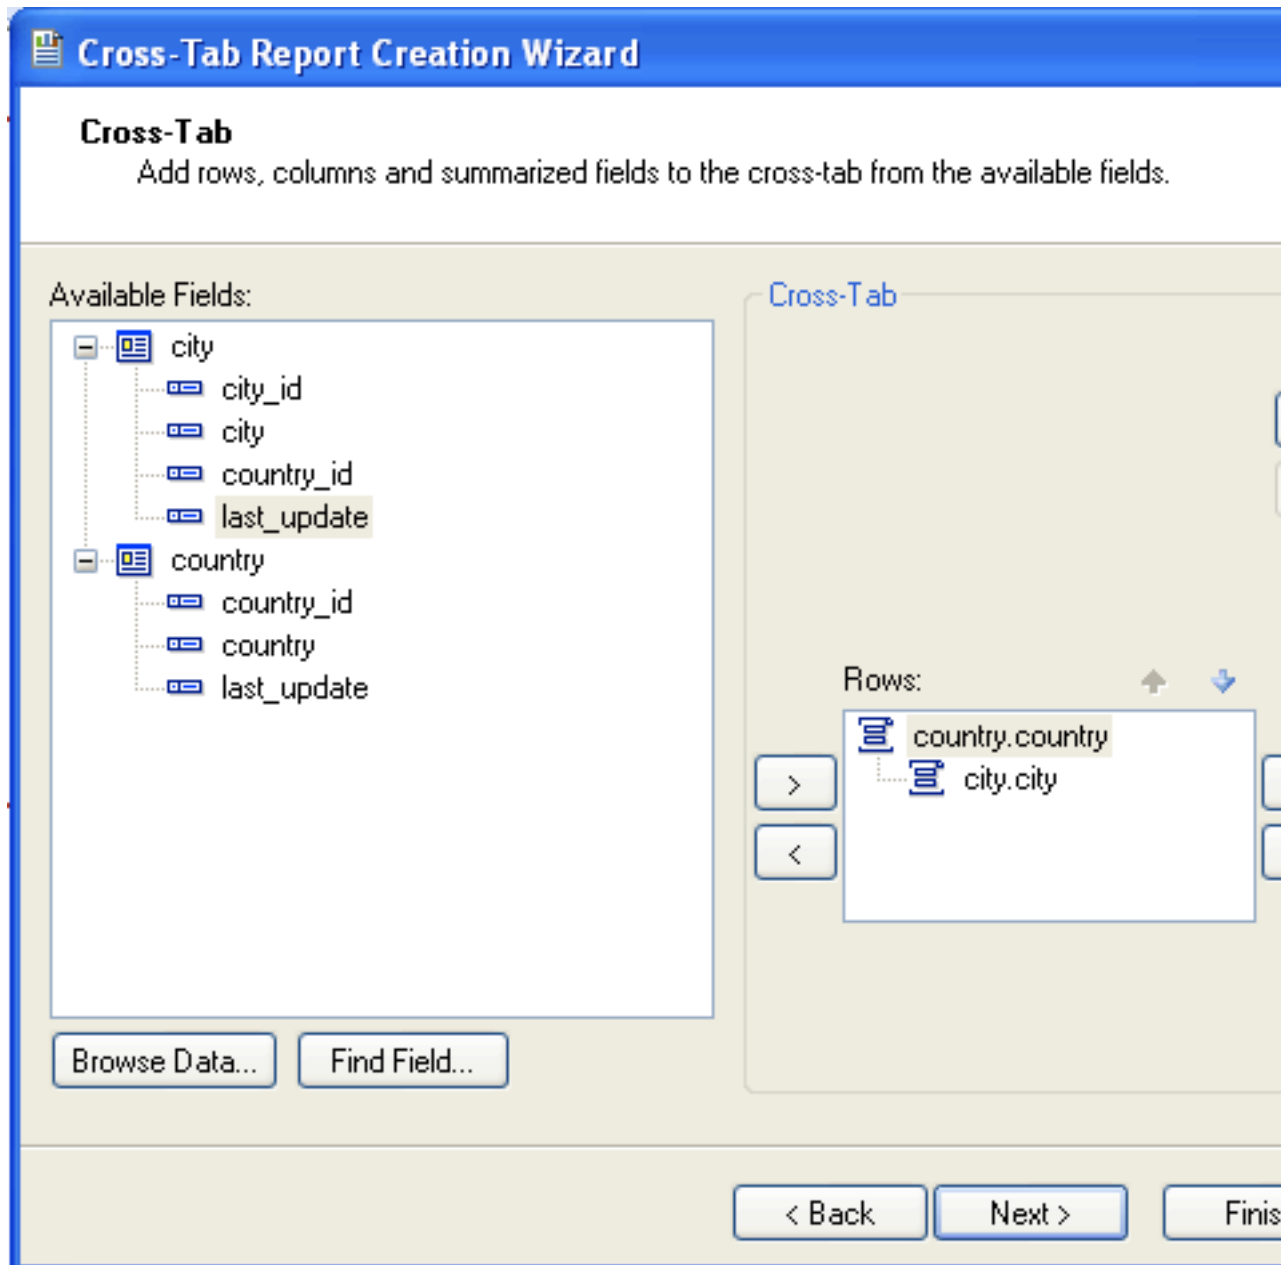

Click **Next** to continue the process.

7. You can now select the columns and rows that to include within the Cross-Tab report. Drag and drop or use the **>** buttons to add fields to each area of the report. In the example shown, we will report on cities, organized by country, incorporating a count of the number of cities within each country. If you want to browse the data, select a field and click the **Browse Data...** button.

Click **Next** to create a graph of the results. Since we are not creating a graph from this data, click **Finish** to generate the report.

8. The finished report will be shown, a sample of the output from the Sakila sample database is shown below.

		Total
<b>Total</b>		600
<b>Afghanistan</b>	<b>Total</b>	1
	<b>Kabul</b>	1
<b>Algeria</b>	<b>Total</b>	3
	<b>Batna</b>	1
	<b>Bchar</b>	1
	<b>Skikda</b>	1
<b>American Samoa</b>	<b>Total</b>	1
	<b>Tafuna</b>	1
<b>Angola</b>	<b>Total</b>	2
	<b>Benguela</b>	1
	<b>Namibe</b>	1
<b>Anguilla</b>	<b>Total</b>	1
	<b>South Hill</b>	1
<b>Argentina</b>	<b>Total</b>	13
	<b>Almirante Brow</b>	1

Once the ODBC connection has been opened within Crystal Reports, you can browse and add any fields within the available tables into your reports.

### 21.1.5.7. Connector/ODBC Programming

With a suitable ODBC Manager and the Connector/ODBC driver installed, any programming language or environment that can support ODBC can connect to a MySQL database through Connector/ODBC.

This includes, but is not limited to, Microsoft support languages (including Visual Basic, C# and interfaces such as ODBC.NET), Perl (through the DBI module, and the DBD::ODBC driver).

#### 21.1.5.7.1. Using Connector/ODBC with Visual Basic Using ADO, DAO and RDO

This section contains simple examples of the use of Connector/ODBC with ADO, DAO and RDO.

### 21.1.5.7.1.1. ADO: `rs.addNew`, `rs.delete`, and `rs.update`

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using Connector/ODBC
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)," _
& "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close

'rs insert
rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
rs.Update
rs.Close

'rs update
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
```

```

rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close

'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close
conn.Close
End Sub

```

#### 21.1.5.7.1.2. DAO: `rs.addNew`, `rs.update`, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```

Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, " _
& "Ts TIMESTAMP(14) NOT NULL, Name varchar(20), Id2 INT)")
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

For i = 10 To 15
rs.AddNew
rs!Name = "insert record" & i
rs!Id2 = i
rs.Update
Next i
rs.Close

'rs update..

```

```

Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub

```

### 21.1.5.7.1.3. RDO: `rs.addNew` and `rs.update`

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```

Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

```

```

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close

End Sub

```

### 21.1.5.7.2. Using Connector/ODBC with .NET

This section contains simple examples that demonstrate the use of Connector/ODBC drivers with ODBC.NET.

#### 21.1.5.7.2.1. Using Connector/ODBC with ODBC.NET and C# (C sharp)

The following sample creates a table `my_odbc_net` and demonstrates its use in C#.

```

/**
 * @sample      : mycon.cs
 * @purpose     : Demo sample for ODBC.NET using Connector/ODBC
 * @author      : Venu, <myodbc@lists.mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 *
 **/

/* build command
 *
 * csc /t:exe
 *      /out:mycon.exe mycon.cs
 *      /r:Microsoft.Data.Odbc.dll
 */

using Console = System.Console;
using Microsoft.Data.Odbc;

```

```
namespace myodbc3
{
    class mycon
    {
        static void Main(string[] args)
        {
            try
            {
                //Connection string for Connector/ODBC 3.51
                string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
                    "SERVER=localhost;" +
                    "DATABASE=test;" +
                    "UID=venu;" +
                    "PASSWORD=venu;" +
                    "OPTION=3";

                //Connect to MySQL using Connector/ODBC
                OdbcConnection MyConnection = new OdbcConnection(MyConString);
                MyConnection.Open();

                Console.WriteLine("\n !!! success, connected successfully !!!\n");

                //Display connection information
                Console.WriteLine("Connection Information:");
                Console.WriteLine("\tConnection String:" +
                    MyConnection.ConnectionString);
                Console.WriteLine("\tConnection Timeout:" +
                    MyConnection.ConnectionTimeout);
                Console.WriteLine("\tDatabase:" +
                    MyConnection.Database);
                Console.WriteLine("\tDataSource:" +
                    MyConnection.DataSource);
                Console.WriteLine("\tDriver:" +
                    MyConnection.Driver);
                Console.WriteLine("\tServerVersion:" +
                    MyConnection.ServerVersion);

                //Create a sample table
                OdbcCommand MyCommand =
                    new OdbcCommand("DROP TABLE IF EXISTS my_odbc_net",
                        MyConnection);
                MyCommand.ExecuteNonQuery();
                MyCommand.CommandText =
                    "CREATE TABLE my_odbc_net(id int, name varchar(20), idb bigint)";
                MyCommand.ExecuteNonQuery();

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(10,'venu', 300)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(20,'mysql',400)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(20,'mysql',500)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Update
                MyCommand.CommandText =
                    "UPDATE my_odbc_net SET id=999 WHERE id=20";
                Console.WriteLine("Update, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //COUNT(*)
            }
        }
    }
}
```

```

Module myvb
Sub Main()
Try

'Connector/ODBC 3.51 connection string
Dim MyConString As String = "DRIVER={MySQL ODBC 3.51 Driver};" & _
"SERVER=localhost;" & _
"DATABASE=test;" & _
"UID=venu;" & _
"PASSWORD=venu;" & _
"OPTION=3;"

'Connection
Dim MyConnection As New OdbcConnection(MyConString)
MyConnection.Open()

Console.WriteLine("Connection State::" & MyConnection.State.ToString)

'Drop
Console.WriteLine("Dropping table")
Dim MyCommand As New OdbcCommand()
MyCommand.Connection = MyConnection
MyCommand.CommandText = "DROP TABLE IF EXISTS my_vb_net"
MyCommand.ExecuteNonQuery()

'Create
Console.WriteLine("Creating...")
MyCommand.CommandText = "CREATE TABLE my_vb_net(id int, name varchar(30))"
MyCommand.ExecuteNonQuery()

'Insert
MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(10,'venu')"
Console.WriteLine("INSERT, Total rows affected:" & _
MyCommand.ExecuteNonQuery())

'Insert

    Console.WriteLine(MyOdbcException.ToString)

'Catch program exception
Catch MyException As Exception
    Console.WriteLine(MyException.ToString)
End Try
End Sub

```

## 21.1.6. Connector/ODBC Reference

This section provides reference material for the Connector/ODBC API, showing supported functions and methods, supported MySQL column types and the corresponding native type in Connector/ODBC, and the error codes returned by Connector/ODBC when a fault occurs.

### 21.1.6.1. Connector/ODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at <http://msdn.microsoft.com/en-us/library/ms714177.aspx>.

An application can call [SQLGetInfo](#) function to obtain conformance information about Connector/ODBC. To obtain information about support for a specific function in the driver, an application can call [SQLGetFunctions](#).

#### Note

For backward compatibility, the Connector/ODBC driver supports all deprecated functions.

The following tables list Connector/ODBC API calls grouped by task:

**Table 21.6. ODBC API Calls for Connecting to a Data Source**

Function Name	Connector/ODBC Supports?	Standard	Purpose
<a href="#">SQLAllocHandle</a>	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
<a href="#">SQLConnect</a>	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
<a href="#">SQLDriverConnect</a>	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.
<a href="#">SQLAllocEnv</a>	Yes	Deprecated	Obtains an environment handle allocated from driver.
<a href="#">SQLAllocConnect</a>	Yes	Deprecated	Obtains a connection handle

**Table 21.7. ODBC API Calls for Obtaining Information about a Driver and Data Source**

Function Name	Connector/ODBC Supports?	Standard	Purpose
<a href="#">SQLDataSources</a>	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
<a href="#">SQLDrivers</a>	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
<a href="#">SQLGetInfo</a>	Yes	ISO 92	Returns information about a specific driver and data source.
<a href="#">SQLGetFunctions</a>	Yes	ISO 92	Returns supported driver functions.
<a href="#">SQLGetTypeInfo</a>	Yes	ISO 92	Returns information about supported data types.

**Table 21.8. ODBC API Calls for Setting and Retrieving Driver Attributes**

Function Name	Connector/ODBC Supports?	Standard	Purpose
<a href="#">SQLSetConnectAttr</a>	Yes	ISO 92	Sets a connection attribute.
<a href="#">SQLGetConnectAttr</a>	Yes	ISO 92	Returns the value of a connection attribute.
<a href="#">SQLSetConnectOption</a>	Yes	Deprecated	Sets a connection option
<a href="#">SQLGetConnectOption</a>	Yes	Deprecated	Returns the value of a connection option
<a href="#">SQLSetEnvAttr</a>	Yes	ISO 92	Sets an environment attribute.
<a href="#">SQLGetEnvAttr</a>	Yes	ISO 92	Returns the value of an environment attribute.
<a href="#">SQLSetStmtAttr</a>	Yes	ISO 92	Sets a statement attribute.
<a href="#">SQLGetStmtAttr</a>	Yes	ISO 92	Returns the value of a statement attribute.
<a href="#">SQLSetStmtOption</a>	Yes	Deprecated	Sets a statement option
<a href="#">SQLGetStmtOption</a>	Yes	Deprecated	Returns the value of a statement option

**Table 21.9. ODBC API Calls for Preparing SQL Requests**

Function Name	Connector/ODBC Supports?	Standard	Purpose
<a href="#">SQLAllocStmt</a>	Yes	Deprecated	Allocates a statement handle
<a href="#">SQLPrepare</a>	Yes	ISO 92	Prepares an SQL statement for later execution.
<a href="#">SQLBindParameter</a>	Yes	ODBC	Assigns storage for a parameter in an SQL statement. Connector/ODBC 5.2 adds support for “out” and “inout” parameters, through the <a href="#">SQL_PARAM_OUTPUT</a> or <a href="#">SQL_PARAM_INPUT_OUTPUT</a> type specifiers. (“Out” and “inout” parameters are not supported for <a href="#">LONGTEXT</a> and <a href="#">LONGBLOB</a> columns.)
<a href="#">SQLGetCursorName</a>	Yes	ISO 92	Returns the cursor name associated with a statement handle.
<a href="#">SQLSetCursorName</a>	Yes	ISO 92	Specifies a cursor name.
<a href="#">SQLSetScrollOptions</a>	Yes	ODBC	Sets options that control cursor behavior.

**Table 21.10. ODBC API Calls for Submitting Requests**

Function Name	Connector/ ODBC Supports?	Standard	Purpose
<code>SQLExecute</code>	Yes	ISO 92	Executes a prepared statement.
<code>SQLExecDirect</code>	Yes	ISO 92	Executes a statement
<code>SQLNativeSql</code>	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
<code>SQLDescribeParam</code>	Yes	ODBC	Returns the description for a specific parameter in a statement.
<code>SQLNumParams</code>	Yes	ISO 92	Returns the number of parameters in a statement.
<code>SQLParamData</code>	Yes	ISO 92	Used in conjunction with <code>SQLPutData</code> to supply parameter data at execution time. (Useful for long data values.)
<code>SQLPutData</code>	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)

**Table 21.11. ODBC API Calls for Retrieving Results and Information about Results**

Function Name	Connector/ ODBC Supports?	Standard	Purpose
<code>SQLRowCount</code>	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
<code>SQLNumResultCols</code>	Yes	ISO 92	Returns the number of columns in the result set.
<code>SQLDescribeCol</code>	Yes	ISO 92	Describes a column in the result set.
<code>SQLColAttribute</code>	Yes	ISO 92	Describes attributes of a column in the result set.
<code>SQLColAttributes</code>	Yes	Deprecated	Describes attributes of a column in the result set.
<code>SQLFetch</code>	Yes	ISO 92	Returns multiple result rows.
<code>SQLFetchScroll</code>	Yes	ISO 92	Returns scrollable result rows.
<code>SQLExtendedFetch</code>	Yes	Deprecated	Returns scrollable result rows.
<code>SQLSetPos</code>	Yes	ODBC	Positions a cursor within a fetched block of data and enables an application to refresh data in the rowset or to update or delete data in the result set.
<code>SQLBulkOperations</code>	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

**Table 21.12. ODBC API Calls for Retrieving Error or Diagnostic Information**

Function Name	Connector/ ODBC Supports?	Standard	Purpose
<code>SQLError</code>	Yes	Deprecated	Returns additional error or status information
<code>SQLGetDiagField</code>	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
<code>SQLGetDiagRec</code>	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

**Table 21.13. ODBC API Calls for Obtaining Information about the Data Source's System Tables (Catalog Functions) Item**

Function Name	Connector/ODBC Supports?	Standard	Purpose
<code>SQLColumnPrivileges</code>	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
<code>SQLColumns</code>	Yes	X/Open	Returns the list of column names in specified tables.
<code>SQLForeignKeys</code>	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
<code>SQLPrimaryKeys</code>	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
<code>SQLSpecialColumns</code>	Yes	X/Open	Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are automatically updated when any value in the row is updated by a transaction.
<code>SQLStatistics</code>	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
<code>SQLTablePrivileges</code>	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
<code>SQLTables</code>	Yes	X/Open	Returns the list of table names stored in a specific data source.

**Table 21.14. ODBC API Calls for Performing Transactions**

Function Name	Connector/ODBC Supports?	Standard	Purpose
<code>SQLTransact</code>	Yes	Deprecated	Commits or rolls back a transaction
<code>SQLEndTran</code>	Yes	ISO 92	<a href="#">Commits</a> or <a href="#">rolls back</a> a <a href="#">transaction</a> .

**Table 21.15. ODBC API Calls for Terminating a Statement**

Function Name	Connector/ODBC Supports?	Standard	Purpose
<code>SQLFreeStmt</code>	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
<code>SQLCloseCursor</code>	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
<code>SQLCancel</code>	Yes	ISO 92	Cancels an SQL statement.

**Table 21.16. ODBC API Calls for Terminating a Connection**

Function Name	Connector/ODBC Supports?	Standard	Purpose
<code>SQLDisconnect</code>	Yes	ISO 92	Closes the connection.
<code>SQLFreeHandle</code>	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.

Function Name	Connector/ODBC Supports?	Standard	Purpose
<code>SQLFreeConnect</code>	Yes	Deprecated	Releases connection handle.
<code>SQLFreeEnv</code>	Yes	Deprecated	Releases an environment handle.

### 21.1.6.2. Connector/ODBC Data Types

The following table illustrates how Connector/ODBC maps the server data types to default SQL and C data types.

**Table 21.17. How Connector/ODBC Maps MySQL Data Types to SQL and C Data Types**

Native Value	SQL Type	C Type
<code>bigint unsigned</code>	<code>SQL_BIGINT</code>	<code>SQL_C_UBIGINT</code>
<code>bigint</code>	<code>SQL_BIGINT</code>	<code>SQL_C_SBIGINT</code>
<code>bit</code>	<code>SQL_BIT</code>	<code>SQL_C_BIT</code>
<code>bit</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>blob</code>	<code>SQL_LONGVARBINARY</code>	<code>SQL_C_BINARY</code>
<code>bool</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>char</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>date</code>	<code>SQL_DATE</code>	<code>SQL_C_DATE</code>
<code>datetime</code>	<code>SQL_TIMESTAMP</code>	<code>SQL_C_TIMESTAMP</code>
<code>decimal</code>	<code>SQL_DECIMAL</code>	<code>SQL_C_CHAR</code>
<code>double precision</code>	<code>SQL_DOUBLE</code>	<code>SQL_C_DOUBLE</code>
<code>double</code>	<code>SQL_FLOAT</code>	<code>SQL_C_DOUBLE</code>
<code>enum</code>	<code>SQL_VARCHAR</code>	<code>SQL_C_CHAR</code>
<code>float</code>	<code>SQL_REAL</code>	<code>SQL_C_FLOAT</code>
<code>int unsigned</code>	<code>SQL_INTEGER</code>	<code>SQL_C_ULONG</code>
<code>int</code>	<code>SQL_INTEGER</code>	<code>SQL_C_SLONG</code>
<code>integer unsigned</code>	<code>SQL_INTEGER</code>	<code>SQL_C_ULONG</code>
<code>integer</code>	<code>SQL_INTEGER</code>	<code>SQL_C_SLONG</code>
<code>long varbinary</code>	<code>SQL_LONGVARBINARY</code>	<code>SQL_C_BINARY</code>
<code>long varchar</code>	<code>SQL_LONGVARCHAR</code>	<code>SQL_C_CHAR</code>
<code>longblob</code>	<code>SQL_LONGVARBINARY</code>	<code>SQL_C_BINARY</code>
<code>longtext</code>	<code>SQL_LONGVARCHAR</code>	<code>SQL_C_CHAR</code>
<code>mediumblob</code>	<code>SQL_LONGVARBINARY</code>	<code>SQL_C_BINARY</code>
<code>mediumint unsigned</code>	<code>SQL_INTEGER</code>	<code>SQL_C_ULONG</code>
<code>mediumint</code>	<code>SQL_INTEGER</code>	<code>SQL_C_SLONG</code>
<code>mediumtext</code>	<code>SQL_LONGVARCHAR</code>	<code>SQL_C_CHAR</code>
<code>numeric</code>	<code>SQL_NUMERIC</code>	<code>SQL_C_CHAR</code>
<code>real</code>	<code>SQL_FLOAT</code>	<code>SQL_C_DOUBLE</code>
<code>set</code>	<code>SQL_VARCHAR</code>	<code>SQL_C_CHAR</code>
<code>smallint unsigned</code>	<code>SQL_SMALLINT</code>	<code>SQL_C_USHORT</code>
<code>smallint</code>	<code>SQL_SMALLINT</code>	<code>SQL_C_SSHORT</code>
<code>text</code>	<code>SQL_LONGVARCHAR</code>	<code>SQL_C_CHAR</code>

Native Value	SQL Type	C Type
time	SQL_TIME	SQL_C_TIME
timestamp [558]	SQL_TIMESTAMP	SQL_C_TIMESTAMP
tinyblob	SQL_LONGVARBINARY	SQL_C_BINARY
tinyint unsigned	SQL_TINYINT	SQL_C_UTINYINT
tinyint	SQL_TINYINT	SQL_C_STINYINT
tinytext	SQL_LONGVARCHAR	SQL_C_CHAR
varchar	SQL_VARCHAR	SQL_C_CHAR
year	SQL_SMALLINT	SQL_C_SHORT

### 21.1.6.3. Connector/ODBC Error Codes

The following tables lists the error codes returned by Connector/ODBC apart from the server errors.

**Table 21.18. Special Error Codes Returned by Connector/ODBC**

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	<code>SQLBindParameter</code> not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification
508	07009	07009	Invalid descriptor index
509	08002	08002	Connection name in use
510	08003	08003	Connection does not exist
511	24000	24000	Invalid cursor state
512	25000	25000	Invalid transaction state
513	25S01	25S01	Transaction state unknown
514	34000	34000	Invalid cursor name
515	S1000	HY000	General driver defined error
516	S1001	HY001	Memory allocation error
517	S1002	HY002	Invalid column number
518	S1003	HY003	Invalid application buffer type
519	S1004	HY004	Invalid SQL data type
520	S1009	HY009	Invalid use of null pointer
521	S1010	HY010	Function sequence error
522	S1011	HY011	Attribute can not be set now
523	S1012	HY012	Invalid transaction operation code
524	S1013	HY013	Memory management error
525	S1015	HY015	No cursor name available

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
526	S1024	HY024	Invalid attribute value
527	S1090	HY090	Invalid string or buffer length
528	S1091	HY091	Invalid descriptor field identifier
529	S1092	HY092	Invalid attribute/option identifier
530	S1093	HY093	Invalid parameter number
531	S1095	HY095	Function type out of range
532	S1106	HY106	Fetch type out of range
533	S1117	HY117	Row value out of range
534	S1109	HY109	Invalid cursor position
535	S1C00	HYC00	Optional feature not implemented
0	21S01	21S01	Column count does not match value count
0	23000	23000	Integrity constraint violation
0	42000	42000	Syntax error or access violation
0	42S02	42S02	Base table or view not found
0	42S12	42S12	Index not found
0	42S21	42S21	Column already exists
0	42S22	42S22	Column not found
0	08S01	08S01	Communication link failure

## 21.1.7. Connector/ODBC Notes and Tips

Here are some common notes and tips for using Connector/ODBC within different environments, applications and tools. The notes provided here are based on the experiences of Connector/ODBC developers and users.

### 21.1.7.1. Connector/ODBC General Functionality

This section provides help with common queries and areas of functionality in MySQL and how to use them with Connector/ODBC.

#### 21.1.7.1.1. Obtaining Auto-Increment Values

Obtaining the value of column that uses `AUTO_INCREMENT` after an `INSERT` statement can be achieved in a number of different ways. To obtain the value immediately after an `INSERT`, use a `SELECT` query with the `LAST_INSERT_ID()` [1269] function.

For example, using Connector/ODBC you would execute two separate statements, the `INSERT` statement and the `SELECT` query to obtain the auto-increment value.

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

If you do not require the value within your application, but do require the value as part of another `INSERT`, the entire process can be handled by executing the following statements:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

Certain ODBC applications (including Delphi and Access) may have trouble obtaining the auto-increment value using the previous examples. In this case, try the following statement as an alternative:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

This alternative method requires that `sql_auto_is_null` [543] variable is not set to 0. See [Section 5.1.4, “Server System Variables”](#).

See also [Section 21.8.14.3, “How to Get the Unique ID for the Last Inserted Row”](#).

#### 21.1.7.1.2. Dynamic Cursor Support

Support for the `dynamic cursor` is provided in Connector/ODBC 3.51, but dynamic cursors are not enabled by default. You can enable this function within Windows by selecting the `Enable Dynamic Cursor` check box within the ODBC Data Source Administrator.

On other platforms, you can enable the dynamic cursor by adding `32` to the `OPTION` value when creating the DSN.

#### 21.1.7.1.3. Connector/ODBC Performance

The Connector/ODBC driver has been optimized to provide very fast performance. If you experience problems with the performance of Connector/ODBC, or notice a large amount of disk activity for simple queries, there are a number of aspects to check:

- Ensure that `ODBC Tracing` is not enabled. With tracing enabled, a lot of information is recorded in the tracing file by the ODBC Manager. You can check, and disable, tracing within Windows using the `Tracing` panel of the ODBC Data Source Administrator. Within Mac OS X, check the `Tracing` panel of ODBC Administrator. See [Section 21.1.4.8, “Getting an ODBC Trace File”](#).
- Make sure you are using the standard version of the driver, and not the debug version. The debug version includes additional checks and reporting measures.
- Disable the Connector/ODBC driver trace and query logs. These options are enabled for each DSN, so make sure to examine only the DSN that you are using in your application. Within Windows, you can disable the Connector/ODBC and query logs by modifying the DSN configuration. Within Mac OS X and Unix, ensure that the driver trace (option value 4) and query logging (option value 524288) are not enabled.

#### 21.1.7.1.4. Setting ODBC Query Timeout in Windows

For more information on how to set the query timeout on Microsoft Windows when executing queries through an ODBC connection, read the Microsoft knowledgebase document at <http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756>.

### 21.1.7.2. Connector/ODBC Application-Specific Tips

Most programs should work with Connector/ODBC, but for each of those listed here, there are specific notes and tips to improve or enhance the way you work with Connector/ODBC and these applications.

With all applications, ensure that you are using the latest Connector/ODBC drivers, ODBC Manager and any supporting libraries and interfaces used by your application. For example, on Windows, using the latest version of Microsoft Data Access Components (MDAC) will improve the compatibility with ODBC in general, and with the Connector/ODBC driver.

#### 21.1.7.2.1. Using Connector/ODBC with Microsoft Applications

The majority of Microsoft applications have been tested with Connector/ODBC, including Microsoft Office, Microsoft Access and the various programming languages supported within ASP and Microsoft Visual Studio.

##### 21.1.7.2.1.1. Microsoft Access

To improve the integration between Microsoft Access and MySQL through Connector/ODBC:

- For all versions of Access, enable the Connector/ODBC `Return matching rows` option. For Access 2.0, also enable the `Simulate ODBC 1.0` option.

- Include a `TIMESTAMP` column in all tables that you want to be able to update. For maximum portability, do not use a length specification in the column declaration (which is unsupported within MySQL in versions earlier than 4.1).
- Include a `primary key` in each MySQL table you want to use with Access. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED#`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records may still display as `#DELETED#`, but newly added/updated records are displayed properly.

- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

Do not use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. Set the `DefaultValue` property for the `TIMESTAMP` column to `NOW() [1220]`. Consider hiding the `TIMESTAMP` column from view so your users are not confused.

- In some cases, Access may generate SQL statements that MySQL cannot understand. You can fix this by selecting `"Query | SQLSpecific | Pass-Through"` from the Access menu.
- On Windows NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, change `BLOB` columns to `TEXT` with `ALTER TABLE`.
- Access cannot always handle the MySQL `DATE` column properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:
  - Return Matching Rows (2)
  - Allow BIG Results (8).

These add up to a value of 10 (`OPTION=10`).

Some external articles and tips that may be useful when using Access, ODBC and Connector/ODBC:

- Read [How to Trap ODBC Login Error Messages in Access](#)
- Optimizing Access ODBC Applications
  - [Optimizing for Client/Server Performance](#)
  - [Tips for Converting Applications to Using ODBCDirect](#)

- [Tips for Optimizing Queries on Attached SQL Tables](#)
- For a list of tools that can be used with Access and ODBC data sources, refer to <http://www.mysql.com/portal/software/convertors/> section for list of available tools.

#### 21.1.7.2.1.2. Microsoft Excel and Column Types

If you have problems importing data into Microsoft Excel, particularly numeric, date, and time values, this is probably because of a bug in Excel, where the column type of the source data is used to determine the data type when that data is inserted into a cell within the worksheet. The result is that Excel incorrectly identifies the content and this affects both the display format and the data when it is used within calculations.

To address this issue, use the `CONCAT()` [1178] function in your queries. The use of `CONCAT()` [1178] forces Excel to treat the value as a string, which Excel will then parse and usually correctly identify the embedded information.

However, even with this option, some data may be incorrectly formatted, even though the source data remains unchanged. Use the `Format Cells` option within Excel to change the format of the displayed information.

#### 21.1.7.2.1.3. Microsoft Visual Basic

To be able to update a table, you must define a `primary key` for the table.

Visual Basic with ADO cannot handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen. You may also want to select the `Return matching rows` option.

#### 21.1.7.2.1.4. Microsoft Visual InterDev

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen.

#### 21.1.7.2.1.5. Visual Objects

Select the `Don't optimize column widths` option.

#### 21.1.7.2.1.6. Microsoft ADO

When you are coding with the ADO API and Connector/ODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation Property` as `adUseServer` returns a result of `-1` for the `RecordCount Property`. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADODB.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT(*)` statement for a similar query to get the correct row count.

To find the number of rows affected by a specific SQL statement in ADO, use the `RecordsAffected` property in the ADO execute method. For more information on the usage of execute method, refer to <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/hlm/mdmthcnnextecute.asp>.

For information, see [ActiveX Data Objects\(ADO\) Frequently Asked Questions](#).

#### 21.1.7.2.1.7. Using Connector/ODBC with Active Server Pages (ASP)

Select the `Return matching rows` option in the DSN.

For more information about how to access MySQL through ASP using Connector/ODBC, refer to the following articles:

- [Using MyODBC To Access Your MySQL Database Via ASP](#)
- [ASP and MySQL at DWAM.NT](#)

A Frequently Asked Questions list for ASP can be found at <http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp>.

#### 21.1.7.2.1.8. Using Connector/ODBC with Visual Basic (ADO, DAO and RDO) and ASP

Some articles that may help with Visual Basic and ASP:

- [MySQL BLOB columns and Visual Basic 6](#) by Mike Hillyer (<mike@openwin.org>).
- [How to map Visual basic data type to MySQL types](#) by Mike Hillyer (<mike@openwin.org>).

#### 21.1.7.2.2. Using Connector/ODBC with Borland Applications

With all Borland applications where the Borland Database Engine (BDE) is used, follow these steps to improve compatibility:

- Update to BDE 3.2 or newer.
- Enable the `Don't optimize column widths` option in the DSN.
- Enabled the `Return matching rows` option in the DSN.

#### 21.1.7.2.2.1. Using Connector/ODBC with Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

#### 21.1.7.2.2.2. Using Connector/ODBC with Delphi

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for Connector/ODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <bryan@flesherfab.com> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', '');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', '');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
```

```
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memo1.Lines.Add('DATABASE NAME=');
Memo1.Lines.Add('USER NAME=');
Memo1.Lines.Add('ODBC DSN=DocumentsFab');
Memo1.Lines.Add('OPEN MODE=READ/WRITE');
Memo1.Lines.Add('BATCH COUNT=200');
Memo1.Lines.Add('LANGDRIVER=');
Memo1.Lines.Add('MAX ROWS=-1');
Memo1.Lines.Add('SCHEMA CACHE DIR=');
Memo1.Lines.Add('SCHEMA CACHE SIZE=8');
Memo1.Lines.Add('SCHEMA CACHE TIME=-1');
Memo1.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memo1.Lines.Add('SQLQRYMODE=');
Memo1.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memo1.Lines.Add('ENABLE BCD=FALSE');
Memo1.Lines.Add('ROWSET SIZE=20');
Memo1.Lines.Add('BLOBS TO CACHE=64');
Memo1.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab', 'MySQL', Memo1.Lines);
```

#### 21.1.7.2.2.3. Using Connector/ODBC with C++ Builder

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named `PRIMARY`, although this has not been a problem.

#### 21.1.7.2.3. Using Connector/ODBC with ColdFusion

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the `unixODBC` driver with Connector/ODBC for MySQL data sources. You can download Connector/ODBC at <http://dev.mysql.com/downloads/connector/odbc/>.

ColdFusion version 4.5.1 lets you use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC data sources drop-down list, build and copy the Connector/ODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The Contrib directory contains the program `mysdn-xxx.zip` which lets you build and remove the DSN registry file for the Connector/ODBC driver on ColdFusion applications.

For more information and guides on using ColdFusion and Connector/ODBC, see the following external sites:

- [Troubleshooting Data Sources and Database Connectivity for Unix Platforms](#).

#### 21.1.7.2.4. Using Connector/ODBC with OpenOffice.org

Open Office (<http://www.openoffice.org>) [How-to: MySQL + OpenOffice](#). [How-to: OpenOffice + MyODBC + unixODBC](#).

#### 21.1.7.2.5. Using Connector/ODBC with Sambar Server

Sambar Server (<http://www.sambarserver.info>) [How-to: MyODBC + SambarServer + MySQL](#).

#### 21.1.7.2.6. Using Connector/ODBC with Pervasive Software DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

#### 21.1.7.2.7. Using Connector/ODBC with SunSystems Vision

---

Select the [Return matching rows](#) option.

### 21.1.7.3. Connector/ODBC Errors and Resolutions (FAQ)

The following section details some common errors and their suggested fix or alternative solution. If you are still experiencing problems, use the Connector/ODBC mailing list; see [Section 21.1.8.1, "Connector/ODBC Community Support"](#).

Many problems can be resolved by upgrading your Connector/ODBC drivers to the latest available release. On Windows, make sure that you have the latest versions of the Microsoft Data Access Components (MDAC) installed.

#### 64-Bit Windows and ODBC Data Source Administrator

I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in [ODBC Data Source Administrator](#).

This is not a bug, but is related to the way Windows x64 editions operate with the ODBC driver. On Windows x64 editions, the Connector/ODBC driver is installed in the `%SystemRoot%\SysWOW64` folder. However, the default [ODBC Data Source Administrator](#) that is available through the [Administrative Tools](#) or [Control Panel](#) in Windows x64 Editions is located in the `%SystemRoot%\system32` folder, and only searches this folder for ODBC drivers.

On Windows x64 editions, use the ODBC administration tool located at `%SystemRoot%\SysWOW64\odbcad32.exe`, this will correctly locate the installed Connector/ODBC drivers and enable you to create a Connector/ODBC DSN.

This issue was originally reported as Bug #20301.

#### Error 10061 (Cannot connect to server)

When connecting or using the [Test](#) button in [ODBC Data Source Administrator](#) I get error 10061 (Cannot connect to server)

This error can be raised by a number of different issues, including server problems, network problems, and firewall and port blocking problems. For more information, see [Section C.5.2.2, "Can't connect to \[local\] MySQL server"](#).

#### "Transactions are not enabled" Error

The following error is reported when using transactions: [Transactions are not enabled](#)

This error indicates that you are trying to use [transactions](#) with a MySQL table that does not support transactions. Transactions are supported within MySQL when using the [InnoDB](#) database engine, which is the default storage engine in MySQL 5.5 and higher. In versions of MySQL before MySQL 5.1, you may also use the [BDB](#) engine.

Check the following before continuing:

- Verify that your MySQL server supports a transactional database engine. Use [SHOW ENGINES](#) to obtain a list of the available engine types.
- Verify that the tables you are updating use a transactional database engine.
- Ensure that you have not enabled the [disable transactions](#) option in your DSN.

#### #DELETED# Records Reported by Access

Access reports records as [#DELETED#](#) when inserting or updating records in linked tables.

If the inserted or updated records are shown as [#DELETED#](#) in Access, then:

- If you are using Access 2000, get and install the newest (version 2.6 or higher) Microsoft MDAC (Microsoft Data Access Components) from <http://support.microsoft.com/kb/110093>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified.

Also, get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5), which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as #DELETED# in Access.

- For all versions of Access, enable the Connector/ODBC `Return matching rows` option. For Access 2.0, also enable the `Simulate ODBC 1.0` option.
- Include a `TIMESTAMP` in all tables that you want to be able to update.
- Include a `primary key` in the table. If not, new or updated rows may show up as #DELETED#.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as #DELETED# or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as #DELETED#. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records still display as #DELETED#, but newly added/updated records are displayed properly.

## Write Conflicts or Row Location Errors

How do I handle Write Conflicts or Row Location errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

```
Write Conflict. Another user has changed your data.
```

```
Row cannot be located for updating. Some values may have been changed since it was last read.
```

## Importing from Access 97

Exporting data from Access 97 to MySQL reports a `Syntax Error`.

This error is specific to Access 97 and versions of Connector/ODBC earlier than 3.51.02. Update to the latest version of the Connector/ODBC driver to resolve this problem.

## Importing from Microsoft DTS

Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.

This error occurs only with MySQL tables using the `TEXT` or `VARCHAR` data types. You can fix this error by upgrading your Connector/ODBC driver to version 3.51.02 or higher.

## SQL\_NO\_DATA Exception from ODBC.NET

Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the `SQL_NO_DATA` exception.

You can get the patch that addresses this problem from <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243>.

## Error with SELECT COUNT(\*)

Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.

This error occurs because the `COUNT(*)` [1283] expression is returning a `BIGINT`, and ADO cannot make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

## Multiple-Step Operation Error

Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors. Check each status value` error is returned.

The `GetChunk()` and `AppendChunk()` methods from ADO do not work as expected when the cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from [http://www.dwam.net/iishelp/ado/docs/adomth02\\_4.htm](http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm)

## Modified Record Error

Access returns `Another user had modified the record that you have modified` while editing records on a Linked Table.

In most cases, this can be solved by doing one of the following things:

- Add a `primary key` for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double-precision float fields. Some programs may fail when they compare single-precision floats.

If these strategies do not help, start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a Connector/ODBC log to help you figure out why things go wrong. For instructions, see [Section 21.1.4.8, "Getting an ODBC Trace File"](#).

## Direct Application Linking Under Unix or Linux

When linking an application directly to the Connector/ODBC library under Unix or Linux, the application crashes.

Connector/ODBC under Unix or Linux is not compatible with direct application linking. To connect to an ODBC source, use a driver manager, such as `iODBC` or `unixODBC`.

## Microsoft Office and DATE or TIMESTAMP Columns

Applications in the Microsoft Office suite cannot update tables that have `DATE` or `TIMESTAMP` columns.

This is a known issue with Connector/ODBC. Ensure that the field has a default value (rather than `NULL`) and that the default value is nonzero (that is, something other than `0000-00-00 00:00:00`).

## INFORMATION\_SCHEMA Database

When connecting Connector/ODBC 5.x to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.

Connector/ODBC 5.x is designed to work with MySQL 5.0 or later, taking advantage of the `INFORMATION_SCHEMA` database to determine data definition information. Support for MySQL 4.1 is planned for the final release.

## S1T00 Error

When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.

The `S1T00` error indicates that a general timeout has occurred within the ODBC system and is not a MySQL error. Typically it indicates that the connection you are using is stale, the server is too busy to accept your request or that the server has gone away.

### "Table does not exist" Error in Access 2000

When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.

There is a known issue with a specific version of the `msjet40.dll` that exhibits this issue. The version affected is 4.0.9025.0. Reverting to an older version will enable you to create the links. If you have recently updated your version, check your `WINDOWS` directory for the older version of the file and copy it to the drivers directory.

### Batched Statements

When I try to use batched statements, the execution of the batched statements fails.

Batched statement support was added in 3.51.18. Support for batched statements is not enabled by default. Enable option `FLAG_MULTI_STATEMENTS`, value 67108864, or select the **Allow multiple statements** flag within a GUI configuration.

### Packet Errors with ADODB and Excel

When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.

This error may be related to Keyboard Logger 1.1 from PanteraSoft.com, which is known to interfere with the network communication between MySQL Connector/ODBC and MySQL.

### Outer Join Error

When using some applications to access a MySQL server using Connector/ODBC and outer joins, an error is reported regarding the Outer Join Escape Sequence.

This is a known issue with MySQL Connector/ODBC which is not correctly parsing the "Outer Join Escape Sequence", as per the specs at [Microsoft ODBC Specs](#). Currently, Connector/ODBC will return a value `> 0` when asked for `SQL_OJ_CAPABILITIES` even though no parsing takes place in the driver to handle the outer join escape sequence.

### Hebrew/CJK Characters

I can correctly store extended characters in the database (Hebrew/CJK) using Connector/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.

When using ASP and UTF8 characters, add the following to your ASP files to ensure that the data returned is correctly encoded:

```
Response.CodePage = 65001
Response.CharSet = "utf-8"
```

### Duplicate Entry in Installed Programs List

I have a duplicate MySQL Connector/ODBC entry within my **Installed Programs** list, but I cannot delete one of them.

This problem can occur when you upgrade an existing Connector/ODBC installation, rather than removing and then installing the updated version.

#### Warning

To fix the problem, use any working uninstallers to remove existing installations; then may have to edit the contents of the registry. Make sure you have a

backup of your registry information before attempting any editing of the registry contents.

## Values Truncated to 255 Characters

When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.

Ensure that the `FLAG_BIG_PACKETS` option is set for your connection. This removes the 255 character limitation on bound parameters.

## Disabling Data-At-Execution

Is it possible to disable data-at-execution using a flag?

If you do not want to use data-at-execution, remove the corresponding calls. For example:

```
SQLLEN ylen = SQL_LEN_DATA_AT_EXEC(10);
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, &ylen);
```

Would become:

```
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, NULL);
```

Note that in the call to `SQLBindCol()`, `&ylen` has been replaced by `NULL`.

For further information, refer to the [MSDN documentation](#) for `SQLBindCol()`.

## NULLABLE Attribute for AUTO\_INCREMENT Columns

When you call `SQLColumns()` for a table column that is `AUTO_INCREMENT`, the `NULLABLE` column of the result set is always `SQL_NULLABLE (1)`.

This is because MySQL reports the `DEFAULT` value for such a column as `NULL`. It means, if you insert a `NULL` value into the column, you will get the next integer value for the table's `auto_increment` counter.

## 21.1.8. Connector/ODBC Support

There are many different places where you can get support for using Connector/ODBC. Always try the Connector/ODBC Mailing List or Connector/ODBC Forum. See [Section 21.1.8.1, "Connector/ODBC Community Support"](#), for help before reporting a specific bug or issue to MySQL.

### 21.1.8.1. Connector/ODBC Community Support

Oracle provides assistance to the user community by means of its mailing lists. For Connector/ODBC-related issues, you can get help from experienced users by using the [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com) mailing list. Archives are available online at <http://lists.mysql.com/myodbc>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.6.1, "MySQL Mailing Lists"](#).

Community support from experienced users is also available through the [ODBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.6.2, "MySQL Community Support at the MySQL Forums"](#).

### 21.1.8.2. How to Report Connector/ODBC Problems or Bugs

If you encounter difficulties or problems with Connector/ODBC, start by making a log file from the [ODBC Manager](#) (the log you get when requesting logs from `ODBC ADMIN`) and Connector/ODBC. The procedure for doing this is described in [Section 21.1.4.8, "Getting an ODBC Trace File"](#).

Check the Connector/ODBC trace file to find out what could be wrong. Determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

Also, try issuing the statements from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in Connector/ODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See [Section 1.6.1, "MySQL Mailing Lists"](#). Please never send the whole Connector/ODBC or ODBC log file!

Ideally, include the following information with the email:

- Operating system and version
- Connector/ODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- Connector/ODBC log file from Connector/ODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at <http://lists.mysql.com/myodbc>.

If you are unable to find out what is wrong, the last option is to create an archive in `tar` or `zip` format that contains a Connector/ODBC trace file, the ODBC log file, and a `README` file that explains the problem. Initiate a bug report for our bugs database at <http://bugs.mysql.com/>, then click the Files tab in the bug report for instructions on uploading the archive to the bugs database. Only MySQL engineers have access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with another SQL server, include an ODBC log file where you perform exactly the same SQL statements so that we can compare the results between the two systems.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

### 21.1.8.3. How to Submit a Connector/ODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to `<myodbc@lists.mysql.com>`.

## 21.2. MySQL Connector/Net

Connector/Net lets you easily develop .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET-aware tools. Developers can build applications using their choice of .NET languages. Connector/Net is a fully managed ADO.NET driver written in 100% pure C#.

For release notes detailing the changes in each release of Connector/Net, see [MySQL Connector/Net Release Notes](#).

Connector/Net includes full support for:

- Features provided by MySQL Server up to and including MySQL Server version 5.5.
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.
- Protocol compression, which enables compressing the data stream between the client and server.
- Connections using TCP/IP sockets, named pipes, or shared memory on Windows.
- Connections using TCP/IP sockets or Unix sockets on Unix.
- The Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

This document is intended as a user's guide to Connector/Net and includes a full syntax reference. Syntax information is also included within the [Documentation.chm](#) file included with the Connector/Net distribution.

If you are using MySQL 5.0 or later, and Visual Studio as your development environment, you can also use the MySQL Visual Studio Plugin. The plugin acts as a DDEX (Data Designer Extensibility) provider: you can use the data design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For more information, see [Section 21.2.3, "Connector/Net Visual Studio Integration"](#).

**Note**

Connector/Net 5.1.2 and later include the Visual Studio Plugin by default.

MySQL Connector/Net supports full versions of Visual Studio 2005, 2008, and 2010, although certain features are only available in Visual Studio 2010 when using MySQL Connector/Net version 6.3.2 and later. Note that MySQL Connector/Net does not currently support Express versions of Microsoft products, including Microsoft Visual Web Developer.

**Key topics:**

- For connection string properties when using the `MySqlConnection` class, see [Section 21.2.6, "Connector/Net Connection String Options Reference"](#).

As of Connector/Net 5.1.2, the Visual Studio Plugin is part of the main Connector/Net package. However, even for versions of Connector/Net older than 5.1.2, the Visual Studio Plugin release notes can be found at [MySQL Connector/Net Release Notes](#).

## 21.2.1. Connector/Net Versions

There are several versions of Connector/Net available:

- Connector/Net 6.6 includes support for MySQL Server 5.6, 5.5, 5.1, and 5.0. Important new features include stored procedure debugging in Microsoft Visual Studio, support for pluggable authentication including the ability to write your own authentication plugin, Entity Framework 4.3 Code First support, and enhancements to partial trust support to allow hosting services to deploy applications without installing the Connector/Net library in the GAC.
- Connector/Net 6.5 includes support for MySQL Server 5.6, 5.5, 5.1, and 5.0. Important new features include interceptor classes for exceptions and commands, support for the MySQL 5.6 fractional seconds feature, better partial-trust support, and better IntelliSense, including auto-completion when editing stored procedures or `.mysql` files.
- Connector/Net 6.4 includes support for MySQL Server 5.5, 5.1, and 5.0. Important new features include support for Windows authentication (when connecting to MySQL Server 5.5+), table caching on the client side, simple connection fail-over support, and improved SQL generation from the Entity Framework provider.

- Connector/Net 6.3 includes support for MySQL Server 5.5, 5.1, and 5.0. Important new features include integration with Visual Studio 2010, such as availability of DDL T4 template for Entity Framework, and a custom MySQL SQL Editor. Other features include refactored transaction scope: Connector/Net now supports nested transactions in a scope where they use the same connection string.
- Connector/Net 6.2 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1. Important new features include a new logging system and client SSL certificates.
- Connector/Net 6.1 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1. Important new features include the MySQL Website Configuration Tool and a Session State Provider.
- Connector/Net 6.0 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1.

This version of Connector/Net is no longer supported.

- Connector/Net 5.2 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1 features. Connector/Net 5.2 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to [GetSchema](#). Connector/Net 5.2 also includes the Visual Studio Plugin as a standard installable component.

This version of Connector/Net is no longer supported.

- Connector/Net 5.1 includes support for MySQL Server 5.5, 5.1, 5.0, 4.1, and 4.0 features. Connector/Net 5.1 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to [GetSchema](#). Connector/Net 5.1 also includes the Visual Studio Plugin as a standard installable component.

This version of Connector/Net is no longer supported.

- Connector/Net 5.0 includes support for MySQL Server 5.1, 5.0, 4.1 and 4.0 features. Connector/Net 5.0 also includes full support for the ADO.Net 2.0 interfaces and subclasses, includes support for the usage advisor and performance monitor (PerfMon) hooks.

This version of Connector/Net is no longer supported.

- Connector/Net 1.0 includes support for MySQL Server 5.0, 4.1, and 4.0 features, and full compatibility with the ADO.NET driver interface.

This version of Connector/Net is no longer supported.

The latest source code for Connector/Net can be downloaded from the MySQL public Subversion server. For further details, see [Section 21.2.2.3, "Installing Connector/Net from the Source Code"](#).

The following table shows the .NET Framework version required, and the MySQL Server version supported by Connector/Net:

**Table 21.19. Connector/Net Requirements for Related Products**

Connector/Net version	ADO.NET version supported	.NET Framework version required	MySQL Server version supported	Currently supported
6.6	2.x+	2.x+, 4.x+ for VS 2010 support	5.6, 5.5, 5.1, 5.0	Yes
6.5	2.x+	2.x+, 4.x+ for VS 2010 support	5.6, 5.5, 5.1, 5.0	Yes
6.4	2.x+	2.x+, 4.x+ for VS 2010 support	5.6, 5.5, 5.1, 5.0	Yes
6.3	2.x+	2.x+, 4.x+ for VS 2010 support	5.6, 5.5, 5.1, 5.0	Yes

Connector/Net version	ADO.NET version supported	.NET Framework version required	MySQL Server version supported	Currently supported
6.2	2.x+	2.x+	5.6, 5.5, 5.1, 5.0, 4.1	Yes
6.1	2.x+	2.x+	5.6, 5.5, 5.1, 5.0, 4.1	Yes
6.0	2.x+	2.x+	5.5, 5.1, 5.0, 4.1	Critical issues only
5.2	2.x+	2.x+	5.5, 5.1, 5.0, 4.1	No
5.1	2.x+	2.x+	5.5, 5.1, 5.0, 4.1, 4.0	No
5.0	2.x+	2.x+	5.0, 4.1, 4.0	No
1.0	1.x	1.x	5.0, 4.1, 4.0	No

#### Note

Version numbers for MySQL products are formatted as X.Y.Z, where Z=0 indicates alpha, Z=1 indicates beta, and Z>=2 indicates GA. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.YY.ZZ. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

## 21.2.2. Connector/Net Installation

Connector/Net runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework (see <http://www.mono-project.com>).

Connector/Net is available for download from <http://dev.mysql.com/downloads/connector/net/>.

### 21.2.2.1. Installing Connector/Net on Windows

On Windows, you can install either through a binary installation process or by downloading a zip file with the Connector/Net components.

Before installing, ensure that your system is up to date, including installing the latest version of the .NET Framework.

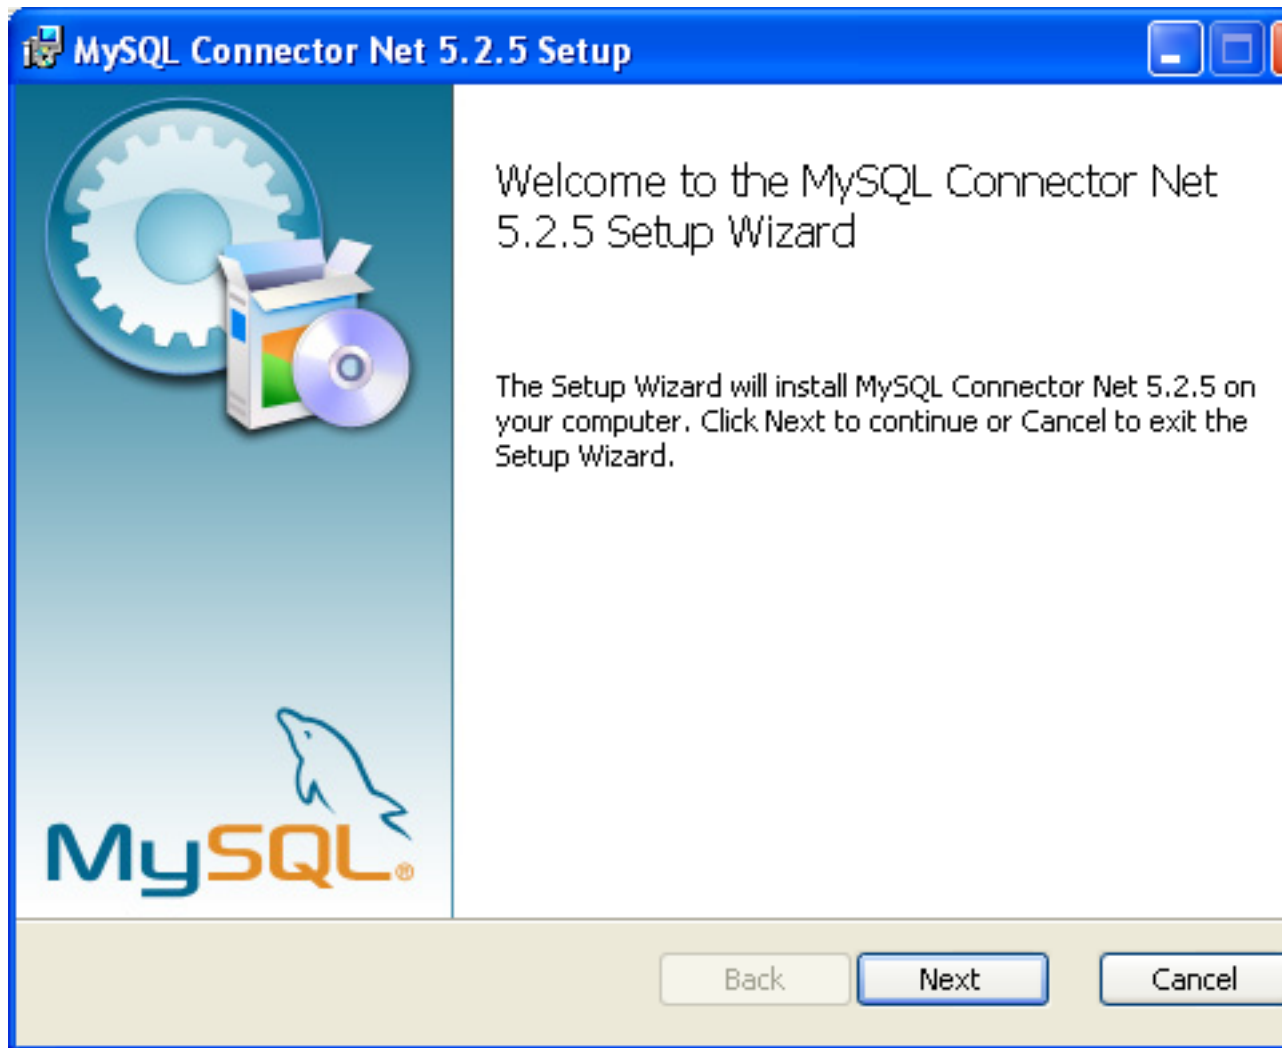

#### 21.2.2.1.1. Installing Connector/Net using the Installer

Using the installer is the most straightforward method of installing Connector/Net on Windows and the installed components include the source code, test code and full reference documentation.

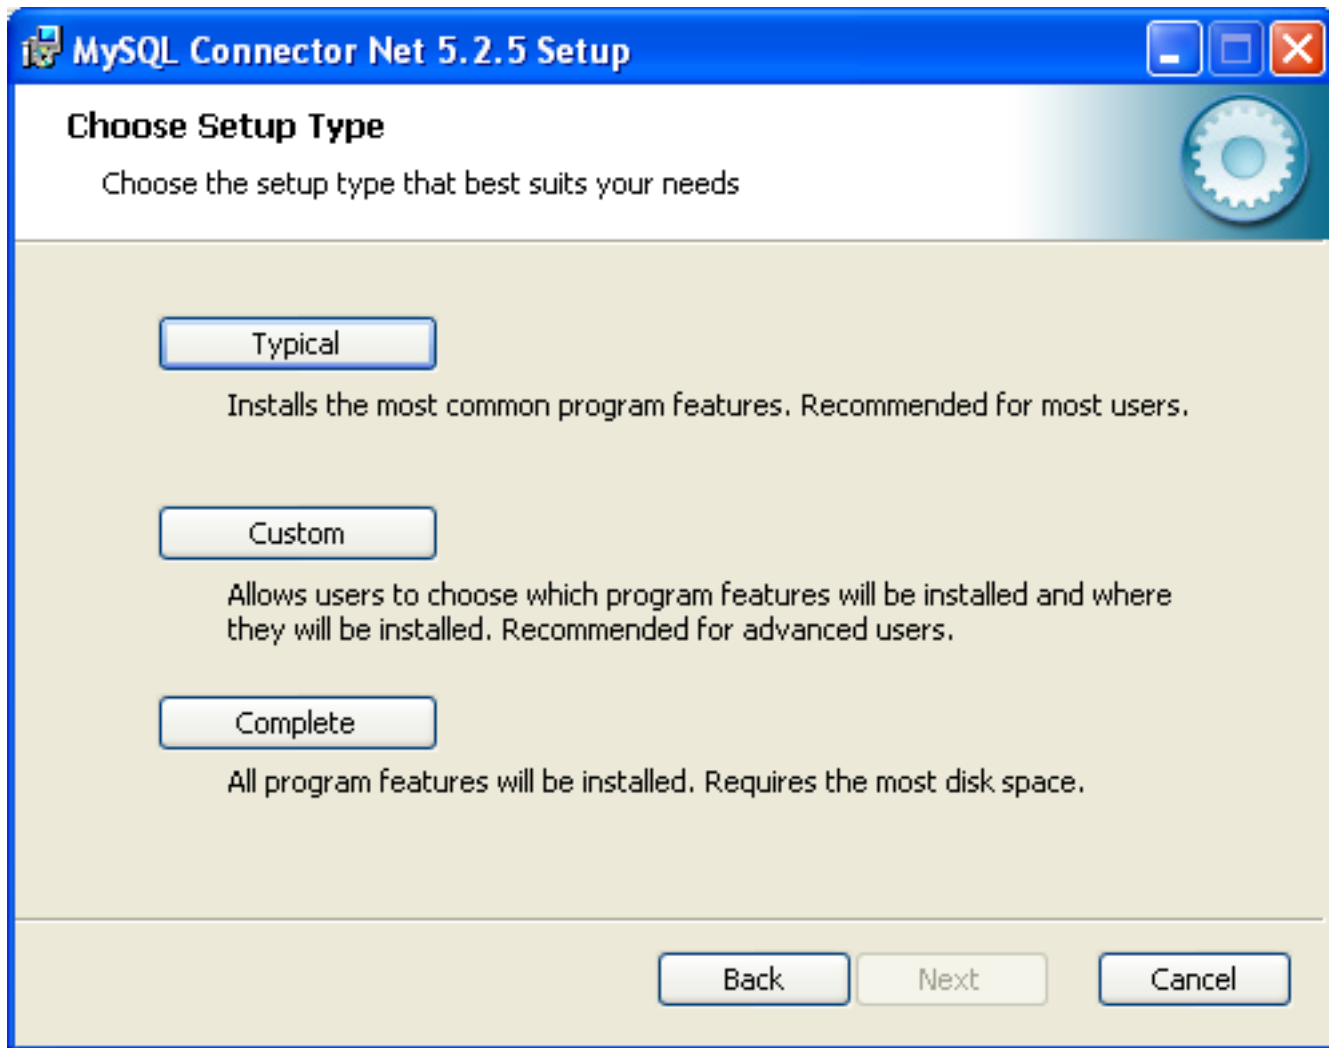

You install Connector/Net through a Windows Installer (.msi) installation package, which can install Connector/Net on all Windows operating systems. The MSI package is contained within a zip archive named `mysql-connector-net-version.zip`, where *version* indicates the Connector/Net version.

To install Connector/Net:

1. Double-click the MSI installer file extracted from the zip you downloaded. Click **Next** to start the installation.

2. You must choose the type of installation to perform.

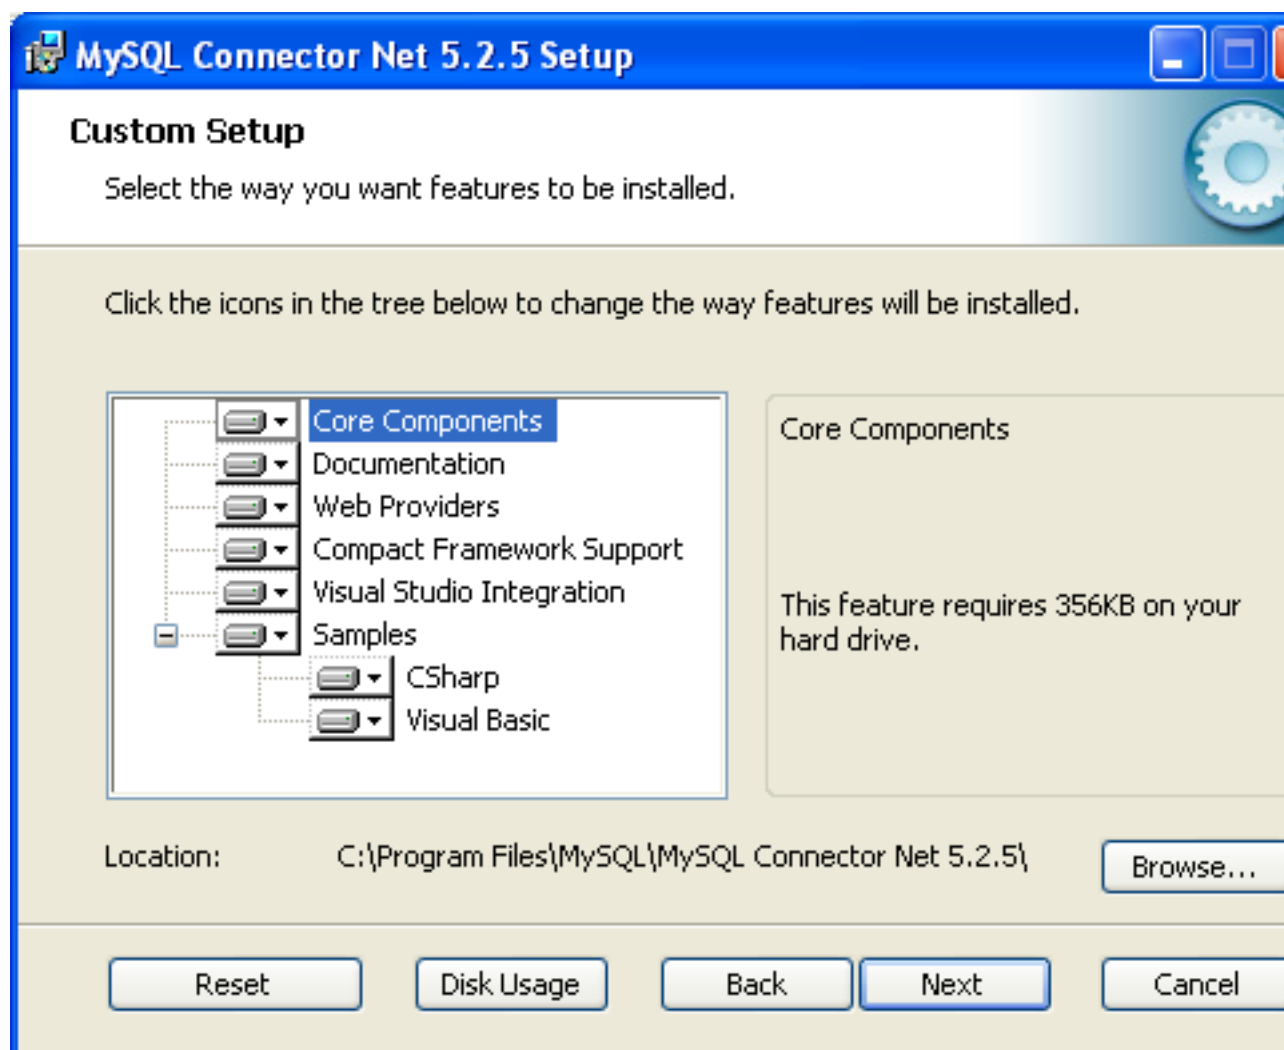

For most situations, the Typical installation is suitable. Click the **Typical** button and proceed to Step 5. A Complete installation installs all the available files. To conduct a Complete installation, click the **Complete** button and proceed to step 5. To customize your installation, including choosing the components to install and some installation options, click the **Custom** button and proceed to Step 3.

The Connector/Net installer will register the connector within the Global Assembly Cache (GAC) - this will make the Connector/Net component available to all applications, not just those where you explicitly reference the Connector/Net component. The installer will also create the necessary links in the Start menu to the documentation and release notes.

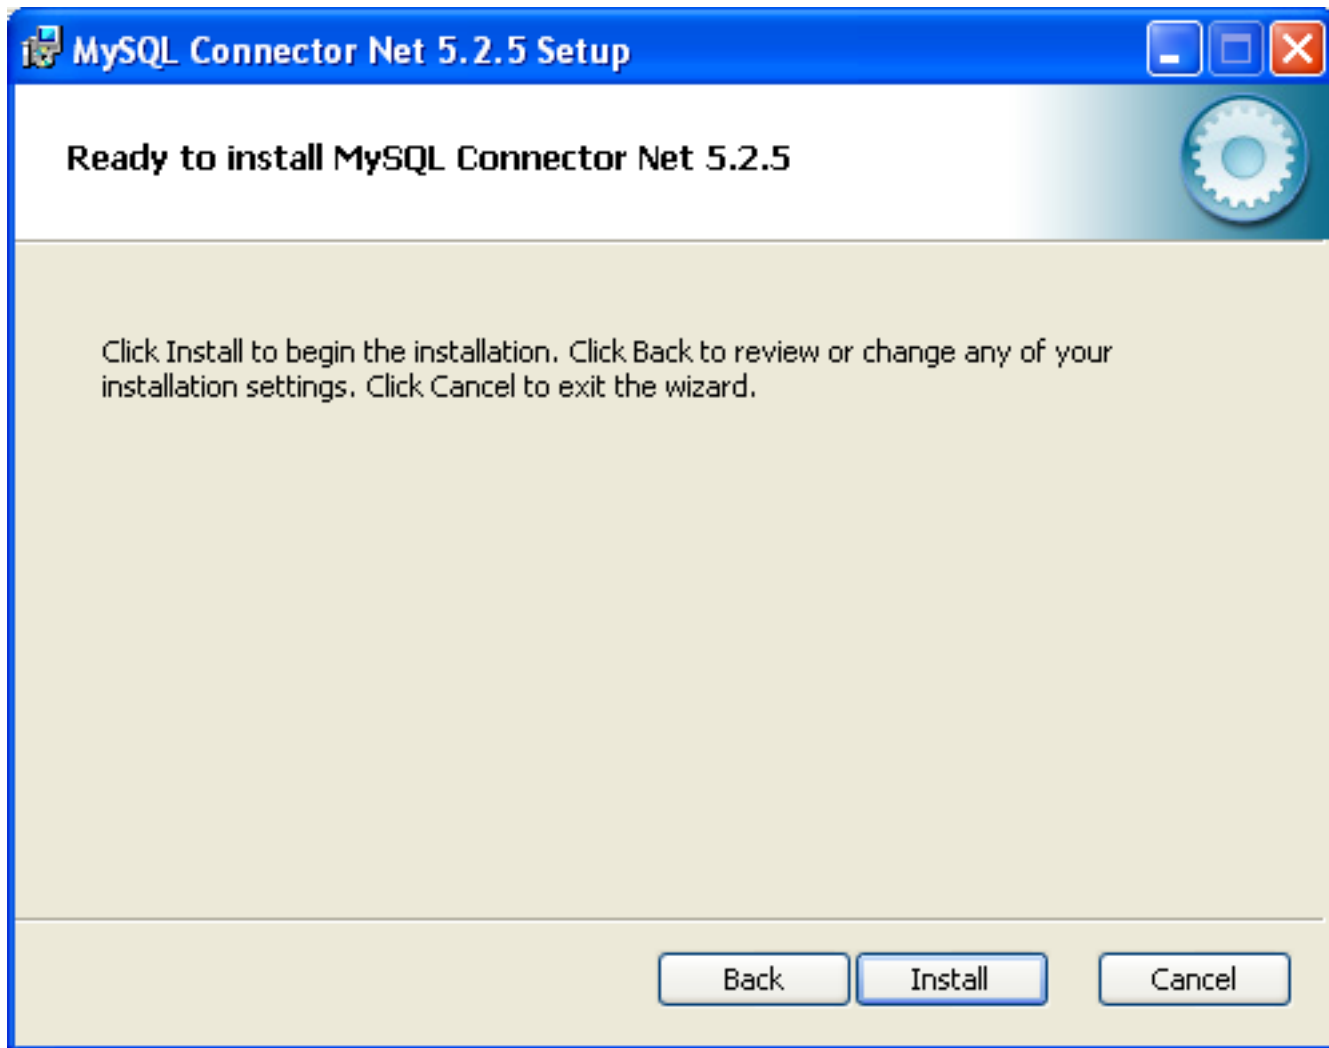

3. If you have chosen a custom installation, you can select the individual components to install, including the core interface component, supporting documentation (a CHM file) samples and examples, and the source code. Select the items, and their installation level, and then click **Next** to continue the installation.

**Note**

For Connector/Net 1.0.8 or lower and Connector 5.0.4 and lower the installer will attempt to install binaries for both 1.x and 2.x of the .NET Framework. If you only have one version of the framework installed, the connector installation may fail. If this happens, you can choose the framework version to be installed through the custom installation step.

4. You will be given a final opportunity to confirm the installation. Click **Install** to copy and install the files onto your machine.

5. Once the installation has been completed, click **Finish** to exit the installer.

Unless you choose otherwise, Connector/Net is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of Connector/Net you are installing. New installations do not overwrite existing versions of Connector/Net.

Depending on your installation type, the installed components will include some or all of the following components:

- `bin`: Connector/Net MySQL libraries for different versions of the .NET environment.
- `docs`: Connector/Net documentation in CHM format.
- `samples`: Sample code and applications that use the Connector/Net component.
- `src`: The source code for the Connector/Net component.

You may also use the `/quiet` or `/q` command-line option with the `msiexec` tool to install the Connector/Net package automatically (using the default options) with no notification to the user. Using this method the user cannot select options. Additionally, no prompts, messages or dialog boxes will be displayed.

```
C:\> msiexec /package connector-net.msi /quiet
```

To provide a progress bar to the user during automatic installation, use the `/passive` option.

#### 21.2.2.1.2. Installing Connector/Net Using the Zip Packages

If you have problems running the installer, you can download a zip file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. After downloading the zip archive, extract the files to a location of your choice.

The file contains the following directories:

- `bin`: Connector/Net MySQL libraries for different versions of the .NET environment.
- `Docs`: Connector/Net documentation in CHM format.
- `Samples`: Sample code and applications that use the Connector/Net component.

Connector/Net 6.0.x has a different directory structure:

- `Assemblies`: A collection of DLLs that make up the connector functionality.
- `Documentation`: Connector/Net documentation in CHM format.
- `Samples`: sample code and applications that use the Connector/Net component.

Another zip file available for download contains the source code distribution. This file is named `mysql-connector-net-version-src.zip`.

The file contains the following directories:

- `Documentation`: Source files to build the documentation into the compiled HTML (CHM) format.
- `Installer`: Source files to build the Connector/Net installer program.
- `MySql.Data`: Source files for the core data provider.
- `MySql.VisualStudio`: Source files for the Microsoft Visual Studio extensions.
- `MySql.Web`: Source files for the web providers. This includes code for the membership provider, role provider and profile provider. These are used in ASP.NET web sites.
- `Samples`: Source files for several example applications.
- `Tests`: A spreadsheet listing test cases.
- `VisualStudio`: Resources used by the Visual Studio plugin.

Finally, ensure that `MySql.Data.dll` is accessible to your program at build time (and runtime). If using Microsoft Visual Studio, add `MySql.Data` as a Reference to your project.

#### Note

If using MySQL Connector/Net 6.3.5 and above, the `MySql.Data.dll` file provided will work with both .NET Framework 2.x and 4.x.

### 21.2.2.2. Installing Connector/Net on Unix with Mono

There is no installer available for installing the Connector/Net component on your Unix installation. Before installing, ensure that you have a working Mono project installation. To test whether your system has Mono installed, enter:

```
shell> mono --version
```

The version of the Mono JIT compiler is displayed.

To compile C# source code, make sure a Mono C# compiler is installed. Note that there are two Mono C# compilers available, `mcs`, which accesses the 1.0-profile libraries, and `gmcs`, which accesses the 2.0-profile libraries.

To install Connector/Net on Unix/Mono:

1. Download the `mysql-connector-net-version-noinstall.zip` and extract the contents to a directory of your choice, for example: `~/connector-net/`.
2. In the directory where you unzipped the connector to, change into the `bin` subdirectory. Ensure the file `MySQL.Data.dll` is present. This filename is case-sensitive.
3. You must register the Connector/Net component, `MySQL.Data`, in the Global Assembly Cache (GAC). In the current directory enter the `gacutil` command:

```
root-shell> gacutil /i MySQL.Data.dll
```

This will register `MySQL.Data` into the GAC. You can check this by listing the contents of `/usr/lib/mono/gac`, where you will find `MySQL.Data` if the registration has been successful.

You are now ready to compile your application. You must ensure that when you compile your application you include the Connector/Net component using the `-r:` command-line option. For example:

```
shell> gmcs -r:System.dll -r:System.Data.dll -r:MySQL.Data.dll HelloWorld.cs
```

Note, the assemblies that are referenced depend on the requirements of the application, but applications using Connector/Net must provide `-r:MySQL.Data` as a minimum.

You can further check your installation by running the compiled program, for example:

```
shell> mono HelloWorld.exe
```

### 21.2.2.3. Installing Connector/Net from the Source Code

#### Caution

Read this section only if you are interested in helping us test our new code. If you just want to get Connector/Net up and running on your system, use a standard release distribution.

#### Obtaining the Source Code

To obtain the most recent development source tree, first download and install Bazaar. You can obtain Bazaar from the [Bazaar VCS Website](#). Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To check out the Connector/Net sources, change to the directory where you want the copy of the Connector/Net tree to be stored, then use the following command:

```
shell> bzip branch lp:connectornet/trunk
```

To download a specific version of Connector/Net, specify the version number instead of `trunk`. For example, to obtain a copy of the 6.0 version of the source tree:

```
shell> bzip branch lp:connectornet/6.0
```

Source packages are also available on the downloads page.

#### Building the Source Code on Windows

The following procedure can be used to build the connector on Microsoft Windows.

- Obtain the source code, either from the Subversion server, or through one of the prepared source code packages.
- Navigate to the root of the source code tree.
- A Microsoft Visual Studio 2005 solution file is available to build the connector, this is called [MySQL-VS2005.sln](#). Click this file to load the solution into Visual Studio.
- Select **Build, Build Solution** from the main menu to build the solution.

## Building the Source Code on Unix

Support for building Connector/Net on Mono/Unix is currently not available.

## 21.2.3. Connector/Net Visual Studio Integration

When MySQL Connector/Net is installed on Microsoft Windows, Visual Studio integration components are also installed and initialized. This enables the developer to work seamlessly with MySQL Connector/Net in the familiar Visual Studio environment, as described in the following sections of the manual.

MySQL Connector/Net supports Visual Studio versions 2005, 2008, and 2010. However, only MySQL Connector/Net version 6.3 and higher fully integrate with Visual Studio 2010, although applications using earlier versions of the connector can be built with the Visual Studio 2010 environment using .NET 2.x frameworks.

Visual Studio 2010 support was introduced with MySQL Connector/Net 6.3.2. From version 6.3.2 the connector ships with both .NET 2.x and .NET 4.x versions of the entity framework support files, [mysql.data.ef.dll](#) and [mysql.visualstudio.dll](#). The .NET 4.x versions are required to enable new integration features supported in Visual Studio 2010, including:

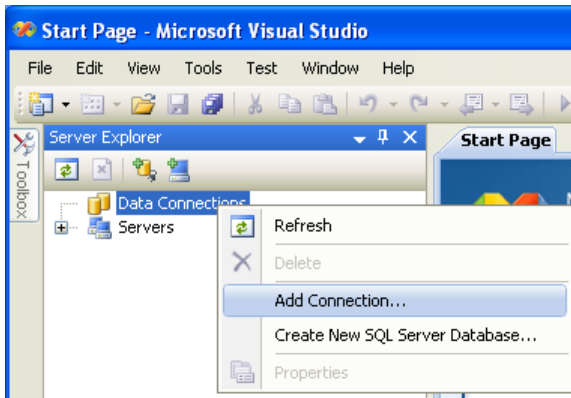

- New DDL T4 template for the Entity Framework (EF) - This enables developers to design an EF model from scratch and use the native Visual Studio 2010 facility to generate MySQL DDL from that model. This is done by creating the model, and with the model open, choosing the SSDLToMySQL template in the properties window. The correct DDL is then generated. The developer can then save this code as a [.mysql](#) file in their project and execute it against the MySQL server.
- New SQL Editor - A new SQL editor lets you connect to a MySQL server to execute SQL. This is activated by creating a new file with a [.mysql](#) extension. A new template lets you create files with this file type using the Visual Studio 2010 main menu item **File, New**. Note that the MySQL SQL Editor is also available in Visual Studio 2005 and 2008.

As of Connector/Net 5.1.2, the Visual Studio Plugin is part of the main Connector/Net package. However, even for versions of Connector/Net older than 5.1.2, the Visual Studio Plugin release notes can be found at [MySQL Connector/Net Release Notes](#).

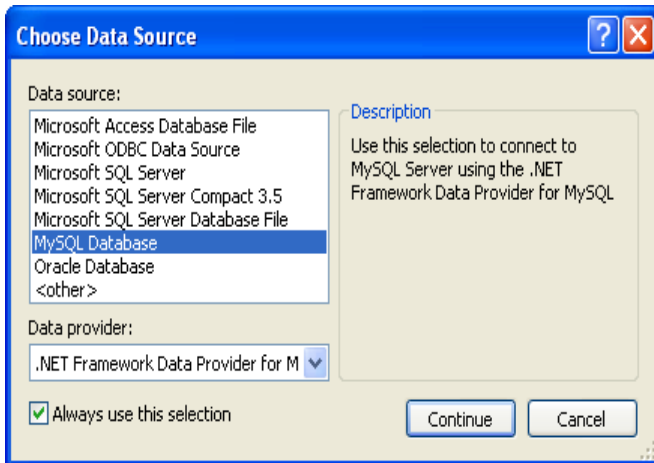

### 21.2.3.1. Making a Connection

Once the connector is installed, you can use it to create, modify, and delete connections to MySQL databases. To create a connection with a MySQL database, perform the following steps:

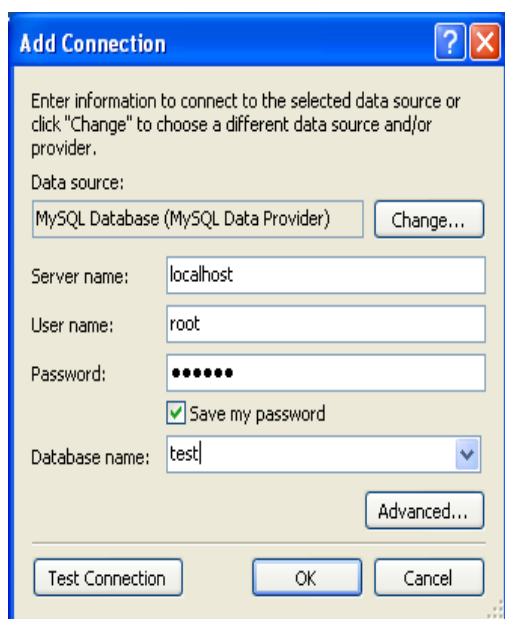

- Start Visual Studio, and open the Server Explorer window (**View, Server Explorer** option in the main Visual Studio menu, or **Control+W, L** keyboard shortcuts).
- Right-click the Data Connections node, and choose the **Add Connection...** menu item.
- Add Connection dialog opens. Press the **Change** button to choose MySQL Database as a data source.

**Figure 21.1. Add Connection Context Menu**

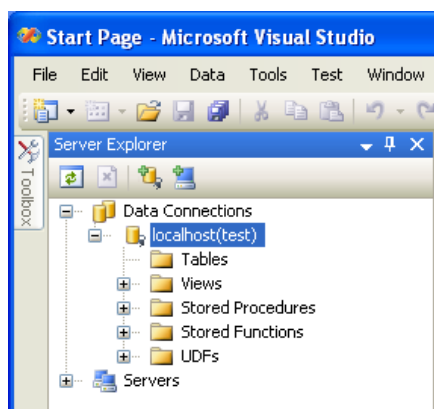

- **Change Data Source** dialog opens. Choose **MySQL Database** in the list of data sources (or the **<other>** option, if MySQL Database is absent), and then choose **.NET Framework Data Provider for MySQL** in the combo box of data providers.

**Figure 21.2. Choose Data Source**

- Input the connection settings: the server host name (for example, localhost if the MySQL server is installed on the local machine), the user name, the password, and the default schema name. Note that you must specify the default schema name to open the connection.

**Figure 21.3. Add Connection Dialog**

- You can also set the port to connect with the MySQL server by pressing the **Advanced** button. To test connection with the MySQL server, set the server host name, the user name, and the password, and press the **Test Connection** button. If the test succeeds, the success confirmation dialog opens.
- After you set all settings and test the connection, press **OK**. The newly created connection is displayed in Server Explorer. Now you can work with the MySQL server through standard Server Explorer GUI.

**Figure 21.4. New Data Connection**

After the connection is successfully established, all settings are saved for future use. When you start Visual Studio for the next time, open the connection node in Server Explorer to establish a connection to the MySQL server again.

To modify and delete a connection, use the Server Explorer context menu for the corresponding node. You can modify any of the settings by overwriting the existing values with new ones. Note that the connection may be modified or deleted only if no active editor for its objects is opened: otherwise, you may lose your data.

### 21.2.3.2. Using IntelliSense in the SQL Editor

IntelliSense support is available starting in Connector/Net 6.5. Once you have established a connection, for example, using the **Connect to MySQL** toolbar button, you can get autocompletion as

you type, or by pressing **Control+J**. Depending on the context, the autocompletion dialog can show the list of available tables, table columns, or stored procedures (with the routine's signature as a tooltip). Typing some characters before pressing **Control+J** filters the choices to those items starting with that prefix.

### 21.2.3.3. Editing Tables

Connector/Net contains a table editor, which enables the visual creation and modification of tables.

The Table Designer can be accessed through a mouse action on table-type node of Server Explorer. To create a new table, right-click the **Tables** node (under the connection node) and choose the **Create Table** command from the context menu.

To modify an existing table, double-click the node of the table to modify, or right-click this node and choose the **Design** item from the context menu. Either of the commands opens the Table Designer.

The table editor is implemented in the manner of the well-known Query Browser Table Editor, but with minor differences.

**Figure 21.5. Editing New Table**

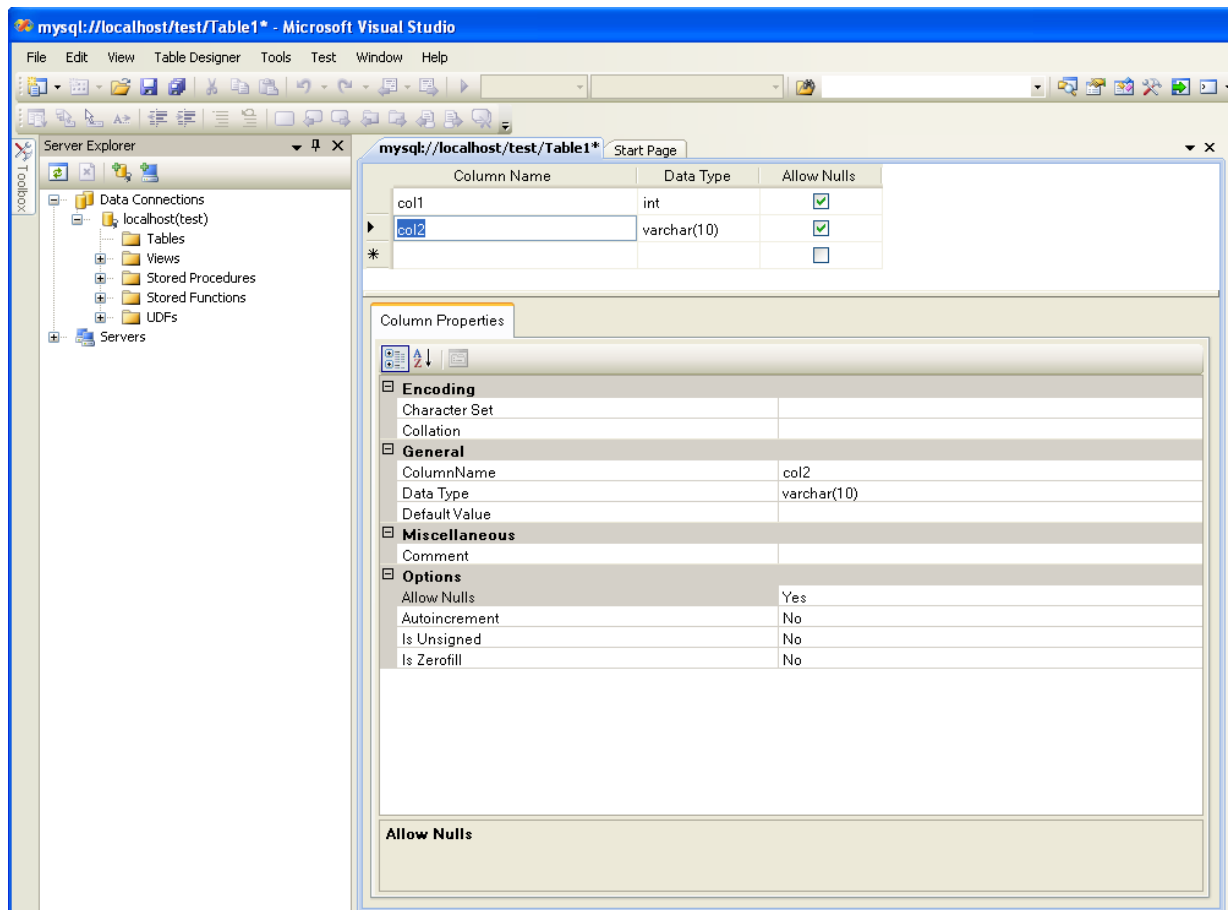

Table Designer consists of the following parts:

- Columns Editor - a data grid on top of the Table Designer. Use the Columns grid for column creation, modification, and deletion.
- Indexes tab - a tab on bottom of the Table Designer. Use the Indexes tab for indexes management.
- Foreign Keys tab - a tab on bottom of the Table Designer. Use the Foreign Keys tab for foreign keys management.

- Column Details tab - a tab on bottom of the Table Designer. Use the Column Details tab to set advanced column options.
- Properties window - a standard Visual Studio Properties window, where the properties of the edited table are displayed. Use the Properties window to set the table properties.

Each of these areas is discussed in more detail in subsequent sections.

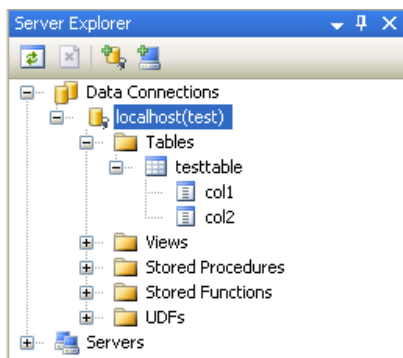

To save changes you have made in the Table Designer, use either **Save** or **Save All** button of the Visual Studio main toolbar, or press **Control+S**. If you have not already named the table, you will be prompted to do so.

**Figure 21.6. Choose Table Name**

Once the table is created, you can view it in the Server Explorer.

**Figure 21.7. Newly Created Table**

The Table Designer main menu lets you set a [primary key](#) column, edit relationships such as [foreign keys](#), and create [indexes](#).

**Figure 21.8. Table Designer Main Menu**

### 21.2.3.3.1. Column Editor

You can use the Column Editor to set or change the name, data type, default value, and other properties of a table column. To set the focus to a needed cell of a grid, use the mouse click. Also you can move through the grid using **Tab** and **Shift+Tab** keys.

To set or change the name, data type, default value and comment of a column, activate the appropriate cell and type the desired value.

To set or unset flag-type column properties (`NOT NULL`, auto incremented, flags), check or uncheck the corresponding check boxes. Note that the set of column flags depends on its data type.

To reorder columns, index columns or foreign key columns in the Column Editor, select the whole column to reorder by clicking the selector column on the left of the column grid. Then move the column by using **Control+Up** (to move the column up) or **Control+Down** (to move the column down) keys.

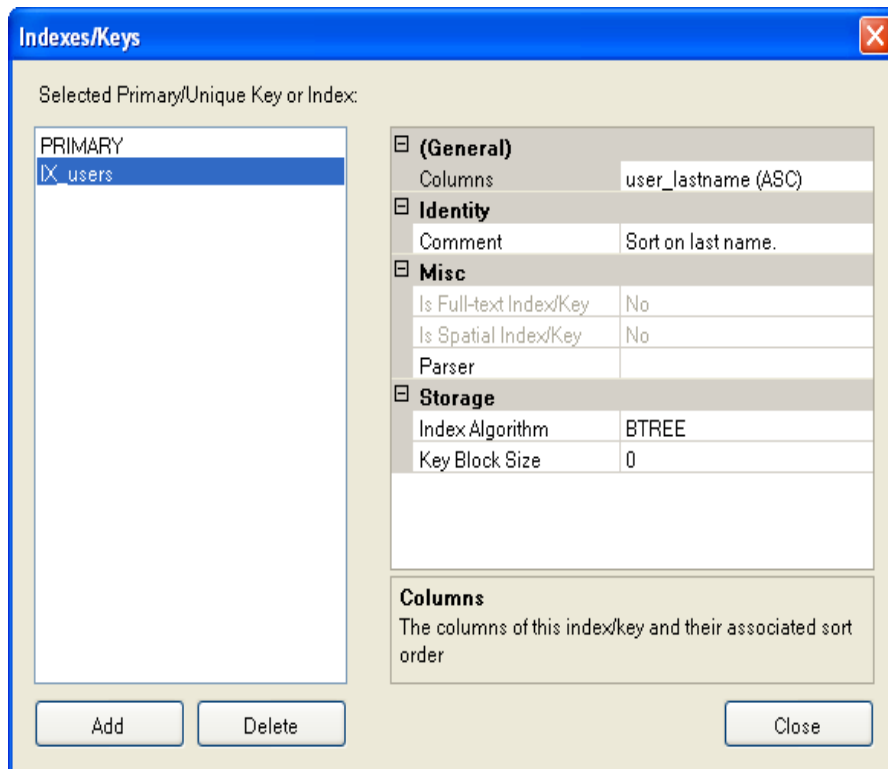

To delete a column, select it by clicking the selector column on the left of the column grid, then press the **Delete** button on a keyboard.

### 21.2.3.3.2. Editing Indexes

Indexes management is performed using the **Indexes/Keys** dialog.

To add an index, select **Table Designer, Indexes/Keys...** from the main menu, and click **Add** to add a new index. You can then set the index name, index kind, index type, and a set of index columns.

**Figure 21.9. Indexes Dialog**

To remove an index, select it in the list box on the left, and click the **Delete** button.

To change index settings, select the needed index in the list box on the left. The detailed information about the index is displayed in the panel on the right hand side. Change the desired values.

### 21.2.3.3.3. Editing Foreign Keys

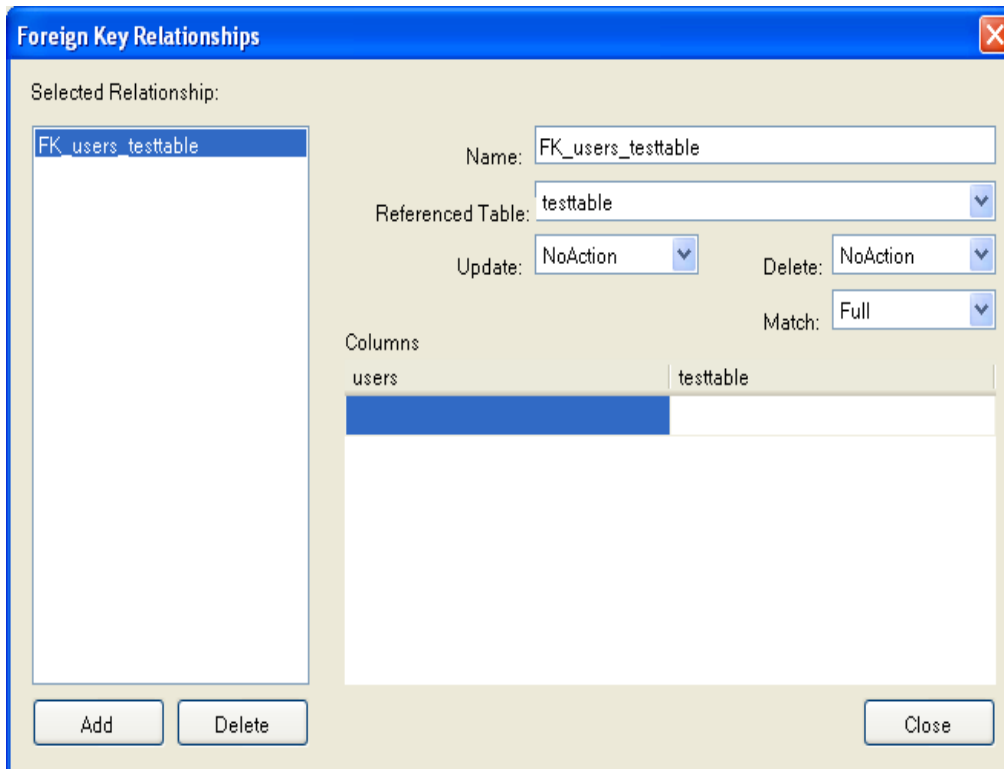

You manage **foreign keys** for **InnoDB** tables using the **Foreign Key Relationships** dialog.

To add a foreign key, select **Table Designer, Relationships...** from the main menu. This displays the **Foreign Key Relationship** dialog. Click **Add**. You can then set the foreign key name, referenced table name, foreign key columns, and actions upon update and delete.

To remove a foreign key, select it in the list box on the left, and click the **Delete** button.

To change foreign key settings, select the required foreign key in the list box on the left. The detailed information about the foreign key is displayed in the right hand panel. Change the desired values.

**Figure 21.10. Foreign Key Relationships Dialog**

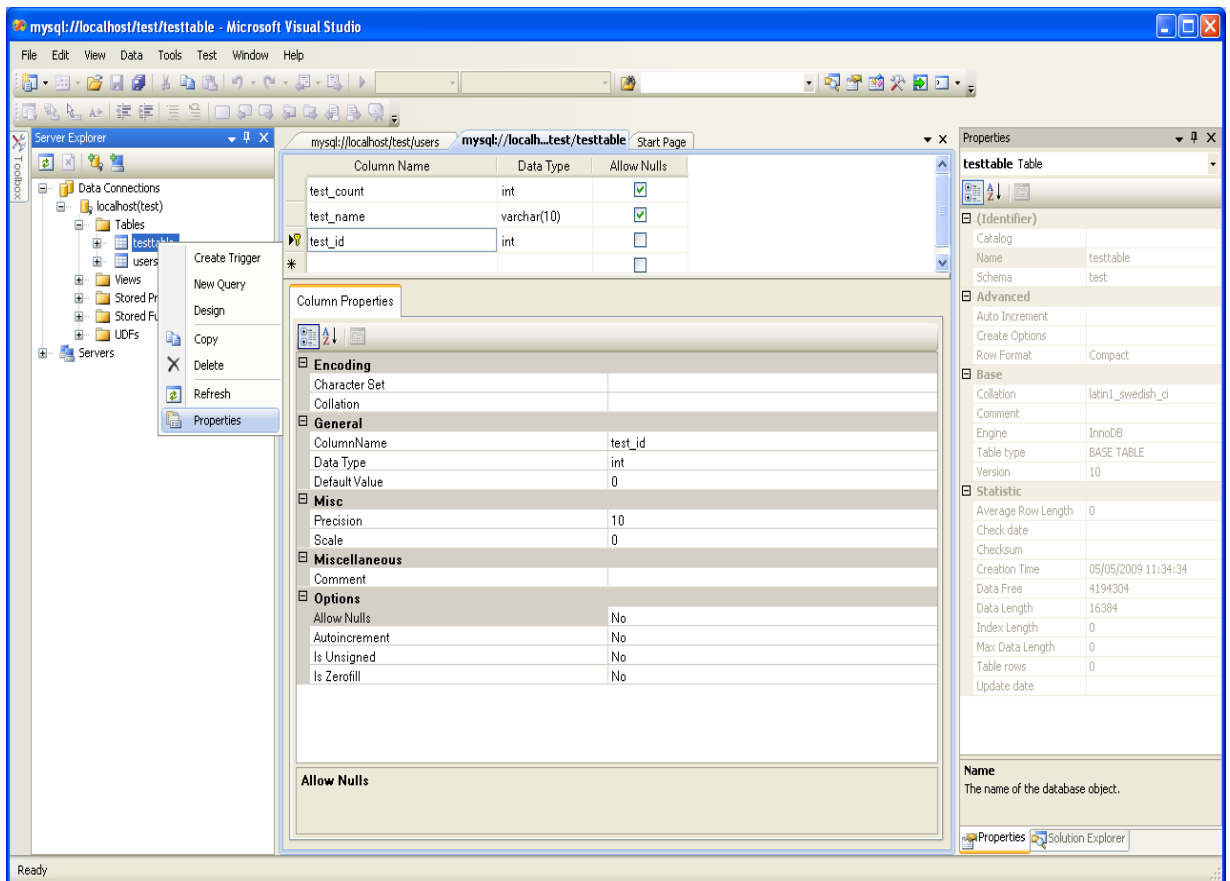

#### 21.2.3.3.4. Column Properties

The **Column Properties** tab can be used to set column options. In addition to the general column properties presented in the Column Editor, in the **Column Properties** tab you can set additional properties such as Character Set, Collation and Precision.

#### 21.2.3.3.5. Table Properties

To bring up Table Properties select the table and right-click to activate the context menu. Select **Properties**. The **Table Properties** dockable window will be displayed.

Figure 21.11. Table Properties Menu Item

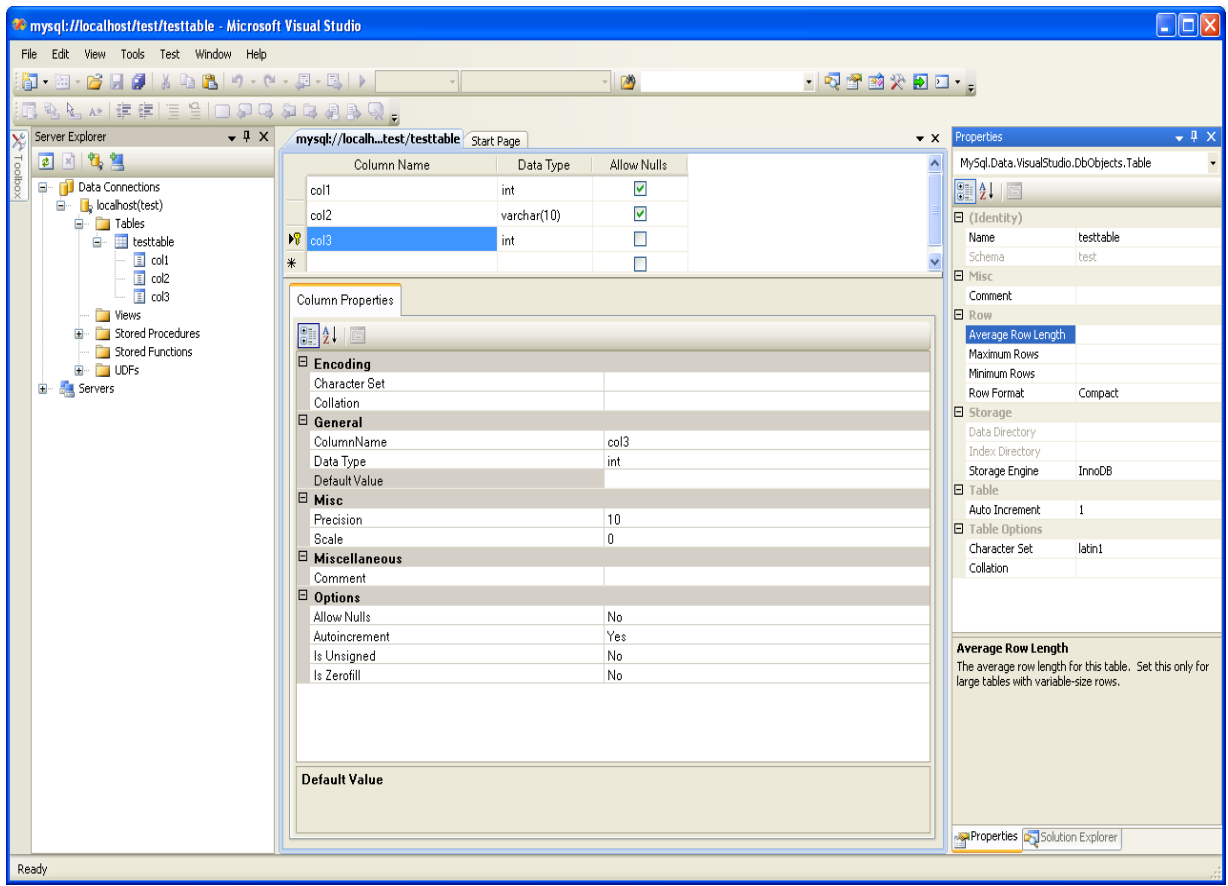

The following table properties can be set:

- Auto Increment.
- Average Row Length.
- Character Set.
- Collation.
- Comment.
- Data Directory.
- Index Directory.
- Maximum Rows.
- Minimum Rows.
- Name.
- Row Format.
- Schema.
- [Storage Engine](#). Note that in MySQL 5.5 and higher, the default storage engine for new tables is [InnoDB](#). See [Section 14.2.1.1, “InnoDB as the Default MySQL Storage Engine”](#) for more information about the choice of storage engine, and considerations if you convert existing tables to [InnoDB](#).

The property [Schema](#) is read-only.

Figure 21.12. Table Properties

### 21.2.3.4. Editing Views

To create a new view, right-click the Views node under the connection node in Server Explorer. From the node's context menu, choose the **Create View** command. This command opens the SQL Editor.

Figure 21.13. Editing View SQL

You can then enter the SQL for your view.

Figure 21.14. View SQL Added

To modify an existing view, double-click a node of the view to modify, or right-click this node and choose the **Alter View** command from a context menu. Either of the commands opens the SQL Editor.

All other view properties can be set in the Properties window. These properties are:

- Catalog

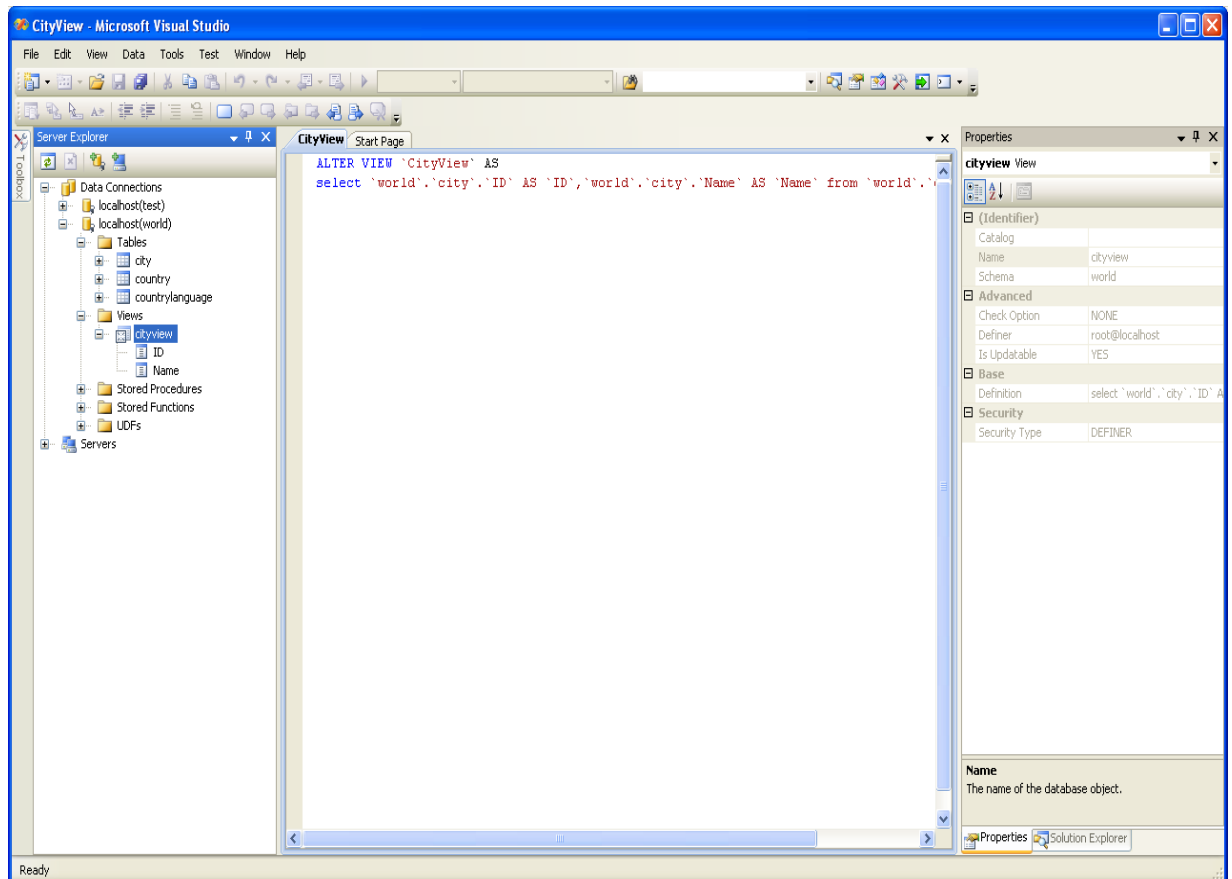

- Check Option
- Definer
- Definition
- Definer
- Is Updatable
- Name
- Schema
- Security Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value with an embedded combobox.

The properties `Is Updatable` and `Schema` are readonly.

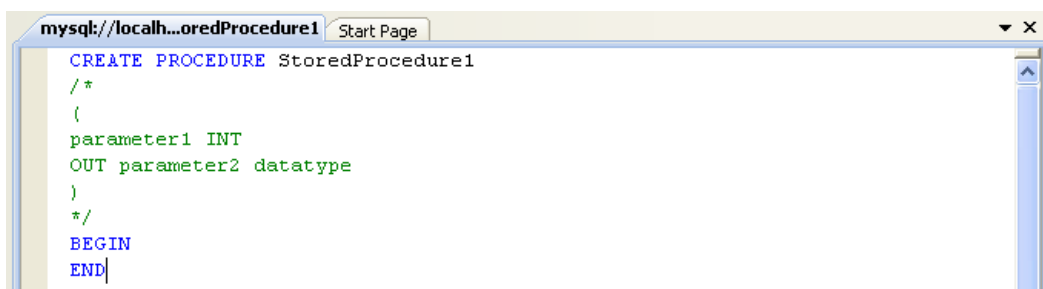

To save changes you have made, use either `Save` or `Save All` buttons of the Visual Studio main toolbar, or press **Control+S**.

**Figure 21.15. View SQL Saved**

### 21.2.3.5. Editing Stored Procedures and Functions

To create a new stored procedure, right-click the **Stored Procedures** node under the connection node in Server Explorer. From the node's context menu, choose the **Create Routine** command. This command opens the SQL Editor.

**Figure 21.16. Edit Stored Procedure SQL**

To create a new stored function, right-click the **Functions** node under the connection node in Server Explorer. From the node's context menu, choose the **Create Routine** command.

To modify an existing stored routine (procedure or function), double-click the node of the routine to modify, or right-click this node and choose the **Alter Routine** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the routine definition using SQL Editor, type this definition in the SQL Editor using standard SQL. All other routine properties can be set in the Properties window. These properties are:

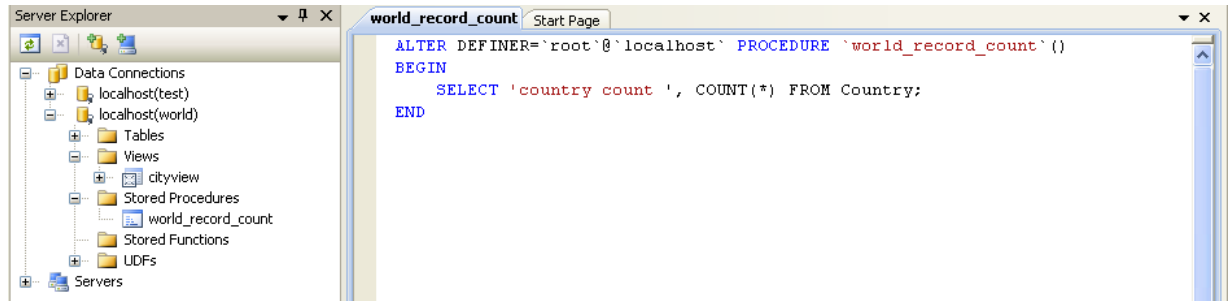

- Body
- Catalog
- Comment
- Creation Time
- Data Access
- Definer
- Definition
- External Name
- External Language
- Is Deterministic
- Last Modified
- Name
- Parameter Style
- Returns
- Schema
- Security Type
- Specific Name
- SQL Mode
- SQL Path
- Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value using the embedded combo box.

You can also set all the options directly in the SQL Editor, using the standard `CREATE PROCEDURE` or `CREATE FUNCTION` statement. However, it is recommended to use the Properties window instead.

To save changes you have made, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**.

**Figure 21.17. Stored Procedure SQL Saved**

To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See [Section 21.2.3.8, “Debugging Stored Procedures and Functions”](#) for details.

### 21.2.3.6. Editing Triggers

To create a new trigger, right-click the node of the table in which to add the trigger. From the node's context menu, choose the **Create Trigger** command. This command opens the SQL Editor.

To modify an existing trigger, double-click the node of the trigger to modify, or right-click this node and choose the **Alter Trigger** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the trigger definition using SQL Editor, type the trigger statement in the SQL Editor using standard SQL.

#### Note

Enter only the trigger statement, that is, the part of the `CREATE TRIGGER` query that is placed after the `FOR EACH ROW` clause.

All other trigger properties are set in the Properties window. These properties are:

- Definer
- Event Manipulation
- Name
- Timing

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value using the embedded combo box.

The properties `Event Table`, `Schema`, and `Server` in the Properties window are read-only.

To save changes you have made, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See [Section 21.2.3.8, “Debugging Stored Procedures and Functions”](#) for details.

### 21.2.3.7. Editing User Defined Functions (UDF)

To create a new User Defined Function (UDF), right-click the **UDFs** node under the connection node in Server Explorer. From the node's context menu, choose the [Create UDF](#) command. This command opens the UDF Editor.

To modify an existing UDF, double-click the node of the UDF to modify, or right-click this node and choose the [Alter UDF](#) command from the context menu. Either of these commands opens the UDF Editor.

The UDF editor enables you to set the following properties:

- Name
- So-name (DLL name)
- Return type
- Is Aggregate

There are text fields for both names, a combo box for the return type, and a check box to indicate if the UDF is aggregate. All these options are also accessible using the Properties window.

The property `Server` in the Properties window is read-only.

To save changes you have made, use either `Save` or `Save All` buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See [Section 21.2.3.8, "Debugging Stored Procedures and Functions"](#) for details.

### 21.2.3.8. Debugging Stored Procedures and Functions

The stored procedure debugger, new in Connector/Net 6.6, provides facilities for setting breakpoints, stepping into individual statements (Step Into, Step Out, Step Over), evaluating and changing local variable values, evaluating breakpoints, and other typical debugging tasks.

#### Installing the Debugger

To enable the stored procedure debugger, install Connector/Net 6.6 or higher and choose the **Complete** option.

#### Privileges

The debugger recreates at the start of each debug session a `serversidedebugger` database in your server. This database helps to track the instrumented code and implement observability logic in the debugged routine. Your current connection needs to have privileges to create that database, and its associated stored routines, functions, and tables.

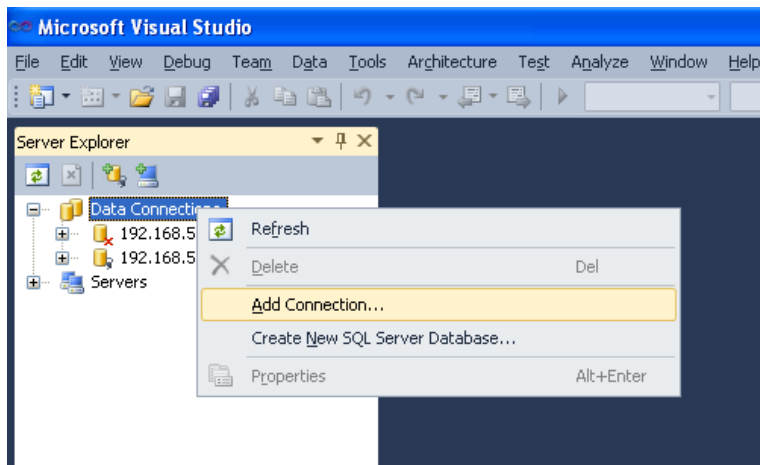

The debugger makes changes behind the scenes to temporarily add instrumentation code to the stored routines that you debug. You must have the `ALTER ROUTINE` privilege for each stored procedure, function, or trigger that you debug. (Including procedures and functions that are called, and triggers that are fired, by a procedure that you are debugging.)

#### Starting the Debugger

To start the debugger, follow these steps:

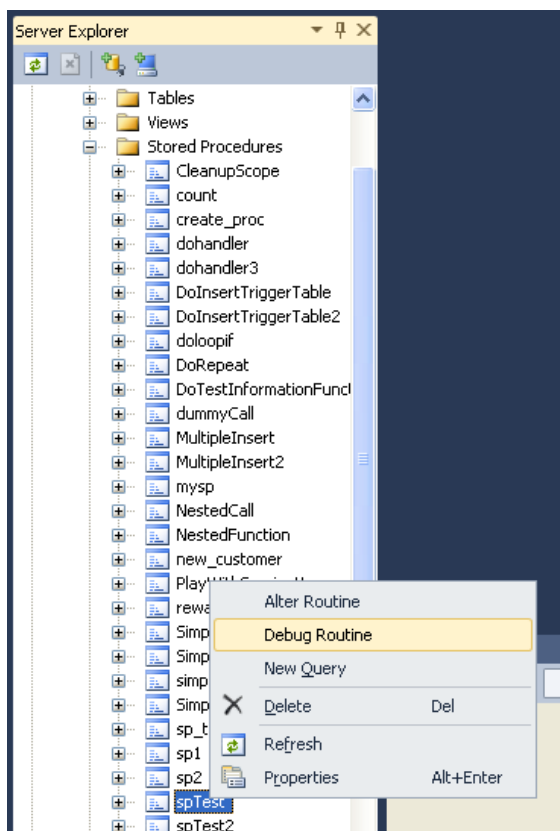

- Choose a connection in the Visual Studio Server Explorer.

**Figure 21.18. Connection Dialog**

- Expand the **Stored Procedures** folder. Only stored procedures can be debugged directly. To debug a user-defined function, create a stored procedure that calls the function.
- Click on a stored procedure node, then right-click and from the context menu choose **Debug Routine**.

**Figure 21.19. Choose a Stored Routine to Debug**

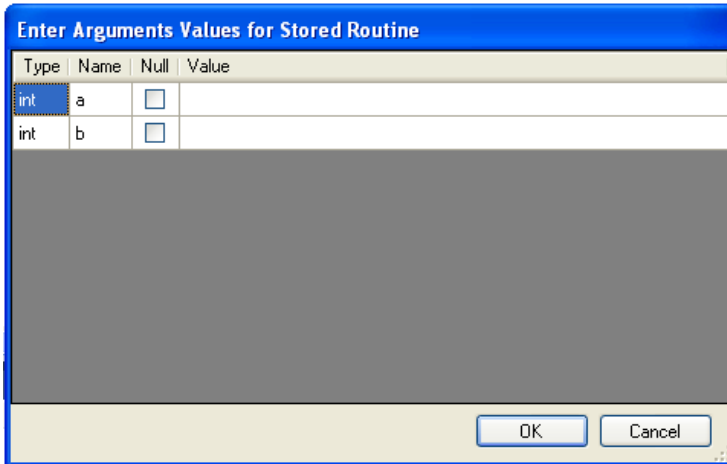

At this point, Visual Studio switches to debug mode, opening the source code of the routine being debugged in step mode, positioned on the first statement.

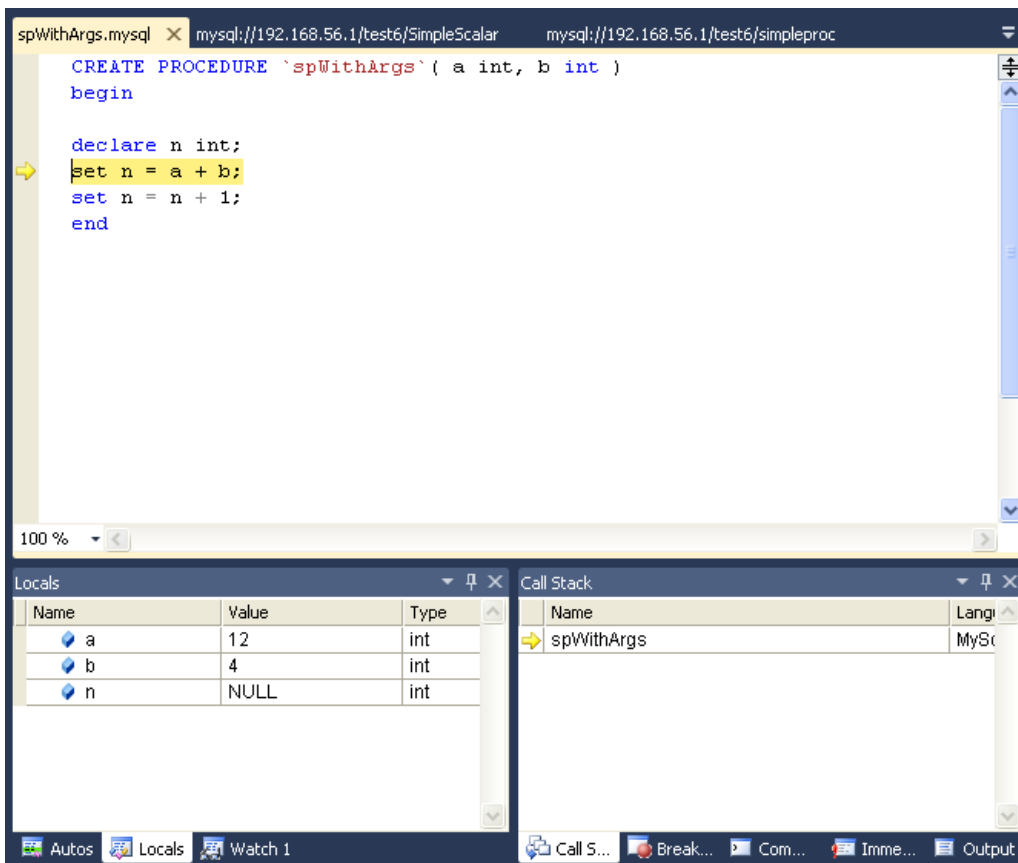

If the initial routine you debug has one or more arguments, a popup will show up with a grid (a row per each argument and three columns: one for the argument, one for the argument value (this is editable)

and one for nullifying that argument value (a checkbox). After setting up all the argument values, you can press **OK** to start the debug session, or **Cancel** to cancel the debug session.

**Figure 21.20. Setting Arguments (1 of 2)**

**Figure 21.21. Setting Arguments (2 of 2)**

## How the Debugger Works

To have visibility into the internal workings of a stored routine, the debugger prepares a special version of the procedure, function, or trigger being debugged, instrumented with extra code to keep track of the current line being stepped into and the values of all the local variables. Any other stored procedures, functions, or triggers called from the routine being debugged are instrumented the same way. The debug versions of the routines are prepared for you automatically, and when the debug session ends (by either pressing **F5** or **Shift+F5**), the original versions of the routines are automatically restored.

A copy of the original version of each instrumented routine (the version without instrumentation) is stored in the `AppData\Roaming\MySQLDebuggerCache` folder for the current Windows user (the path returned by calling `System.Environment.GetFolderPath(Environment.SpecialFolder.ApplicationData)` in .NET, plus appending `MySQLDebuggerCache`). There is one file for each instrumented routine, named `routine_name.mysql`. For example, in Windows 7, for a user named `fergs`, the path is `C:\Users\fergs\AppData\Roaming\MySQLDebuggerCache`.

Two threads are used, one for the debugger and one for the routine being debugged. The threads run in strict alternation, switching between the debugger and the routine as each statement is executed in the stored routine.

## Basic Debugging Operations

The debugger has the same look and feel as the standard Visual Studio debuggers for C#, VB.NET or C++. In particular, the following are true:

### Locals and Watches

- To show the Locals tab, choose the menu item **Debug -> Windows -> Locals**.

The **Locals** tab lists all the variables available in the current scope: variables defined with `DECLARE` at any point in the routine, argument parameters, and session variables that are referenced.

- If the last step operation changes the value of a local, its value will be highlighted in red (until another statement is executed or stepped).
- You can change the value of any local.
- To show the **Watch** tab, choose the menu item **Debug -> Windows -> Watch**.

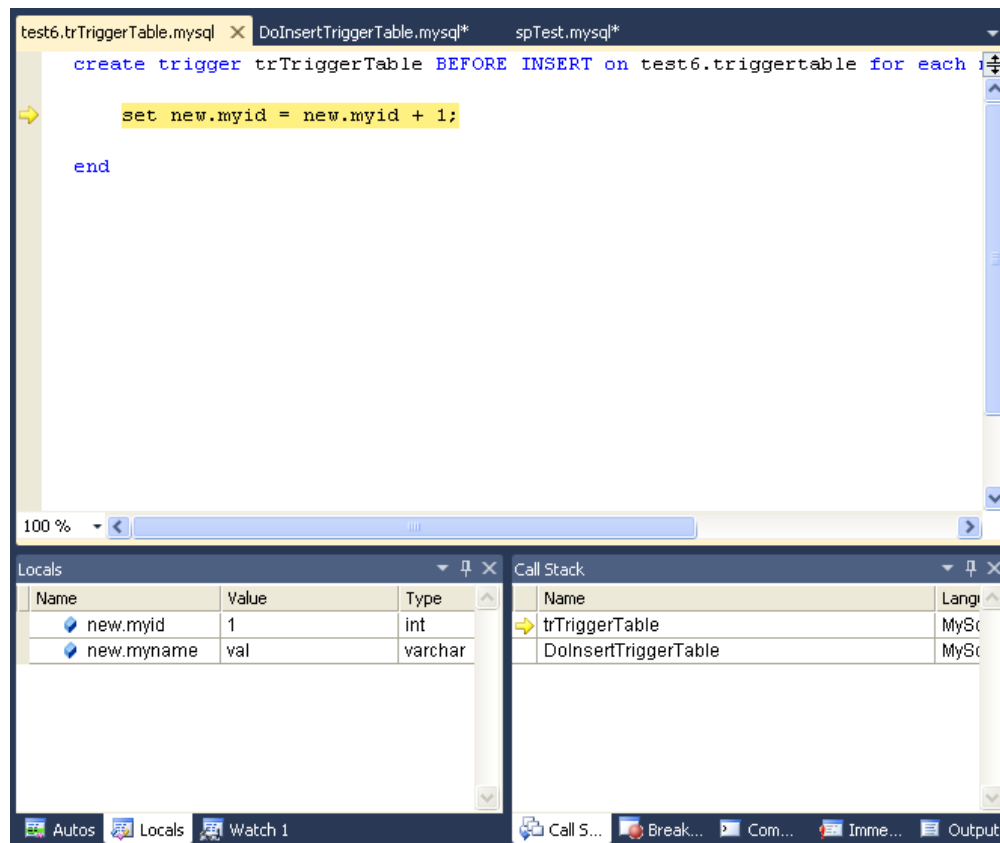

To define a watch, type any valid MySQL expression, optionally including function calls. If the watch evaluation makes sense in the current context (current stack frame), it will show its value, otherwise it will show an error message in the same row the watch was defined.

- When debugging a trigger, in addition to any locals declared or session variables referenced, the new and old object (when applicable) will be listed. For example in a trigger for `INSERT`, for a table defined like:

```
create table t1( id int, myname varchar( 50 ));
```

the locals will list the extra variables `new.id` and `new.myname`. For an `UPDATE` trigger, you will also get the extra variables `old.id` and `old.myname`. These variables from the new and old objects can be manipulated the same way as any ordinary local variable.

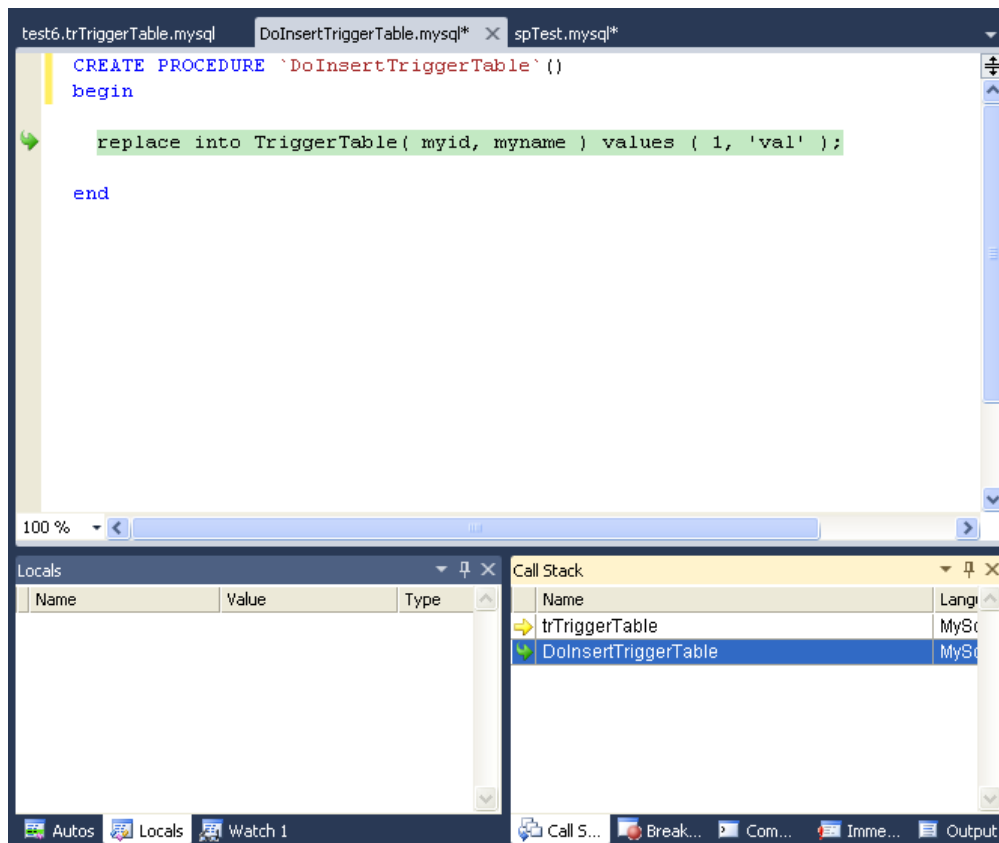

Figure 21.22. Debugging a Trigger

### Call Stack

- To show the **Call Stack** tab, choose the menu item **Debug -> Windows -> Call Stack**.
- The stack trace (in the **Call Stack** tab) will list all the stack traces, one for each routine invocation. The one with a yellow mark is the current stepping point. Clicking in another will activate in the editor the tab for that routine source, highlighting in green the last statement stepped.

Figure 21.23. Call Stack

### Stepping

- Stepping of a new routine starts in the first executable instruction (excluding declares, handlers, cursor declarations, and so on).

Figure 21.24. Debug Stepping

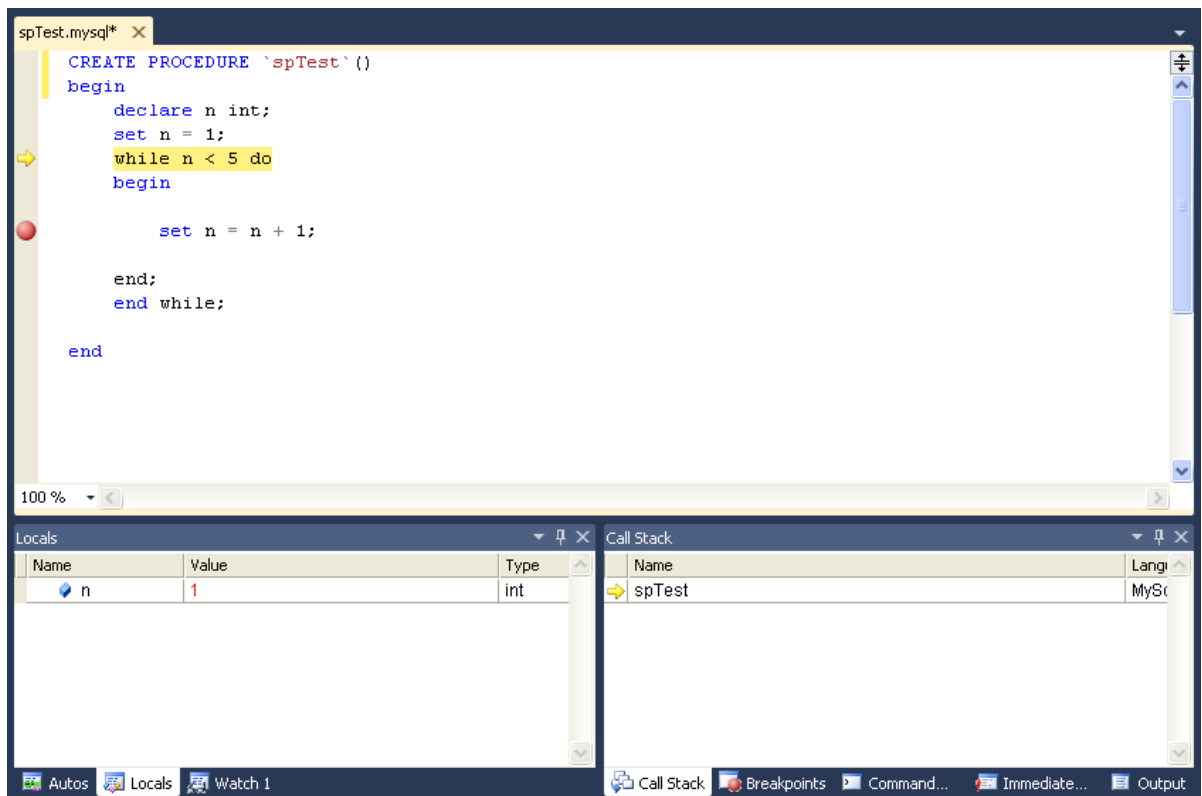

Figure 21.25. Function Stepping (1 of 2)

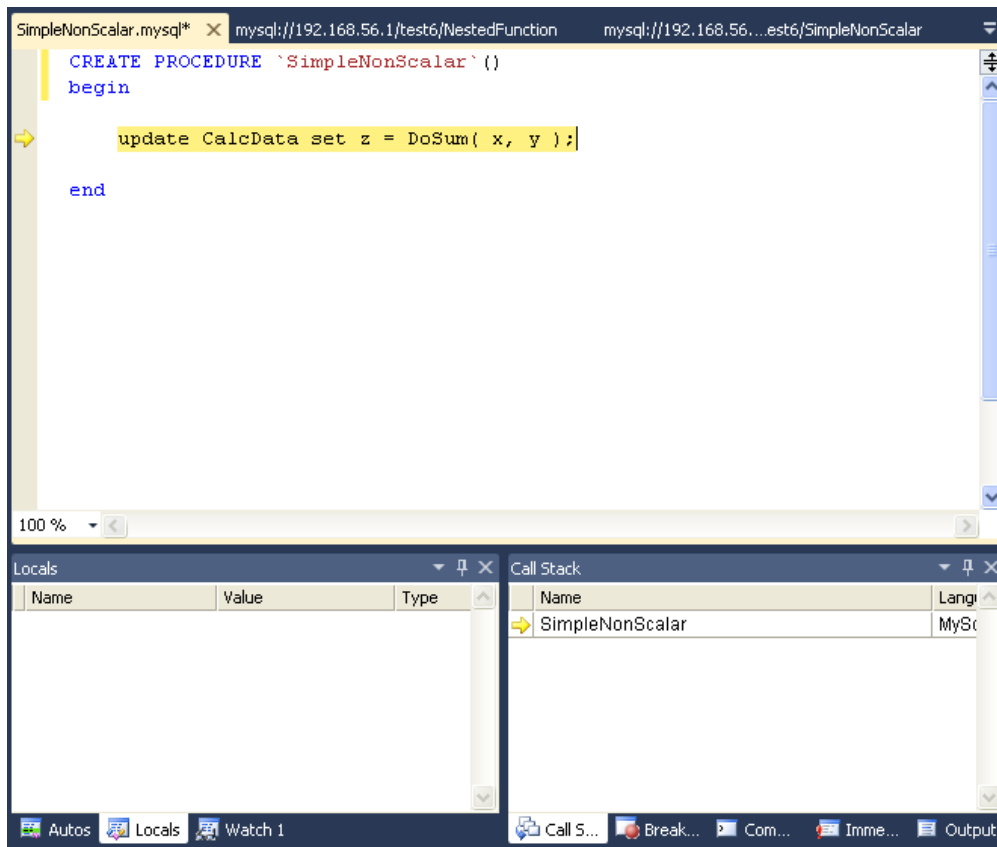

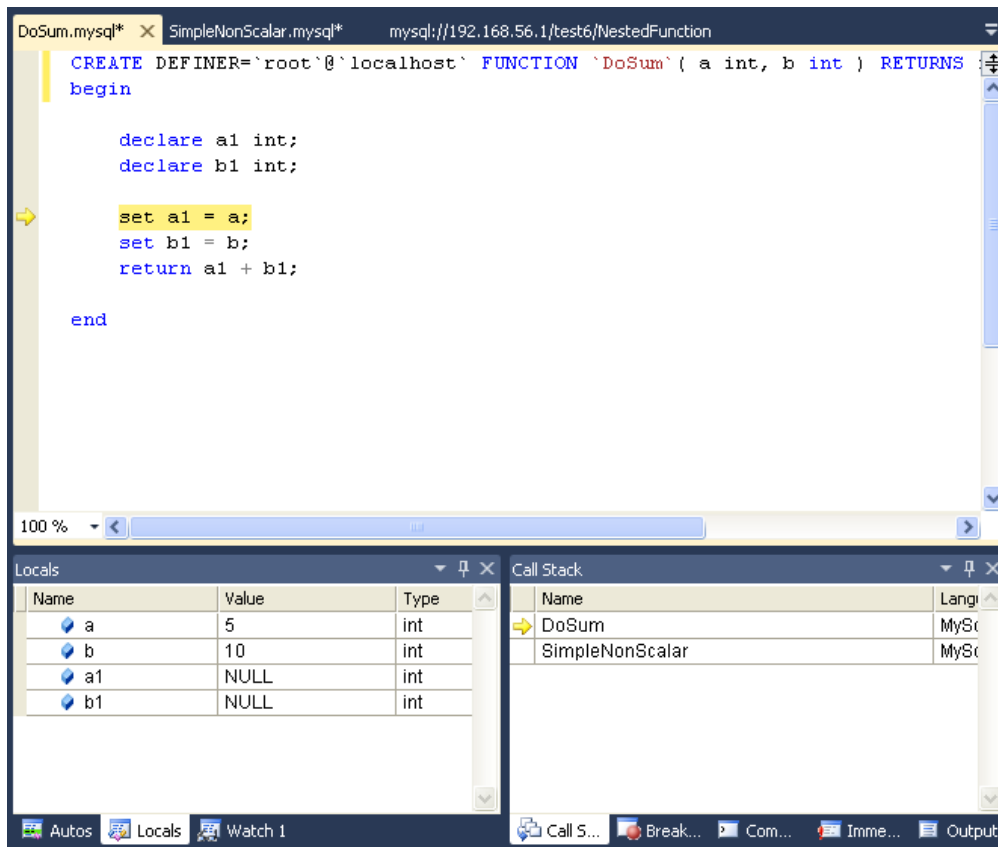

Figure 21.26. Function Stepping (2 of 2)

- To step into the code of a condition handler, the condition must be triggered in the rest of the MySQL routine.
- The next statement to be executed is highlighted in yellow.
- To continue stepping, you can choose between **Step Into** (by pressing **F11**), **Step Out** (by pressing **F10**) or **Step Over** (by pressing **Shift+F11**).
- You can step out of any of functions, triggers or stored procedures. If you step from the main routine, it will run that routine to completion and finish the debug session.
- You can step over stored procedure calls, stored functions, and triggers. (To step over a trigger, step over the statement that would cause the trigger to fire.)
- When stepping into a single statement, the debugger will step into each individual function invoked by that statement and each trigger fired by that statement. The order in which they are debugged is the same order in which the MySQL server executes them.
- You can step into triggers triggered from [INSERT](#), [DELETE](#), [UPDATE](#), and [REPLACE](#) statements.
- Also, the number of times you enter into a stored function or trigger depends on how many rows are evaluated by the function or affected by the trigger. For example, if you press **F11 (Step Into)** into an [UPDATE](#) statement that modifies three rows (calling a function for a column in the [SET](#) clause, thus invoking the function for each of the three rows), you will step into into that function three times in succession, once for each of the rows. You can accelerate this debug session by disabling any breakpoints defined in the given stored function and pressing **Shift+F11** to step out. In this example, the order in which the different instances of the stored function are debugged is server-specific: the same order used by the current MySQL server instance to evaluate the three function invocations.

### Breakpoints

- To show the **Breakpoints** tab, choose the menu item **Debug -> Windows -> Breakpoints**.
- The **Breakpoints** tab will show all the breakpoints defined. From here, you can enable and disable breakpoints one by one or all at once (using the toolbar on top of the **Breakpoints** tab).
- You can define new breakpoints only in the middle of a debug session. Click in the left gray border of any MySQL editor, or click anywhere in a MySQL editor and press **F9**. In the familiar Visual Studio way, you press **F9** once to create a breakpoint in that line, and press it again to remove that breakpoint.
- Once a breakpoint is defined, it will appear enabled (as filled red circle left to the current row if that line is a valid statement to put a breakpoint) or disabled (as a non-filled red circle left to the current row if that row is not valid to put a breakpoint).
- To define conditional breakpoints, after creating the breakpoint, right click in the red dot and choose **Condition...**. There you can put any valid MySQL expression and state if the condition is **Is True** or **Has changed**. The former will trigger the breakpoint every time the condition is true, the latter every time the condition value has changed. (If you define a conditional breakpoint, it is not enough to step into the line with the breakpoint defined to trigger such a breakpoint.)

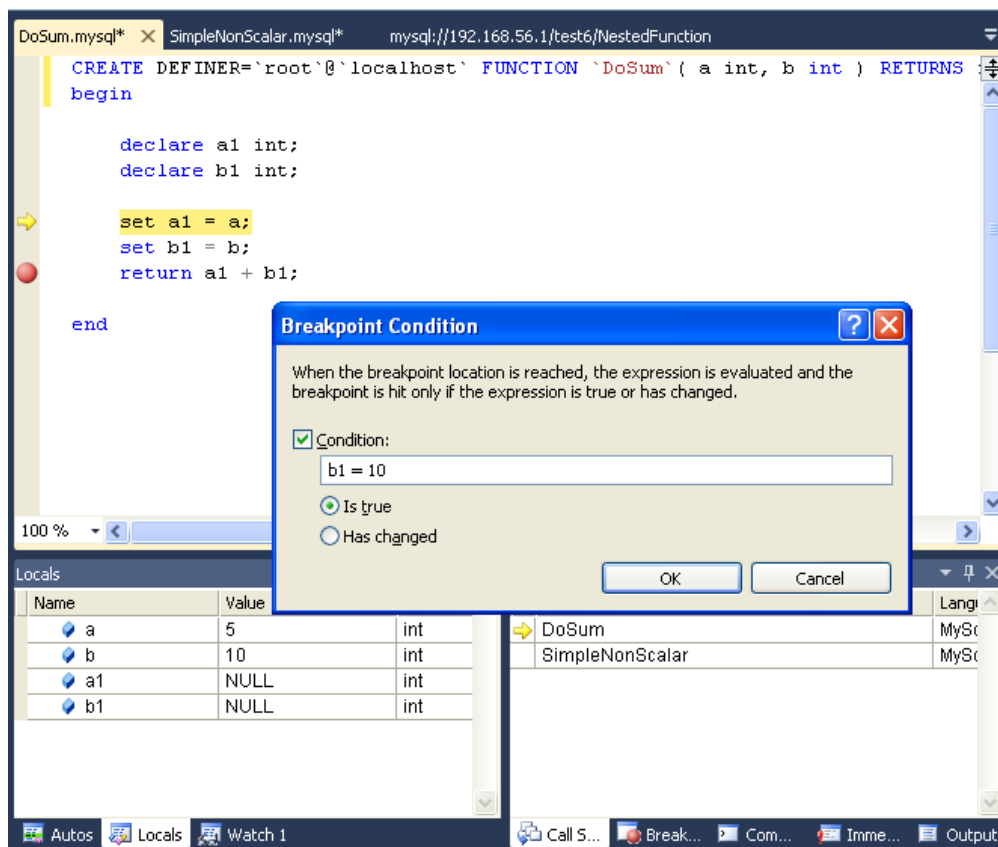

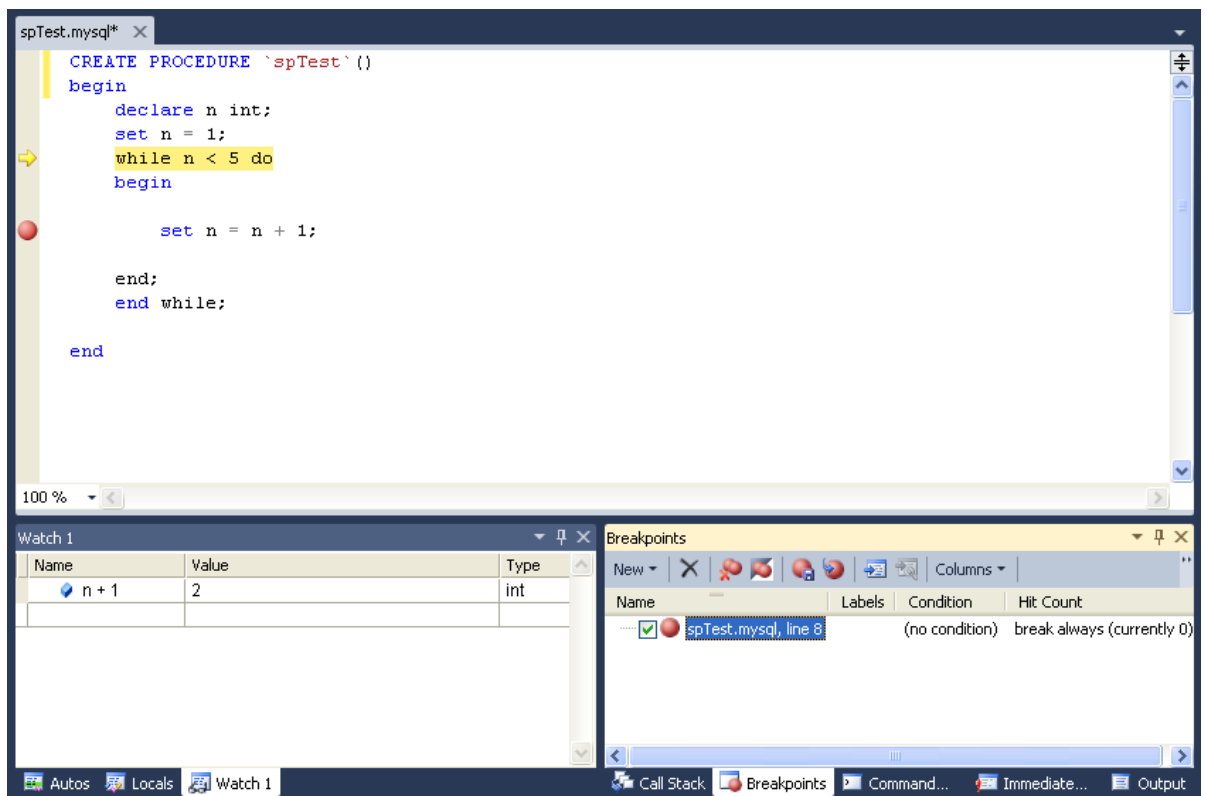

**Figure 21.27. Conditional Breakpoints**

Figure 21.28. Expressions and Breakpoints

- To define pass count breakpoints, after creating the breakpoint, right click in the red dot and choose **Hit Count...**. In the popup dialog, define the specific condition to set. For example, **break when the hit count is equal to** and a value 3 will trigger the breakpoint the third time it is hit.

## Other Features

- To abort the debug session (and the execution of the current call stack of routines), press Shift+F5.
- To run the routine to completion (or until next breakpoint hit), press F5.
- For all functionality you can use (in addition to the shortcuts documented), see the options in the **Debug** menu of Visual Studio.

## Limitations

- Code being debugged must not use `get_lock` or `release_lock` MySQL functions, since they are used internally by the debugger infrastructure to synchronize the debugger and the debugged routine.
- Code being debugged must avoid using any transaction code (`START TRANSACTION`, `COMMIT`, `ROLLBACK`) due to the possibility of wiping out the contents of the debugger tables. (This limitation may be removed in the future).
- You cannot debug the routines in the `serversidedebugger` database.
- The MySQL server running the routine being debugged can be any version between 5.0 and 5.6, running on Windows, Linux, or any other supported platform.
- We recommend always running debug sessions on test and development servers, rather than against a MySQL production server, because debugging can cause temporary performance issues or even deadlocks. The instrumented versions of the routines being debugged use locks, that the rest of the production code may not be aware of.

## Keyboard Shortcuts

The following list summarizes the keyboard shortcuts for debugging:

- **F9** Toggles breakpoints
- **F11**: Step into once
- **F10**: Step over once
- **Shift+F11**: Step out once
- **F5**: Run
- **Shift+F5**: Abort current debug session

### 21.2.3.9. Cloning Database Objects

Tables, views, stored procedures, and functions can be cloned using the appropriate Clone command from the context menu: [Clone Table](#), [Clone View](#), [Clone Routine](#). The clone commands open the corresponding editor for a new object: the **Table Editor** for cloning a table, and the **SQL Editor** for cloning a view or a routine.

The editor is filled with values of the original object. You can modify these values in the usual manner.

To save the cloned object, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

### 21.2.3.10. Dropping Database Objects

Tables, views, stored routines, triggers, and UDFs can be dropped with the appropriate Drop command selected from its context menu: [Drop Table](#), [Drop View](#), [Drop Routine](#), [Drop Trigger](#), [Drop UDF](#).

You will be asked to confirm the execution of the corresponding drop query in a confirmation dialog.

You can only drop a single object at a time.

### 21.2.3.11. Using the ADO.NET Entity Framework

Connector/Net 6.0 introduced support for the ADO.NET Entity Framework. ADO.NET Entity Framework was included with .NET Framework 3.5 Service Pack 1, and Visual Studio 2008 Service Pack 1. ADO.NET Entity Framework was released on 11th August 2008.

ADO.NET Entity Framework provides an Object Relational Mapping (ORM) service, mapping the relational database schema to objects. The ADO.NET Entity Framework defines several layers, these can be summarized as:

- **Logical** - this layer defines the relational data and is defined by the Store Schema Definition Language (SSDL).
- **Conceptual** - this layer defines the .NET classes and is defined by the Conceptual Schema Definition Language (CSDL)
- **Mapping** - this layer defines the mapping from .NET classes to relational tables and associations, and is defined by Mapping Specification Language (MSL).

Connector/Net integrates with Visual Studio 2008 to provide a range of helpful tools to assist the developer.

A full treatment of ADO.NET Entity Framework is beyond the scope of this manual. If you are unfamiliar with ADO.NET, review the [Microsoft ADO.NET Entity Framework documentation](#).

Tutorials on getting started with ADO.NET Entity Framework are available. See [Section 21.2.4.5, "Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source"](#) and [Section 21.2.4.6, "Tutorial: Databinding in ASP.NET using LINQ on Entities"](#).

### 21.2.3.12. MySQL Website Configuration Tool

MySQL Connector/Net 6.1 introduced the MySQL Website Configuration Tool. This is a facility available in Visual Studio that enables you to configure the Membership, Role, Session State and Profile Provider, without editing configuration files. You set your configuration options within the tool, and the tool modifies your `web.config` file accordingly.

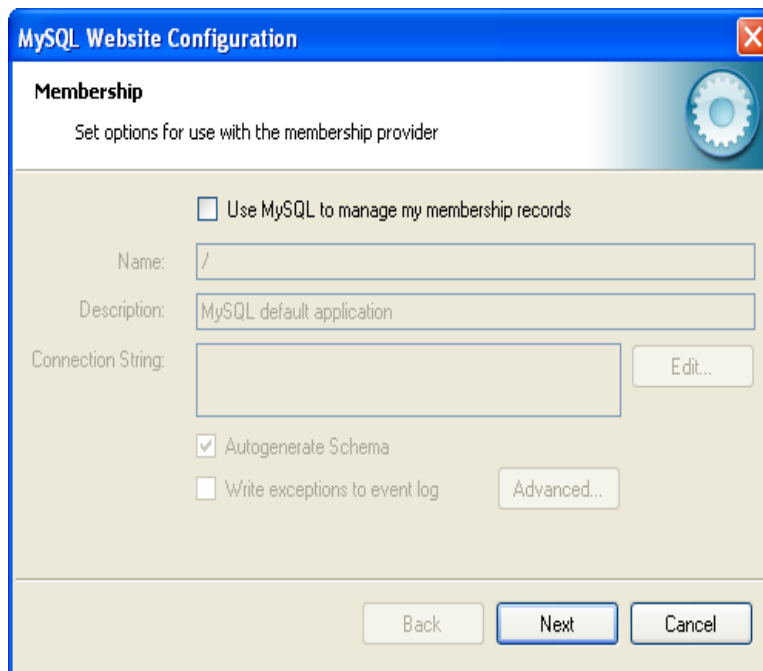

The MySQL Website Configuration Tool appears as a small icon on the Solution Explorer toolbar in Visual Studio, as show by the following screenshot:

**Figure 21.29. MySQL Website Configuration Tool**

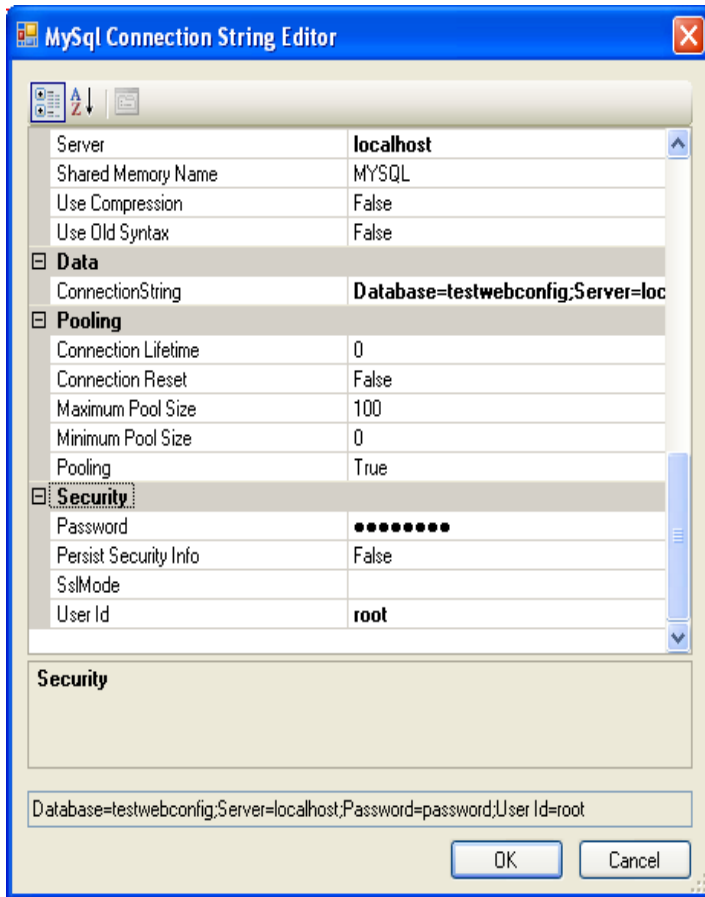

Clicking the Website Configuration Tool icon launches the wizard and displays the first screen:

**Figure 21.30. MySQL Website Configuration Tool - Membership**

This allows you to enable use of the MySQL Membership Provider. Click the check box to enable this. You can now enter the name of the application that you are creating the configuration for. You can also enter a description for the application.

You can then click the `Edit...` button to launch the Connection String Editor:

**Figure 21.31. MySQL Website Configuration Tool - Connection String Editor**

Note that if you have already defined a connection string for the providers manually in `web.config`, or previously using the tool, this will be automatically loaded and displayed, and can then be modified in this dialog.

You can also ensure that the necessary schemas are created automatically for you by selecting the Autogenerate Schema check box. These schemas are used to store membership information. The database used to storage is the one specified in the connection string.

You can also ensure that exceptions generated by the application will be written to the Windows event log by selecting the **Write exceptions to event log** check box.

Clicking the **Advanced...** button launches a dialog that enables you to set Membership Options. These options dictate such variables as password length required when a user signs up, whether the password is encrypted and whether the user can reset their password or not.

**Figure 21.32. MySQL Website Configuration Tool - Advanced Options**

The screenshot shows the 'Membership Options' dialog box with the following settings:

- Password Options:**
  - Minimum Required Password Length: 7
  - Min Required Non-alphanumeric Characters: 1
  - Password strength regular expression: (empty text box)
  - Password Format: Clear
- User Options:**
  - Require Question/Answer
  - Enable Password Reset
  - Requires Unique Email
  - Enable Password Retrieval
- Access Options:**
  - Maximum Invalid Password Attempts: 5
  - Password Attempt Window: 10

Buttons: OK, Cancel

Once information has been set up as required for configuration of the Membership Provider, the **Next** button can be clicked to display the Roles Provider screen:

**Figure 21.33. MySQL Website Configuration Tool - Roles**

The screenshot shows the 'Roles' configuration dialog box with the following settings:

- Roles:** Set options for use with the role provider
- Use MySQL to manage my roles
- Name: /
- Description: (empty text box)
- Connection String: (empty text box)
- Autogenerate Schema
- Write exceptions to event log

Buttons: Back, Next, Cancel

Again the connection string can be edited, a description added and Autogenerate Schema can be enabled before clicking **Next** to go to the Profiles Provider screen:

**Figure 21.34. MySQL Website Configuration Tool - Profiles**

The screenshot shows the 'MySQL Website Configuration' dialog box with the 'Profiles' tab selected. The title bar reads 'MySQL Website Configuration' and the subtitle is 'Profiles'. Below the subtitle, it says 'Set options for use with the profile provider'. There is a gear icon in the top right corner. The main area contains the following options:

- Use MySQL to manage my profiles
- Name: /
- Description: Profiles
- Connection String: [Empty text box] with an 'Edit...' button to its right.
- Autogenerate Schema

At the bottom, there are three buttons: 'Back', 'Finish', and 'Cancel'.

This screen display similar options to the previous screens.

Click **Next** to proceed to the Session State configuration page:

**Figure 21.35. MySQL Website Configuration Tool - Session State**

The screenshot shows the 'MySQL Website Configuration' dialog box with the 'Session State' tab selected. The title bar reads 'MySQL Website Configuration' and the subtitle is 'Session State'. Below the subtitle, it says 'Set options for use with the session state provider'. There is a gear icon in the top right corner. The main area contains the following options:

- Use MySQL to manage my ASP.Net session date
- Name: /
- Description: [Empty text box]
- Connection String: [Empty text box] with an 'Edit...' button to its right.
- Autogenerate Schema
- Write exceptions to event log

At the bottom, there are three buttons: 'Back', 'Finish', and 'Cancel'.

Once you have set up the Session State Provider as required, click **Finish** to exit the wizard.

At this point, select the **Authentication Type** to **From Internet**. Launch the ASP.NET Configuration Tool and select the Security tab. Click the **Select authentication type** link and ensure that the

From the **internet** radio button is selected. You can now examine the database you created to store membership information. All the necessary tables will have been created for you:

Figure 21.36. MySQL Website Configuration Tool - Tables

```
mysql> show tables;
Empty set (0.01 sec)

mysql> show tables;
Empty set (0.00 sec)

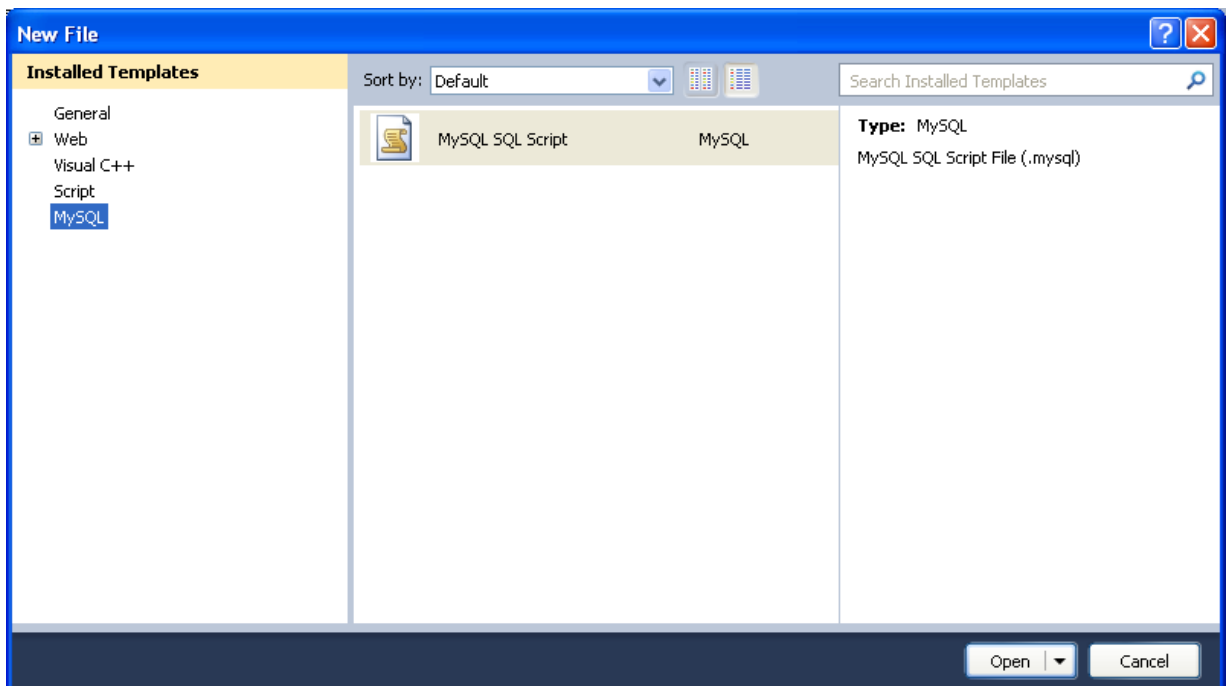

mysql> show tables;
+-----+
| Tables_in_testwebconfig |
+-----+
| my_aspnet_applications  |
| my_aspnet_membership    |
| my_aspnet_profiles      |
| my_aspnet_roles        |
| my_aspnet_schemaversion |
| my_aspnet_sessioncleanup |
| my_aspnet_sessions     |
| my_aspnet_users        |
| my_aspnet_usersinroles |
+-----+
9 rows in set (0.01 sec)

mysql>
```

### 21.2.3.13. MySQL SQL Editor

MySQL Connector/Net 6.3.2 introduced a new MySQL SQL Editor. The easiest way to invoke the editor is by selecting the **New, File** menu item from the Visual Studio main menu. This displays the **New File** dialog:

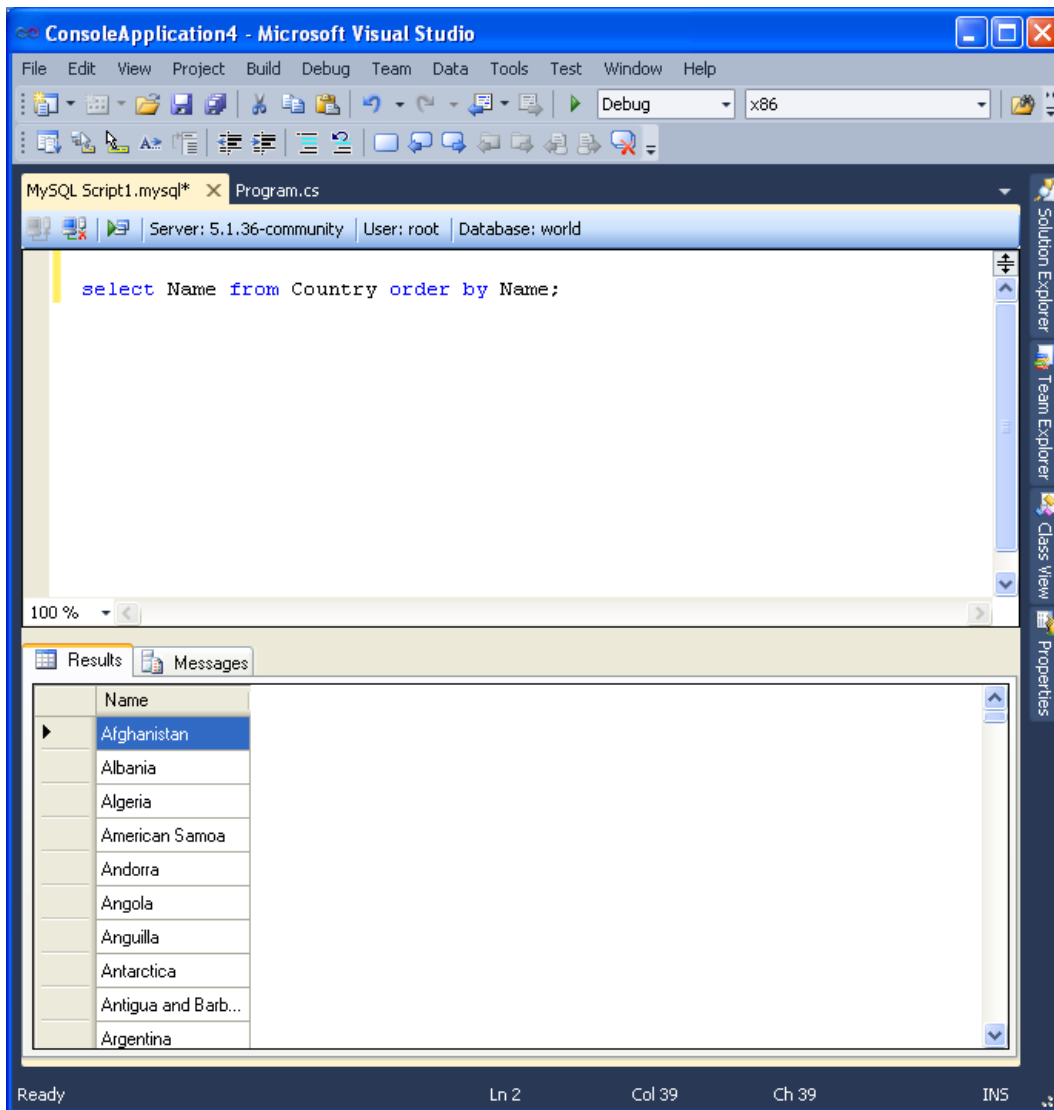

Figure 21.37. MySQL SQL Editor - New File

From the **New File** dialog, select the MySQL template, and then double-click the **MySQL SQL Script** document, or click the **Open** button.

The MySQL SQL Editor will be displayed. You can now enter SQL code as required, or connect to a MySQL server. Click the **Connect to MySQL** button in the MySQL SQL Editor toolbar. You can enter the connection details into the **Connect to MySQL** dialog that is displayed. You can enter the server name, user ID, password and database to connect to, or click the **Advanced** button to select other connection string options. Click the **Connect** button to connect to the MySQL server. To execute your SQL code against the server, click the **Run SQL** button on the toolbar.

**Figure 21.38. MySQL SQL Editor - Query**

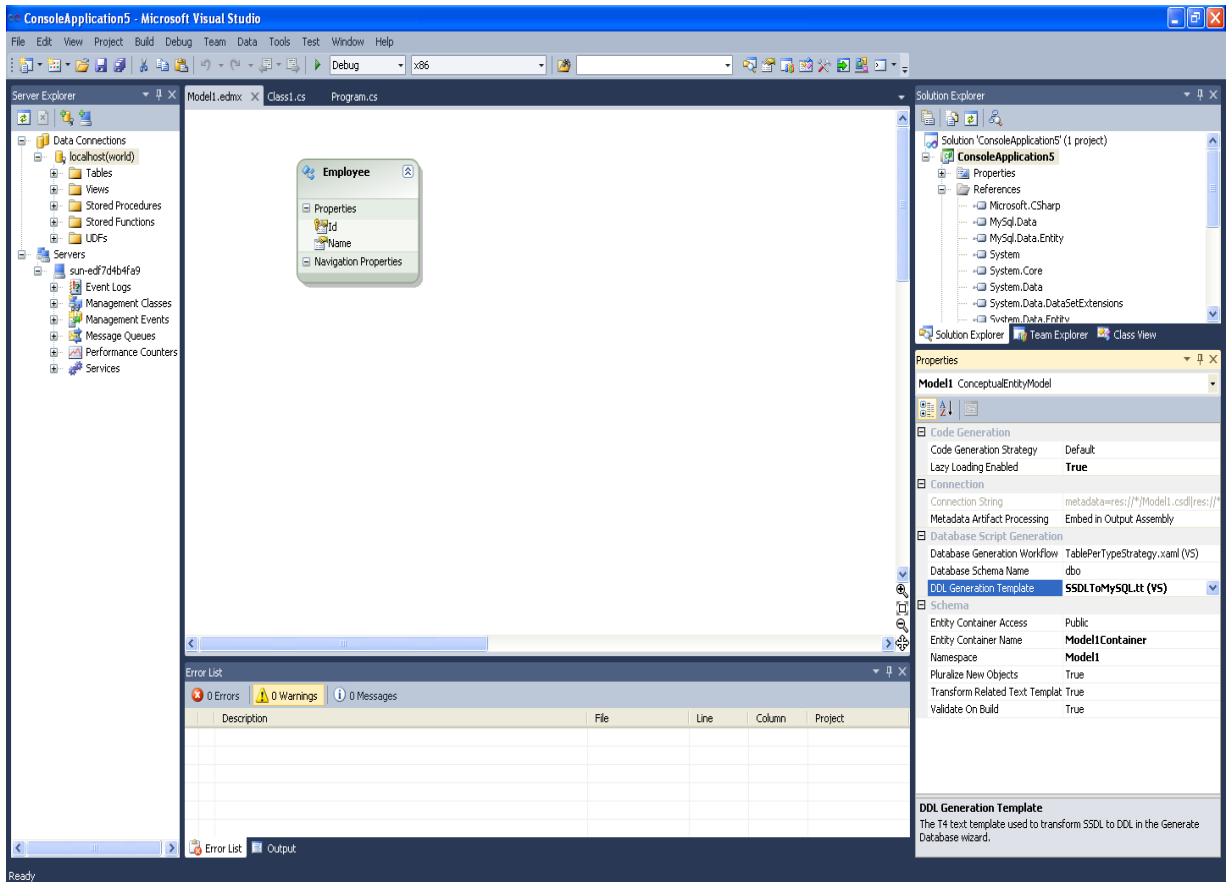

The results from any queries are displayed on the **Results** tab. Any errors are displayed on the **Messages** tab.

#### 21.2.3.14. DDL T4 Template Macro

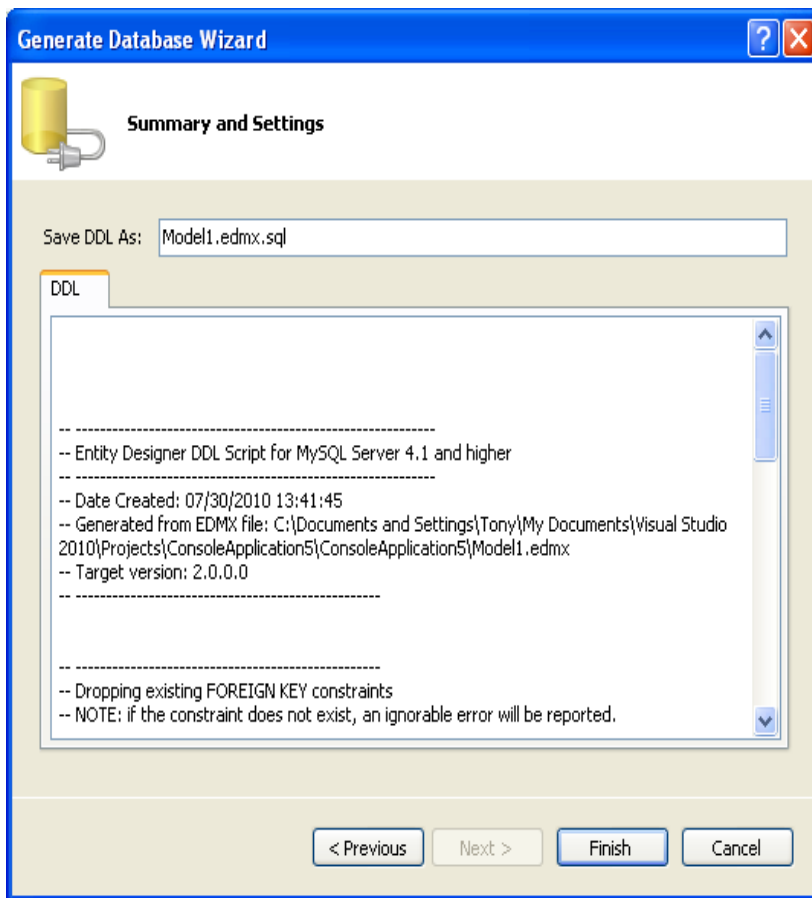

MySQL Connector/Net 6.3 introduced the ability to convert an Entity Framework model to MySQL **DDL** code. Starting with a blank model, you can develop an entity model in Visual Studio's designer. Once the model is created, you can select the model's properties, and in the Database Script Generation category of the model's properties, the property **DDL Generation** can be found. Select the value **SSDLToMySQL.tt(VS)** from the drop-down listbox.

Figure 21.39. DDL T4 Template Macro - Model Properties

Right-clicking the model design area displays a context-sensitive menu. Selecting **Generate Database from Model** from the menu displays the **Generate Database Wizard**. The wizard can then be used to generate MySQL DDL code.

Figure 21.40. DDL T4 Template Macro - Generate Database Wizard

## 21.2.4. Connector/Net Tutorials

The following tutorials illustrate how to develop MySQL programs using technologies such as Visual Studio, C#, ASP.NET, and the .NET and Mono frameworks. Work through the first tutorial to verify that you have the right software components installed and configured, then choose other tutorials to try depending on the features you intend to use in your applications.

### 21.2.4.1. Tutorial: An Introduction to Connector/Net Programming

This section provides a gentle introduction to programming with Connector/Net. The example code is written in C#, and is designed to work on both Microsoft .NET Framework and Mono.

This tutorial is designed to get you up and running with Connector/Net as quickly as possible, it does not go into detail on any particular topic. However, the following sections of this manual describe each of the topics introduced in this tutorial in more detail. In this tutorial you are encouraged to type in and run the code, modifying it as required for your setup.

This tutorial assumes you have MySQL and Connector/Net already installed. It also assumes that you have installed the World example database, which can be downloaded from the [MySQL Documentation page](#). You can also find details on how to install the database on the same page.

#### Note

Before compiling the example code, make sure that you have added References to your project as required. The References required are [System](#), [System.Data](#) and [MySql.Data](#).

### 21.2.4.1.1. The MySqlConnection Object

For your Connector/Net application to connect to a MySQL database, it must establish a connection by using a [MySqlConnection](#) object.

The [MySqlConnection](#) constructor takes a connection string as one of its parameters. The connection string provides necessary information to make the connection to the MySQL database. The connection string is discussed more fully in [Section 21.2.5.1, "Connecting to MySQL Using Connector/Net"](#). For a list of supported connection string options, see [Section 21.2.6, "Connector/Net Connection String Options Reference"](#).

The following code shows how to create a connection object:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial1
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();
            // Perform database operations
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

When the [MySqlConnection](#) constructor is invoked, it returns a connection object, which is used for subsequent database operations. Open the connection before any other operations take place. Before the application exits, close the connection to the database by calling [Close](#) on the connection object.

Sometimes an attempt to perform an [Open](#) on a connection object can fail, generating an exception that can be handled using standard exception handling code.

In this section you have learned how to create a connection to a MySQL database, and open and close the corresponding connection object.

### 21.2.4.1.2. The MySqlCommand Object

Once a connection has been established with the MySQL database, the next step is do carry out the desired database operations. This can be achieved through the use of the [MySqlCommand](#) object.

You will see how to create a [MySqlCommand](#) object. Once it has been created, there are three main methods of interest that you can call:

- **ExecuteReader** - used to query the database. Results are usually returned in a [MySqlDataReader](#) object, created by [ExecuteReader](#).
- **ExecuteNonQuery** - used to insert and delete data.
- **ExecuteScalar** - used to return a single value.

Once a [MySqlCommand](#) object has been created, you will call one of the above methods on it to carry out a database operation, such as perform a query. The results are usually returned into a

[MySqlDataReader](#) object, and then processed, for example the results might be displayed. The following code demonstrates how this could be done.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial2
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            MySqlDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr[0]+" -- "+rdr[1]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

When a connection has been created and opened, the code then creates a [MySqlCommand](#) object. Note that the SQL query to be executed is passed to the [MySqlCommand](#) constructor. The [ExecuteReader](#) method is then used to generate a [MySqlReader](#) object. The [MySqlReader](#) object contains the results generated by the SQL executed on the command object. Once the results have been obtained in a [MySqlReader](#) object, the results can be processed. In this case, the information is printed out by a `while` loop. Finally, the [MySqlReader](#) object is disposed of by running its `Close` method on it.

In the next example, you will see how to use the [ExecuteNonQuery](#) method.

The procedure for performing an [ExecuteNonQuery](#) method call is simpler, as there is no need to create an object to store results. This is because [ExecuteNonQuery](#) is only used for inserting, updating and deleting data. The following example illustrates a simple update to the [Country](#) table:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial3
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();
```

```
        string sql = "INSERT INTO Country (Name, HeadOfState, Continent) VALUES ('Disneyland', 'Mick  
        MySqlCommand cmd = new MySqlCommand(sql, conn);  
        cmd.ExecuteNonQuery();  
    }  
    catch (Exception ex)  
    {  
        Console.WriteLine(ex.ToString());  
    }  
  
    conn.Close();  
    Console.WriteLine("Done.");  
}  
}
```

The query is constructed, the command object created and the [ExecuteNonQuery](#) method called on the command object. You can access your MySQL database with the `mysql` command interpreter and verify that the update was carried out correctly.

Finally, you will see how the [ExecuteScalar](#) method can be used to return a single value. Again, this is straightforward, as a [MySqlCommandReader](#) object is not required to store results, a simple variable will do. The following code illustrates how to use [ExecuteScalar](#):

```
using System;  
using System.Data;  
  
using MySql.Data;  
using MySql.Data.MySqlClient;  
  
public class Tutorial4  
{  
    public static void Main()  
    {  
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";  
        MySqlConnection conn = new MySqlConnection(connStr);  
        try  
        {  
            Console.WriteLine("Connecting to MySQL...");  
            conn.Open();  
  
            string sql = "SELECT COUNT(*) FROM Country";  
            MySqlCommand cmd = new MySqlCommand(sql, conn);  
            object result = cmd.ExecuteScalar();  
            if (result != null)  
            {  
                int r = Convert.ToInt32(result);  
                Console.WriteLine("Number of countries in the World database is: " + r);  
            }  
        }  
        catch (Exception ex)  
        {  
            Console.WriteLine(ex.ToString());  
        }  
  
        conn.Close();  
        Console.WriteLine("Done.");  
    }  
}
```

This example uses a simple query to count the rows in the [Country](#) table. The result is obtained by calling [ExecuteScalar](#) on the command object.

### 21.2.4.1.3. Working with Decoupled Data

Previously, when using [MySqlCommandReader](#), the connection to the database was continually maintained, unless explicitly closed. It is also possible to work in a manner where a connection is only established when needed. For example, in this mode, a connection could be established to read a chunk of data, the data could then be modified by the application as required. A connection could then

be reestablished only if and when the application writes data back to the database. This decouples the working data set from the database.

This decoupled mode of working with data is supported by Connector/Net. There are several parts involved in allowing this method to work:

- **Data Set** - The Data Set is the area in which data is loaded to read or modify it. A `DataSet` object is instantiated, which can store multiple tables of data.
- **Data Adapter** - The Data Adapter is the interface between the Data Set and the database itself. The Data Adapter is responsible for efficiently managing connections to the database, opening and closing them as required. The Data Adapter is created by instantiating an object of the `MySqlDataAdapter` class. The `MySqlDataAdapter` object has two main methods: `Fill` which reads data into the Data Set, and `Update`, which writes data from the Data Set to the database.
- **Command Builder** - The Command Builder is a support object. The Command Builder works in conjunction with the Data Adapter. When a `MySqlDataAdapter` object is created, it is typically given an initial `SELECT` statement. From this `SELECT` statement the Command Builder can work out the corresponding `INSERT`, `UPDATE` and `DELETE` statements that would be required to update the database. To create the Command Builder, an object of the class `MySqlCommandBuilder` is created.

Each of these classes will now be discussed in more detail.

### Instantiating a DataSet object

A `DataSet` object can be created simply, as shown in the following example code snippet:

```
DataSet dsCountry;  
...  
dsCountry = new DataSet();
```

Although this creates the `DataSet` object, it has not yet filled it with data. For that, a Data Adapter is required.

### Instantiating a MySqlDataAdapter object

The `MySqlDataAdapter` can be created as illustrated by the following example:

```
MySqlDataAdapter daCountry;  
...  
string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";  
daCountry = new MySqlDataAdapter (sql, conn);
```

Note, the `MySqlDataAdapter` is given the SQL specifying the data to work with.

### Instantiating a MySqlCommandBuilder object

Once the `MySqlDataAdapter` has been created, it is necessary to generate the additional statements required for inserting, updating and deleting data. There are several ways to do this, but in this tutorial you will see how this can most easily be done with `MySqlCommandBuilder`. The following code snippet illustrates how this is done:

```
MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);
```

Note that the `MySqlDataAdapter` object is passed as a parameter to the command builder.

### Filling the Data Set

To do anything useful with the data from your database, you need to load it into a Data Set. This is one of the jobs of the `MySqlDataAdapter` object, and is carried out with its `Fill` method. The following example code illustrates this:

```
DataSet dsCountry;  
...  
dsCountry = new DataSet();  
...
```

```
daCountry.Fill(dsCountry, "Country");
```

Note the `Fill` method is a `MySqlDataAdapter` method, the Data Adapter knows how to establish a connection with the database and retrieve the required data, and then populates the Data Set when the `Fill` method is called. The second parameter "Country" is the table in the Data Set to update.

### Updating the Data Set

The data in the Data Set can now be manipulated by the application as required. At some point, changes to data will need to be written back to the database. This is achieved through a `MySqlDataAdapter` method, the `Update` method.

```
daCountry.Update(dsCountry, "Country");
```

Again, the Data Set and the table within the Data Set to update are specified.

### Working Example

The interactions between the `DataSet`, `MySqlDataAdapter` and `MySqlCommandBuilder` classes can be a little confusing, so their operation can perhaps be best illustrated by working code.

In this example, data from the World database is read into a Data Grid View control. Here, the data can be viewed and changed before clicking an update button. The update button then activates code to write changes back to the database. The code uses the principles explained above. The application was built using the Microsoft Visual Studio to place and create the user interface controls, but the main code that uses the key classes described above is shown below, and is portable.

```
using System;
using System.Collections.Generic;
using System.ComponentModel;
using System.Data;
using System.Drawing;
using System.Linq;
using System.Text;
using System.Windows.Forms;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace WindowsFormsApplication5
{
    public partial class Form1 : Form
    {
        MySqlDataAdapter daCountry;
        DataSet dsCountry;

        public Form1()
        {
            InitializeComponent();
        }

        private void Form1_Load(object sender, EventArgs e)
        {
            string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                label2.Text = "Connecting to MySQL...";

                string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
                daCountry = new MySqlDataAdapter(sql, conn);
                MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);

                dsCountry = new DataSet();
                daCountry.Fill(dsCountry, "Country");
                dataGridView1.DataSource = dsCountry;
                dataGridView1.DataMember = "Country";
            }
        }
    }
}
```

```

        catch (Exception ex)
        {
            label2.Text = ex.ToString();
        }
    }

    private void button1_Click(object sender, EventArgs e)
    {
        daCountry.Update(dsCountry, "Country");
        label2.Text = "MySQL Database Updated!";
    }
}

```

The application running is shown below:

**Figure 21.41. World Database Application**

#### 21.2.4.1.4. Working with Parameters

This part of the tutorial shows you how to use parameters in your Connector/Net application.

Although it is possible to build SQL query strings directly from user input, this is not advisable as it does not prevent erroneous or malicious information being entered. It is safer to use parameters as they will be processed as field data only. For example, imagine the following query was constructed from user input:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = "+user_continent;
```

If the string `user_continent` came from a Text Box control, there would potentially be no control over the string entered by the user. The user could enter a string that generates a runtime error, or in the worst case actually harms the system. When using parameters it is not possible to do this because a parameter is only ever treated as a field parameter, rather than an arbitrary piece of SQL code.

The same query written using a parameter for user input would be:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = @Continent";
```

Note that the parameter is preceded by an '@' symbol to indicate it is to be treated as a parameter.

As well as marking the position of the parameter in the query string, it is necessary to add a parameter to the Command object. This is illustrated by the following code snippet:

```
cmd.Parameters.AddWithValue("@Continent", "North America");
```

In this example the string "North America" is supplied as the parameter value statically, but in a more practical example it would come from a user input control.

A further example illustrates the complete process:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial5
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent=@Continent";
            MySqlCommand cmd = new MySqlCommand(sql, conn);

            Console.WriteLine("Enter a continent e.g. 'North America', 'Europe': ");
            string user_input = Console.ReadLine();

            cmd.Parameters.AddWithValue("@Continent", user_input);

            MySqlDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr["Name"]+" --- "+rdr["HeadOfState"]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

In this part of the tutorial you have see how to use parameters to make your code more secure.

#### 21.2.4.1.5. Working with Stored Procedures

This section illustrates how to work with stored procedures. Putting database-intensive operations into stored procedures lets you define an API for your database application. You can reuse this API across multiple applications and multiple programming languages. This technique avoids duplicating database code, saving time and effort when you make updates due to schema changes, tune the performance of queries, or add new database operations for logging, security, and so on. Before working through this tutorial, familiarize yourself with the [CREATE PROCEDURE](#) and [CREATE FUNCTION](#) statements that create different kinds of stored routines.

For the purposes of this tutorial, you will create a simple stored procedure to see how it can be called from Connector/Net. In the MySQL Client program, connect to the World database and enter the following stored procedure:

```
DELIMITER //
CREATE PROCEDURE country_hos
(IN con CHAR(20))
BEGIN
    SELECT Name, HeadOfState FROM Country
    WHERE Continent = con;
END //
DELIMITER ;
```

Test that the stored procedure works as expected by typing the following into the `mysql` command interpreter:

```
CALL country_hos('Europe');
```

Note that The stored routine takes a single parameter, which is the continent to restrict your search to.

Having confirmed that the stored procedure is present and correct, you can see how to access it from Connector/Net.

Calling a stored procedure from your Connector/Net application is similar to techniques you have seen earlier in this tutorial. A `MySqlCommand` object is created, but rather than taking an SQL query as a parameter, it takes the name of the stored procedure to call. Set the `MySqlCommand` object to the type of stored procedure, as shown by the following code snippet:

```
string rtn = "country_hos";
MySqlCommand cmd = new MySqlCommand(rtn, conn);
cmd.CommandType = CommandType.StoredProcedure;
```

In this case, the stored procedure requires you to pass a parameter. This can be achieved using the techniques seen in the previous section on parameters, [Section 21.2.4.1.4, "Working with Parameters"](#), as shown in the following code snippet:

```
cmd.Parameters.AddWithValue("@con", "Europe");
```

The value of the parameter `@con` could more realistically have come from a user input control, but for simplicity it is set as a static string in this example.

At this point, everything is set up and you can call the routine using techniques also learned in earlier sections. In this case, the `ExecuteReader` method of the `MySqlCommand` object is used.

Complete working code for the stored procedure example is shown below:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial6
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string rtn = "country_hos";
            MySqlCommand cmd = new MySqlCommand(rtn, conn);
            cmd.CommandType = CommandType.StoredProcedure;

            cmd.Parameters.AddWithValue("@con", "Europe");

            MySqlDataReader rdr = cmd.ExecuteReader();
            while (rdr.Read())
            {
                Console.WriteLine(rdr[0] + " --- " + rdr[1]);
            }
        }
    }
}
```

```

        rdr.Close();
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.ToString());
    }

    conn.Close();
    Console.WriteLine("Done.");
}
}

```

In this section, you have seen how to call a stored procedure from Connector/Net. For the moment, this concludes our introductory tutorial on programming with Connector/Net.

#### 21.2.4.2. Tutorial: MySQL Connector/Net ASP.NET Membership and Role Provider

Many web sites feature the facility for the user to create a user account. They can then log into the web site and enjoy a personalized experience. This requires that the developer creates database tables to store user information, along with code to gather and process this data. This represents a burden on the developer, and there is the possibility for security issues to creep into the developed code. However, ASP.NET 2.0 introduced the Membership system. This system is designed around the concept of Membership, Profile and Role Providers, which together provide all of the functionality to implement a user system, that previously would have to have been created by the developer from scratch.

Currently, MySQL Connector/Net provides Membership, Role, Profile and Session State Providers.

This tutorial shows you how to set up your ASP.NET web application to use the MySQL Connector/Net Membership and Role Providers. It assumes that you have MySQL Server installed, along with MySQL Connector/Net and Microsoft Visual Studio. This tutorial was tested with MySQL Connector/Net 6.0.4 and Microsoft Visual Studio 2008 Professional Edition. It is recommended you use 6.0.4 or above for this tutorial.

1. Create a new database in the MySQL Server using the MySQL Command-Line Client program ([mysql](#)), or other suitable tool. It does not matter what name is used for the database, but record it. You specify it in the connection string constructed later in this tutorial. This database contains the tables, automatically created for you later, used to store data about users and roles.
2. Create a new ASP.NET Web Site in Visual Studio. If you are not sure how to do this, refer to [Section 21.2.4.6, "Tutorial: Databinding in ASP.NET using LINQ on Entities"](#), which demonstrates how to create a simple ASP.NET web site.
3. Add References to [MySQL.Data](#) and [MySQL.Web](#) to the web site project.
4. Locate the [machine.config](#) file on your system, which is the configuration file for the .NET Framework.
5. Search the [machine.config](#) file to find the membership provider [MySQLMembershipProvider](#).
6. Add the attribute [autogenerateschema="true"](#). The appropriate section should now resemble the following (note: for the sake of brevity some information has been excluded):

```

<membership>
  <providers>
    <add name="AspNetSqlMembershipProvider"
      type="System.Web.Security.SqlMembershipProvider"
      ...
      connectionStringName="LocalSqlServer"
      ... />
    <add name="MySQLMembershipProvider"
      autogenerateschema="true"
      type="MySQL.Web.Security.MySQLMembershipProvider, MySQL.Web, Version=6.0.4.0, Culture=neutral,
      connectionStringName="LocalMySQLServer"
      ... />
  </providers>

```

```
</membership>
```

Note that the name for the connection string to be used to connect to the server that contains the membership database is `LocalMySqlServer`.

The `autogenerateschema="true"` attribute will cause MySQL Connector/Net to silently create, or upgrade, the schema on the database server, to contain the required tables for storing membership information.

7. It is now necessary to create the connection string referenced in the previous step. Load the web site's `web.config` file into Visual Studio.
8. Locate the section marked `<connectionStrings>`. Add the following connection string information:

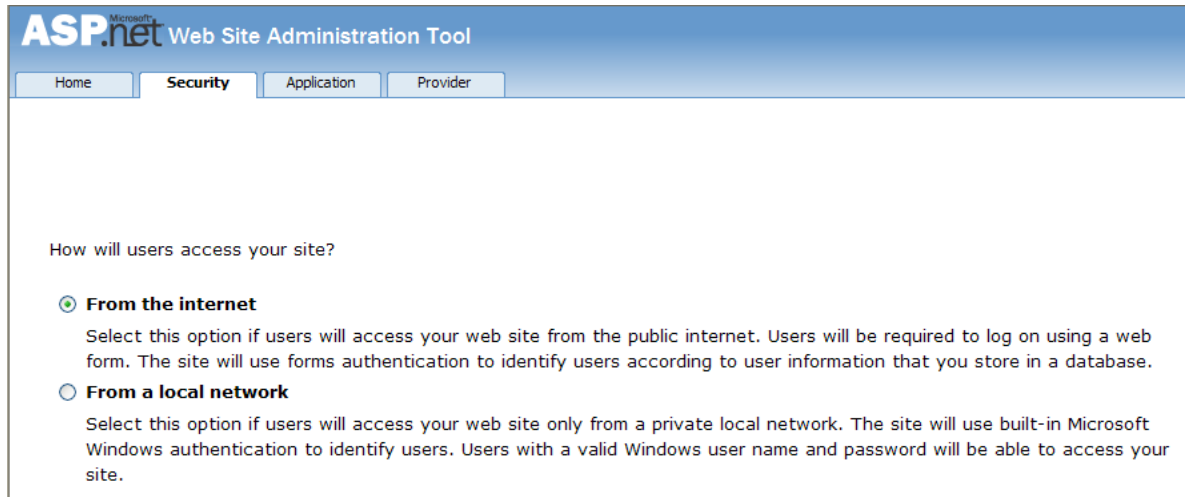

```
<connectionStrings>
  <remove name="LocalMySqlServer" />
  <add name="LocalMySqlServer"
        connectionString="Datasource=localhost;Database=users;uid=root;pwd=password;"
        providerName="MySql.Data.MySqlClient" />
</connectionStrings>
```

The database specified is the one created in the first step. You could alternatively have used an existing database.

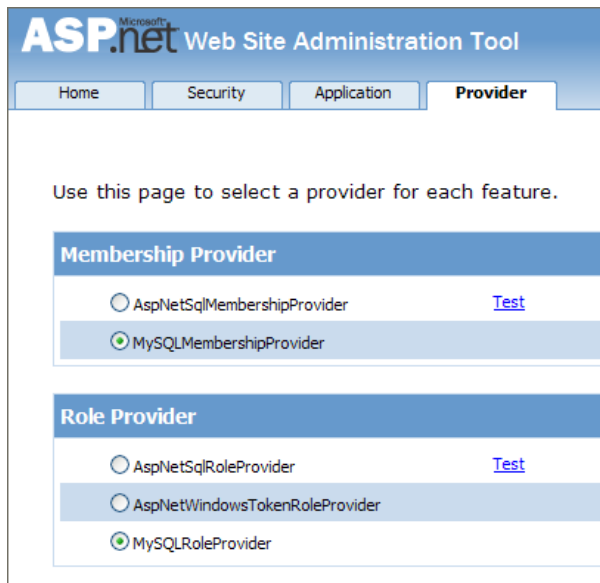

9. At this point build the solution to ensure no errors are present. This can be done by selecting **Build**, **Build Solution** from the main menu, or pressing **F6**.
10. ASP.NET supports the concept of locally and remotely authenticated users. With local authentication the user is validated using their Windows credentials when they attempt to access the web site. This can be useful in an Intranet environment. With remote authentication, a user is prompted for their login details when accessing the web site, and these credentials are checked against the membership information stored in a database server such as MySQL Server. You will now see how to choose this form of authentication.

Start the ASP.NET Web Site Administration Tool. This can be done quickly by clicking the small hammer/Earth icon in the Solution Explorer. You can also launch this tool by selecting **Website**, **ASP.NET Configuration** from the main menu.

11. In the ASP.NET Web Site Administration Tool click the **Security** tab.
12. Now click the **User Authentication Type** link.
13. Select the **From the internet** radio button. The web site will now need to provide a form to allow the user to enter their login details. These will be checked against membership information stored in the MySQL database.

**Figure 21.42. Authentication Type**

14. You now need to specify the Role and Membership Provider to be used. Click the **Provider** tab.
15. Click the **Select a different provider for each feature (advanced)** link.
16. Now select the **MySQLMembershipProvider** and the **MySQLRoleProvider** radio buttons.

**Figure 21.43. Select Membership and Role Provider**

17. In Visual Studio, rebuild the solution by selecting **Build, Rebuild Solution** from the main menu.
18. Check that the necessary schema has been created. This can be achieved using the `mysql` command interpreter.

Figure 21.44. Membership and Role Provider Tables

```

MySQL Command Line Client
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| test |
| users |
| world |
+-----+
5 rows in set (0.01 sec)

mysql> show tables;
+-----+
| Tables_in_users |
+-----+
| my_aspnet_applications |
| my_aspnet_membership |
| my_aspnet_profiles |
| my_aspnet_roles |
| my_aspnet_schemaversion |
| my_aspnet_users |
| my_aspnet_usersinroles |
+-----+
7 rows in set (0.00 sec)

mysql>

```

19. Assuming all is present and correct, you can now create users and roles for your web application. The easiest way to do this is with the ASP.NET Web Site Administration Tool. However, many web applications contain their own modules for creating roles and users. For simplicity, the ASP.NET Web Site Administration Tool will be used in this tutorial.
20. In the ASP.NET Web Site Administration Tool, click the **Security** tab. Now that both the Membership and Role Provider are enabled, you will see links for creating roles and users. Click the **Create or Manage Roles** link.

Figure 21.45. Security Tab

**ASP.NET** Web Site Administration Tool

Home Security Application Provider

You can use the Web Site Administration Tool to manage all the security settings for your application. You can set up users and passwords (authentication), create roles (groups of users), and create permissions (rules for controlling access to parts of your application).

By default, user information is stored in a Microsoft SQL Server Express database in the Data folder of your Web site. If you want to store user information in a different database, use the Provider tab to select a different provider.

[Use the security Setup Wizard to configure security step by step.](#)

Click the links in the table to manage the settings for your application.

Users	Roles	Access Rules
Existing users: <b>1</b> <a href="#">Create user</a> <a href="#">Manage users</a> <a href="#">Select authentication type</a>	Existing roles: <b>2</b> <a href="#">Disable Roles</a> <a href="#">Create or Manage roles</a>	<a href="#">Create access rules</a> <a href="#">Manage access rules</a>

21. You can now enter the name of a new Role and click **Add Role** to create the new Role. Create new Roles as required.

22. Click the **Back** button.
23. Click the **Create User** link. You can now fill in information about the user to be created, and also allocate that user to one or more Roles.

**Figure 21.46. Create User**

ASP.NET Web Site Administration Tool

Home Security Application Provider

Add a user by entering the user's ID, password, and e-mail address on this page.

**Create User**

Sign Up for Your New Account

User Name: johndoe

Password: ●●●●●●●●

Confirm Password: ●●●●●●●●

E-mail: johndoe@example.com

Security Question: Statler and ...

Security Answer: Waldorf

Create User

Active User

**Roles**

Select roles for this user:

Visitors

Admins

24. Using the `mysql` command interpreter, you can check that your database has been correctly populated with the Membership and Role data.

**Figure 21.47. Membership and Roles Table Contents**

```

MySQL Command Line Client
mysql> show tables;
+-----+
| my_aspnet_roles |
| my_aspnet_schemaversion |
| my_aspnet_users |
| my_aspnet_usersinroles |
+-----+
7 rows in set (0.00 sec)

mysql> select * from my_aspnet_users;
+----+-----+-----+-----+-----+
| id | applicationId | name | isAnonymous | lastActivityDate |
+----+-----+-----+-----+-----+
| 1 | 1 | johndoe | 0 | 2009-07-14 17:17:25 |
+----+-----+-----+-----+-----+
1 row in set (0.01 sec)

mysql> select * from my_aspnet_roles;
+----+-----+-----+
| id | applicationId | name |
+----+-----+-----+
| 1 | 1 | Visitors |
| 2 | 1 | Admins |
+----+-----+-----+
2 rows in set (0.00 sec)

mysql>

```

In this tutorial, you have seen how to set up the MySQL Connector/Net Membership and Role Providers for use in your ASP.NET web application.

### 21.2.4.3. Tutorial: MySQL Connector/Net ASP.NET Session State Provider

MySQL Connector/Net from version 6.1 has included a MySQL Session State Provider. This provider enables you to store session state in a MySQL database. The following tutorial shows you how to prepare to use the MySQL Session State Provider, and then store session data into the MySQL database. This tutorial uses Microsoft Visual Studio 2008 Professional Edition, MySQL Connector/Net 6.1.1 and MySQL Server 5.1. This tutorial also assumes you have created an empty database, for example `test`, where you will store session data. You could do this using the `mysql` command interpreter.

1. In Visual Studio, create a new ASP.NET web site. If you are not sure how to do this, refer to the tutorial [Section 21.2.4.6, "Tutorial: Databinding in ASP.NET using LINQ on Entities"](#), which demonstrates how to do this.
2. Launch the MySQL Website Configuration tool. Due to a bug in 6.1.1, this may not appear unless you are connected to a server in the Server Explorer. If you are unfamiliar with the MySQL Website Configuration tool, consider first working through the tutorial in [Section 21.2.3.12, "MySQL Website Configuration Tool"](#).
3. Navigate through the wizard to the Session State page. Make sure the check box **Use MySQL to manage my ASP.NET session data** is selected.
4. On the same page, configure the connection string to the database that will contain your session data. If this database is empty, MySQL Connector/Net will create the schema required to store session data.
5. Ensure that the check box **Autogenerate Schema** is selected so that MySQL Connector/Net will create the schema in your database to store the session data correctly.
6. Enter the name of your application.
7. Click **Finish**. The MySQL Website Configuration tool will now update your application's `web.config` file with information about the connection string and default providers to be used. In this case, we have selected the MySQL Session State Provider.

At this point, you are ready to use the MySQL database to store session data. To test that the set up has worked, you can write a simple program that uses session variables.

1. Open `Default.aspx.cs`. In the `Page_Load` method, add the following code:

```
Session["SessionVariable1"] = "Test string";
```

2. Build your solution.
3. Run the solution (without debugging). When the application runs, the provider will autogenerate tables required in the database you chose when setting up the application.
4. Check that the schema was in fact created. Using the MySQL Command-Line Client use the target database and then type `SHOW TABLES;`. You will see that MySQL Connector/Net has created the required schema automatically, as we selected this to happen in the MySQL Website Configuration tool.
5. Now view the contents of these tables by typing `SELECT * FROM my_aspnet_sessions;` in the `mysql` command interpreter. This will display the session data our application used. Note that this is stored in binary format so some data may not display as expected.

At this point, you have installed the Session State Provider and carried out a preliminary test of the installation. You will now work a bit more with the Session State Provider.

In this part of the tutorial, you will set and retrieve a session variable. You can work with your existing project.

1. Select the `Default.aspx` and switch to Design View. Add a text box and three buttons. Change the text property for the buttons to “Store Session Variable”, “Clear Textbox”, and “Show Session Variable”. These will be `Button1`, `Button2` and `Button3` respectively. Build your solution to ensure that no errors have been introduced.
2. Still in the Design View, double-click `Button1`. Now to the `Button1_Click` event handler add code some the handler resembles the following:

```
protected void Button1_Click(object sender, EventArgs e)
{
    Session["SessionString"] = TextBox1.Text;
}
```

You have created a new Session variable accessed using the key “SessionString”. This will be set to the text that was entered into the text box when `Button1` is clicked.

3. In Design View, double-click `Button2` to add its click event handler. This button needs to clear text from the text box. The code to do this is as follows:

```
protected void Button2_Click(object sender, EventArgs e)
{
    TextBox1.Text = "";
}
```

The code simply assigns an empty string to the `Text` property of the text box.

4. In the Design View double-click `Button3` and modify the click handler as follows:

```
protected void Button3_Click(object sender, EventArgs e)
{
    TextBox1.Text = (String)Session["SessionString"];
}
```

This will retrieve the session string and display it in the text box.

5. Now modify the `Page_Load` method as follows:

```
protected void Page_Load(object sender, EventArgs e)
{
    if (!IsPostBack)
    {
        TextBox1.Text = "Enter some text";
    }
}
```

This ensures that when the page loads the text box `Text` property is reset.

6. Ensure that the solution is saved and then rebuild the solution.
7. Run the solution without debugging.
8. The form will be displayed. Enter some text into the text box. Now click `Store Session Variable`. At this point you have stored the string in a session variable.
9. Now click `Clear Text` to clear the text box.
10. Now click `Show Session Variable` to retrieve and display the session variable.
11. Refresh the page to destroy the form and display a new form.
12. Click `Show Session Variable` the text box will display the stored session variable, demonstrating that the refreshing the page does not destroy the session variable.

This illustrates that the session state data is not destroyed when a page is reloaded.

#### 21.2.4.4. Tutorial: MySQL Connector/Net ASP.NET Profile Provider

This tutorial shows you how to use the MySQL Profile Provider to store user profile information in a MySQL database. The tutorial uses MySQL Connector/Net 6.1.1, MySQL Server 5.1 and Microsoft Visual Studio 2008 Professional Edition.

Many modern web sites allow the user to create a personal profile. This requires a significant amount of code, but ASP.NET reduces this considerably by including the functionality in its Profile classes. The Profile Provider provides an abstraction between these classes and a data source. The MySQL Profile Provider enables profile data to be stored in a MySQL database. This enables the profile properties to be written to a persistent store, and be retrieved when required. The Profile Provider also enables profile data to be managed effectively, for example it enables profiles that have not been accessed since a specific date to be deleted.

The following steps show you how you can select the MySQL Profile Provider.

1. Create a new ASP.NET web project.
2. Select the MySQL Website Configuration tool. Due to a bug in 6.1.1 you may have to first connect to a server in Server Explorer before the tool's icon will display in the toolbar of the Solution Explorer.
3. In the MySQL Website Configuration tool navigate through the tool to the Profiles page.
4. Select the **Use MySQL to manage my profiles** check box.
5. Select the **Autogenerate Schema** check box.
6. Click the **Edit...** button and configure a connection string for the database that will be used to store user profile information.
7. Navigate to the last page of the tool and click **Finish** to save your changes and exit the tool.

At this point you are now ready to start using the MySQL Profile Provider. With the following steps you can carry out a preliminary test of your installation.

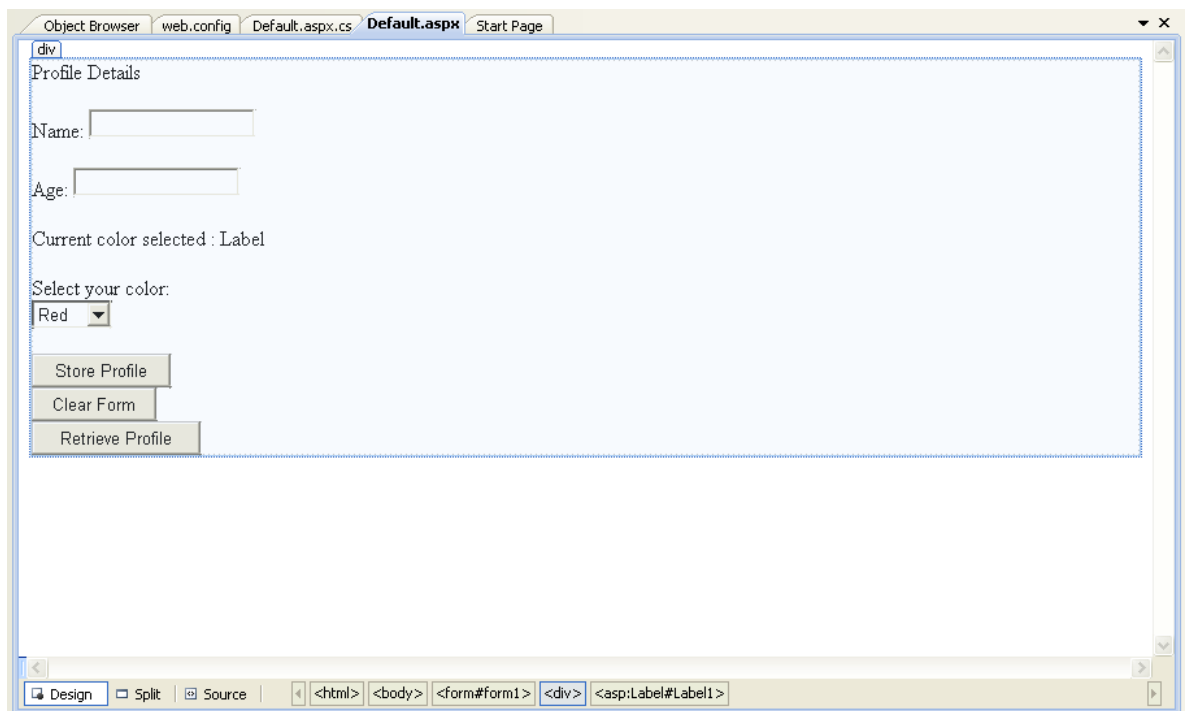

1. Open your `web.config` file.
2. Add a simple profile such as the following:

```
<system.web>
  <anonymousIdentification enabled="true" />
  <profile defaultProvider="MySQLProfileProvider">
    ...
    <properties>
      <add name="Name" allowAnonymous="true" />
      <add name="Age" allowAnonymous="true" type="System.UInt16" />
      <group name="UI">
        <add name="Color" allowAnonymous="true" defaultValue="Blue" />
        <add name="Style" allowAnonymous="true" defaultValue="Plain" />
      </group>
    </properties>
  </profile>
  ...
```

Note that `anonymousIdentification` has been set to true. This enables users who have not been authenticated to use profiles. They are identified by a GUID in a cookie rather than by user name.

Now that the simple profile has been defined in `web.config`, the next step is to write some code to test the profile.

1. In Design View design a simple page with the following controls:

**Figure 21.48. Simple Profile Application**

These will allow the user to enter some profile information. The user can also use the buttons to save their profile, clear the page, and restore their profile data.

2. In the Code View add code as follows:

```

...
protected void Page_Load(object sender, EventArgs e)
{
    if (!IsPostBack)
    {
        TextBox1.Text = Profile.Name;
        TextBox2.Text = Profile.Age.ToString();
        Label1.Text = Profile.UI.Color;
    }
}

// Store Profile
protected void Button1_Click(object sender, EventArgs e)
{
    Profile.Name = TextBox1.Text;
    Profile.Age = UInt16.Parse(TextBox2.Text);
}

// Clear Form
protected void Button2_Click(object sender, EventArgs e)
{
    TextBox1.Text = "";
    TextBox2.Text = "";
    Label1.Text = "";
}

// Retrieve Profile
protected void Button3_Click(object sender, EventArgs e)
{
    TextBox1.Text = Profile.Name;
    TextBox2.Text = Profile.Age.ToString();
    Label1.Text = Profile.UI.Color;
}

protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)

```

```
{
    Profile.UI.Color = DropDownList1.SelectedValue;
}
...
```

3. Save all files and build the solution to check that no errors have been introduced.
4. Run the application.
5. Enter your name, age and select a color from the listbox. Now store this information in your profile by clicking **Store Profile**. Note that if you do not select a color from the listbox your profile will use the default color **Blue** that was specified in the `web.config` file.
6. Click **Clear Form** to clear text from the textboxes and the label that displays your chosen color.
7. Now click **Retrieve Profile** to restore your profile data from the MySQL database.
8. Now exit the browser to terminate the application.
9. Run the application again. Note that when the page loads your profile information is restored from the MySQL database.

In this tutorial you have seen how to using the MySQL Profile Provider with MySQL Connector/Net.

#### 21.2.4.5. Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source

In this tutorial you will learn how to create a Windows Forms Data Source from an Entity in an Entity Data Model. This tutorial assumes that you have installed the World example database, which can be downloaded from the [MySQL Documentation page](#). You can also find details on how to install the database on the same page. It will also be convenient for you to create a connection to the World database after it is installed. For instructions on how to do this see [Section 21.2.3.1, "Making a Connection"](#).

##### Creating a new Windows Forms application

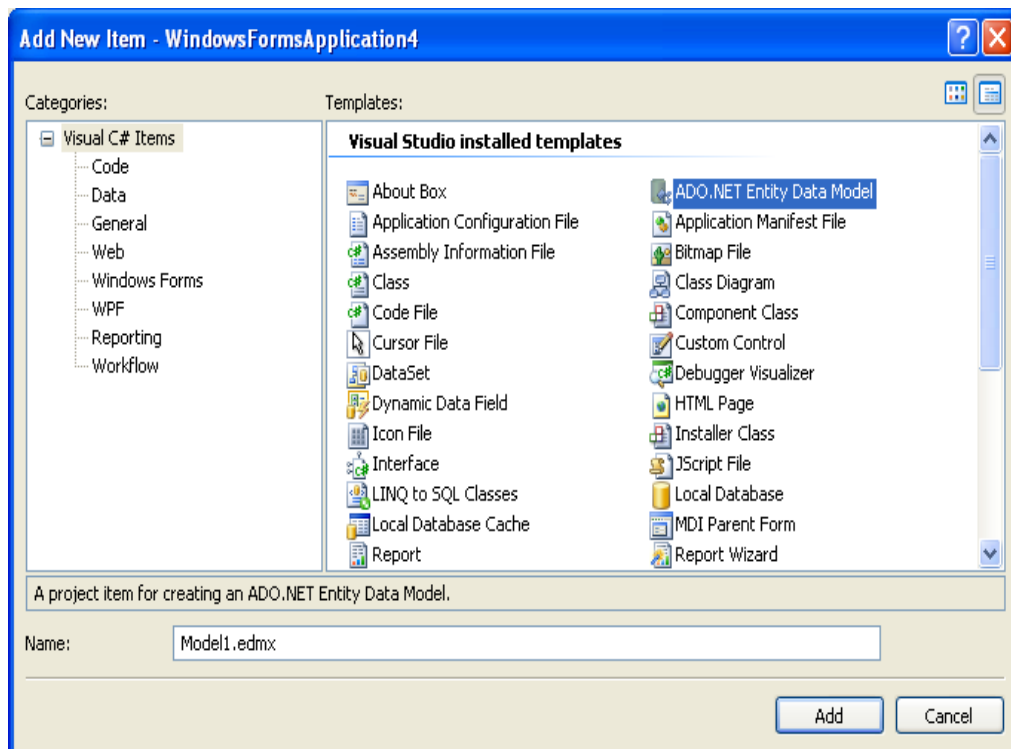

The first step is to create a new Windows Forms application.

1. In Visual Studio, select **File, New, Project** from the main menu.
2. Choose the **Windows Forms Application** installed template. Click **OK**. The solution is created.

##### Adding an Entity Data Model

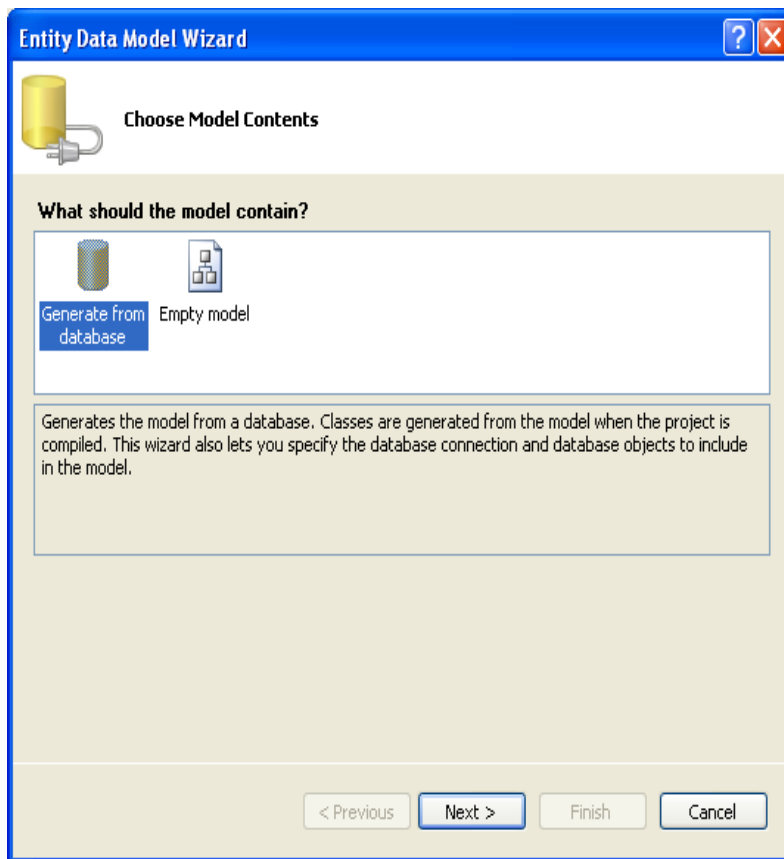

You will now add an Entity Data Model to your solution.

1. In the Solution Explorer, right-click your application and select **Add, New Item...**. From **Visual Studio installed templates** select **ADO.NET Entity Data Model**. Click **Add**.

**Figure 21.49. Add Entity Data Model**

2. You will now see the Entity Data Model Wizard. You will use the wizard to generate the Entity Data Model from the world example database. Select the icon **Generate from database**. Click **Next**.

Figure 21.50. Entity Data Model Wizard Screen 1

3. You can now select the connection you made earlier to the World database. If you have not already done so, you can create the new connection at this time by clicking **New Connection...**. For further instructions on creating a connection to a database see [Section 21.2.3.1, "Making a Connection"](#).

Figure 21.51. Entity Data Model Wizard Screen 2

**Entity Data Model Wizard**

**Choose Your Data Connection**

Which data connection should your application use to connect to the database?

localhost(world) [v] New Connection...

This connection string appears to contain sensitive data (for example, a password) that is required to connect to the database. Storing sensitive data in the connection string can be a security risk. Do you want to include this sensitive data in the connection string?

No, exclude sensitive data from the connection string. I will set it in my application code.

Yes, include the sensitive data in the connection string.

Entity connection string:

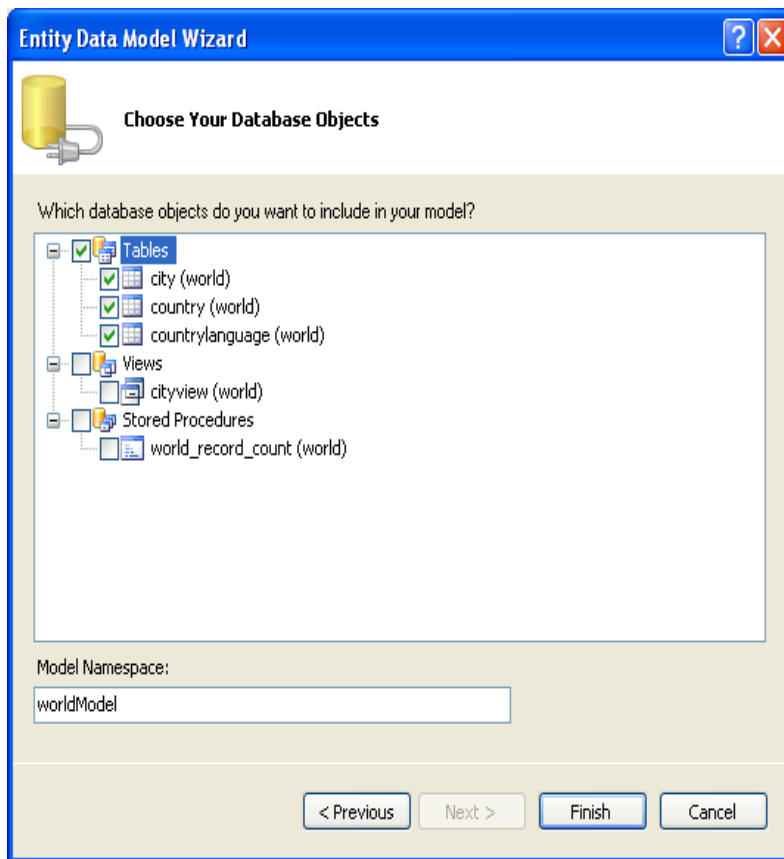

```
metadata=res://*/Model1.csdl|res://*/Model1.ssdl|res://*/Model1.msl;provider=MySql.Data.MySqlClient;provider connection string="server=localhost;user id=root;persist security info=True;database=world"
```

Save entity connection settings in App.Config as:

worldEntities

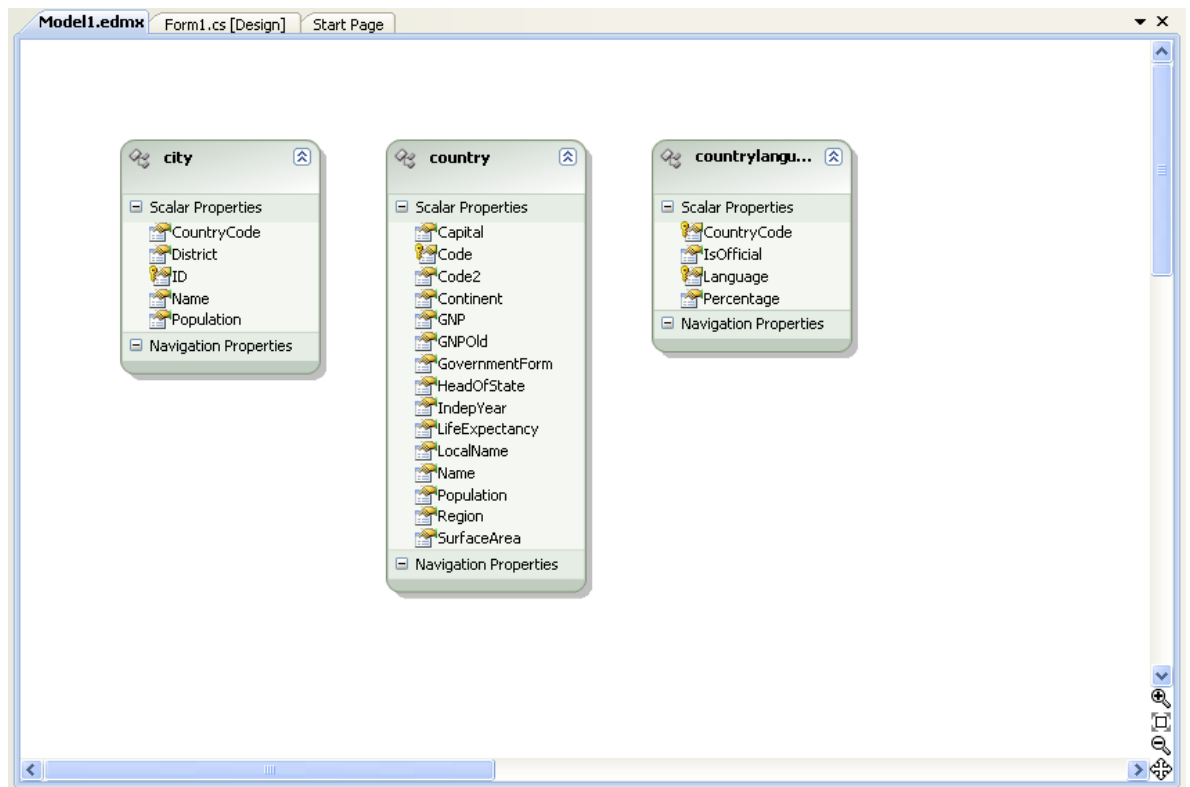

< Previous Next > Finish Cancel

4. Make a note of the entity connection settings to be used in App.Config, as these will be used later to write the necessary control code.
5. Click **Next**.
6. The Entity Data Model Wizard connects to the database. You are then presented with a tree structure of the database. From this you can select the object you would like to include in your model. If you had created Views and Stored Routines these will be displayed along with any tables. In this example you just need to select the tables. Click **Finish** to create the model and exit the wizard.

**Figure 21.52. Entity Data Model Wizard Screen 3**

7. Visual Studio will generate the model and then display it.

Figure 21.53. Entity Data Model Diagram

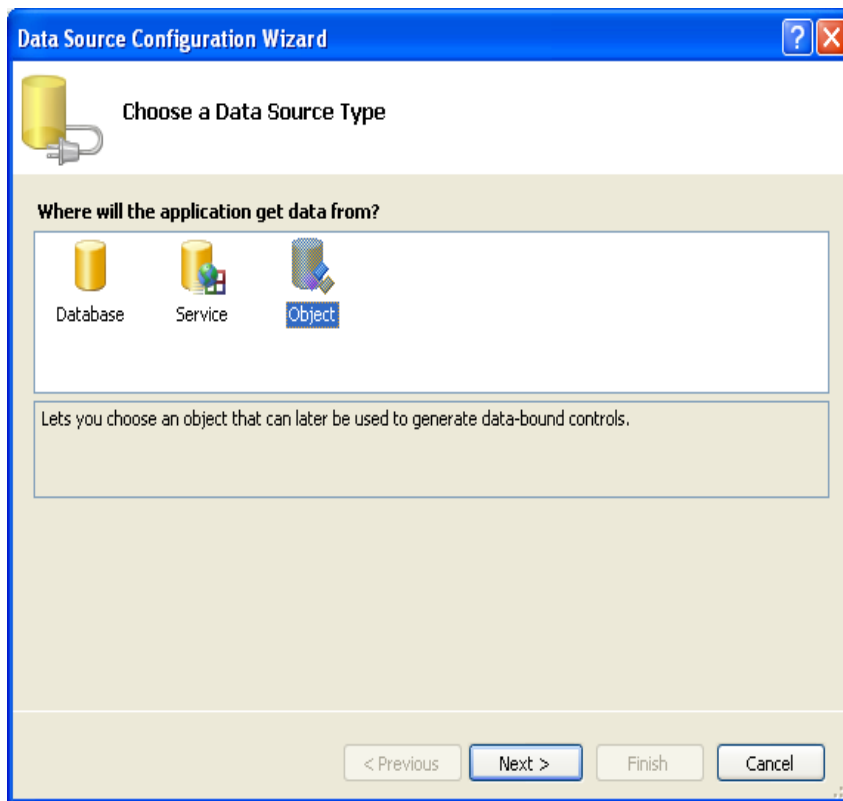

8. From the Visual Studio main menu select **Build, Build Solution**, to ensure that everything compiles correctly so far.

### Adding a new Data Source

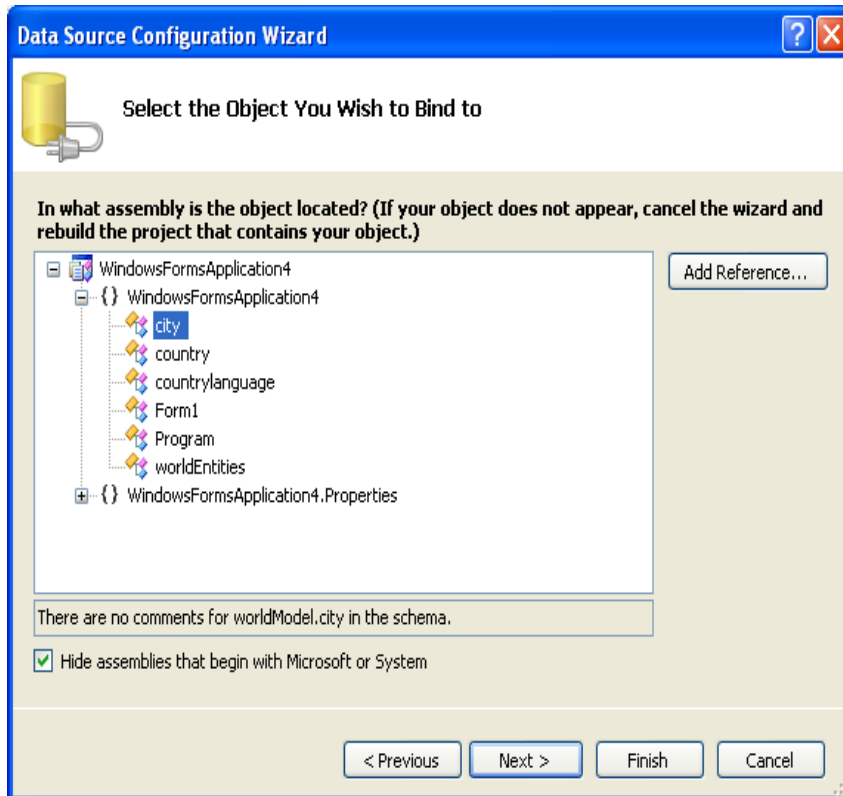

You will now add a new Data Source to your project and see how it can be used to read and write to the database.

1. From the Visual Studio main menu select **Data, Add New Data Source...**. You will be presented with the Data Source Configuration Wizard.

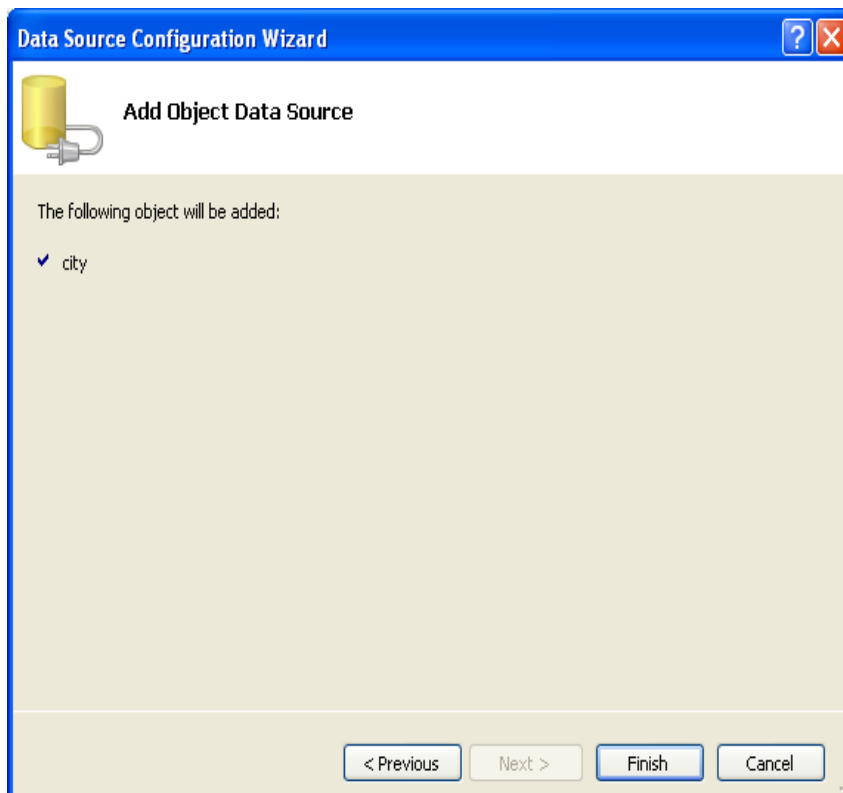

Figure 21.54. Entity Data Source Configuration Wizard Screen 1

2. Select the **Object** icon. Click **Next**.
3. You will now select the Object to bind to. Expand the tree. In this tutorial, you will select the city table. Once the city table has been selected click **Next**.

**Figure 21.55. Entity Data Source Configuration Wizard Screen 2**

4. The wizard will confirm that the city object is to be added. Click **Finish**.

**Figure 21.56. Entity Data Source Configuration Wizard Screen 3**

5. The city object will be display in the Data Sources panel. If the Data Sources panel is not displayed, select **Data**, **Show Data Sources** from the Visual Studio main menu. The docked panel will then be displayed.

**Figure 21.57. Data Sources**

### Using the Data Source in a Windows Form

You will now learn how to use the Data Source in a Windows Form.

1. In the Data Sources panel select the Data Source you just created and drag and drop it onto the Form Designer. By default the Data Source object will be added as a Data Grid View control. Note that the Data Grid View control is bound to the `cityBindingSource` and the Navigator control is bound to `cityBindingNavigator`.

Figure 21.58. Data Form Designer

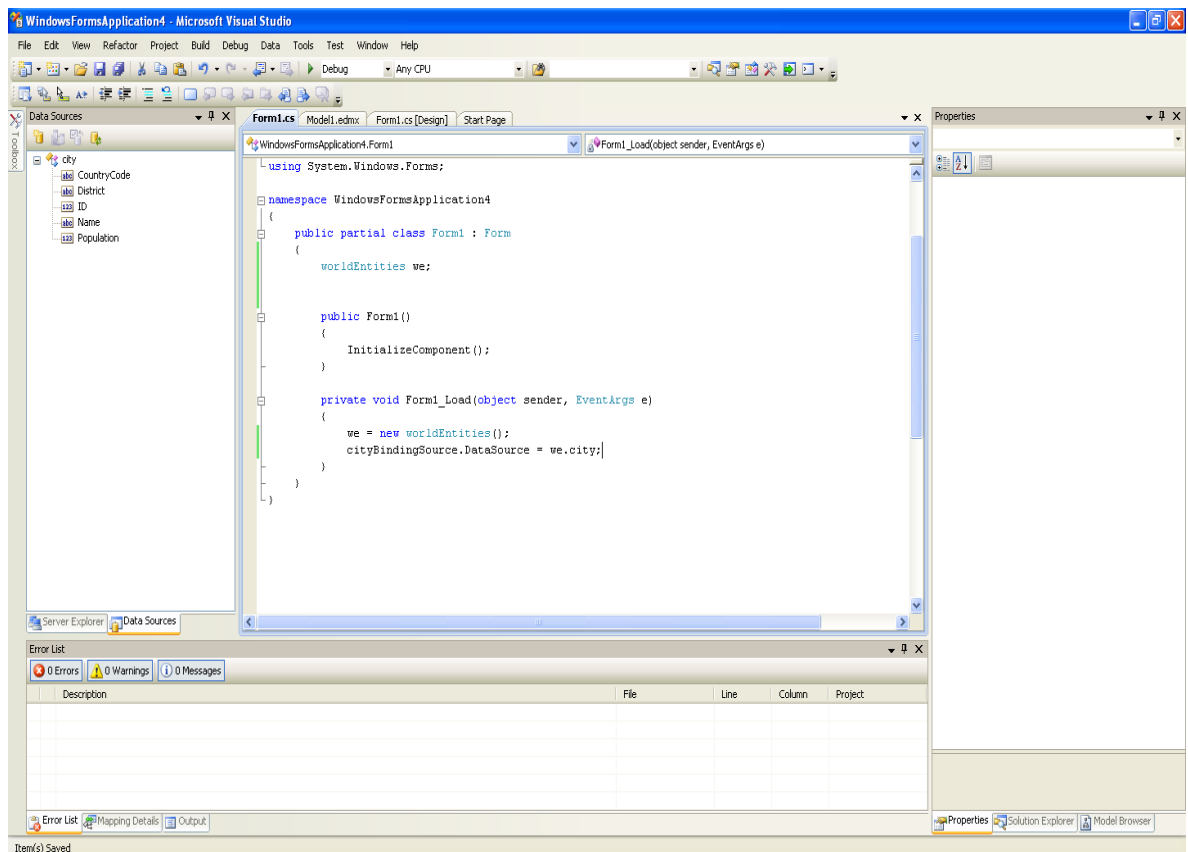

2. Save and rebuild the solution before continuing.

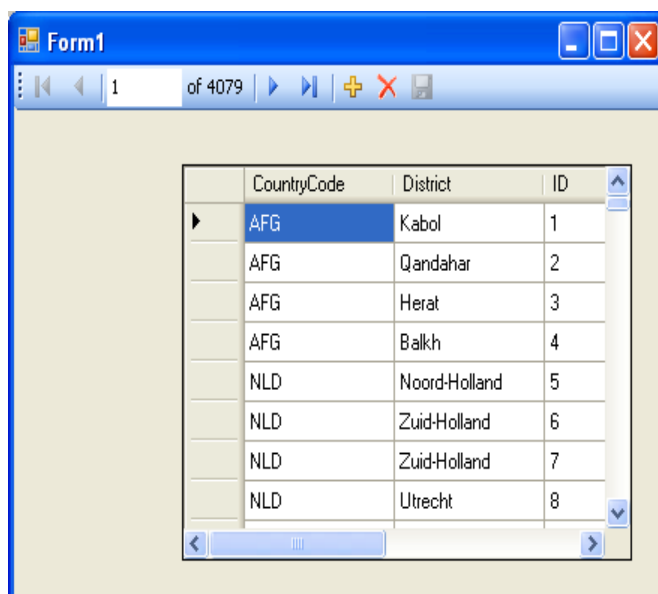

### Adding Code to Populate the Data Grid View

You are now ready to add code to ensure that the Data Grid View control will be populated with data from the City database table.

1. Double-click the form to access its code.
2. Add code to instantiate the Entity Data Model's EntityContainer object and retrieve data from the database to populate the control.

**Figure 21.59. Adding Code to the Form**

3. Save and rebuild the solution.
4. Run the solution. Ensure the grid is populated and you can navigate the database.

**Figure 21.60. The Populated Grid Control**

### Adding Code to Save Changes to the Database

You will now add code to enable you to save changes to the database.

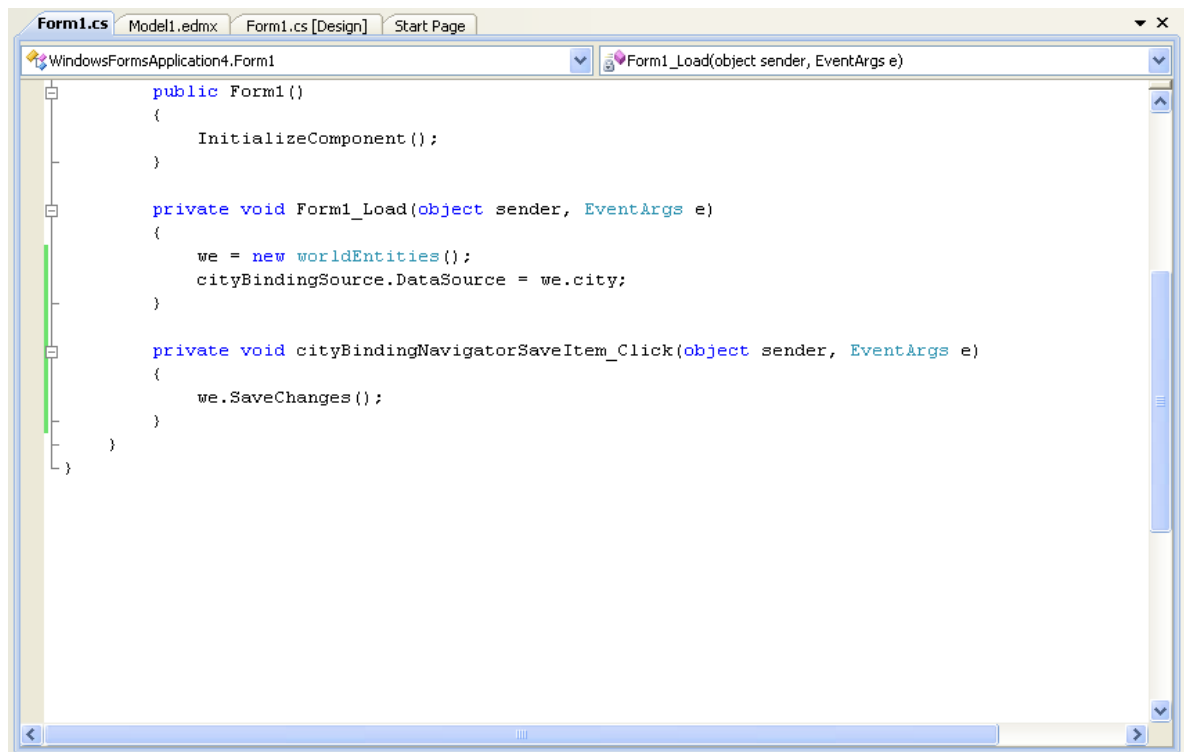

The Binding source component ensures that changes made in the Data Grid View control are also made to the Entity classes bound to it. However, that data needs to be saved back from the entities to the database itself. This can be achieved by the enabling of the Save button in the Navigator control, and the addition of some code.

1. In the Form Designer, click the Save icon in the Form toolbar and ensure that its Enabled property is set to True.

**Figure 21.61. Save Button Enabled**

2. Double-click the Save icon in the Form toolbar to display its code.
3. You now need to add code to ensure that data is saved to the database when the save button is clicked in the application.

**Figure 21.62. Adding Save Code to the Form**

4. Once the code has been added, save the solution and rebuild it. Run the application and verify that changes made in the grid are saved.

#### 21.2.4.6. Tutorial: Databinding in ASP.NET using LINQ on Entities

In this tutorial you create an ASP.NET web page that binds LINQ queries to entities using the Entity Framework mapping.

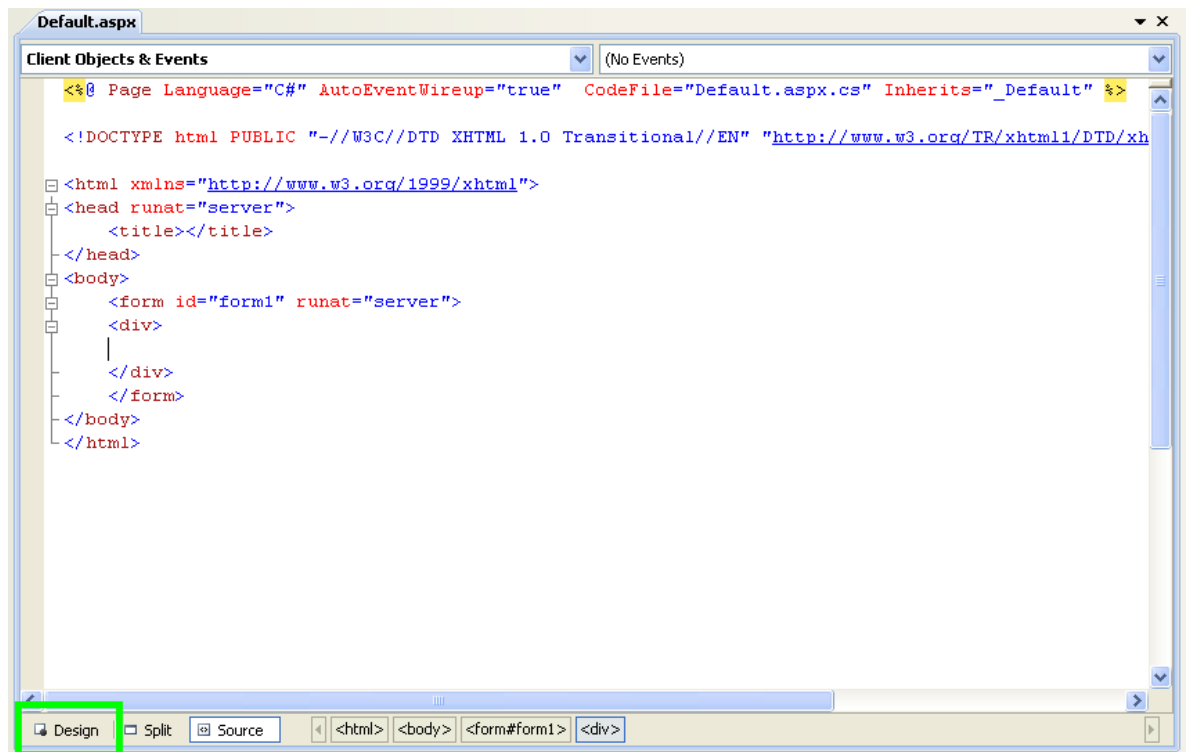

If you have not already done so, install the World example database prior to attempting this tutorial. See the tutorial [Section 21.2.4.5, "Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source"](#) for instructions on downloading and installing this database.

##### Creating an ASP.NET web site

In this part of the tutorial, you create an ASP.NET web site. The web site uses the World database. The main web page features a drop down list from which you can select a country. Data about that country's cities is then displayed in a grid view control.

1. From the Visual Studio main menu select **File**, **New**, **Web Site...**.
2. From the Visual Studio installed templates select **ASP.NET Web Site**. Click **OK**. You will be presented with the Source view of your web page by default.
3. Click the Design view tab situated underneath the Source view panel.

Figure 21.63. The Design Tab

- In the Design view panel, enter some text to decorate the blank web page.
- Click Toolbox. From the list of controls select **DropDownList**. Drag and drop the control to a location beneath the text on your web page.

Figure 21.64. Drop Down List

- From the **DropDownList** control's context menu, ensure that the **Enable AutoPostBack** check box is enabled. This will ensure the control's event handler is called when an item is selected. The user's choice will in turn be used to populate the **GridView** control.

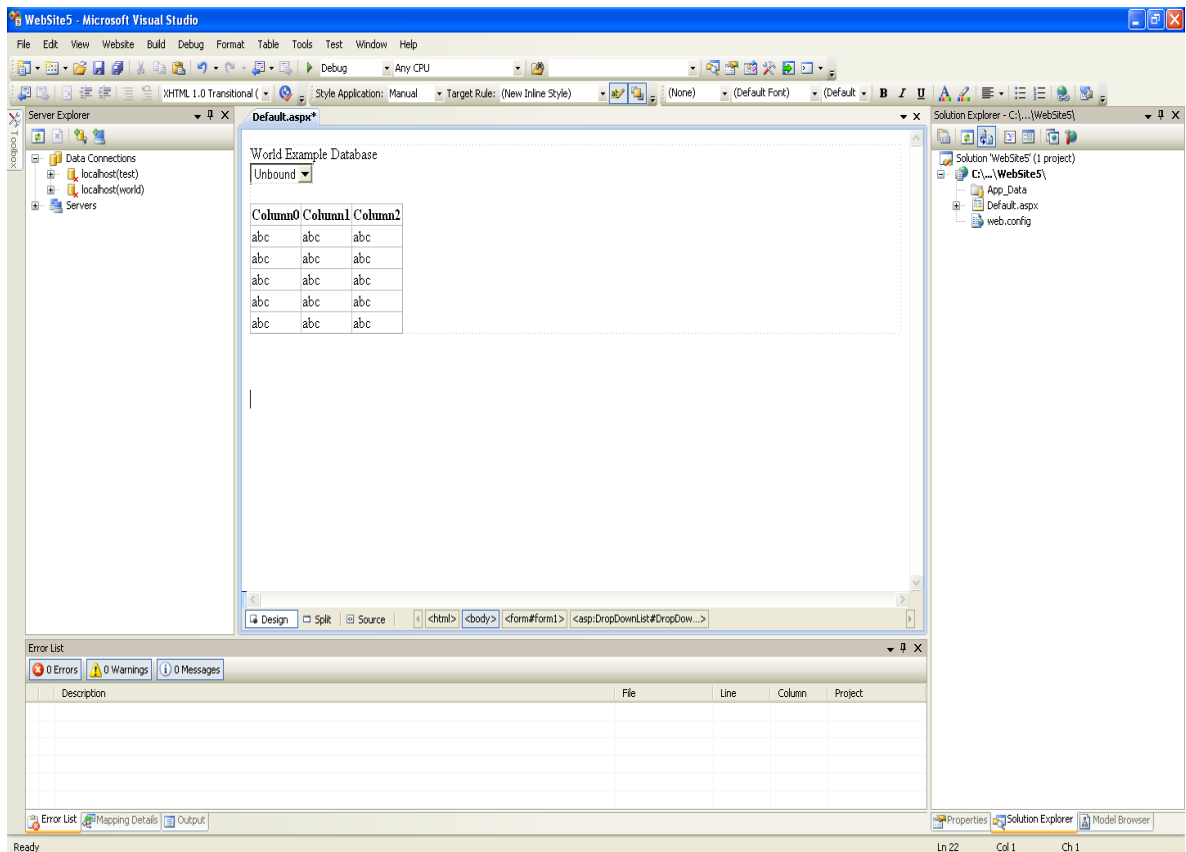

Figure 21.65. Enable AutoPostBack

- From the Toolbox select the **GridView** control.

**Figure 21.66. Grid View Control**

Drag and drop the Grid View control to a location just below the Drop Down List you already placed.

**Figure 21.67. Placed Grid View Control**

8. At this point it is recommended that you save your solution, and build the solution to ensure that there are no errors.
9. If you run the solution you will see that the text and drop down list are displayed, but the list is empty. Also, the grid view does not appear at all. Adding this functionality is described in the following sections.

At this stage you have a web site that will build, but further functionality is required. The next step will be to use the Entity Framework to create a mapping from the World database into entities that you can control programmatically.

### Creating an ADO.NET Entity Data Model

In this stage of the tutorial you will add an ADO.NET Entity Data Model to your project, using the World database at the storage level. The procedure for doing this is described in the tutorial [Section 21.2.4.5, "Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source"](#), and so will not be repeated here.

## Populating a Drop Data List Box with using the results of a entity LINQ query

In this part of the tutorial you will write code to populate the DropDownList control. When the web page loads the data to populate the list will be achieved by using the results of a LINQ query on the model created previously.

1. In the Design view panel, double-click any blank area. This brings up the [Page\\_Load](#) method.
2. Modify the relevant section of code according to the following listing:

```
...
public partial class _Default : System.Web.UI.Page
{
    worldModel.worldEntities we;

    protected void Page_Load(object sender, EventArgs e)
    {
        we = new worldModel.worldEntities();

        if (!IsPostBack)
        {
            var countryQuery = from c in we.country
                               orderby c.Name
                               select new { c.Code, c.Name };
            DropDownList1.DataValueField = "Code";
            DropDownList1.DataTextField = "Name";
            DropDownList1.DataSource = countryQuery;
            DataBind();
        }
    }
}
...
```

Note that the list control only needs to be populated when the page first loads. The conditional code ensures that if the page is subsequently reloaded, the list control is not repopulated, which would cause the user selection to be lost.

3. Save the solution, build it and run it. You should see the list control has been populated. You can select an item, but as yet the grid view control does not appear.

At this point you have a working Drop Down List control, populated by a LINQ query on your entity data model.

## Populating a Grid View control using an entity LINQ query

In the last part of this tutorial you will populate the Grid View Control using a LINQ query on your entity data model.

1. In the Design view, double-click the **DropDownList** control. This causes its [SelectedIndexChanged](#) code to be displayed. This method is called when a user selects an item in the list control and thus fires an AutoPostBack event.
2. Modify the relevant section of code accordingly to the following listing:

```
...
protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
    var cityQuery = from c in we.city
                    where c.CountryCode == DropDownList1.SelectedValue
                    orderby c.Name
                    select new { c.Name, c.Population, c.CountryCode };
    GridView1.DataSource = cityQuery;
    DataBind();
}
...
```

The grid view control is populated from the result of the LINQ query on the entity data model.

3. As a check compare your code to that shown in the following screenshot:

Figure 21.68. Source Code

```

protected void Page_Load(object sender, EventArgs e)
{
    we = new worldModel.worldEntities();

    if (!IsPostBack)
    {
        var countryQuery = from c in we.country
                           orderby c.Name
                           select new { c.Code, c.Name };
        DropDownList1.DataValueField = "Code";
        DropDownList1.DataTextField = "Name";
        DropDownList1.DataSource = countryQuery;
        DataBind();
    }
}

protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
    var cityQuery = from c in we.city
                    where c.CountryCode == DropDownList1.SelectedValue
                    orderby c.Name
                    select new { c.Name, c.Population, c.CountryCode };
    GridView1.DataSource = cityQuery;
    DataBind();
}

```

4. Save, build and run the solution. As you select a country you will see its cities are displayed in the grid view control.

Figure 21.69. The Working Web Site

In this tutorial you have seen how to create an ASP.NET web site, you have also seen how you can access a MySQL database using LINQ queries on an entity data model.

#### 21.2.4.7. Tutorial: Using SSL with MySQL Connector/Net

In this tutorial you will learn how you can use MySQL Connector/Net to connect to a MySQL server configured to use SSL. Support for SSL client certificates was added with MySQL Connector/Net 6.2.

MySQL Server uses the PEM format for certificates and private keys. This tutorial will use the test certificates from the server test suite by way of example. You can obtain the MySQL Server source code from [MySQL Downloads](#). The certificates can be found in the directory `./mysql-test/std_data`.

To carry out the steps in this tutorial, you must have Open SSL installed. This can be downloaded for Microsoft Windows at no charge from [Shining Light Productions](#).

Further details on the connection string options used in this tutorial can be found at [Section 21.2.6, "Connector/Net Connection String Options Reference"](#).

### Configuring the MySQL Server to use SSL

1. In the MySQL Server configuration file, set the SSL parameters as follows:

```
ssl-ca=path/to/repo/mysql-test/std_data/cacert.pem
ssl-cert=path/to/repo/mysql-test/std_data/server-cert.pem
ssl-key=path/to/repo/mysql-test/std_data/server-key.pem
```

Adjust the directories according to the location in which you installed the MySQL source code.

2. In this step you create a test user and set the user to require SSL.

Using the MySQL Command-Line Client, connect as `root` and create the user `sslclient`.

3. To set privileges and requirements, issue the following command:

```
GRANT ALL PRIVILEGES ON *.* TO sslclient@%' REQUIRE SSL;
```

### Creating a certificate file to use with the .NET client

1. The .NET client does not use the PEM file format, as .NET does not support this format natively. You will be using test client certificates from the same server repository, for the purposes of this example. Convert these to PFX format first. This format is also known as PKCS#12. An article describing this procedure can be found at the [Citrix website](#). From the directory `server-repository-root/mysql-test/std_data`, issue the following command:

```
openssl pkcs12 -export -in client-cert.pem -inkey client-key.pem -certfile cacert.pem -out client.pfx
```

2. When asked for an export password, enter the password "pass". The file `client.pfx` will be generated. This file is used in the remainder of the tutorial.

### Connecting to the server using a file-based certificate

1. You will use PFX file, `client.pfx` you created in the previous step to authenticate the client. The following example demonstrates how to connect using the `SSL Mode`, `CertificateFile` and `CertificatePassword` connection string options:

```
using (MySQLConnection connection = new MySQLConnection(
    "database=test;user=sslclient;" +
    "CertificateFile=H:\\bzt\\mysql-trunk\\mysql-test\\std_data\\client.pfx" +
    "CertificatePassword=pass;" +
    "SSL Mode=Required "))
{
    connection.Open();
}
```

The path to the certificate file will need to be changed to reflect your individual installation.

### Connecting to the server using a store-based certificate

1. The first step is to import the PFX file, `client.pfx`, into the Personal Store. Double-click the file in Windows explorer. This launches the Certificate Import Wizard.
2. Follow the steps dictated by the wizard, and when prompted for the password for the PFX file, enter "pass".

- Click **Finish** to close the wizard and import the certificate into the personal store.

### Examine certificates in the Personal Store

- Start the Microsoft Management Console by entering `mmc.exe` at a command prompt.
- Select **File**, **Add/Remove snap-in**. Click **Add**. Select **Certificates** from the list of available snap-ins in the dialog.
- Click **Add** button in the dialog, and select the **My user account** radio button. This is used for personal certificates.
- Click the **Finish** button.
- Click **OK** to close the Add/Remove Snap-in dialog.
- You will now have **Certificates – Current User** displayed in the left panel of the Microsoft Management Console. Expand the Certificates - Current User tree item and select **Personal, Certificates**. The right-hand panel will display a certificate issued to MySQL. This is the certificate that was previously imported. Double-click the certificate to display its details.
- After you have imported the certificate to the Personal Store, you can use a more succinct connection string to connect to the database, as illustrated by the following code:

```
using (MySQLConnection connection = new MySQLConnection(
    "database=test;user=sslclient;" +
    "Certificate Store Location=CurrentUser;" +
    "SSL Mode=Required"))
{
    connection.Open();
}
```

### Certificate Thumbprint Parameter

If you have a large number of certificates in your store, and many have the same Issuer, this can be a source of confusion and result in the wrong certificate being used. To alleviate this situation, there is an optional Certificate Thumbprint parameter that can additionally be specified as part of the connection string. As mentioned before, you can double-click a certificate in the Microsoft Management Console to display the certificate's details. When the Certificate dialog is displayed click the **Details** tab and scroll down to see the thumbprint. The thumbprint will typically be a number such as `#47 94 36 00 9a 40 f3 01 7a 14 5c f8 47 9e 76 94 d7 aa de f0`. This thumbprint can be used in the connection string, as the following code illustrates:

```
using (MySQLConnection connection = new MySQLConnection(
    "database=test;user=sslclient;" +
    "Certificate Store Location=CurrentUser;" +
    "Certificate Thumbprint=479436009a40f3017a145cf8479e7694d7aadeef0;" +
    "SSL Mode=Required"))
{
    connection.Open();
}
```

Spaces in the thumbprint parameter are optional and the value is case-insensitive.

### 21.2.4.8. Tutorial: Using MySqlCommand

This tutorial teaches you how to use the `MySqlCommand` class. This class enables you to execute a series of statements. Depending on the circumstances, this can be more convenient than using the `MySQLCommand` approach.

Further details of the `MySqlCommand` class can be found in the reference documentation supplied with MySQL Connector/Net.

To run the example programs in this tutorial, set up a simple test database and table using the `mysql` Command-Line Client or MySQL Workbench. Commands for the `mysql` Command-Line Client are given here:

```
CREATE DATABASE TestDB;
USE TestDB;
CREATE TABLE TestTable (id INT NOT NULL PRIMARY KEY
    AUTO_INCREMENT, name VARCHAR(100));
```

The main method of the `MySqlCommand` class is the `Execute` method. This method causes the script (sequence of statements) assigned to the `Query` property of the `MySqlCommand` object to be executed. Note the `Query` property can be set through the `MySqlCommand` constructor or using the `Query` property. `Execute` returns the number of statements executed.

The `MySqlCommand` object will execute the specified script on the connection set using the `Connection` property. Again, this property can be set directly or through the `MySqlCommand` constructor. The following code snippets illustrate this:

```
string sql = "SELECT * FROM TestTable";
...
MySqlCommand script = new MySqlCommand(conn, sql);
...
MySqlCommand script = new MySqlCommand();
script.Query = sql;
script.Connection = conn;
...
script.Execute();
```

The `MySqlCommand` class has several events associated with it. There are:

1. `Error` - generated if an error occurs.
2. `ScriptCompleted` - generated when the script successfully completes execution.
3. `StatementExecuted` - generated after each statement is executed.

It is possible to assign event handlers to each of these events. These user-provided routines are called back when the connected event occurs. The following code shows how the event handlers are set up.

```
script.Error += new MySqlCommandErrorHandler(script_Error);
script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
script.StatementExecuted += new MySqlCommandStatementExecutedEventHandler(script_StatementExecuted);
```

In VisualStudio, you can save typing by using tab completion to fill out stub routines. Start by typing, for example, "`script.Error +=`". Then press **TAB**, and then press **TAB** again. The assignment is completed, and a stub event handler created. A complete working example is shown below:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace MySqlCommandTest
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "INSERT INTO TestTable(name) VALUES ('Superman');" +
                    "INSERT INTO TestTable(name) VALUES ('Batman');" +
                    "INSERT INTO TestTable(name) VALUES ('Wolverine');" +
                    "INSERT INTO TestTable(name) VALUES ('Storm');";
```

```

        MySqlScript script = new MySqlScript(conn, sql);

        script.Error += new MySqlScriptErrorHandler(script_Error);
        script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
        script.StatementExecuted += new MySqlStatementExecutedEventHandler(script_StatementExecuted);

        int count = script.Execute();

        Console.WriteLine("Executed " + count + " statement(s).");
        Console.WriteLine("Delimiter: " + script.Delimiter);
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.ToString());
    }

    conn.Close();
    Console.WriteLine("Done.");
}

static void script_StatementExecuted(object sender, MySqlScriptEventArgs args)
{
    Console.WriteLine("script_StatementExecuted");
}

static void script_ScriptCompleted(object sender, EventArgs e)
{
    /// EventArgs e will be EventArgs.Empty for this method
    Console.WriteLine("script_ScriptCompleted!");
}

static void script_Error(Object sender, MySqlScriptErrorEventArgs args)
{
    Console.WriteLine("script_Error: " + args.Exception.ToString());
}
}
}
}

```

Note that in the `script_ScriptCompleted` event handler, the `EventArgs` parameter `e` will be `EventArgs.Empty`. In the case of the `ScriptCompleted` event there is no additional data to be obtained, which is why the event object is `EventArgs.Empty`.

#### 21.2.4.8.1. Using Delimiters with MySqlScript

Depending on the nature of the script, you may need control of the delimiter used to separate the statements that will make up a script. The most common example of this is where you have a multi-statement stored routine as part of your script. In this case if the default delimiter of “;” is used you will get an error when you attempt to execute the script. For example, consider the following stored routine:

```

CREATE PROCEDURE test_routine()
BEGIN
    SELECT name FROM TestTable ORDER BY name;
    SELECT COUNT(name) FROM TestTable;
END

```

This routine actually needs to be executed on the MySQL Server as a single statement. However, with the default delimiter of “;”, the `MySqlScript` class would interpret the above as two statements, the first being:

```

CREATE PROCEDURE test_routine()
BEGIN
    SELECT name FROM TestTable ORDER BY name;

```

Executing this as a statement would generate an error. To solve this problem `MySqlScript` supports the ability to set a different delimiter. This is achieved through the `Delimiter` property. For example, you could set the delimiter to “??”, in which case the above stored routine would no longer generate an error when executed. Multiple statements can be delimited in the script, so for example, you could have a three statement script such as:

```
string sql = "DROP PROCEDURE IF EXISTS test_routine??" +
    "CREATE PROCEDURE test_routine() " +
    "BEGIN " +
    "SELECT name FROM TestTable ORDER BY name;" +
    "SELECT COUNT(name) FROM TestTable;" +
    "END??" +
    "CALL test_routine()";
```

You can change the delimiter back at any point by setting the Delimiter property. The following code shows a complete working example:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication8
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "DROP PROCEDURE IF EXISTS test_routine??" +
                    "CREATE PROCEDURE test_routine() " +
                    "BEGIN " +
                    "SELECT name FROM TestTable ORDER BY name;" +
                    "SELECT COUNT(name) FROM TestTable;" +
                    "END??" +
                    "CALL test_routine()";

                MySqlScript script = new MySqlScript(conn);

                script.Query = sql;
                script.Delimiter = "??";
                int count = script.Execute();
                Console.WriteLine("Executed " + count + " statement(s)");
                script.Delimiter = ";";
                Console.WriteLine("Delimiter: " + script.Delimiter);
                Console.WriteLine("Query: " + script.Query);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

#### 21.2.4.9. Tutorial: Generating MySQL DDL from an Entity Framework Model

In this tutorial, you will learn how to create MySQL [DDL](#) from an Entity Framework model. Use Visual Studio 2010 and MySQL Connector/Net 6.3 to carry out this tutorial.

1. Create a new console application in Visual Studio 2010.
2. Using the **Solution Explorer**, add a reference to `MySql.Data.Entity`.

3. From the **Solution Explorer** select **Add, New Item**. In the **Add New Item** dialog select **Online Templates**. Select **ADO.NET Entity Data Model** and click Add. The **Entity Data Model** dialog will be displayed.
4. In the **Entity Data Model** dialog select **Empty Model**. Click **Finish**. A blank model will be created.
5. Create a simple model. A single Entity will do for the purposes of this tutorial.
6. In the **Properties** panel select **ConceptualEntityModel** from the drop-down listbox.
7. In the **Properties** panel, locate the **DDL Generation Template** in the category **Database Script Generation**.
8. For the **DDL Generation** property select **SSDLToMySQL.tt(VS)** from the drop-down listbox.
9. Save the solution.
10. Right-click an empty space in the model design area. The context-sensitive menu will be displayed.
11. From the context-sensitive menu select **Generate Database from Model**. The **Generate Database Wizard** dialog will be displayed.
12. In the **Generate Database Wizard** dialog select an existing connection, or create a new connection to a server. Select an appropriate radio button to show or hide sensitive data. For the purposes of this tutorial you can select **Yes** (although you might skip this for commercial applications).
13. Click **Next**. MySQL compatible DDL code will be generated. Click **Finish** to exit the wizard.

You have seen how to create MySQL DDL code from an Entity Framework model.

## 21.2.5. Connector/Net Programming

Connector/Net comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of Connector/Net:

- **MySqlCommand**: Represents an SQL statement to execute against a MySQL database.
- **MySqlCommandBuilder**: Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- **MySqlConnection**: Represents an open connection to a MySQL Server database.
- **MySqlDataAdapter**: Represents a set of data commands and a database connection that are used to fill a data set and update a MySQL database.
- **MySqlDataReader**: Provides a means of reading a forward-only stream of rows from a MySQL database.
- **MySqlException**: The exception that is thrown when MySQL returns an error.
- **MySqlHelper**: Helper class that makes it easier to work with the provider.
- **MySqlTransaction**: Represents an SQL **transaction** to be made in a MySQL database.

In the following sections, you will learn about some common use cases for Connector/Net, including BLOB handling, date handling, and using Connector/Net with common tools such as Crystal Reports.

### 21.2.5.1. Connecting to MySQL Using Connector/Net

All interaction between a .NET application and the MySQL server is routed through a **MySqlConnection** object. Before your application can interact with the server, it must instantiate, configure, and open a **MySqlConnection** object.

Even when using the `MySQLHelper` class, a `MySQLConnection` object is created by the helper class.

This section describes how to connect to MySQL using the `MySQLConnection` object.

### 21.2.5.2. Creating a Connector/Net Connection String

The `MySQLConnection` object is configured using a connection string. A connection string contains several key/value pairs, separated by semicolons. In each key/value pair, the option name and its corresponding value are joined by an equal sign. For the list of option names to use in the connection string, see [Section 21.2.6, "Connector/Net Connection String Options Reference"](#).

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the `MySQLConnection` object is configured to connect to a MySQL server at `127.0.0.1`, with a user name of `root` and a password of `12345`. The default database for all statements will be the `test` database.

#### Note

Using the '@' symbol for parameters is now the preferred approach, although the old pattern of using '?' is still supported. To avoid conflicts when using the '@' symbol in combination with user variables, see the [Allow User Variables](#) connection string option in [Section 21.2.6, "Connector/Net Connection String Options Reference"](#). The [Old Syntax](#) connection string option has now been deprecated.

#### 21.2.5.2.1. Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a `MySQLConnection` object, assign the connection string, and open the connection.

Connector/Net can also connect using the native Windows authentication plugin. See [Section 21.2.5.5, "Using the Windows Native Authentication Plugin"](#) for details.

You can further extend the authentication mechanism by writing your own authentication plugin. See [Section 21.2.5.6, "Writing a Custom Authentication Plugin"](#) for details.

#### Visual Basic Example

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    conn.ConnectionString = myConnectionString
    conn.Open()

Catch ex As MySql.Data.MySqlClient.MySqlException
    MessageBox.Show(ex.Message)
End Try
```

#### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";
```

```

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection();
    conn.ConnectionString = myConnectionString;
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}

```

You can also pass the connection string to the constructor of the [MySqlConnection](#) class:

### Visual Basic Example

```

Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    MessageBox.Show(ex.Message)
End Try

```

### C# Example

```

MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}

```

Once the connection is open it can be used by the other Connector/Net classes to communicate with the MySQL server.

#### 21.2.5.2.2. Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the [MySqlConnection](#) class will return a [MySqlException](#) object. This object has two properties that are of interest when handling errors:

- **Message:** A message that describes the current exception.
- **Number:** The MySQL error number.

When handling errors, you can your application's response based on the error number. The two most common error numbers when connecting are as follows:

- **0:** Cannot connect to server.
- **1045:** Invalid user name and/or password.

The following code shows how to adapt the application's response based on the actual error:

## Visual Basic Example

```

Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    Select Case ex.Number
        Case 0
            MessageBox.Show("Cannot connect to server. Contact administrator")
        Case 1045
            MessageBox.Show("Invalid username/password, please try again")
    End Select
End Try

```

## C# Example

```

MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    switch (ex.Number)
    {
        case 0:
            MessageBox.Show("Cannot connect to server. Contact administrator");
        case 1045:
            MessageBox.Show("Invalid username/password, please try again");
    }
}

```

### Important

Note that if you are using multilanguage databases you must specify the character set in the connection string. If you do not specify the character set, the connection defaults to the `latin1` charset. You can specify the character set as part of the connection string, for example:

```

MySqlConnection myConnection = new MySqlConnection("server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;Charset=latin1;");

```

### 21.2.5.2.3. Using GetSchema on a Connection

The `GetSchema()` method of the connection object can be used to retrieve schema information about the database currently connected to. The schema information is returned in the form of a `DataTable`. The schema information is organized into a number of collections. Different forms of the `GetSchema()` method can be used depending on the information required. There are three forms of the `GetSchema()` method:

- `GetSchema()` - This call will return a list of available collections.
- `GetSchema(String)` - This call returns information about the collection named in the string parameter. If the string "MetaDataCollections" is used then a list of all available collections is returned. This is the same as calling `GetSchema()` without any parameters.

- `GetSchema(String, String[])` - In this call the first string parameter represents the collection name, and the second parameter represents a string array of restriction values. Restriction values limit the amount of data that will be returned. Restriction values are explained in more detail in the [Microsoft .NET documentation](#).

#### 21.2.5.2.3.1. Collections

The collections can be broadly grouped into two types: collections that are common to all data providers, and collections specific to a particular provider.

##### Common

The following collections are common to all data providers:

- `MetaDataCollections`
- `DataSourceInformation`
- `DataTypes`
- `Restrictions`
- `ReservedWords`

##### Provider-specific

The following are the collections currently provided by MySQL Connector/Net, in addition to the common collections above:

- `Databases`
- `Tables`
- `Columns`
- `Users`
- `Foreign Keys`
- `IndexColumns`
- `Indexes`
- `Foreign Key Columns`
- `UDF`
- `Views`
- `ViewColumns`
- `Procedure Parameters`
- `Procedures`
- `Triggers`

##### Example Code

A list of available collections can be obtained using the following code:

```
using System;
using System.Data;
using System.Text;
using MySql.Data;
```

```

using MySql.Data.MySqlClient;

namespace ConsoleApplication2
{
    class Program
    {
        private static void DisplayData(System.Data.DataTable table)
        {
            foreach (System.Data.DataRow row in table.Rows)
            {
                foreach (System.Data.DataColumn col in table.Columns)
                {
                    Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
                }
                Console.WriteLine("=====");
            }
        }

        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                DataTable table = conn.GetSchema("MetaDataCollections");
                //DataTable table = conn.GetSchema("UDF");
                DisplayData(table);

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            Console.WriteLine("Done.");
        }
    }
}

```

Further information on the [GetSchema\(\)](#) method and schema collections can be found in the [Microsoft .NET documentation](#).

### 21.2.5.3. Using MySqlCommand

A [MySqlCommand](#) has the [CommandText](#) and [CommandType](#) properties associated with it. The [CommandText](#) will be handled differently depending on the setting of [CommandType](#). [CommandType](#) can be one of:

1. Text - A SQL text command (default)
2. StoredProcedure - The name of a Stored Procedure
3. TableDirect - The name of a table (new in Connector/Net 6.2)

The default [CommandType](#), [Text](#), is used for executing queries and other SQL commands. Some example of this can be found in the following section [Section 21.2.4.1.2, "The MySqlCommand Object"](#).

If [CommandType](#) is set to [StoredProcedure](#), set [CommandText](#) to the name of the Stored Procedure to access.

If [CommandType](#) is set to [TableDirect](#), all rows and columns of the named table will be returned when you call one of the Execute methods. In effect, this command performs a `SELECT *` on the table

specified. The `CommandText` property is set to the name of the table to query. This is illustrated by the following code snippet:

```
...
MySQLCommand cmd = new MySQLCommand();
cmd.CommandText = "mytable";
cmd.Connection = someConnection;
cmd.CommandType = CommandType.TableDirect;
MySQLDataReader reader = cmd.ExecuteReader();
while (reader.Read())
{
    Console.WriteLine(reader[0], reader[1]...);
}
...
```

Examples of using the `CommandType` of `StoredProcedure` can be found in the section [Section 21.2.5.9, "Accessing Stored Procedures with Connector/Net"](#).

Commands can have a timeout associated with them. This is useful as you may not want a situation where a command takes up an excessive amount of time. A timeout can be set using the `CommandTimeout` property. The following code snippet sets a timeout of one minute:

```
MySQLCommand cmd = new MySQLCommand();
cmd.CommandTimeout = 60;
```

The default value is 30 seconds. Avoid a value of 0, which indicates an indefinite wait. To change the default command timeout, use the connection string option `Default Command Timeout`.

Prior to MySQL Connector/Net 6.2, `MySQLCommand.CommandTimeout` included user processing time, that is processing time not related to direct use of the connector. Timeout was implemented through a .NET Timer, that triggered after `CommandTimeout` seconds. This timer consumed a thread.

MySQL Connector/Net 6.2 introduced timeouts that are aligned with how Microsoft handles `SqlCommand.CommandTimeout`. This property is the cumulative timeout for all network reads and writes during command execution or processing of the results. A timeout can still occur in the `MySQLReader.Read` method after the first row is returned, and does not include user processing time, only IO operations. The 6.2 implementation uses the underlying stream timeout facility, so is more efficient in that it does not require the additional timer thread as was the case with the previous implementation.

Further details on this can be found in the relevant [Microsoft documentation](#).

#### 21.2.5.4. Using Connector/Net with Connection Pooling

The Connector/Net supports connection pooling for better performance and scalability with database-intensive applications. This is enabled by default. You can turn it off or adjust its performance characteristics using the connection string options `Pooling`, `Connection Reset`, `Connection Lifetime`, `Cache Server Properties`, `Max Pool Size` and `Min Pool Size`. See [Section 21.2.5.2, "Creating a Connector/Net Connection String"](#) for further information.

Connection pooling works by keeping the native connection to the server live when the client disposes of a `MySQLConnection`. Subsequently, if a new `MySQLConnection` object is opened, it will be created from the connection pool, rather than creating a new native connection. This improves performance.

#### Guidelines

To work as designed, it is best to let the connection pooling system manage all connections. Do not create a globally accessible instance of `MySQLConnection` and then manually open and close it. This interferes with the way the pooling works and can lead to unpredictable results or even exceptions.

One approach that simplifies things is to avoid manually creating a `MySQLConnection` object. Instead use the overloaded methods that take a connection string as an argument. Using this approach,

Connector/Net will automatically create, open, close and destroy connections, using the connection pooling system for best performance.

Typed Datasets and the [MembershipProvider](#) and [RoleProvider](#) classes use this approach. Most classes that have methods that take a [MySQLConnection](#) as an argument, also have methods that take a connection string as an argument. This includes [MySQLDataAdapter](#).

Instead of manually creating [MySQLCommand](#) objects, you can use the static methods of the [MySQLHelper](#) class. These take a connection string as an argument, and they fully support connection pooling.

## Resource Usage

Starting with MySQL Connector/Net 6.2, there is a background job that runs every three minutes and removes connections from pool that have been idle (unused) for more than three minutes. The pool cleanup frees resources on both client and server side. This is because on the client side every connection uses a socket, and on the server side every connection uses a socket and a thread.

Prior to this change, connections were never removed from the pool, and the pool always contained the peak number of open connections. For example, a web application that peaked at 1000 concurrent database connections would consume 1000 threads and 1000 open sockets at the server, without ever freeing up those resources from the connection pool. Note, connections, no matter how old, will not be closed if the number of connections in the pool is less than or equal to the value set by the [Min Pool Size](#) connection string parameter.

### 21.2.5.5. Using the Windows Native Authentication Plugin

Connector/Net applications can authenticate to a MySQL server using the Windows Native Authentication Plugin as of Connector/Net 6.4.4 and MySQL 5.5.16/5.6.10. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For background and usage information about the authentication plugin, see, [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).

The interface matches the [MySQL.Data.MySqlClient](#) object. To enable, pass in [Integrated Security](#) to the connection string with a value of `yes` or `sspi`.

Passing in a user ID is optional. When Windows authentication is set up, a MySQL user is created and configured to be used by Windows authentication. By default, this user ID is named `auth_windows`, but can be defined using a different name. If the default name is used, then passing the user ID to the connection string from Connector/Net is optional, because it will use the `auth_windows` user. Otherwise, the name must be passed to the [connection string](#) using the standard user ID element.

### 21.2.5.6. Writing a Custom Authentication Plugin

Advanced users with special security requirements can create their own authentication plugins for Connector/Net applications. You can extend the handshake protocol, adding custom logic. This capability requires Connector/Net 6.6.3 or higher, and MySQL 5.5.16 or higher. For background and usage information about MySQL authentication plugins, see, [Section 22.2.3.7, “Authentication Plugins”](#) and [Section 22.2.4.9, “Writing Authentication Plugins”](#).

To write a custom authentication plugin, you will need a reference to the assembly `MySQL.Data.dll`. The classes relevant for writing authentication plugins are available at the namespace `MySQL.Data.MySqlClient.Authentication`.

## How the Custom Authentication Plugin Works

At some point during handshake, the internal method

```
void Authenticate(bool reset)
```

of [MySQLAuthenticationPlugin](#) is called. This method in turns calls several overridable methods of the current plugin.

## Creating the Authentication Plugin Class

You put the authentication plugin logic inside a new class derived from `MySql.Data.MySqlClient.Authentication.MySqlAuthenticationPlugin`. The following methods are available to be overridden:

```
protected virtual void CheckConstraints()
protected virtual void AuthenticationFailed(Exception ex)
protected virtual void AuthenticationSuccessful()
protected virtual byte[] MoreData(byte[] data)
protected virtual void AuthenticationChange()
public abstract string PluginName { get; }
public virtual string GetUsername()
public virtual object GetPassword()
protected byte[] AuthData;
```

The following is a brief explanation of each one:

```
/// <summary>
/// This method must check authentication method specific constraints in the
environment and throw an Exception
/// if the conditions are not met. The default implementation does nothing.
/// </summary>
protected virtual void CheckConstraints()

/// <summary>
/// This method, called when the authentication failed, provides a chance to
plugins to manage the error
/// the way they consider decide (either showing a message, logging it, etc.).
/// The default implementation wraps the original exception in a MySqlConnection
with an standard message and rethrows it.
/// </summary>
/// <param name="ex">The exception with extra information on the error.</param>
protected virtual void AuthenticationFailed(Exception ex)

/// <summary>
/// This method is invoked when the authentication phase was successful accepted
by the server.
/// Derived classes must override this if they want to be notified of such
condition.
/// </summary>
/// <remarks>The default implementation does nothing.</remarks>
protected virtual void AuthenticationSuccessful()

/// <summary>
/// This method provides a chance for the plugin to send more data when the
server requests so during the
/// authentication phase. This method will be called at least once, and more
than one depending upon whether the
/// server response packets have the 0x01 prefix.
/// </summary>
/// <param name="data">The response data from the server, during the
authentication phase the first time is called is null, in
subsequent calls contains the server response.</param>
/// <returns>The data generated by the plugin for server consumption.</returns>
/// <remarks>The default implementation always returns null.</remarks>
protected virtual byte[] MoreData(byte[] data)

/// <summary>
/// The plugin name.
/// </summary>
public abstract string PluginName { get; }

/// <summary>
/// Gets the user name to send to the server in the authentication phase.
/// </summary>
/// <returns>An string with the user name</returns>
/// <remarks>Default implementation returns the UserId passed from the
connection string.</remarks>
public virtual string GetUsername()
```

```

/// <summary>
/// Gets the password to send to the server in the authentication phase. This
/// can be a string or a
/// </summary>
/// <returns>An object, can be byte[], string or null, with the password.
</returns>
/// <remarks>Default implementation returns null.</remarks>
public virtual object GetPassword()

/// <summary>
/// The authentication data passed when creating the plugin.
/// For example in mysql_native_password this is the seed to encrypt the
/// password.
/// </summary>
protected byte[] AuthData;

```

## Sample Authentication Plugin

Here is an example showing how to create the authentication plugin, then enable it by means of a configuration file. Follow these steps:

1. Create a console app, adding a reference to `MySql.Data.dll`.
2. Design the main program as follows:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using MySql.Data.MySqlClient;

namespace AuthPluginTest
{
    class Program
    {
        static void Main(string[] args)
        {
            // Customize the connection string as necessary.
            MySqlConnection con = new MySqlConnection("server=localhost;
database=test; user id=myuser; password=mypass");
            con.Open();
            con.Close();
        }
    }
}

```

3. Create your plugin class. In this example, we add an “alternative” implementation of the Native password plugin by just using the same code from the original plugin. We name our class `MySqlNativePasswordPlugin2`:

```

using System.IO;
using System;
using System.Text;
using System.Security.Cryptography;
using MySql.Data.MySqlClient.Authentication;
using System.Diagnostics;

namespace AuthPluginTest
{
    public class MySqlNativePasswordPlugin2 : MySqlAuthenticationPlugin
    {
        public override string PluginName
        {
            get { return "mysql_native_password"; }
        }

        public override object GetPassword()
        {

```

```

    Debug.WriteLine("Calling MySqlNativePasswordPlugin2.GetPassword");
    return Get411Password(Settings.Password, AuthData);
}

/// <summary>
/// Returns a byte array containing the proper encryption of the
/// given password/seed according to the new 4.1.1 authentication scheme.
/// </summary>
/// <param name="password"></param>
/// <param name="seed"></param>
/// <returns></returns>
private byte[] Get411Password(string password, byte[] seedBytes)
{
    // if we have no password, then we just return 1 zero byte
    if (password.Length == 0) return new byte[1];

    SHA1 sha = new SHA1CryptoServiceProvider();

    byte[] firstHash = sha.ComputeHash(Encoding.Default.GetBytes(password));
    byte[] secondHash = sha.ComputeHash(firstHash);

    byte[] input = new byte[seedBytes.Length + secondHash.Length];
    Array.Copy(seedBytes, 0, input, 0, seedBytes.Length);
    Array.Copy(secondHash, 0, input, seedBytes.Length, secondHash.Length);
    byte[] thirdHash = sha.ComputeHash(input);

    byte[] finalHash = new byte[thirdHash.Length + 1];
    finalHash[0] = 0x14;
    Array.Copy(thirdHash, 0, finalHash, 1, thirdHash.Length);

    for (int i = 1; i < finalHash.Length; i++)
        finalHash[i] = (byte)(finalHash[i] ^ firstHash[i - 1]);
    return finalHash;
}
}
}

```

4. Notice that the plugin implementation just overrides `GetPassword`, and provides an implementation to encrypt the password using the 4.1 protocol. We also put the following line in the `GetPassword` body:

```
Debug.WriteLine("Calling MySqlNativePasswordPlugin2.GetPassword");
```

to provide confirmation that the plugin was effectively used. (You could also put a breakpoint on that method.)

5. Enable the new plugin in the configuration file:

```

<?xml version="1.0"?>
<configuration>
  <configSections>
    <section name="MySQL" type="MySql.Data.MySqlClient.MySqlConfiguration,
MySql.Data"/>
  </configSections>
  <MySQL>
    <AuthenticationPlugins>
      <add name="mysql_native_password"
type="AuthPluginTest.MySqlNativePasswordPlugin2, AuthPluginTest"></add>
    </AuthenticationPlugins>
  </MySQL>
</startup><supportedRuntime version="v4.0" sku=".NETFramework,Version=v4.0"/>
</startup></configuration>

```

6. Run the application. In Visual Studio, you will see the message `Calling MySqlNativePasswordPlugin2.GetPassword` in the debug window.
7. Continue enhancing the authentication logic, overriding more methods if you required.

### 21.2.5.7. Using Connector/Net with Table Caching

This feature exists with Connector/Net versions 6.4 and above.

Table caching is a feature that can be used to cache slow-changing datasets on the client side. This is useful for applications that are designed to use readers, but still want to minimize trips to the server for slow-changing tables.

This feature is transparent to the application, and is disabled by default.

## Configuration

- To enable table caching, add `'table cache = true'` to the connection string.
- Optionally, specify the `'Default Table Cache Age'` connection string option, which represents the number of seconds a table is cached before the cached data is discarded. The default value is `60`.
- You can turn caching on and off and set caching options at runtime, on a per-command basis.

### 21.2.5.8. Using the Connector/Net with Prepared Statements

As of MySQL 4.1, it is possible to use prepared statements with Connector/Net. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

#### 21.2.5.8.1. Preparing Statements in Connector/Net

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySQLCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the execute method again, there is no need to set the `.CommandText` property or redefine the parameters.

#### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = strConnection

Try
    conn.Open()
    cmd.Connection = conn

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)"
    cmd.Prepare()

    cmd.Parameters.AddWithValue("@number", 1)
    cmd.Parameters.AddWithValue("@text", "One")

    For i = 1 To 1000
        cmd.Parameters("@number").Value = i
        cmd.Parameters("@text").Value = "A string value"

        cmd.ExecuteNonQuery()
```

```

        Next
    Catch ex As MySqlException
        MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
    End Try

```

## C# Example

```

MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)";
    cmd.Prepare();

    cmd.Parameters.AddWithValue("@number", 1);
    cmd.Parameters.AddWithValue("@text", "One");

    for (int i=1; i <= 1000; i++)
    {
        cmd.Parameters["@number"].Value = i;
        cmd.Parameters["@text"].Value = "A string value";

        cmd.ExecuteNonQuery();
    }
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

### 21.2.5.9. Accessing Stored Procedures with Connector/Net

MySQL server version 5 and up supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that is stored in the server. Clients make a single call to the stored procedure, passing parameters that can influence the procedure logic and query conditions, rather than issuing individual hardcoded SQL statements.

Stored procedures can be particularly useful in situations such as the following:

- Stored procedures can act as an API or abstraction layer, allowing multiple client applications to perform the same database operations. The applications can be written in different languages and run on different platforms. The applications do not need to hardcode table and column names, complicated queries, and so on. When you extend and optimize the queries in a stored procedure, all the applications that call the procedure automatically receive the benefits.
- When security is paramount, stored procedures keep applications from directly manipulating tables, or even knowing details such as table and column names. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Connector/Net supports the calling of stored procedures through the [MySqlCommand](#) object. Data can be passed in and out of a MySQL stored procedure through use of the [MySqlCommand.Parameters](#) collection.

**Note**

When you call a stored procedure, the command object makes an additional `SELECT` call to determine the parameters of the stored procedure. You must ensure that the user calling the procedure has the `SELECT [755]` privilege on the `mysql.proc` table to enable them to verify the parameters. Failure to do this will result in an error when calling the procedure.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to <http://dev.mysql.com/doc/mysql/en/stored-routines.html>.

A sample application demonstrating how to use stored procedures with Connector/Net can be found in the `Samples` directory of your Connector/Net installation.

### 21.2.5.9.1. Using Stored Routines from Connector/Net

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using MySQL Workbench. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySqlCommand` object.

Unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in Connector/Net.

To call a stored procedure using Connector/Net, you create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. You then set the `.CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, you create one `MySqlCommand` parameter for every parameter in the stored procedure. `IN` parameters are defined with the parameter name and the object containing the value, `OUT` parameters are defined with the parameter name and the data type that is expected to be returned. All parameters need the parameter direction defined.

After defining the parameters, you call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method.

Once the stored procedure is called, the values of the output parameters can be retrieved by using the `.Value` property of the `MySqlConnection.Parameters` collection.

**Note**

When a stored procedure is called using `MySqlCommand.ExecuteReader`, and the stored procedure has output parameters, the output parameters are only set after the `MySqlDataReader` returned by `ExecuteReader` is closed.

The following C# example code demonstrates the use of stored procedures. It assumes the database 'employees' has already been created:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace UsingStoredRoutines
{
    class Program
    {
        static void Main(string[] args)
        {
            MySqlConnection conn = new MySqlConnection();
            conn.ConnectionString = "server=localhost;user=root;database=employees;port=3306;password=";
```

```

MySQLCommand cmd = new MySQLCommand();

try
{
    Console.WriteLine("Connecting to MySQL...");
    conn.Open();
    cmd.Connection = conn;
    cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp";
    cmd.ExecuteNonQuery();
    cmd.CommandText = "DROP TABLE IF EXISTS emp";
    cmd.ExecuteNonQuery();
    cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY
    cmd.ExecuteNonQuery();

    cmd.CommandText = "CREATE PROCEDURE add_emp(" +
        "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno
        "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
        "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

    cmd.ExecuteNonQuery();
}
catch (MySQLException ex)
{
    Console.WriteLine ("Error " + ex.Number + " has occurred: " + ex.Message);
}
conn.Close();
Console.WriteLine("Connection closed.");
try
{
    Console.WriteLine("Connecting to MySQL...");
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "add_emp";
    cmd.CommandType = CommandType.StoredProcedure;

    cmd.Parameters.AddWithValue("@lname", "Jones");
    cmd.Parameters["@lname"].Direction = ParameterDirection.Input;

    cmd.Parameters.AddWithValue("@fname", "Tom");
    cmd.Parameters["@fname"].Direction = ParameterDirection.Input;

    cmd.Parameters.AddWithValue("@bday", "1940-06-07");
    cmd.Parameters["@bday"].Direction = ParameterDirection.Input;

    cmd.Parameters.AddWithValue("@empno", MySQLDbType.Int32);
    cmd.Parameters["@empno"].Direction = ParameterDirection.Output;

    cmd.ExecuteNonQuery();

    Console.WriteLine("Employee number: "+cmd.Parameters["@empno"].Value);
    Console.WriteLine("Birthday: " + cmd.Parameters["@bday"].Value);
}
catch (MySQL.Data.MySqlClient.MySQLException ex)
{
    Console.WriteLine("Error " + ex.Number + " has occurred: " + ex.Message);
}
conn.Close();
Console.WriteLine("Done.");
}
}
}

```

The following code shows the same application in Visual Basic:

```

Imports System
Imports System.Collections.Generic
Imports System.Linq
Imports System.Text

Imports System.Data

```

```

Imports MySql.Data
Imports MySql.Data.MySqlClient

Module Module1

    Sub Main()
        Dim conn As New MySqlConnection()
        conn.ConnectionString = "server=localhost;user=root;database=world;port=3306;password=*****;"
        Dim cmd As New MySqlCommand()

        Try
            Console.WriteLine("Connecting to MySQL...")
            conn.Open()
            cmd.Connection = conn
            cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp"
            cmd.ExecuteNonQuery()
            cmd.CommandText = "DROP TABLE IF EXISTS emp"
            cmd.ExecuteNonQuery()
            cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY

            cmd.CommandText = "CREATE PROCEDURE add_emp(" & "IN fname VARCHAR(20), IN lname VARCHAR(20)

            cmd.ExecuteNonQuery()
        Catch ex As MySqlException
            Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
        End Try
        conn.Close()
        Console.WriteLine("Connection closed.")
        Try
            Console.WriteLine("Connecting to MySQL...")
            conn.Open()
            cmd.Connection = conn

            cmd.CommandText = "add_emp"
            cmd.CommandType = CommandType.StoredProcedure

            cmd.Parameters.AddWithValue("@lname", "Jones")
            cmd.Parameters("@lname").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@fname", "Tom")
            cmd.Parameters("@fname").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@bday", "1940-06-07")
            cmd.Parameters("@bday").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32)
            cmd.Parameters("@empno").Direction = ParameterDirection.Output

            cmd.ExecuteNonQuery()

            Console.WriteLine("Employee number: " & cmd.Parameters("@empno").Value)
            Console.WriteLine("Birthday: " & cmd.Parameters("@bday").Value)
        Catch ex As MySql.Data.MySqlClient.MySqlException
            Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
        End Try
        conn.Close()
        Console.WriteLine("Done.")

    End Sub

End Module

```

### 21.2.5.10. Handling BLOB Data With Connector/Net

One common use for MySQL is the storage of binary data in [BLOB](#) columns. MySQL supports four different BLOB data types: [TINYBLOB](#), [BLOB](#), [MEDIUMBLOB](#), and [LONGBLOB](#), all described in [Section 11.4.3, “The BLOB and TEXT Types”](#) and [Section 11.6, “Data Type Storage Requirements”](#).

Data stored in a [BLOB](#) column can be accessed using Connector/Net and manipulated using client-side code. There are no special requirements for using Connector/Net with [BLOB](#) data.

Simple code examples will be presented within this section, and a full sample application can be found in the [Samples](#) directory of the Connector/Net installation.

### 21.2.5.10.1. Preparing the MySQL Server

The first step is using MySQL with **BLOB** data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an **AUTO\_INCREMENT** column of appropriate size (**UNSIGNED SMALLINT**) to serve as a primary key to identify the file, a **VARCHAR** column that stores the file name, an **UNSIGNED MEDIUMINT** column that stores the size of the file, and a **MEDIUMBLOB** column that stores the file itself. For this example, I will use the following table definition:

```
CREATE TABLE file(  
file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
file_name VARCHAR(64) NOT NULL,  
file_size MEDIUMINT UNSIGNED NOT NULL,  
file MEDIUMBLOB NOT NULL);
```

After creating a table, you might need to modify the `max_allowed_packet` system variable. This variable determines how large of a packet (that is, a single row) can be sent to the MySQL server. By default, the server only accepts a maximum size of 1MB from the client application. If you intend to exceed 1MB in your file transfers, increase this number.

The `max_allowed_packet` option can be modified using the MySQL Workbench **Server Administration** screen. Adjust the Maximum permitted option in the **Data / Memory size** section of the Networking tab to an appropriate setting. After adjusting the value, click the **Apply** button and restart the server using the **Startup / Shutdown** screen of MySQL Workbench. You can also adjust this value directly in the `my.cnf` file (add a line that reads `max_allowed_packet=xxM`), or use the `SET max_allowed_packet=xxM;` syntax from within MySQL.

Try to be conservative when setting `max_allowed_packet`, as transfers of BLOB data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

### 21.2.5.10.2. Writing a File to the Database

To write a file to a database, we need to convert the file to a byte array, then use the byte array as a parameter to an **INSERT** query.

The following code opens a file using a **FileStream** object, reads it into a byte array, and inserts it into the `file` table:

#### Visual Basic Example

```
Dim conn As New MySqlConnection  
Dim cmd As New MySqlCommand  
  
Dim SQL As String  
  
Dim fileSize As UInt32  
Dim rawData() As Byte  
Dim fs As FileStream  
  
conn.ConnectionString = "server=127.0.0.1;" _  
    & "uid=root;" _  
    & "pwd=12345;" _  
    & "database=test"  
  
Try  
    fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)  
    fileSize = fs.Length  
  
    rawData = New Byte(fileSize) {}  
    fs.Read(rawData, 0, fileSize)  
    fs.Close()
```

```

conn.Open()

SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)"

cmd.Connection = conn
cmd.CommandText = SQL
cmd.Parameters.AddWithValue("@FileName", strFileName)
cmd.Parameters.AddWithValue("@FileSize", FileSize)
cmd.Parameters.AddWithValue("@File", rawData)

cmd.ExecuteNonQuery()

MessageBox.Show("File Inserted into database successfully!", _
"Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", _
        MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

### C# Example

```

MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
    FileSize = fs.Length;

    rawData = new byte[FileSize];
    fs.Read(rawData, 0, FileSize);
    fs.Close();

    conn.Open();

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)";

    cmd.Connection = conn;
    cmd.CommandText = SQL;
    cmd.Parameters.AddWithValue("@FileName", strFileName);
    cmd.Parameters.AddWithValue("@FileSize", FileSize);
    cmd.Parameters.AddWithValue("@File", rawData);

    cmd.ExecuteNonQuery();

    MessageBox.Show("File Inserted into database successfully!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    conn.Close();
}
catch (MySQL.Data.MySqlClient.MySQLException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The [Read](#) method of the [FileStream](#) object is used to load the file into a byte array which is sized according to the [Length](#) property of the [FileStream](#) object.

After assigning the byte array as a parameter of the `MySQLCommand` object, the `ExecuteNonQuery` method is called and the `BLOB` is inserted into the `file` table.

### 21.2.5.10.3. Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the `file` table, we can use the `MySQLDataReader` class to retrieve it.

The following code retrieves a row from the `file` table, then loads the data into a `FileStream` object to be written to disk:

#### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySQLDataReader
Dim SQL As String
Dim rawData() As Byte
Dim fileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
    conn.Open()

    cmd.Connection = conn
    cmd.CommandText = SQL

    myData = cmd.ExecuteReader

    If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save")

    myData.Read()

    fileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
    rawData = New Byte(fileSize) {}

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, fileSize)

    fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write)
    fs.Write(rawData, 0, fileSize)
    fs.Close()

    MessageBox.Show("File successfully written to disk!", "Success!", MessageBoxButtons.OK, MessageBoxIcon.Information)

    myData.Close()
    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

#### C# Example

```
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;
MySQL.Data.MySqlClient.MySqlDataReader myData;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 fileSize;
byte[] rawData;
FileStream fs;
```

```

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
    conn.Open();

    cmd.Connection = conn;
    cmd.CommandText = SQL;

    myData = cmd.ExecuteReader();

    if (!myData.HasRows)
        throw new Exception("There are no BLOBs to save");

    myData.Read();

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
    rawData = new byte[FileSize];

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, (int)FileSize);

    fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write);
    fs.Write(rawData, 0, (int)FileSize);
    fs.Close();

    MessageBox.Show("File successfully written to disk!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    myData.Close();
    conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

After connecting, the contents of the `file` table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the `MySqlDataReader` is used to load the `BLOB` into a byte array, which is then written to disk using a `FileStream` object.

The `GetOrdinal` method of the `MySqlDataReader` can be used to determine the integer index of a named column. Use of the `GetOrdinal` method prevents errors if the column order of the `SELECT` query is changed.

### 21.2.5.11. Using the Connector/Net Interceptor Classes

An interceptor is a software design pattern that provides a transparent way to extend or modify some aspect of a program, similar to a user exit. No recompiling is required. With Connector/Net, the interceptors are enabled and disabled by updating the connection string to refer to different sets of interceptor classes that you instantiate.

Connector/Net includes the following interceptor classes:

- The `BaseCommandInterceptor` lets you perform additional operations when a program issues a SQL command. For example, you can examine the SQL statement for logging or debugging purposes, substitute your own result set to implement a caching mechanism, and so on. Depending on the use case, your code can supplement the SQL command or replace it entirely.

The `BaseCommandInterceptor` class has these methods that you can override:

```

public virtual bool ExecuteScalar(string sql, ref object returnValue);
public virtual bool ExecuteNonQuery(string sql, ref int returnValue);
public virtual bool ExecuteReader(string sql, CommandBehavior behavior, ref MySqlDataReader returnValue);
public virtual void Init(MySqlConnection connection);

```

If your interceptor overrides one of the `Execute...` methods, set the `returnValue` output parameter and return `true` if you handled the event, or `false` if you did not handle the event. The SQL command is processed normally only when all command interceptors return `false`.

The connection passed to the `Init` method is the connection that is attached to this interceptor.

- The `BaseExceptionInterceptor` lets you perform additional operations when a program encounters a SQL exception. The exception interception mechanism is modeled after the Connector/J model. You can code an interceptor class and connect it to an existing program without recompiling, and intercept exceptions when they are created. You can then change the exception type and optionally attach information to it. This capability lets you turn on and off logging and debugging code without hardcoding anything in the application. This technique applies to exceptions raised at the SQL level, not to lower-level system or I/O errors.

You develop an exception interceptor first by creating a subclass of the `BaseExceptionInterceptor` class. You must override the `InterceptException()` method. You can also override the `Init()` method to do some one-time initialization.

Each exception interceptor has 2 methods:

```
public abstract Exception InterceptException(Exception exception,
    MySqlConnection connection);
public virtual void Init(MySqlConnection connection);
```

The connection passed to `Init()` is the connection that is attached to this interceptor.

Each interceptor is required to override `InterceptException` and return an exception. It can return the exception it is given, or it can wrap it in a new exception. We currently do not offer the ability to suppress the exception.

Here are examples of using the FQN (fully qualified name) on the connection string:

```
MySqlConnection c1 = new MySqlConnection(@"server=localhost;pooling=false;
commandinterceptors=CommandApp.MyCommandInterceptor,CommandApp");

MySqlConnection c2 = new MySqlConnection(@"server=localhost;pooling=false;
exceptioninterceptors=ExceptionStackTraceTest.MyExceptionInterceptor,ExceptionStackTraceTest");
```

In this example, the command interceptor is called `CommandApp.MyCommandInterceptor` and exists in the `CommandApp` assembly. The exception interceptor is called `ExceptionStackTraceTest.MyExceptionInterceptor` and exists in the `ExceptionStackTraceTest` assembly.

To shorten the connection string, you can register your exception interceptors in your `app.config` or `web.config` file like this:

```
<configSections>
<section name="MySQL" type="MySql.Data.MySqlClient.MySqlConfiguration,
MySql.Data" />
</configSections>
<MySQL>
<CommandInterceptors>
<add name="myC" type="CommandApp.MyCommandInterceptor,CommandApp" />
</CommandInterceptors>
</MySQL>

<configSections>
<section name="MySQL" type="MySql.Data.MySqlClient.MySqlConfiguration,
MySql.Data" />
</configSections>
<MySQL>
<ExceptionInterceptors>
<add name="myE"
type="ExceptionStackTraceTest.MyExceptionInterceptor,ExceptionStackTraceTest" />
</ExceptionInterceptors>
</MySQL>
```

```
</ExceptionInterceptors>  
</MySQL>
```

Once you have done that, your connection strings can look like these:

```
MySqlConnection c1 = new MySqlConnection(@"server=localhost;pooling=false;  
commandinterceptors=myC");  
  
MySqlConnection c2 = new MySqlConnection(@"server=localhost;pooling=false;  
exceptioninterceptors=myE");
```

### 21.2.5.12. Handling Date and Time Information in Connector/Net

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as '0000-00-00 00:00:00'. These differences can cause problems if not properly handled.

The following sections demonstrate how to properly handle date and time information when using Connector/Net.

#### 21.2.5.12.1. Fractional Seconds

Connector/Net 6.5 and higher support the fractional seconds feature introduced in MySQL 5.6.4. Fractional seconds could always be specified in a date literal or passed back and forth as parameters and return values, but the fractional part was always stripped off when stored in a table column. In MySQL 5.6.4 and higher, the fractional part is now preserved in data stored and retrieved through SQL. For fractional second handling in MySQL 5.6.4 and higher, see [Section 11.3.6, "Fractional Seconds in Time Values"](#). For the behavior of fractional seconds prior to MySQL 5.6.4, see [Fractional Seconds in Time Values](#).

To use the more precise date and time types, specify a value from 1 to 6 when creating the table column, for example `TIME(3)` or `DATETIME(6)`, representing the number of digits of precision after the decimal point. Specifying a precision of 0 leaves the fractional part out entirely. In your C# or Visual Basic code, refer to the `Millisecond` member to retrieve the fractional second value from the `MySqlDateTime` object returned by the `GetMySqlDateTime` function. The `DateTime` object returned by the `GetDateTime` function also contains the fractional value, but only the first 3 digits.

For related code examples, see the following blog post: [https://blogs.oracle.com/MySqlOnWindows/entry/milliseconds\\_value\\_support\\_on\\_datetime](https://blogs.oracle.com/MySqlOnWindows/entry/milliseconds_value_support_on_datetime)

#### 21.2.5.12.2. Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET `DateTime` objects, including `NULL` dates.

Because of this issue, .NET `DataSet` objects cannot be populated by the `Fill` method of the `MySqlDataAdapter` class as invalid dates will cause a `System.ArgumentOutOfRangeException` exception to occur.

#### 21.2.5.12.3. Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET `DateTime` class to handle dates. The `DateTime` class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new `traditional` SQL mode to restrict invalid date values. For information on using the `traditional` SQL mode, see [Section 5.1.7, "Server SQL Modes"](#).

#### 21.2.5.12.4. Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySqlDateTime` data type.

The `MySqlDateTime` data type supports the same date values that are supported by the MySQL server. The default behavior of Connector/Net is to return a .NET `DateTime` object for valid date values, and return an error for invalid dates. This default can be modified to cause Connector/Net to return `MySqlDateTime` objects for invalid dates.

To instruct Connector/Net to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, `2005-02-23 08:50:25`). This differs from the `ToString` behavior of the .NET `DateTime` class.
3. The `MySqlDateTime` class supports NULL dates, while the .NET `DateTime` class does not. This can cause errors when trying to convert a `MySQLDateTime` to a `DateTime` if you do not check for NULL first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

#### 21.2.5.12.5. Handling NULL Dates

The .NET `DateTime` data type cannot handle `NULL` values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact `NULL`.

When using a `MySqlDataReader`, use the `.IsDBNull` method to check whether a value is `NULL` before making the assignment:

#### Visual Basic Example

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
    myTime = DateTime.MinValue
End If
```

#### C# Example

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
    myTime = DateTime.MinValue;
```

`NULL` values will work in a data set and can be bound to form controls without special handling.

#### 21.2.5.13. Using the `MySqlBulkLoader` Class

MySQL Connector/Net features a bulk loader class that wraps the MySQL statement `LOAD DATA INFILE`. This gives MySQL Connector/Net the ability to load a data file from a local or remote host

to the server. The class concerned is [MySQLBulkLoader](#). This class has various methods, the main one being `load` to cause the specified file to be loaded to the server. Various parameters can be set to control how the data file is processed. This is achieved through setting various properties of the class. For example, the field separator used, such as comma or tab, can be specified, along with the record terminator, such as newline.

The following code shows a simple example of using the [MySQLBulkLoader](#) class. First an empty table needs to be created, in this case in the `test` database:

```
CREATE TABLE Career (
    Name VARCHAR(100) NOT NULL,
    Age INTEGER,
    Profession VARCHAR(200)
);
```

A simple tab-delimited data file is also created (it could use any other field delimiter such as comma):

```
Table Career in Test Database
Name Age Profession

Tony 47 Technical Writer
Ana 43 Nurse
Fred 21 IT Specialist
Simon 45 Hairy Biker
```

Note that with this test file the first three lines will need to be ignored, as they do not contain table data. This can be achieved using the [NumberOfLinesToSkip](#) property. This file can then be loaded and used to populate the `Career` table in the `test` database:

```
using System;
using System.Text;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=test;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            MySQLBulkLoader bl = new MySQLBulkLoader(conn);
            bl.TableName = "Career";
            bl.FieldTerminator = "\t";
            bl.LineTerminator = "\n";
            bl.FileName = "c:/career_data.txt";
            bl.NumberOfLinesToSkip = 3;

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                // Upload data from file
                int count = bl.Load();
                Console.WriteLine(count + " lines uploaded.");

                string sql = "SELECT Name, Age, Profession FROM Career";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();

                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " -- " + rdr[1] + " -- " + rdr[2]);
                }

                rdr.Close();
            }
        }
    }
}
```

```

        conn.Close();
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.ToString());
    }
    Console.WriteLine("Done.");
}
}
}

```

Further information on `LOAD DATA INFILE` can be found in [Section 13.2.6, "LOAD DATA INFILE Syntax"](#). Further information on `MySQLBulkLoader` can be found in the reference documentation that was included with your connector.

#### 21.2.5.14. Using the MySQL Connector/Net Trace Source Object

MySQL Connector/Net 6.2 introduced support for .NET 2.0 compatible tracing, using `TraceSource` objects.

The .NET 2.0 tracing architecture consists of four main parts:

- *Source* - This is the originator of the trace information. The source is used to send trace messages. The name of the source provided by MySQL Connector/Net is `mysql`.
- *Switch* - This defines the level of trace information to emit. Typically, this is specified in the `app.config` file, so that it is not necessary to recompile an application to change the trace level.
- *Listener* - Trace listeners define where the trace information will be written to. Supported listeners include, for example, the Visual Studio Output window, the Windows Event Log, and the console.
- *Filter* - Filters can be attached to listeners. Filters determine the level of trace information that will be written. While a switch defines the level of information that will be written to all listeners, a filter can be applied on a per-listener basis, giving finer grained control of trace information.

To use tracing a `TraceSource` object first needs to be created. To create a `TraceSource` object in MySQL Connector/Net you would use code similar to the following:

```
TraceSource ts = new TraceSource("mysql");
```

To enable trace messages, configure a trace switch. There are three main switch classes, `BooleanSwitch`, `SourceSwitch`, and `TraceSwitch`. Trace switches also have associated with them a trace level enumeration, these are `Off`, `Error`, `Warning`, `Info`, and `Verbose`. The following code snippet illustrates creating a switch:

```
ts.Switch = new SourceSwitch("MySwitch", "Verbose");
```

This creates a `SourceSwitch`, called `MySwitch`, and sets the trace level to `Verbose`, meaning that all trace messages will be written.

It is convenient to be able to change the trace level without having to recompile the code. This is achieved by specifying the trace level in application configuration file, `app.config`. You then simply need to specify the desired trace level in the configuration file and restart the application. The trace source is configured within the `system.diagnostics` section of the file. The following XML snippet illustrates this:

```

<configuration>
  ...
  <system.diagnostics>
    <sources>
      <source name="mysql" switchName="MySwitch"
        switchType="System.Diagnostics.SourceSwitch" />
    </sources>
  </system.diagnostics>
</configuration>

```

```

...
</sources>
<switches>
  <add name="MySwitch" value="Verbose"/>
  ...
</switches>
</system.diagnostics>
...
</configuration>

```

By default, trace information is written to the Output window of Microsoft Visual Studio. There are a wide range of listeners that can be attached to the trace source, so that trace messages can be written out to various destinations. You can also create custom listeners to allow trace messages to be written to other destinations as mobile devices and web services. A commonly used example of a listener is [ConsoleTraceListener](#), which writes trace messages to the console.

To add a listener at runtime, use code such as the following:

```
ts.Listeners.Add(new ConsoleTraceListener());
```

Then, call methods on the trace source object to generate trace information. For example, the [TraceInformation\(\)](#), [TraceEvent\(\)](#), or [TraceData\(\)](#) methods can be used.

The [TraceInformation\(\)](#) method simply prints a string passed as a parameter. The [TraceEvent\(\)](#) method, as well as the optional informational string, requires a [TraceEventType](#) value to be passed to indicate the trace message type, and also an application specific ID. The [TraceEventType](#) can have a value of [Verbose](#), [Information](#), [Warning](#), [Error](#), and [Critical](#). Using the [TraceData\(\)](#) method you can pass any object, for example an exception object, instead of a message.

To ensure that these generated trace messages gets flushed from the trace source buffers to listeners, invoke the [Flush\(\)](#) method. When you are finished using a trace source, call the [Close\(\)](#) method. The [Close\(\)](#) method first calls [Flush\(\)](#), to ensure any remaining data is written out. It then frees up resources, and closes the listeners associated with the trace source.

```

ts.TraceInformation("Informational message");
ts.TraceEvent(TraceEventType.Error, 3, "Optional error message");
ts.TraceData(TraceEventType.Error, 3, ex); // pass exception object
ts.Flush();
...
ts.Close();

```

#### 21.2.5.14.1. Viewing MySQL Trace Information

This section describes how to set up your application to view MySQL trace information.

The first thing you need to do is create a suitable `app.config` file for your application. An example is shown in the following code:

```

<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <system.diagnostics>
    <sources>
      <source name="mysql" switchName="SourceSwitch"
        switchType="System.Diagnostics.SourceSwitch" >
        <listeners>
          <add name="console" />
          <remove name="Default" />
        </listeners>
      </source>
    </sources>
    <switches>
      <!-- You can set the level at which tracing is to occur -->
      <add name="SourceSwitch" value="Verbose" />
      <!-- You can turn tracing off -->

```

```

    <!--add name="SourceSwitch" value="Off" -->
  </switches>
  <sharedListeners>
    <add name="console"
      type="System.Diagnostics.ConsoleTraceListener"
      initializeData="false"/>
  </sharedListeners>
</system.diagnostics>
</configuration>

```

This ensures a suitable trace source is created, along with a switch. The switch level in this case is set to `Verbose` to display the maximum amount of information.

In the application the only other step required is to add `logging=true` to the connection string. An example application could be:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Diagnostics;
using MySql.Data;
using MySql.Data.MySqlClient;
using MySql.Web;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=world;port=3306;password=*****;logging=true";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();

                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " -- " + rdr[1]);
                }

                rdr.Close();

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            Console.WriteLine("Done.");
        }
    }
}

```

This simple application will then generate the following output:

```

Connecting to MySQL...
mysql Information: 1 : 1: Connection Opened: connection string = 'server=localhost;User Id=root;database=world;password=*****;logging=True'
mysql Information: 3 : 1: Query Opened: SHOW VARIABLES
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=272, skipped rows=0, size (bytes)=7058
mysql Information: 6 : 1: Query Closed

```

```
mysql Information: 3 : 1: Query Opened: SHOW COLLATION
mysql Information: 4 : 1: Resultset Opened: field(s) = 6, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=127, skipped rows=0, size (bytes)=4102
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SET character_set_results=NULL
mysql Information: 4 : 1: Resultset Opened: field(s) = 0, affected rows = 0, inserted id = 0
mysql Information: 5 : 1: Resultset Closed. Total rows=0, skipped rows=0, size (bytes)=0
mysql Information: 6 : 1: Query Closed
mysql Information: 10 : 1: Set Database: world
mysql Information: 3 : 1: Query Opened: SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
American Samoa -- George W. Bush
Australia -- Elisabeth II
...
Wallis and Futuna -- Jacques Chirac
Vanuatu -- John Bani
United States Minor Outlying Islands -- George W. Bush
mysql Information: 5 : 1: Resultset Closed. Total rows=28, skipped rows=0, size (bytes)=788
mysql Information: 6 : 1: Query Closed
Done.
mysql Information: 2 : 1: Connection Closed
```

The first number displayed in the trace message corresponds to the MySQL event type:

Event	Description
1	ConnectionOpened: connection string
2	ConnectionClosed:
3	QueryOpened: mysql server thread id, query text
4	ResultOpened: field count, affected rows (-1 if select), inserted id (-1 if select)
5	ResultClosed: total rows read, rows skipped, size of resultset in bytes
6	QueryClosed:
7	StatementPrepared: prepared sql, statement id
8	StatementExecuted: statement id, mysql server thread id
9	StatementClosed: statement id
10	NonQuery: [varies]
11	UsageAdvisorWarning: usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5.
12	Warning: level, code, message
13	Error: error number, error message

The second number displayed in the trace message is the connection count.

Although this example uses the `ConsoleTraceListener`, any of the other standard listeners could have been used. Another possibility is to create a custom listener that uses the information passed using the `TraceEvent` method. For example, a custom trace listener could be created to perform active monitoring of the MySQL event messages, rather than simply writing these to an output device.

It is also possible to add listeners to the MySQL Trace Source at runtime. This can be done with the following code:

```
MySqlTrace.Listeners.Add(new ConsoleTraceListener());
```

MySQL Connector/Net 6.3.2 introduced the ability to switch tracing on and off at runtime. This can be achieved using the calls `MySqlTrace.EnableQueryAnalyzer(string host, int postInterval)` and `MySqlTrace.DisableQueryAnalyzer()`. The parameter `host` is the URL of

the MySQL Enterprise Monitor server to monitor. The parameter `postInterval` is how often to post the data to MySQL Enterprise Monitor, in seconds.

#### 21.2.5.14.2. Building Custom Listeners

To build custom listeners that work with the MySQL Connector/Net Trace Source, it is necessary to understand the key methods used, and the event data formats used.

The main method involved in passing trace messages is the `TraceSource.TraceEvent` method. This has the prototype:

```
public void TraceEvent(  
    TraceEventType eventType,  
    int id,  
    string format,  
    params Object[] args  
)
```

This trace source method will process the list of attached listeners and call the listener's `TraceListener.TraceEvent` method. The prototype for the `TraceListener.TraceEvent` method is as follows:

```
public virtual void TraceEvent(  
    TraceEventCache eventCache,  
    string source,  
    TraceEventType eventType,  
    int id,  
    string format,  
    params Object[] args  
)
```

The first three parameters are used in the standard as [defined by Microsoft](#). The last three parameters contain MySQL-specific trace information. Each of these parameters is now discussed in more detail.

##### `int id`

This is a MySQL-specific identifier. It identifies the MySQL event type that has occurred, resulting in a trace message being generated. This value is defined by the `MySQLTraceEventType` public enum contained in the MySQL Connector/Net code:

```
public enum MySQLTraceEventType : int  
{  
    ConnectionOpened = 1,  
    ConnectionClosed,  
    QueryOpened,  
    ResultOpened,  
    ResultClosed,  
    QueryClosed,  
    StatementPrepared,  
    StatementExecuted,  
    StatementClosed,  
    NonQuery,  
    UsageAdvisorWarning,  
    Warning,  
    Error  
}
```

The MySQL event type also determines the contents passed using the parameter `params Object[] args`. The nature of the `args` parameters are described in further detail in the following material.

##### `string format`

This is the format string that contains zero or more format items, which correspond to objects in the `args` array. This would be used by a listener such as `ConsoleTraceListener` to write a message to the output device.

`params Object[] args`

This is a list of objects that depends on the MySQL event type, `id`. However, the first parameter passed using this list is always the driver id. The driver id is a unique number that is incremented each time the connector is opened. This enables groups of queries on the same connection to be identified. The parameters that follow driver id depend on the MySQL event id, and are as follows:

MySQL-specific event type	Arguments (params Object[] args)
ConnectionOpened	Connection string
ConnectionClosed	No additional parameters
QueryOpened	mysql server thread id, query text
ResultOpened	field count, affected rows (-1 if select), inserted id (-1 if select)
ResultClosed	total rows read, rows skipped, size of resultset in bytes
QueryClosed	No additional parameters
StatementPrepared	prepared sql, statement id
StatementExecuted	statement id, mysql server thread id
StatementClosed	statement id
NonQuery	Varies
UsageAdvisorWarning	usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5.
Warning	level, code, message
Error	error number, error message

This information will allow you to create custom trace listeners that can actively monitor the MySQL-specific events.

### 21.2.5.15. Binary/Nonbinary Issues

There are certain situations where MySQL will return incorrect metadata about one or more columns. More specifically, the server will sometimes report that a column is binary when it is not and vice versa. In these situations, it becomes practically impossible for the connector to be able to correctly identify the correct metadata.

Some examples of situations that may return incorrect metadata are:

- Execution of `SHOW PROCESSLIST`. Some of the columns will be returned as binary even though they only hold string data.
- When a temporary table is used to process a resultset, some columns may be returned with incorrect binary flags.
- Some server functions such `DATE_FORMAT` will incorrectly return the column as binary.

With the availability of `BINARY` and `VARBINARY` data types, it is important that we respect the metadata returned by the server. However, we are aware that some existing applications may break with this change, so we are creating a connection string option to enable or disable it. By default, Connector/Net 5.1 respects the binary flags returned by the server. You might need to make small changes to your application to accommodate this change.

In the event that the changes required to your application would be too large, adding `'respect binary flags=false'` to your connection string causes the connector to use the prior behavior: any column that is marked as string, regardless of binary flags, will be returned as string. Only columns that are specifically marked as a `BLOB` will be returned as `BLOB`.

### 21.2.5.16. Character Set Considerations for Connector/Net

## Treating Binary Blobs As UTF8

MySQL doesn't currently support 4-byte UTF8 sequences. This makes it difficult to represent some multi-byte languages such as Japanese. To try and alleviate this, Connector/Net now supports a mode where binary blobs can be treated as strings.

To do this, you set the '[Treat Blobs As UTF8](#)' connection string keyword to [yes](#). This is all that needs to be done to enable conversion of all binary blobs to UTF8 strings. To convert only some of your BLOB columns, you can make use of the '[BlobAsUTF8IncludePattern](#)' and '[BlobAsUTF8ExcludePattern](#)' keywords. Set these to a regular expression pattern that matches the column names to include or exclude respectively.

When the regular expression patterns both match a single column, the include pattern is applied before the exclude pattern. The result, in this case, would be that the column would be excluded. Also, be aware that this mode does not apply to columns of type [BINARY](#) or [VARBINARY](#) and also do not apply to nonbinary [BLOB](#) columns.

Currently, this mode only applies to reading strings out of MySQL. To insert 4-byte UTF8 strings into blob columns, use the .NET [Encoding.GetBytes](#) function to convert your string to a series of bytes. You can then set this byte array as a parameter for a [BLOB](#) column.

## 21.2.5.17. Using Connector/Net with Crystal Reports

Crystal Reports is a common tool used by Windows application developers to perform reporting and document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/Net.

### 21.2.5.17.1. Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a data set that matches the one expected by your report.

The second option is to create a data set in VB.NET and save it as XML. This XML file can then be used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the data set. If you forget a column you must re-create the data set before the column can be added to the report.

The following code can be used to create a data set from a query and write it to disk:

### Visual Basic Example

```
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn
```

```

myAdapter.SelectCommand = cmd
myAdapter.Fill(myData)

myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

## C# Example

```

DataSet myData = new DataSet();
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;
MySQL.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();
myAdapter = new MySQL.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from [dev.mysql.com](http://dev.mysql.com).

### 21.2.5.17.2. Creating the Report

For most purposes, the Standard Report wizard helps with the initial creation of a report. To start the wizard, open Crystal Reports and choose the **New > Standard Report** option from the File menu.

The wizard first prompts you for a data source. If you use Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved data set, choose the ADO.NET (XML) option and browse to your saved data set.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

### 21.2.5.17.3. Displaying the Report

To display a report we first populate a data set with the data needed for the report, then load the report and bind it to the data set. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrystalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a data set saved using the code shown in [Section 21.2.5.17.1, "Creating a Data Source"](#), and have a crViewer control on your form named `myViewer`.

### Visual Basic Example

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _
    "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()

    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.SetDataSource(myData)
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

### C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
        "country.name, country.population, country.continent " +
```

```

        "FROM country, city ORDER BY country.continent, country.name";
cmd.Connection = conn;

myAdapter.SelectCommand = cmd;
myAdapter.Fill(myData);

myReport.Load(@".\world_report.rpt");
myReport.SetDataSource(myData);
myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

A new data set is generated using the same query used to generate the previously saved data set. Once the data set is filled, a ReportDocument is used to load the report file and bind it to the data set. The ReportDocument is then passed as the ReportSource of the crViewer.

This same approach is taken when a report is created from a single table using Connector/ODBC. The data set replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using Connector/ODBC, a data set with multiple tables must be created in our application. This enables each table in the report data source to be replaced with a report in the data set.

We populate a data set with multiple tables by providing multiple [SELECT](#) statements in our MySqlCommand object. These [SELECT](#) statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```

SELECT `country`.`Name`, `country`.`Continent`, `country`.`Population`, `city`.`Name`, `city`.`Populati
FROM `world`.`country` `country` LEFT OUTER JOIN `world`.`city` `city` ON `country`.`Code`=`city`.`Coun
ORDER BY `country`.`Continent`, `country`.`Name`, `city`.`Name`

```

This query is converted to two [SELECT](#) queries and displayed with the following code:

### Visual Basic Example

```

Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY countrycode, name;" _
        & "SELECT name, population, code, continent FROM country ORDER BY continent, name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(@".\world_report.rpt")
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Err

```

```
End Try
```

## C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
        "BY countrycode, name; SELECT name, population, code, continent FROM " +
        "country ORDER BY continent, name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

It is important to order the [SELECT](#) queries in alphabetic order, as this is the order the report will expect its source tables to be in. One `SetDataSource` statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved data set.

### 21.2.5.18. ASP.NET Provider Model

MySQL Connector/Net provides support for the ASP.NET 2.0 provider model. This model enables application developers to focus on the business logic of their application instead of having to recreate such boilerplate items as membership and roles support.

MySQL Connector/Net supplies the following providers:

- Membership Provider
- Role Provider
- Profile Provider
- Session State Provider (MySQL Connector/Net 6.1 and later)

The following tables show the supported providers, their default provider and the corresponding MySQL provider.

#### Membership Provider

Default Provider	MySQL Provider
System.Web.Security.SqlMembershipProvider	MySql.Web.Security.MySQLMembershipProvider

### Role Provider

Default Provider	MySQL Provider
System.Web.Security.SqlRoleProvider	MySql.Web.Security.MySQLRoleProvider

### Profile Provider

Default Provider	MySQL Provider
System.Web.Profile.SqlProfileProvider	MySql.Web.Profile.MySQLProfileProvider

### SessionState Provider

Default Provider	MySQL Provider
System.Web.SessionState.InProcSessionStateStore	MySql.Web.SessionState.MySqlSessionStateStore

#### Note

The MySQL Session State provider uses slightly different capitalization on the class name compared to the other MySQL providers.

### Installing The Providers

The installation of Connector/Net 5.1 or later will install the providers and register them in your machine's .NET configuration file, `machine.config`. The additional entries created will result in the `system.web` section appearing similar to the following code:

```
<system.web>
  <processModel autoConfig="true" />
  <httpHandlers />
  <membership>
    <providers>
      <add name="AspNetSqlMembershipProvider" type="System.Web.Security.SqlMembershipProvider, System.W
      <add name="MySQLMembershipProvider" type="MySql.Web.Security.MySQLMembershipProvider, MySql.Web,
    </providers>
  </membership>
  <profile>
    <providers>
      <add name="AspNetSqlProfileProvider" connectionStringName="LocalSqlServer" applicationName="/" ty
      <add name="MySQLProfileProvider" type="MySql.Web.Profile.MySQLProfileProvider, MySql.Web, Version
    </providers>
  </profile>
  <roleManager>
    <providers>
      <add name="AspNetSqlRoleProvider" connectionStringName="LocalSqlServer" applicationName="/" type=
      <add name="AspNetWindowsTokenRoleProvider" applicationName="/" type="System.Web.Security.WindowsT
      <add name="MySQLRoleProvider" type="MySql.Web.Security.MySQLRoleProvider, MySql.Web, Version=6.1.
    </providers>
  </roleManager>
</system.web>
```

Each provider type can have multiple provider implementations. The default provider can also be set here using the `defaultProvider` attribute, but usually this is set in the `web.config` file either manually or by using the ASP.NET configuration tool.

At time of writing, the `MySqlSessionStateStore` is not added to `machine.config` at install time, and so add the following:

```
<sessionState>
```

```
<providers>
  <add name="MySQLSessionStateStore" type="MySQL.Web.SessionState.MySQLSessionStateStore, MySQL.Web, Ver
</providers>
</sessionState>
```

The SessionState Provider uses the `customProvider` attribute, rather than `defaultProvider`, to set the provider as the default. A typical `web.config` file might contain:

```
<system.web>
  <membership defaultProvider="MySQLMembershipProvider" />
  <roleManager defaultProvider="MySQLRoleProvider" />
  <profile defaultProvider="MySQLProfileProvider" />
  <sessionState customProvider="MySQLSessionStateStore" />
  <compilation debug="false">
    ...
```

This sets the MySQL Providers as the defaults to be used in this web application.

The providers are implemented in the file `mysql.web.dll` and this file can be found in your MySQL Connector/Net installation folder. There is no need to run any type of SQL script to set up the database schema, as the providers create and maintain the proper schema automatically.

### Using The Providers

The easiest way to start using the providers is to use the ASP.NET configuration tool that is available on the Solution Explorer toolbar when you have a website project loaded.

In the web pages that open, you can select the MySQL membership and roles providers by picking a custom provider for each area.

When the provider is installed, it creates a dummy connection string named `LocalMySQLServer`. Although this has to be done so that the provider will work in the ASP.NET configuration tool, you override this connection string in your `web.config` file. You do this by first removing the dummy connection string and then adding in the proper one, as shown in the following example:

```
<connectionStrings>
  <remove name="LocalMySQLServer" />
  <add name="LocalMySQLServer" connectionString="server=xxx;uid=xxx;pwd=xxx;database=xxx;" />
</connectionStrings>
```

Note the database to connect to must be specified.

Rather than manually editing configuration files, consider using the MySQL Website Configuration tool to configure your desired provider setup. From MySQL Connector/Net 6.1.1 onwards, all providers can be selected and configured from this wizard. The tool modifies your `website.config` file to the desired configuration. A tutorial on doing this is available in the following section [Section 21.2.3.12, "MySQL Website Configuration Tool"](#).

A tutorial demonstrating how to use the Membership and Role Providers can be found in the following section [Section 21.2.4.2, "Tutorial: MySQL Connector/Net ASP.NET Membership and Role Provider"](#).

### Deployment

To use the providers on a production server, distribute the `MySQL.Data` and the `MySQL.Web` assemblies, and either register them in the remote systems Global Assembly Cache or keep them in your application's `bin/` directory.

#### 21.2.5.19. Working with Partial Trust / Medium Trust

.NET applications operate under a given trust level. Normal desktop applications operate under full trust, while web applications that are hosted in shared environments are normally run under the partial trust level (also known as "medium trust"). Some hosting providers host shared applications in their own app pools and allow the application to run under full trust, but this configuration is relatively rare.

The Connector/Net support for partial trust has improved over time to simplify the configuration and deployment process for hosting providers.

### 21.2.5.19.1. Evolution of Partial Trust Support Across Connector/Net Versions

The partial trust support for Connector/Net has improved rapidly throughout the 6.5.x and 6.6.x versions. The latest enhancements do require some configuration changes in existing deployments. Here is a summary of the changes for each version.

#### 6.6.4 and Above: Library Can Be Inside or Outside GAC

Now you can install the `MySql.Data.dll` library in the Global Assembly Cache (GAC) as explained in [Section 21.2.5.19.2, “Configuring Partial Trust with Connector/Net Library Installed in GAC”](#), or in a `bin` or `lib` folder inside the project or solution as explained in [Section 21.2.5.19.3, “Configuring Partial Trust with Connector/Net Library Not Installed in GAC”](#). If the library is not in the GAC, the only protocol supported is TCP/IP.

#### 6.5.1 and Above: Partial Trust Requires Library in the GAC

Connector/Net 6.5 fully enables our provider to run in a partial trust environment when the library is installed in the Global Assembly Cache (GAC). The new `MySQLClientPermission` class, derived from the `.NET DBDataPermission` class, helps to simplify the permission setup.

#### 5.0.8 / 5.1.3 and Above: Partial Trust Requires Socket Permissions

Starting with these versions, Connector/Net can be used under partial trust hosting that has been modified to allow the use of sockets for communication. By default, partial trust does not include `SocketPermission`. Connector/Net uses sockets to talk with the MySQL server, so the hosting provider must create a new trust level that is an exact clone of partial trust but that has the following permissions added:

- `System.Net.SocketPermission`
- `System.Security.Permissions.ReflectionPermission`
- `System.Net.DnsPermission`
- `System.Security.Permissions.SecurityPermission`

#### Prior to 5.0.8 / 5.1.3: Partial Trust Not Supported

Connector/Net versions prior to 5.0.8 and 5.1.3 were not compatible with partial trust hosting.

### 21.2.5.19.2. Configuring Partial Trust with Connector/Net Library Installed in GAC

If the library is installed in the GAC, you must include the connection option `includesecurityasserts=true` in your connection string. This is a new requirement as of Connector/Net 6.6.4.

The following list shows steps and code fragments needed to run a Connector/Net application in a partial trust environment. For illustration purposes, we use the Pipe Connections protocol in this example.

1. Install Connector/Net: version 6.6.1 or higher, or 6.5.4 or higher.
2. After installing the library, make the following configuration changes:

In the `SecurityClasses` section, add a definition for the `MySQLClientPermission` class, including the version to use.

```
<configuration>
  <mscorlib>
    <security>
```

```
<policy>
  <PolicyLevel version="1">
    <SecurityClasses>
      ....
    <SecurityClass Name="MySQLClientPermission" Description="MySQL.Data.MySQLClient.MySQLClientPermission" />
  </PolicyLevel>
</policy>
```

Scroll down to the [ASP.Net](#) section:

```
<PermissionSet class="NamedPermissionSet" version="1" Name="ASP.Net">
```

Add a new entry for the detailed configuration of the [MySQLClientPermission](#) class:

```
<IPermission class="MySQLClientPermission" version="1" Unrestricted="true"/>
```

Note: This configuration is the most generalized way that includes all keywords.

- Configure the MySQL server to accept pipe connections, by adding the `--enable-named-pipe` option on the command line. If you need more information about this, see [Section 2.3, "Installing MySQL on Microsoft Windows"](#).
- Confirm that the hosting provider has installed the Connector/Net library (`MySQL.Data.dll`) in the GAC.
- Optionally, the hosting provider can avoid granting permissions globally by using the new [MySQLClientPermission](#) class in the trust policies. (The alternative is to globally enable the permissions [System.Net.SocketPermission](#), [System.Security.Permissions.ReflectionPermission](#), [System.Net.DnsPermission](#), and [System.Security.Permissions.SecurityPermission](#).)
- Create a simple web application using Visual Studio 2010.
- Add the reference in your application for the [MySQL.Data.MySQLClient](#) library.
- Edit your `web.config` file so that your application runs using a Medium trust level:

```
<system.web>
  <trust level="Medium"/>
</system.web>
```

- Add the [MySQL.Data.MySQLClient](#) namespace to your server-code page.
- Define the connection string, in slightly different ways depending on the Connector/Net version.

**Only for 6.6.4 or later:** To use the connections inside any web application that will run in Medium trust, add the new `includesecurityasserts` option to the connection string. `includesecurityasserts=true` that makes the library request the following permissions when required: [SocketPermissions](#), [ReflectionPermissions](#), [DnsPermissions](#), [SecurityPermissions](#) among others that are not granted in Medium trust levels.

**For Connector/Net 6.6.3 or earlier:** No special setting for security is needed within the connection string.

```
MySQLConnectionStringBuilder myconnString = new MySQLConnectionStringBuilder("server=localhost;User Id=
myconnString.PipeName = "MySQL55";
myconnString.ConnectionProtocol = MySQLConnectionProtocol.Pipe;
// Following attribute is a new requirement when the library is in the GAC.
// Could also be done by adding includesecurityasserts=true; to the string literal
// in the constructor above.
// Not needed with Connector/Net 6.6.3 and earlier.myconnString.IncludeSecurityAsserts = true;
```

- Define the [MySQLConnection](#) to use:

```
MySQLConnection myconn = new MySQLConnection(myconnString.ConnectionString);
```

```
myconn.Open();
```

- Retrieve some data from your tables:

```
MySQLCommand cmd = new MySQLCommand("Select * from products", myconn);
MySQLDataAdapter da = new MySQLDataAdapter(cmd);
DataSet1 tds = new DataSet1();
da.Fill(tds, tds.Tables[0].TableName);
GridView1.DataSource = tds;
GridView1.DataBind();
myconn.Close();
```

- Run the program. It should execute successfully, without requiring any special code or encountering any security problems.

### 21.2.5.19.3. Configuring Partial Trust with Connector/Net Library Not Installed in GAC

When deploying a web application to a Shared Hosted environment, where this environment is configured to run all their .NET applications under a partial or medium trust level, you might not be able to install the Connector/Net library in the GAC. Instead, you put a reference to the library in the [bin](#) or [lib](#) folder inside the project or solution. In this case, you configure the security in a different way than when the library is in the GAC.

Connector/Net is commonly used by applications that run in Windows environments where the default communication for the protocol is used via sockets or by TCP/IP. For this protocol to operate is necessary have the required socket permissions in the web configuration file as follows:

- Open the medium trust policy web configuration file, which should be under this folder:

```
%windir%\Microsoft.NET\Framework\{version}\CONFIG\web_mediumtrust.config
```

Use [Framework64](#) in the path instead of [Framework](#) if you are using a 64-bit installation of the framework.

- Locate the [SecurityClasses](#) tag:

```
<SecurityClass Name="SocketPermission"
Description="System.Net.SocketPermission, System, Version=4.0.0.0,
Culture=neutral, PublicKeyToken=b77a5c561934e089" />
```

- Scroll down and look for the following [PermissionSet](#):

```
<PermissionSet version="1" Name="ASP.Net">
```

- Add the following inside this [PermissionSet](#):

```
<IPermission class="SocketPermission" version="1" Unrestricted="true" />
```

This configuration lets you use the driver with the default Windows protocol TCP/IP without having any security issues. This approach only supports the TCP/IP protocol, so you cannot use any other type of connection.

Also, since the [MySQLClientPermissions](#) class is not added to the medium trust policy, you cannot use it. This configuration is the minimum required in order to work with Connector/Net without the GAC.

## 21.2.6. Connector/Net Connection String Options Reference

For usage information about connection strings, see [Section 21.2.5.2, "Creating a Connector/Net Connection String"](#). The first table list options that apply generally to all server configurations. The options related to systems using a connection pool are split into a separate table.

## General Options

**Table 21.20. Connector/Net Connection String Options - General**

Name	Default	Description
<code>Allow Batch, AllowBatch</code>	true	When true, multiple SQL statements can be sent with one command execution. Note: starting with MySQL 4.1.1, batch statements should be separated by the server-defined separator character. Statements sent to earlier versions of MySQL should be separated by ';'. 
<code>Allow User Variables, AllowUserVariables</code>	false	Setting this to <code>true</code> indicates that the provider expects user variables in the SQL. This option was added in Connector/Net version 5.2.2. 
<code>Allow Zero Datetime, AllowZeroDateTime</code>	false	If set to <code>True</code> , <code>MySqlDataReader.GetValue()</code> returns a <code>MySqlDateTime</code> object for date or datetime columns that have disallowed values, such as zero datetime values, and a <code>System.DateTime</code> object for valid values. If set to <code>False</code> (the default setting) it causes a <code>System.DateTime</code> object to be returned for all valid values and an exception to be thrown for disallowed values, such as zero datetime values. 
<code>Auto Enlist, AutoEnlist</code>	true	If <code>AutoEnlist</code> is set to <code>true</code> , which is the default, a connection opened using <code>TransactionScope</code> participates in this scope, it commits when the scope commits and rolls back if <code>TransactionScope</code> does not commit. However, this feature is considered security sensitive and therefore cannot be used in a medium trust environment. 
<code>BlobAsUTF8ExcludePattern</code>	null	A POSIX-style regular expression that matches the names of BLOB columns that do not contain UTF-8 character data. See <a href="#">Section 21.2.5.16, "Character Set Considerations for Connector/Net"</a> for usage details. 
<code>BlobAsUTF8IncludePattern</code>	null	A POSIX-style regular expression that matches the names of BLOB columns containing UTF-8 character data. See <a href="#">Section 21.2.5.16, "Character Set Considerations for Connector/Net"</a> for usage details. 
<code>Certificate File, CertificateFile</code>	null	This option specifies the path to a certificate file in PKCS #12 format ( <code>.pfx</code> ). For an example of usage, see <a href="#">Section 21.2.4.7, "Tutorial: Using SSL with MySQL Connector/Net"</a> . Was introduced with 6.2.1. 
<code>Certificate Password, CertificatePassword</code>	null	Specifies a password that is used in conjunction with a certificate specified using the option <code>CertificateFile</code> . For an example of usage, see <a href="#">Section 21.2.4.7, "Tutorial: Using SSL with MySQL Connector/Net"</a> . Was introduced with 6.2.1. 
<code>Certificate Store Location, CertificateStoreLocation</code>	null	Enables you to access a certificate held in a personal store, rather than use a certificate file and password combination. For an example of usage, see <a href="#">Section 21.2.4.7, "Tutorial: Using SSL with MySQL Connector/Net"</a> . Was introduced with 6.2.1. 
<code>Certificate Thumbprint, CertificateThumbprint</code>	null	Specifies a certificate thumbprint to ensure correct identification of a certificate contained within a personal store. For an example of usage, see <a href="#">Section 21.2.4.7, "Tutorial: Using SSL with MySQL Connector/Net"</a> . Was introduced with 6.2.1. 

Name	Default	Description
<code>CharSet</code> , <code>Character Set</code> , <code>CharacterSet</code>		Specifies the character set that should be used to encode all queries sent to the server. Resultsets are still returned in the character set of the result data.
<code>Check Parameters</code> , <code>CheckParameters</code>	true	Indicates if stored routine parameters should be checked against the server.
<code>Command Interceptors</code> , <code>CommandInterceptors</code>		The list of interceptors that can intercept SQL command operations.
<code>Connect Timeout</code> , <code>Connection Timeout</code> , <code>ConnectionTimeout</code>	15	The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error.
<code>Connect_Attrs</code>		Passes a predefined set of key/value pairs containing connection-specific data items to the server, for application-defined purposes. connector/Net automatically transmits the following attributes: <code>_pid</code> , <code>_client_version</code> , <code>_platform</code> , <code>_program_name</code> , <code>_os</code> , <code>_os_details</code> , and <code>_thread</code> . See <a href="#">Section 20.9.7, "Performance Schema Connection Attribute Tables"</a> for the <a href="#">Performance Schema</a> tables to query on the server side to make use of these attributes.
<code>Convert Zero Datetime</code> , <code>ConvertZeroDateTime</code>	false	True to have <code>MySqlDataReader.GetValue()</code> and <code>MySqlDataReader.GetDateTime()</code> return <code>DateTime.MinValue</code> for date or datetime columns that have disallowed values.
<code>Default Command Timeout</code> , <code>DefaultCommandTimeout</code>	30	Sets the default value of the command timeout to be used. This does not supercede the individual command timeout property on an individual command object. If you set the command timeout property, that will be used. This option was added in Connector/Net 5.1.4
<code>Default Table Cache Age</code> , <code>DefaultTableCacheAge</code>	60	Specifies how long a <code>TableDirect</code> result should be cached, in seconds. For usage information about table caching, see <a href="#">Section 21.2.5.7, "Using Connector/Net with Table Caching"</a> . This option was added in Connector/Net 6.4.
<code>enableSessionExpireCallback</code>	false	When set to <code>true</code> , causes the session-expiry scanner to raise the <code>session_end</code> event before deleting the session data stored in the <code>my_aspnet_sessions</code> table, when a session times out. Enable this option to write additional application-specific cleanup code to handle the <code>session_end</code> event of the <code>global.asax</code> class, before the stored data of the session gets deleted. Within the <code>session_end</code> method, any other required cleanup can be done. This option was added in Connector/Net 6.4.5; it is not yet available in Connector/Net 6.5.x releases.
<code>Encrypt</code> , <code>UseSSL</code>	false	For Connector/Net 5.0.3 and later, when <code>true</code> , SSL encryption is used for all data sent between the client and server if the server has a certificate installed. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> . In versions before 5.0.3, this option had no effect. From version 6.2.1, this option is deprecated and is replaced by <code>SSL Mode</code> . The option still works if used. If this

Name	Default	Description
		option is set to true, it is equivalent to <code>SSL Mode = Preferred</code> .
<code>Exception Interceptors</code> , <code>ExceptionInterceptors</code>		The list of interceptors that can triage thrown <code>MySqlConnection</code> exceptions.
<code>Functions Return String</code> , <code>FunctionsReturnString</code>	false	Causes the connector to return binary/varbinary values as strings, if they do not have a tablename in the metadata.
<code>Host</code> , <code>Server</code> , <code>Data Source</code> , <code>DataSource</code> , <code>Address</code> , <code>Addr</code> , <code>Network Address</code>	localhost	The name or network address of the instance of MySQL to which to connect. Multiple hosts can be specified separated by commas. This can be useful where multiple MySQL servers are configured for replication and you are not concerned about the precise server you are connecting to. No attempt is made by the provider to synchronize writes to the database, so take care when using this option. In Unix environment with Mono, this can be a fully qualified path to a MySQL socket file. With this configuration, the Unix socket is used instead of the TCP/IP socket. Currently, only a single socket name can be given, so accessing MySQL in a replicated environment using Unix sockets is not currently supported.
<code>Ignore Prepare</code> , <code>IgnorePrepare</code>	true	When true, instructs the provider to ignore any calls to <code>MySqlCommand.Prepare()</code> . This option is provided to prevent issues with corruption of the statements when used with server-side prepared statements. If you use server-side prepare statements, set this option to false. This option was added in Connector/Net 5.0.3 and Connector/Net 1.0.9.
<code>includesecurityasserts</code> , <code>include security asserts</code>	false	Must be set to <code>true</code> when using the <code>MySQLClientPermissions</code> class in a partial trust environment, with the library installed in the GAC of the hosting environment. This requirement is new for partial-trust applications in Connector/Net 6.6.4 and higher. See <a href="#">Section 21.2.5.19, "Working with Partial Trust / Medium Trust"</a> for details.
<code>Initial Catalog</code> , <code>Database</code>	mysql	The case-sensitive name of the database to use initially.
<code>Interactive</code> , <code>Interactive Session</code> , <code>InteractiveSession</code>	false	If set to true, the client is interactive. An interactive client is one where the server variable <code>CLIENT_INTERACTIVE</code> is set. If an interactive client is set, the <code>wait_timeout</code> variable is set to the value of <code>interactive_timeout</code> . The client will then time out after this period of inactivity. For more details, see <a href="#">Section 5.1.4, "Server System Variables"</a> in the MySQL Reference Manual.
<code>Integrated Security</code> , <code>IntegratedSecurity</code>	no	Use Windows authentication when connecting to server. By default, it is turned off. To enable, specify a value of <code>yes</code> . (You can also use the value <code>sspi</code> as an alternative to <code>yes</code> .) For details, see <a href="#">Section 21.2.5.5, "Using the Windows Native Authentication Plugin"</a> . This option was introduced in Connector/Net 6.4.4.

Name	Default	Description
<code>Keep Alive, Keepalive</code>	0	For TCP connections, idle connection time measured in seconds, before the first keepalive packet is sent. A value of 0 indicates that keepalive is not used.
<code>Logging</code>	false	When true, various pieces of information is output to any configured TraceListeners. See <a href="#">Section 21.2.5.14, "Using the MySQL Connector/Net Trace Source Object"</a> for further details.
<code>Old Guids, OldGuids</code>	false	This option was introduced in Connector/Net 6.1.1. The backend representation of a GUID type was changed from <code>BINARY(16)</code> to <code>CHAR(36)</code> . This was done to allow developers to use the server function <code>UUID() [1280]</code> to populate a GUID table - <code>UUID()</code> generates a 36-character string. Developers of older applications can add <code>'Old Guids=true'</code> to the connection string to use a GUID of data type <code>BINARY(16)</code> .
<code>Old Syntax, OldSyntax, Use Old Syntax, UseOldSyntax</code>	false	This option was deprecated in Connector/Net 5.2.2. All code should now be written using the '@' symbol as the parameter marker.
<code>Password, pwd</code>		The password for the MySQL account being used.
<code>Persist Security Info, PersistSecurityInfo</code>	false	When set to <code>false</code> or <code>no</code> (strongly recommended), security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Resetting the connection string resets all connection string values, including the password. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> .
<code>Pipe Name, Pipe, PipeName</code>	mysql	When set to the name of a named pipe, the <code>MySqlConnection</code> attempts to connect to MySQL on that named pipe. This setting only applies to the Windows platform.
<code>Port</code>	3306	The port MySQL is using to listen for connections. This value is ignored if Unix socket is used.
<code>Procedure Cache Size, ProcedureCacheSize, procedure cache, procedurecache</code>	25	Sets the size of the stored procedure cache. By default, Connector/Net stores the metadata (input/output data types) about the last 25 stored procedures used. To disable the stored procedure cache, set the value to zero (0). This option was added in Connector/Net 5.0.2 and Connector/Net 1.0.9.
<code>Protocol, Connection Protocol, ConnectionProtocol</code>	socket	Specifies the type of connection to make to the server. Values can be: <code>socket</code> or <code>tcp</code> for a socket connection, <code>pipe</code> for a named pipe connection, <code>unix</code> for a Unix socket connection, <code>memory</code> to use MySQL shared memory.
<code>Replication</code>	false	Indicates if this connection is to use replicated servers.
<code>Respect Binary Flags, RespectBinaryFlags</code>	true	Setting this option to <code>false</code> means that Connector/Net ignores a column's binary flags as set by the server. This option was added in Connector/Net version 5.1.3.
<code>Shared Memory Name, SharedMemoryName</code>	MYSQL	The name of the shared memory object to use for communication if the connection protocol is set to <code>memory</code> .

Name	Default	Description
Sql Server Mode, sqlservermode	false	Allow SQL Server syntax. When set to <code>true</code> , enables Connector/Net to support square brackets around symbols instead of backticks. This enables Visual Studio wizards that bracket symbols with <code>[]</code> to work with Connector/Net. This option incurs a performance hit, so should only be used if necessary. This option was added in version 6.3.1.
SSL Mode, SslMode	None	<p>This option has the following values:</p> <ul style="list-style-type: none"> <li>• <b>None</b> - do not use SSL.</li> <li>• <b>Preferred</b> - use SSL if the server supports it, but allow connection in all cases.</li> <li>• <b>Required</b> - Always use SSL. Deny connection if server does not support SSL.</li> <li>• <b>VerifyCA</b> - Always use SSL. Validate the CA but tolerate name mismatch.</li> <li>• <b>VerifyFull</b> - Always use SSL. Fail if the host name is not correct.</li> </ul> <p>This option was introduced in MySQL Connector/Net 6.2.1.</p>
Table Cache, tablecache, tablecaching	false	Enables or disables caching of <code>TableDirect</code> commands. A value of <code>true</code> enables the cache while <code>false</code> disables it. For usage information about table caching, see <a href="#">Section 21.2.5.7, “Using Connector/Net with Table Caching”</a> . This option was added in Connector/Net 6.4.
Treat BLOBs as UTF8, TreatBlobsAsUTF8	false	
Treat Tiny As Boolean, TreatTinyAsBoolean	true	Setting this value to <code>false</code> causes <code>TINYINT(1)</code> to be treated as an <code>INT</code> . See <a href="#">Section 11.1.1, “Numeric Type Overview”</a> for a further explanation of the <code>TINYINT</code> and <code>BOOL</code> data types.
Use Affected Rows, UseAffectedRows	false	When <code>true</code> , the connection reports changed rows instead of found rows. This option was added in Connector/Net version 5.2.6.
Use Procedure Bodies, UseProcedureBodies, procedure bodies	true	When set to <code>true</code> , the default value, MySQL Connector/Net expects the body of the procedure to be viewable. This enables it to determine the parameter types and order. Set the option to <code>false</code> when the user connecting to the database does not have the <code>SELECT [755]</code> privileges for the <code>mysql.proc</code> (stored procedures) table, or cannot view <code>INFORMATION_SCHEMA.ROUTINES</code> . In this case, MySQL Connector/Net cannot determine the types and order of the parameters, and must be alerted to this fact by setting this option to <code>false</code> . When set to <code>false</code> , MySQL Connector/Net does not rely on this information being available when the procedure is called. Because MySQL Connector/Net will not be able to determine this information, explicitly set the types of all the parameters

Name	Default	Description
		before the call and add the parameters to the command in the same order as they appear in the procedure definition. This option was added in MySQL Connector/Net 5.0.4 and MySQL Connector/Net 1.0.10.
User Id, UserID, Username, Uid, User name, User		The MySQL login account being used.
Compress, Use Compression, UseCompression	false	<p>Setting this option to <code>true</code> enables compression of packets exchanged between the client and the server. This exchange is defined by the MySQL client/server protocol.</p> <p>Compression is used if both client and server support ZLIB compression, and the client has requested compression using this option.</p> <p>A compressed packet header is: packet length (3 bytes), packet number (1 byte), and Uncompressed Packet Length (3 bytes). The Uncompressed Packet Length is the number of bytes in the original, uncompressed packet. If this is zero, the data in this packet has not been compressed. When the compression protocol is in use, either the client or the server may compress packets. However, compression will not occur if the compressed length is greater than the original length. Thus, some packets will contain compressed data while other packets will not.</p>
Use Usage Advisor, Usage Advisor, UseUsageAdvisor	false	Logs inefficient database operations.
Use Performance Monitor, UsePerformanceMonitor, userperfmon, perfmon	false	Indicates that performance counters should be updated during execution.

## Connection Pooling Options

The following table lists the valid names for options related to connection pooling within the `ConnectionString`. For more information about connection pooling, see [Section 21.2.5.4, "Using Connector/Net with Connection Pooling"](#).

**Table 21.21. Connector/Net Connection String Options - Connection Pooling**

Name	Default	Description
Cache Server Properties, CacheServerProperties	false	Specifies whether server variable settings are updated by a <code>SHOW VARIABLES</code> command each time a pooled connection is returned. Enabling this setting speeds up connections in a connection pool environment. Your application is not informed of any changes to configuration variables made by other connections. This option was added in Connector/Net 6.3.
Connection Lifetime, ConnectionLifeTime	0	When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by <code>Connection Lifetime</code> . This is useful in clustered configurations to force load balancing between a running server and a server just brought online. A value of zero (0) causes

Name	Default	Description
		pooled connections to have the maximum connection timeout.
<a href="#">Connection Reset</a> , <a href="#">ConnectionReset</a>	false	If true, the connection state is reset when it is retrieved from the pool. The default value of false avoids making an additional server round trip when obtaining a connection, but the connection state is not reset.
<a href="#">Maximum Pool Size</a> , <a href="#">Max Pool Size</a> , <a href="#">maximumpoolsize</a>	100	The maximum number of connections allowed in the pool.
<a href="#">Minimum Pool Size</a> , <a href="#">Min Pool Size</a> , <a href="#">MinimumPoolSize</a>	0	The minimum number of connections allowed in the pool.
<a href="#">Pooling</a>	true	When <a href="#">true</a> , the <a href="#">MySQLConnection</a> object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool. Recognized values are <a href="#">true</a> , <a href="#">false</a> , <a href="#">yes</a> , and <a href="#">no</a> .

## 21.2.7. Connector/Net API Reference

This section of the manual contains a complete reference to the Connector/Net ADO.NET component, automatically generated from the embedded documentation.

### 21.2.7.1. [MySQL.Data.MySqlClient](#) Namespace

[Namespace hierarchy](#)

#### Classes

Class	Description
<a href="#">BaseCommandInterceptor</a>	Provides a means of enhancing or replacing SQL commands through the connection string rather than recompiling.
<a href="#">BaseExceptionInterceptor</a>	Provides a means of enabling and disabling exception handling through the connection string rather than recompiling.
<a href="#">MySQLClientPermission</a>	Derived from the .NET <a href="#">DBDataPermission</a> class. For usage information, see <a href="#">Section 21.2.5.19</a> , “ <a href="#">Working with Partial Trust / Medium Trust</a> ”.
<a href="#">MySQLCommand</a>	
<a href="#">MySQLCommandBuilder</a>	
<a href="#">MySQLConnection</a>	
<a href="#">MySQLDataAdapter</a>	
<a href="#">MySQLDataReader</a>	Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.
<a href="#">MySQLError</a>	Collection of error codes that can be returned by the server
<a href="#">MySQLException</a>	The exception that is thrown when MySQL returns an error. This class cannot be inherited.
<a href="#">MySQLHelper</a>	Helper class that makes it easier to work with the provider.
<a href="#">MySQLInfoMessageEventArgs</a>	Provides data for the InfoMessage event. This class cannot be inherited.

Class	Description
<a href="#">MySqlParameter</a>	Represents a parameter to a <a href="#">MySqlCommand</a> , and optionally, its mapping to DataSet columns. This class cannot be inherited.
<a href="#">MySqlParameterCollection</a>	Represents a collection of parameters relevant to a <a href="#">MySqlCommand</a> as well as their respective mappings to columns in a DataSet. This class cannot be inherited.
<a href="#">MySqlRowUpdatedEventArgs</a>	Provides data for the RowUpdated event. This class cannot be inherited.
<a href="#">MySqlRowUpdatingEventArgs</a>	Provides data for the RowUpdating event. This class cannot be inherited.
<a href="#">MySqlTransaction</a>	

### Delegates

Delegate	Description
<a href="#">MySqlInfoMessageEventHandler</a>	Represents the method that will handle the <a href="#">InfoMessage</a> event of a <a href="#">MySqlConnection</a> .
<a href="#">MySqlRowUpdatedEventHandler</a>	Represents the method that will handle the RowUpdated event of a <a href="#">MySqlDataAdapter</a> .
<a href="#">MySqlRowUpdatingEventHandler</a>	Represents the method that will handle the RowUpdating event of a <a href="#">MySqlDataAdapter</a> .

### Enumerations

Enumeration	Description
<a href="#">MySqlDbType</a>	Specifies MySQL-specific data type of a field, property, for use in a <a href="#">MySqlParameter</a> .
<a href="#">MySqlErrorCode</a>	

#### 21.2.7.1.1. [MySql.Data.MySqlClientHierarchy](#)

##### See Also

[MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2. [BaseCommandInterceptor](#)

The [BaseCommandInterceptor](#) class has these methods that you can override:

```
public virtual bool ExecuteScalar(string sql, ref object returnValue);
public virtual bool ExecuteNonQuery(string sql, ref int returnValue);
public virtual bool ExecuteReader(string sql, CommandBehavior behavior, ref MySqlDataReader returnValue);
public virtual void Init(MySqlConnection connection);
```

If your interceptor overrides one of the [Execute...](#) methods, set the [returnValue](#) output parameter and return [true](#) if you handled the event, or [false](#) if you did not handle the event. The SQL command is processed normally only when all command interceptors return [false](#).

The connection passed to the [Init](#) method is the connection that is attached to this interceptor.

For full usage and examples, see [Section 21.2.5.11, "Using the Connector/Net Interceptor Classes"](#).

#### 21.2.7.1.3. [BaseExceptionInterceptor](#)

You develop an exception interceptor first by creating a subclass of the [BaseExceptionInterceptor](#) class. You must override the [InterceptException\(\)](#) method. You can also override the [Init\(\)](#) method to do some one-time initialization.

Each exception interceptor has 2 methods:

```
public abstract Exception InterceptException(Exception exception,
    MySqlConnection connection);
public virtual void Init(MySqlConnection connection);
```

The connection passed to [Init\(\)](#) is the connection that is attached to this interceptor.

Each interceptor is required to override [InterceptException](#) and return an exception. It can return the exception it is given, or it can wrap it in a new exception. We currently do not offer the ability to suppress the exception.

For full usage and examples, see [Section 21.2.5.11, "Using the Connector/Net Interceptor Classes"](#).

#### 21.2.7.1.4. [MySqlCommand](#) Class

For a list of all members of this type, see [MySqlCommand Members](#).

##### Syntax: Visual Basic

```
NotInheritable Public Class MySqlCommand_
    Inherits Component_
    Implements IDbCommand, ICloneable
```

##### Syntax: C#

```
public sealed class MySqlCommand : Component, IDbCommand, ICloneable
```

##### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

##### Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: [MySql.Data](#) (in [MySql.Data.dll](#))

##### See Also

[MySqlCommand Members](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1. [MySqlCommand](#) Members

[MySqlCommand overview](#)

##### Public Instance Constructors

<a href="#">MySqlCommand</a>	Overloaded. Initializes a new instance of the <a href="#">MySqlCommand</a> class.
------------------------------	-----------------------------------------------------------------------------------

##### Public Instance Properties

<a href="#">CommandText</a>	
<a href="#">CommandTimeout</a>	
<a href="#">CommandType</a>	

<a href="#">Connection</a>	
Container (inherited from Component)	Gets the IContainer that contains the Component.
<a href="#">IsPrepared</a>	
<a href="#">Parameters</a>	
Site (inherited from Component)	Gets or sets the ISite of the Component.
<a href="#">Transaction</a>	
<a href="#">UpdatedRowSource</a>	

**Public Instance Methods**

<a href="#">Cancel</a>	Attempts to cancel the execution of a MySqlCommand. This operation is not supported.
CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
<a href="#">CreateParameter</a>	Creates a new instance of a <a href="#">MySqlParameter</a> object.
Dispose (inherited from Component)	Releases all resources used by the Component.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
<a href="#">ExecuteNonQuery</a>	
<a href="#">ExecuteReader</a>	Overloaded.
<a href="#">ExecuteScalar</a>	
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">Prepare</a>	
ToString (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.

**Public Instance Events**

Disposed (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
-------------------------------------	-------------------------------------------------------------------------

**Implements**

[IDbConnection.ConnectionString](#)

**See Also**

[MySqlConnection Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.1.3.1.1.3. [ConnectionTimeout](#) Property**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property ConnectionTimeout As Integer _  
    Implements IDbConnection.ConnectionTimeout
```

**Syntax: C#**

```
public int ConnectionTimeout {get;}
```

**Implements**

[IDbConnection.ConnectionTimeout](#)

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.4. Database Property

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property Database As String _  
-  
    Implements IDbConnection.Database
```

**Syntax: C#**

```
public string Database {get;}
```

**Implements**

IDbConnection.Database

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.5. DataSource Property

Gets the name of the MySQL server to which to connect.

**Syntax: Visual Basic**

```
Public ReadOnly Property DataSource As String
```

**Syntax: C#**

```
public string DataSource {get;}
```

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.6. ServerThread Property

Returns the ID of the server thread this connection is executing on

**Syntax: Visual Basic**

```
Public ReadOnly Property ServerThread As Integer
```

**Syntax: C#**

```
public int ServerThread {get;}
```

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.7. ServerVersion Property

**Syntax: Visual Basic**

```
Public ReadOnly Property ServerVersion As String
```

**Syntax: C#**

```
public string ServerVersion {get;}
```

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.8. State Property

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property State As ConnectionState _  
-  
    Implements IDbConnection.State
```

**Syntax: C#**

```
public System.Data.ConnectionState State {get;}
```

**Implements**

IDbConnection.State

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.9. UseCompression Property

Indicates if this connection should use compression when communicating with the server.

**Syntax: Visual Basic**

```
Public ReadOnly Property UseCompression As Boolean
```

**Syntax: C#**

```
public bool UseCompression {get;}
```

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.10. BeginTransaction Method

**Overload List**

- [public MySqlTransaction BeginTransaction\(\);](#)
- [public MySqlTransaction BeginTransaction\(IsolationLevel\);](#)

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.1.3.1.1.10.1. [MySQLConnection.BeginTransaction](#) Method**Syntax: Visual Basic**

```
Overloads Public Function BeginTransaction() As MySqlTransaction
```

**Syntax: C#**

```
public MySqlTransaction BeginTransaction();
```

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLConnection.BeginTransaction Overload List](#)

21.2.7.1.4.1.1.3.1.1.10.1.1.1. [MySQLTransaction](#) Class

For a list of all members of this type, see [MySQLTransaction Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySQLTransaction_
    Implements IDbTransaction, IDisposable
```

**Syntax: C#**

```
public sealed class MySQLTransaction : IDbTransaction, IDisposable
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

**See Also**

[MySQLTransaction Members](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.1.3.1.1.10.1.1.1.1. [MySQLTransaction](#) Members

[MySQLTransaction overview](#)

**Public Instance Properties**

<a href="#">Connection</a>	Gets the <a href="#">MySQLConnection</a> object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.
<a href="#">IsolationLevel</a>	Specifies the IsolationLevel for this transaction.

**Public Instance Methods**

<a href="#">Commit</a>	
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
<a href="#">Rollback</a>	
ToString (inherited from Object)	Returns a String that represents the current Object.

**See Also**

[MySQLTransaction Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.10.1.1.1.1.1.1. Connection Property

Gets the [MySQLConnection](#) object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.

**Syntax: Visual Basic**

```
Public ReadOnly Property Connection As MySqlConnection
```

**Syntax: C#**

```
public MySqlConnection Connection {get;}
```

**Property Value**

The [MySqlConnection](#) object associated with this transaction.

**Remarks**

A single application may have multiple database connections, each with zero or more transactions. This property enables you to determine the connection object associated with a particular transaction created by [BeginTransaction](#).

**See Also**

[MySqlTransaction Class](#), [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.1.3.1.1.10.1.1.1.2. IsolationLevel Property

Specifies the IsolationLevel for this transaction.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property IsolationLevel As IsolationLevel _  
_ Implements IDbTransaction.IsolationLevel
```

**Syntax: C#**

```
public System.Data.IsolationLevel IsolationLevel {get;}
```

**Property Value**

The IsolationLevel for this transaction. The default is ReadCommitted.

**Implements**

IDbTransaction.IsolationLevel

**Remarks**

Parallel transactions are not supported. Therefore, the IsolationLevel applies to the entire transaction.

**See Also**

[MySqlTransaction Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.1.3.1.1.10.1.1.1.3. [MySqlTransaction.Commit](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Sub Commit() _  
_ Implements IDbTransaction.Commit
```

**Syntax: C#**

```
public void Commit();
```

**Implements**

---

IDbTransaction.Commit

**See Also**

[MySQLTransaction Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.1.3.1.1.10.1.1.1.4. [MySQLTransaction.Rollback](#) Method

**Syntax: Visual Basic**

```
NotOverridable Public Sub Rollback() _  
-  
    Implements IDbTransaction.Rollback
```

**Syntax: C#**

```
public void Rollback();
```

**Implements**

IDbTransaction.Rollback

**See Also**

[MySQLTransaction Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.1.3.1.1.10.2. [MySQLConnection.BeginTransaction](#) Method

**Syntax: Visual Basic**

```
Overloads Public Function BeginTransaction( _  
    ByVal iso As IsolationLevel _  
) As MySQLTransaction
```

**Syntax: C#**

```
public MySQLTransaction BeginTransaction(  
    IsolationLevel iso  
);
```

**See Also**

[MySQLConnection Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLConnection.BeginTransaction Overload List](#)

21.2.7.1.4.1.1.3.1.1.11. [MySQLConnection.ChangeDatabase](#) Method

**Syntax: Visual Basic**

```
NotOverridable Public Sub ChangeDatabase( _  
    ByVal databaseName As String _  
) _  
-  
    Implements IDbConnection.ChangeDatabase
```

**Syntax: C#**

```
public void ChangeDatabase(  
    string databaseName  
);
```

**Implements**

IDbConnection.ChangeDatabase

**See Also**

[MySQLConnection Class, MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.1.3.1.1.12. [MySQLConnection.Close](#) Method

##### Syntax: Visual Basic

```
NotOverridable Public Sub Close() _  
-  
    Implements IDbConnection.Close
```

##### Syntax: C#

```
public void Close();
```

##### Implements

IDbConnection.Close

##### See Also

21.2.7.1.4.1.1.3.1.1.16. [MySqlConnection.InfoMessage](#) Event**Syntax: Visual Basic**

```
Public Event InfoMessage As MySqlInfoMessageEventHandler
```

**Syntax: C#**

```
public event MySqlInfoMessageEventHandler InfoMessage;
```

**See Also**

[MySqlConnection Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.1.3.1.1.16.1. [MySqlInfoMessageEventHandler](#) Delegate

Represents the method that will handle the [InfoMessage](#) event of a [MySqlConnection](#).

**Syntax: Visual Basic**

```
Public Delegate Sub MySqlInfoMessageEventHandler( _  
    ByVal sender As Object, _  
    ByVal args As MySqlInfoMessageEventArgs _  
)
```

**Syntax: C#**

```
public delegate void MySqlInfoMessageEventHandler(  
    object sender,  
    MySqlInfoMessageEventArgs args  
);
```

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

[MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.1.3.1.1.16.1.1. [MySqlInfoMessageEventArgs](#) Class

Provides data for the [InfoMessage](#) event. This class cannot be inherited.

For a list of all members of this type, see [MySqlInfoMessageEventArgs Members](#) .

**Syntax: Visual Basic**

```
Public Class MySqlInfoMessageEventArgs_  
    Inherits EventArgs
```

**Syntax: C#**

```
public class MySqlInfoMessageEventArgs : EventArgs
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

### Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

[MySqlInfoMessageEventArgs](#) overview

### Public Instance Constructors

<a href="#">MySqlInfoMessageEventArgs</a> Constructor	Initializes a new instance of the <a href="#">MySqlInfoMessageEventArgs</a> class.
-------------------------------------------------------	------------------------------------------------------------------------------------

### Public Instance Fields

<a href="#">errors</a>	
------------------------	--

### Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

### Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

#### 21.2.7.1.4.1.7. Parameters Property

**Syntax: Visual Basic**

```
Public ReadOnly Property Parameters As MySqlParameterCollection
```

**Syntax: C#**

```
public MySqlParameterCollection Parameters {get;}
```

**See Also**

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.7.1. [MySqlParameterCollection](#) Class

Represents a collection of parameters relevant to a [MySqlCommand](#) as well as their respective mappings to columns in a DataSet. This class cannot be inherited.

For a list of all members of this type, see [MySqlParameterCollection Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlParameterCollection_  
    Inherits MarshalByRefObject_  
    Implements IDataParameterCollection, IList, ICollection, IEnumerable
```

**Syntax: C#**

```
public sealed class MySqlParameterCollection : MarshalByRefObject, IDataParameterCollection, IList, ICollection
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

[MySqlParameterCollection overview](#)

### Public Instance Constructors

<a href="#">MySqlParameterCollection Constructor</a>	Initializes a new instance of the <a href="#">MySqlParameterCollection</a> class.
------------------------------------------------------	-----------------------------------------------------------------------------------

### Public Instance Properties

<a href="#">Count</a>	Gets the number of <a href="#">MySqlParameter</a> objects in the collection.
<a href="#">Item</a>	Overloaded. Gets the <a href="#">MySqlParameter</a> with a specified attribute. In C#, this property is the indexer for the <a href="#">MySqlParameterCollection</a> class.

### Public Instance Methods

<a href="#">Add</a>	Overloaded. Adds the specified <a href="#">MySqlParameter</a> object to the <a href="#">MySqlParameterCollection</a> .
<a href="#">Clear</a>	Removes all items from the collection.
<a href="#">Contains</a>	Overloaded. Gets a value indicating whether a <a href="#">MySqlParameter</a> exists in the collection.
<a href="#">CopyTo</a>	Copies <a href="#">MySqlParameter</a> objects from the <a href="#">MySqlParameterCollection</a> to the specified array.
CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
<a href="#">IndexOf</a>	Overloaded. Gets the location of a <a href="#">MySqlParameter</a> in the collection.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">Insert</a>	Inserts a <a href="#">MySqlParameter</a> into the collection at the specified index.
<a href="#">Remove</a>	Removes the specified <a href="#">MySqlParameter</a> from the collection.

<a href="#">RemoveAt</a>	Overloaded. Removes the specified <a href="#">MySQLParameter</a> from the collection.
ToString (inherited from Object)	Returns a String that represents the current Object.

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.7.1.1.1. [MySQLParameterCollection](#) Constructor

Initializes a new instance of the [MySQLParameterCollection](#) class.

**Syntax: Visual Basic**

```
Public Sub New()
```

**Syntax: C#**

```
public MySQLParameterCollection();
```

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.2. Count Property

Gets the number of [MySQLParameter](#) objects in the collection.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property Count As Integer _  
_ Implements ICollection.Count
```

**Syntax: C#**

```
public int Count {get;}
```

**Implements**

ICollection.Count

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.3. Item Property

Gets the [MySQLParameter](#) with a specified attribute. In C#, this property is the indexer for the [MySQLParameterCollection](#) class.

**Overload List**

Gets the [MySQLParameter](#) at the specified index.

- `public MySQLParameter this[int] {get; set;}`

Gets the [MySQLParameter](#) with the specified name.

- `public MySQLParameter this[string] {get; set;}`

**See Also**

[MySQLParameterCollection Class, MySql.Data.MySqlClient Namespace](#)21.2.7.1.4.1.7.1.1.3.1. [MySQLParameter](#) Class

Represents a parameter to a [MySQLCommand](#), and optionally, its mapping to DataSet columns. This class cannot be inherited.

For a list of all members of this type, see [MySQLParameter Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySQLParameter_
    Inherits MarshalByRefObject_
    Implements IDataParameter, IDbDataParameter, ICloneable
```

**Syntax: C#**

```
public sealed class MySQLParameter : MarshalByRefObject, IDataParameter, IDbDataParameter, ICloneable
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

[MySQLParameter overview](#)

**Public Instance Constructors**

<a href="#">MySQLParameter</a>	Overloaded. Initializes a new instance of the MySQLParameter class.
--------------------------------	---------------------------------------------------------------------

**Public Instance Properties**

<a href="#">DbType</a>	Gets or sets the DbType of the parameter.
<a href="#">Direction</a>	Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.
<a href="#">IsNullable</a>	Gets or sets a value indicating whether the parameter accepts null values.
<a href="#">IsUnsigned</a>	
<a href="#">MySqlDbType</a>	Gets or sets the MySqlDbType of the parameter.
<a href="#">ParameterName</a>	Gets or sets the name of the MySQLParameter.
<a href="#">Precision</a>	Gets or sets the maximum number of digits used to represent the <a href="#">Value</a> property.
<a href="#">Scale</a>	Gets or sets the number of decimal places to which <a href="#">Value</a> is resolved.

<a href="#">Size</a>	Gets or sets the maximum size, in bytes, of the data within the column.
<a href="#">SourceColumn</a>	Gets or sets the name of the source column that is mapped to the DataSet and used for loading or returning the <a href="#">Value</a> .
<a href="#">SourceVersion</a>	Gets or sets the DataRowVersion to use when loading <a href="#">Value</a> .
<a href="#">Value</a>	Gets or sets the value of the parameter.

**Public Instance Methods**

CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">ToString</a>	Overridden. Gets a string containing the <a href="#">ParameterName</a> .

21.2.7.1.4.1.7.1.1.3.1.1.1. [MySQLParameter](#) Constructor

Initializes a new instance of the MySQLParameter class.

**Overload List**

Initializes a new instance of the MySQLParameter class.

- [public MySQLParameter\(\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and the data type.

- [public MySQLParameter\(string,MySQLDbType\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#), and the size.

- [public MySQLParameter\(string,MySQLDbType,int\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a ParameterDirection, the precision of the parameter, the scale of the parameter, the source column, a DataRowVersion to use, and the value of the parameter.

- [public MySQLParameter\(string,MySQLDbType,int,ParameterDirection,bool,byte,byte,string,DataRowVersion,object\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#), the size, and the source column name.

- `public MySQLParameter(string,MySQLDbType,int,string);`

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and a value of the new [MySQLParameter](#).

- `public MySQLParameter(string,object);`

Specifies MySQL-specific data type of a field, property, for use in a [MySQLParameter](#).

#### Syntax: Visual Basic

```
Public Enum MySqlDbType
```

**Syntax: C#**

```
public enum MySqlDbType
```

**Members**

Member Name	Description
Newdate	Obsolete. Use Datetime or Date type.
Timestamp	A timestamp. The range is '1970-01-01 00:00:01.000000' to '2038-01-19 03:14:07.999999'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.)
Time	The range is '-838:59:59.000000' to '838:59:59.000000'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.)
Date	The supported range is '1000-01-01' to '9999-12-31'.
Datetime	The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.)
Year	A year in 2- or 4-digit format (default is 4-digit). The allowable values are 1901 to 2155, 0000 in the 4-digit year format, and 1970-2069 if you use the 2-digit format (70-69).
TinyBlob	A BLOB column with a maximum length of 255 (2 <sup>8</sup> - 1) characters.
Blob	A BLOB column with a maximum length of 65535 (2 <sup>16</sup> - 1) characters.
MediumBlob	A BLOB column with a maximum length of 16777215 (2 <sup>24</sup> - 1) characters.
LongBlob	A BLOB column with a maximum length of 4294967295 or 4G (2 <sup>32</sup> - 1) characters.
Int16	A 16-bit signed integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535.
Int24	Specifies a 24 (3 byte) signed or unsigned value.
Int32	A 32-bit signed integer.
Int64	A 64-bit signed integer.
Byte	The signed range is -128 to 127. The unsigned range is 0 to 255.
Float	A small (single-precision) floating-point number. Allowable values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38.
Double	A normal-size (double-precision) floating-point number. Allowable

	values are -1.7976931348623157E+308 to -2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308.
UByte	An 8-bit unsigned value.
UInt16	A 16-bit unsigned value.
UInt24	A 24-bit unsigned value.
UInt32	A 32-bit unsigned value.
UInt64	A 64-bit unsigned value.
Decimal	A fixed precision and scale numeric value between $-10^{38-1}$ and $10^{38-1}$ .
NewDecimal	New Decimal
Set	A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... A SET can have a maximum of 64 members.
String	Obsolete. Use VarChar type.
VarChar	A variable-length string containing 0 to 255 characters.
VarString	A variable-length string containing 0 to 65535 characters.
Enum	An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special "" error value. An ENUM can have a maximum of 65535 distinct values.
Geometry	
Bit	Bit-field data type.
TinyText	A nonbinary string column supporting a maximum length of 255 ( $2^8 - 1$ ) characters.
Text	A nonbinary string column supporting a maximum length of 65535 ( $2^{16} - 1$ ) characters.
MediumText	A nonbinary string column supporting a maximum length of 16777215 ( $2^{24} - 1$ ) characters.
LongText	A nonbinary string column supporting a maximum length of 4294967295 ( $2^{32} - 1$ ) characters.

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

[MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.7.1.1.3.1.1.3. [MySqlParameter](#) Constructor (String, MySqlDbType, Int32)

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the [MySqlDbType](#), and the size.

**Syntax: Visual Basic**

```
Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer _
)
```

**Syntax: C#**

```
public MySqlParameter(
    stringparameterName,
    MySqlDbTypedbType,
    intsize
);
```

**Parameters**

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the parameter.

**See Also**

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameter Constructor Overload List](#)

21.2.7.1.4.1.7.1.1.3.1.1.4. [MySqlParameter](#) Constructor

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a [ParameterDirection](#), the precision of the parameter, the scale of the parameter, the source column, a [DataRowVersion](#) to use, and the value of the parameter.

**Syntax: Visual Basic**

```
Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer, _
    ByVal direction As ParameterDirection, _
    ByVal isNullable As Boolean, _
    ByVal precision As Byte, _
    ByVal scale As Byte, _
    ByVal sourceColumn As String, _
    ByVal sourceVersion As DataRowVersion, _
    ByVal value As Object _
)
```

**Syntax: C#**

```
public MySqlParameter(
    stringparameterName,
    MySqlDbTypedbType,
    intsize,
    ParameterDirectiondirection,
    boolisNullable,
    byteprecision,
    bytescale,
    stringsourceColumn,
    DataRowVersionsourceVersion,
    objectvalue
);
```

**Parameters**

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.

- **size**: The length of the parameter.
- **direction**: One of the ParameterDirection values.
- **isNullable**: true if the value of the field can be null, otherwise false.
- **precision**: The total number of digits to the left and right of the decimal point to which **Value** is resolved.
- **scale**: The total number of decimal places to which **Value** is resolved.
- **sourceColumn**: The name of the source column.
- **sourceVersion**: One of the DataRowVersion values.
- **value**: An Object that is the value of the **MySqlParameter**.

Initializes a new instance of the **MySqlParameter** class with the parameter name, the **MySqlDbType**, the size, and the source column name.

#### Syntax: Visual Basic

```
Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer, _
    ByVal sourceColumn As String _
)
```

#### Syntax: C#

```
public MySqlParameter(  
    stringparameterName,  
    MySqlDbTypeDbType,  
    intsize,  
    stringsourceColumn  
);
```

### Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the parameter.
- `sourceColumn`: The name of the source column.

### See Also

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameter Constructor Overload List](#)

#### 21.2.7.1.4.1.7.1.1.3.1.1.6. [MySqlParameter](#) Constructor

Initializes a new instance of the [MySqlParameter](#) class with the parameter name and a value of the new [MySqlParameter](#).

### Syntax: Visual Basic

```
Overloads Public Sub New( _  
    ByVal parameterName As String, _  
    ByVal value As Object _  
)
```

### Syntax: C#

```
public MySqlParameter(  
    stringparameterName,  
    objectvalue  
);
```

### Parameters

- `parameterName`: The name of the parameter to map.
- `value`: An Object that is the value of the [MySqlParameter](#).

### See Also

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameter Constructor Overload List](#)

#### 21.2.7.1.4.1.7.1.1.3.1.1.2. DbType Property

Gets or sets the DbType of the parameter.

### Syntax: Visual Basic

```
NotOverridable Public Property DbType As DbType _  
-  
    Implements IDataParameter.DbType
```

### Syntax: C#

```
public System.Data.DbType DbType {get; set;}
```

**Implements**

IDataParameter.DbType

**See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.3.1.3. Direction Property

Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.

**Syntax: Visual Basic**

```
NotOverridable Public Property Direction As ParameterDirection _
-
    Implements IDataParameter.Direction
```

**Syntax: C#**

```
public System.Data.ParameterDirection Direction {get; set;}
```

**Implements**

IDataParameter.Direction

**See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.3.1.4. IsNullable Property

Gets or sets a value indicating whether the parameter accepts null values.

**Syntax: Visual Basic**

```
NotOverridable Public Property IsNullable As Boolean _
-
    Implements IDataParameter.IsNullable
```

**Syntax: C#**

```
public bool IsNullable {get; set;}
```

**Implements**

IDataParameter.IsNullable

**See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.3.1.5. IsUnsigned Property

**Syntax: Visual Basic**

```
Public Property IsUnsigned As Boolean
```

**Syntax: C#**

```
public bool IsUnsigned {get; set;}
```

**See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.7.1.1.3.1.1.6. MySQLDbType Property

Gets or sets the MySQLDbType of the parameter.

##### Syntax: Visual Basic

```
Public Property MySQLDbType As MySQLDbType
```

##### Syntax: C#

```
public MySQLDbType MySQLDbType {get; set;}
```

##### See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.7.1.1.3.1.1.7. ParameterName Property

Gets or sets the name of the MySQLParameter.

##### Syntax: Visual Basic

```
NotOverridable Public Property ParameterName As String _  
-  
    Implements IDataParameter.ParameterName
```

##### Syntax: C#

```
public string ParameterName {get; set;}
```

##### Implements

IDataParameter.ParameterName

##### See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.7.1.1.3.1.1.8. Precision Property

Gets or sets the maximum number of digits used to represent the [Value](#) property.

##### Syntax: Visual Basic

```
NotOverridable Public Property Precision As Byte _  
-  
    Implements IDbDataParameter.Precision
```

##### Syntax: C#

```
public byte Precision {get; set;}
```

##### Implements

IDbDataParameter.Precision

##### See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.7.1.1.3.1.1.9. Scale Property

Gets or sets the number of decimal places to which [Value](#) is resolved.

**Syntax: Visual Basic**

```
NotOverridable Public Property Scale As Byte _  
-  
    Implements IDbDataParameter.Scale
```

**Syntax: C#**

```
public byte Scale {get; set;}
```

**Implements**

IDbDataParameter.Scale

**See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.3.1.1.10. Size Property

Gets or sets the maximum size, in bytes, of the data within the column.

**Syntax: Visual Basic**

```
NotOverridable Public Property Size As Integer _  
-  
    Implements IDbDataParameter.Size
```

**Syntax: C#**

```
public int Size {get; set;}
```

**Implements**

IDbDataParameter.Size

**See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.3.1.1.11. SourceColumn Property

Gets or sets the name of the source column that is mapped to the DataSet and used for loading or returning the [Value](#).

**Syntax: Visual Basic**

```
NotOverridable Public Property SourceColumn As String _  
-  
    Implements IDataParameter.SourceColumn
```

**Syntax: C#**

```
public string SourceColumn {get; set;}
```

**Implements**

IDataParameter.SourceColumn

**See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.3.1.1.12. SourceVersion Property

Gets or sets the DataRowVersion to use when loading [Value](#).

**Syntax: Visual Basic**

```
NotOverridable Public Property SourceVersion As DataRowVersion _
    Implements IDataParameter.SourceVersion
```

**Syntax: C#**

```
public System.Data.DataRowVersion SourceVersion {get; set;}
```

**Implements**

IDataParameter.SourceVersion

**See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.7.1.1.3.1.13. [MySQLParameter.ToString](#) Method

Overridden. Gets a string containing the [ParameterName](#).

**Syntax: Visual Basic**

```
Overrides Public Function ToString() As String
```

**Syntax: C#**

```
public override string ToString();
```

**Return Value****See Also**

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.3.2. Item Property (Int32)

Gets the [MySQLParameter](#) at the specified index.

**Syntax: Visual Basic**

```
Overloads Public Default Property Item( _
    ByVal index As Integer _
) As MySQLParameter
```

**Syntax: C#**

```
public MySQLParameter this[
    int index
] {get; set;}
```

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.Item Overload List](#)

## 21.2.7.1.4.1.7.1.1.3.3. Item Property (String)

Gets the [MySQLParameter](#) with the specified name.

**Syntax: Visual Basic**

```
Overloads Public Default Property Item( _
    ByVal name As String _
) As MySQLParameter
```

**Syntax: C#**

```
public MySqlParameter this[
    stringname
] {get; set;}
```

**See Also**

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#),  
[MySqlParameterCollection.Item Overload List](#)

## 21.2.7.1.4.1.7.1.1.4. Add Method

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#).

**Overload List**

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#).

- [public MySqlParameter Add\(MySqlParameter\);](#)

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#).

- [public int Add\(object\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the parameter name and the data type.

- [public MySqlParameter Add\(string,MySqlDbType\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, and the column length.

- [public MySqlParameter Add\(string,MySqlDbType,int\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

- [public MySqlParameter Add\(string,MySqlDbType,int,string\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the specified parameter name and value.

- [public MySqlParameter Add\(string,object\);](#)

**See Also**

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.7.1.1.4.1. [MySqlParameterCollection.Add](#) Method

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#).

**Syntax: Visual Basic**

```
Overloads Public Function Add( _
    ByVal value As MySqlParameter _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter Add(
    MySqlParameter value
);
```

**Parameters**

- **value**: The [MySQLParameter](#) to add to the collection.

**Return Value**

The newly added [MySQLParameter](#) object.

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.Add Overload List](#)

21.2.7.1.4.1.7.1.1.4.2. [MySQLParameterCollection.Add](#) Method

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#).

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function Add( _
    ByVal value As Object _
) As Integer _
-
    Implements IList.Add
```

**Syntax: C#**

```
public int Add(
    objectvalue
);
```

**Parameters**

- **value**: The [MySQLParameter](#) to add to the collection.

**Return Value**

The index of the new [MySQLParameter](#) object.

**Implements**

IList.Add

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.Add Overload List](#)

21.2.7.1.4.1.7.1.1.4.3. [MySQLParameterCollection.Add](#) Method

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) given the parameter name and the data type.

**Syntax: Visual Basic**

```
Overloads Public Function Add( _
    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType _
) As MySQLParameter
```

**Syntax: C#**

```
public MySQLParameter Add(
    stringparameterName,
    MySqlDbTypedbType
);
```

## Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySQLDbType](#) values.

## Return Value

The newly added [MySQLParameter](#) object.

## See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.Add Overload List](#)

### 21.2.7.1.4.1.7.1.1.4.4. [MySQLParameterCollection.Add](#) Method

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) with the parameter name, the data type, and the column length.

#### Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySQLDbType, _  
    ByVal size As Integer _  
) As MySQLParameter
```

#### Syntax: C#

```
public MySQLParameter Add(  
    string parameterName,  
    MySQLDbType dbType,  
    int size  
);
```

## Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySQLDbType](#) values.
- `size`: The length of the column.

## Return Value

The newly added [MySQLParameter](#) object.

## See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.Add Overload List](#)

### 21.2.7.1.4.1.7.1.1.4.5. [MySQLParameterCollection.Add](#) Method

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

#### Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySQLDbType, _  
    ByVal size As Integer, _  
    ByVal sourceColumn As String _  
) As MySQLParameter
```

**Syntax: C#**

```
public MySqlParameter Add(  
stringparameterName,  
MySqlDbTypeDbType,  
intsize,  
stringsourceColumn  
);
```

**Parameters**

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the column.
- `sourceColumn`: The name of the source column.

**Return Value**

The newly added [MySqlParameter](#) object.

**See Also**

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#),  
[MySqlParameterCollection.Add Overload List](#)

**21.2.7.1.4.1.7.1.1.4.6. [MySqlParameterCollection.Add](#) Method**

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the specified parameter name and value.

**Syntax: Visual Basic**

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal value As Object _  
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter Add(  
stringparameterName,  
objectvalue  
);
```

**Parameters**

- `parameterName`: The name of the parameter.
- `value`: The [Value](#) of the [MySqlParameter](#) to add to the collection.

**Return Value**

The newly added [MySqlParameter](#) object.

**See Also**

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#),  
[MySqlParameterCollection.Add Overload List](#)

**21.2.7.1.4.1.7.1.1.5. [MySqlParameterCollection.Clear](#) Method**

Removes all items from the collection.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Clear() _
-
  Implements IList.Clear
```

**Syntax: C#**

```
public void Clear();
```

**Implements**

IList.Clear

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.6. Contains Method

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

**Overload List**

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

- [public bool Contains\(object\);](#)

Gets a value indicating whether a [MySQLParameter](#) with the specified parameter name exists in the collection.

- [public bool Contains\(string\);](#)

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.6.1. MySQLParameterCollection.Contains Method

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function Contains( _
  ByVal value As Object _
) As Boolean _
-
  Implements IList.Contains
```

**Syntax: C#**

```
public bool Contains(
  objectvalue
);
```

**Parameters**

- [value](#): The value of the [MySQLParameter](#) object to find.

**Return Value**

true if the collection contains the [MySQLParameter](#) object; otherwise, false.

**Implements**

IList.Contains

## See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.Contains Overload List](#)

### 21.2.7.1.4.1.7.1.1.6.2. [MySQLParameterCollection.Contains](#) Method

Gets a value indicating whether a [MySQLParameter](#) with the specified parameter name exists in the collection.

#### Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _  
    ByVal name As String _  
) As Boolean _  
-  
    Implements IDataParameterCollection.Contains
```

#### Syntax: C#

```
public bool Contains(  
    stringname  
);
```

#### Parameters

- **name**: The name of the [MySQLParameter](#) object to find.

#### Return Value

true if the collection contains the parameter; otherwise, false.

#### Implements

[IDataParameterCollection.Contains](#)

#### See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.Contains Overload List](#)

### 21.2.7.1.4.1.7.1.1.7. [MySQLParameterCollection.CopyTo](#) Method

Copies [MySQLParameter](#) objects from the [MySQLParameterCollection](#) to the specified array.

#### Syntax: Visual Basic

```
NotOverridable Public Sub CopyTo( _  
    ByVal array As Array, _  
    ByVal index As Integer _  
) _  
-  
    Implements ICollection.CopyTo
```

#### Syntax: C#

```
public void CopyTo(  
    Arrayarray,  
    intindex  
);
```

#### Parameters

- **array**:
- **index** [899]:

**Implements**

ICollection.CopyTo

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.1.8. IndexOf Method

Gets the location of a [MySQLParameter](#) in the collection.

**Overload List**

Gets the location of a [MySQLParameter](#) in the collection.

- `public int IndexOf(object);`

Gets the location of the [MySQLParameter](#) in the collection with a specific parameter name.

- `public int IndexOf(string);`

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.7.1.1.8.1. [MySQLParameterCollection.IndexOf](#) Method

Gets the location of a [MySQLParameter](#) in the collection.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function IndexOf( _  
    ByVal value As Object _  
) As Integer _  
-  
    Implements IList.IndexOf
```

**Syntax: C#**

```
public int IndexOf(  
    objectvalue  
);
```

**Parameters**

- `value`: The [MySQLParameter](#) object to locate.

**Return Value**

The zero-based location of the [MySQLParameter](#) in the collection.

**Implements**

IList.IndexOf

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.IndexOf Overload List](#)

21.2.7.1.4.1.7.1.1.8.2. [MySQLParameterCollection.IndexOf](#) Method

Gets the location of the [MySQLParameter](#) in the collection with a specific parameter name.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function IndexOf( _  
    ByVal parameterName As String _  
) As Integer _  
-  
    Implements IDataParameterCollection.IndexOf
```

### Syntax: C#

```
public int IndexOf(  
    string parameterName  
);
```

### Parameters

- `parameterName`: The name of the [MySqlParameter](#) object to retrieve.

### Return Value

The zero-based location of the [MySqlParameter](#) in the collection.

### Implements

[IDataParameterCollection.IndexOf](#)

### See Also

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#),  
[MySqlParameterCollection.IndexOf Overload List](#)

#### 21.2.7.1.4.1.7.1.1.9. [MySqlParameterCollection.Insert](#) Method

Inserts a [MySqlParameter](#) into the collection at the specified index.

### Syntax: Visual Basic

```
NotOverridable Public Sub Insert( _  
    ByVal index As Integer, _  
    ByVal value As Object _  
) _  
-  
    Implements IList.Insert
```

### Syntax: C#

```
public void Insert(  
    int index,  
    object value  
);
```

### Parameters

- `index` [899]:
- `value`:

### Implements

[IList.Insert](#)

### See Also

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.7.1.1.10. [MySqlParameterCollection.Remove](#) Method

Removes the specified [MySqlParameter](#) from the collection.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Remove( _
    ByVal value As Object _
) _
- Implements IList.Remove
```

**Syntax: C#**

```
public void Remove(
    objectvalue
);
```

**Parameters**

- `value`:

**Implements**

IList.Remove

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.7.1.11. RemoveAt Method

Removes the specified [MySQLParameter](#) from the collection.

**Overload List**

Removes the specified [MySQLParameter](#) from the collection using a specific index.

- `public void RemoveAt(int);`

Removes the specified [MySQLParameter](#) from the collection using the parameter name.

- `public void RemoveAt(string);`

**See Also**

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.7.1.11.1. [MySQLParameterCollection.RemoveAt](#) Method

Removes the specified [MySQLParameter](#) from the collection using a specific index.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Sub RemoveAt( _
    ByVal index As Integer _
) _
- Implements IList.RemoveAt
```

**Syntax: C#**

```
public void RemoveAt(
    intindex
);
```

**Parameters**

- `index` [899]: The zero-based index of the parameter.

**Implements**

IList.RemoveAt

### See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.RemoveAt Overload List](#)

#### 21.2.7.1.4.1.7.1.11.2. [MySQLParameterCollection.RemoveAt](#) Method

Removes the specified [MySQLParameter](#) from the collection using the parameter name.

### Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _  
    ByVal name As String _  
) _  
- Implements IDataParameterCollection.RemoveAt
```

### Syntax: C#

```
public void RemoveAt(  
    stringname  
);
```

### Parameters

- [name](#): The name of the [MySQLParameter](#) object to retrieve.

### Implements

[IDataParameterCollection.RemoveAt](#)

### See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),  
[MySQLParameterCollection.RemoveAt Overload List](#)

#### 21.2.7.1.4.1.8. Transaction Property

### Syntax: Visual Basic

```
Public Property Transaction As MySQLTransaction
```

### Syntax: C#

```
public MySQLTransaction Transaction {get; set;}
```

### See Also

[MySQLCommand Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.9. UpdatedRowSource Property

### Syntax: Visual Basic

```
NotOverridable Public Property UpdatedRowSource As UpdateRowSource _  
- Implements IDbCommand.UpdatedRowSource
```

### Syntax: C#

```
public System.Data.UpdateRowSource UpdatedRowSource {get; set;}
```

### Implements

IDbCommand.UpdatedRowSource

**See Also**

[MySqlCommand Class](#),  [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.10.  [MySqlCommand.Cancel](#) Method

Attempts to cancel the execution of a MySqlCommand. This operation is not supported.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Cancel() _
-
    Implements IDbCommand.Cancel
```

**Syntax: C#**

```
public void Cancel();
```

**Implements**

IDbCommand.Cancel

**Remarks**

Cancelling an executing command is currently not supported on any version of MySQL.

**Exceptions**

Exception Type	Condition
NotSupportedException	This operation is not supported.

**See Also**

[MySqlCommand Class](#),  [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.11.  [MySqlCommand.CreateParameter](#) Method

Creates a new instance of a  [MySqlParameter](#) object.

**Syntax: Visual Basic**

```
Public Function CreateParameter() As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter CreateParameter();
```

**Return Value**

A  [MySqlParameter](#) object.

**Remarks**

This method is a strongly-typed version of CreateParameter.

**See Also**

[MySqlCommand Class](#),  [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.12.  [MySqlCommand.ExecuteNonQuery](#) Method

**Syntax: Visual Basic**

```
NotOverridable Public Function ExecuteNonQuery() As Integer _
_
_ Implements IDbCommand.ExecuteNonQuery
```

**Syntax: C#**

```
public int ExecuteNonQuery();
```

**Implements**

IDbCommand.ExecuteNonQuery

**See Also**

[MySQLCommand Class](#), [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.13. ExecuteReader Method

**Overload List**

- [public MySqlDataReader ExecuteReader\(\);](#)
- [public MySqlDataReader ExecuteReader\(CommandBehavior\);](#)

**See Also**

[MySQLCommand Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1. [MySQLCommand.ExecuteReader](#) Method**Syntax: Visual Basic**

```
Overloads Public Function ExecuteReader() As MySqlDataReader
```

**Syntax: C#**

```
public MySqlDataReader ExecuteReader();
```

**See Also**

[MySQLCommand Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLCommand.ExecuteReader Overload List](#)

21.2.7.1.4.1.13.1.1. [MySqlDataReader](#) Class

Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.

For a list of all members of this type, see [MySqlDataReader Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlDataReader_
_ Inherits MarshalByRefObject_
_ Implements IEnumerable, IDataReader, IDisposable, IDataRecord
```

**Syntax: C#**

```
public sealed class MySqlDataReader : MarshalByRefObject, IEnumerable, IDataReader, IDisposable, IDataRecord
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

### See Also

[MySqlDataReader Members](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.1. [MySqlDataReader](#) Members

[MySqlDataReader overview](#)

### Public Instance Properties

<a href="#">Depth</a>	Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.
<a href="#">FieldCount</a>	Gets the number of columns in the current row.
<a href="#">HasRows</a>	Gets a value indicating whether the <a href="#">MySqlDataReader</a> contains one or more rows.
<a href="#">IsClosed</a>	Gets a value indicating whether the data reader is closed.
<a href="#">Item</a>	Overloaded. Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the <a href="#">MySqlDataReader</a> class.
<a href="#">RecordsAffected</a>	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

### Public Instance Methods

<a href="#">Close</a>	Closes the <a href="#">MySqlDataReader</a> object.
<a href="#">CreateObjRef</a> (inherited from <a href="#">MarshalByRefObject</a> )	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
<a href="#">Equals</a> (inherited from <a href="#">Object</a> )	Determines whether the specified <a href="#">Object</a> is equal to the current <a href="#">Object</a> .
<a href="#">GetBoolean</a>	Gets the value of the specified column as a <a href="#">Boolean</a> .
<a href="#">GetByte</a>	Gets the value of the specified column as a byte.
<a href="#">GetBytes</a>	Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.
<a href="#">GetChar</a>	Gets the value of the specified column as a single character.
<a href="#">GetChars</a>	Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
<a href="#">GetDataTypeName</a>	Gets the name of the source data type.
<a href="#">GetDateTime</a>	
<a href="#">GetDecimal</a>	
<a href="#">GetDouble</a>	
<a href="#">GetFieldType</a>	Gets the <a href="#">Type</a> that is the data type of the object.

<a href="#">GetFloat</a>	
<a href="#">GetGuid</a>	
<a href="#">GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetInt16</a>	
<a href="#">GetInt32</a>	
<a href="#">GetInt64</a>	
<a href="#">GetLifetimeService</a> (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
<a href="#">GetMySqlDateTime</a>	
<a href="#">GetName</a>	Gets the name of the specified column.
<a href="#">GetOrdinal</a>	Gets the column ordinal, given the name of the column.
<a href="#">GetSchemaTable</a>	Returns a DataTable that describes the column metadata of the MySqlDataReader.
<a href="#">GetString</a>	
<a href="#">GetTimeSpan</a>	
<a href="#">GetType</a> (inherited from Object)	Gets the Type of the current instance.
<a href="#">GetUInt16</a>	
<a href="#">GetUInt32</a>	
<a href="#">GetUInt64</a>	
<a href="#">GetValue</a>	Gets the value of the specified column in its native format.
<a href="#">GetValues</a>	Gets all attribute columns in the collection for the current row.
<a href="#">InitializeLifetimeService</a> (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">IsDBNull</a>	Gets a value indicating whether the column contains non-existent or missing values.
<a href="#">NextResult</a>	Advances the data reader to the next result, when reading the results of batch SQL statements.
<a href="#">Read</a>	Advances the MySqlDataReader to the next record.
<a href="#">ToString</a> (inherited from Object)	Returns a String that represents the current Object.

## 21.2.7.1.4.1.13.1.1.1.1. Depth Property

Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property Depth As Integer _
    Implements IDataReader.Depth
```

**Syntax: C#**

```
public int Depth {get;}
```

**Implements**

IDataReader.Depth

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.13.1.1.1.2. FieldCount Property

Gets the number of columns in the current row.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property FieldCount As Integer _  
- Implements IDataRecord.FieldCount
```

**Syntax: C#**

```
public int FieldCount {get;}
```

**Implements**

IDataRecord.FieldCount

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.13.1.1.1.3. HasRows Property

Gets a value indicating whether the MySqlDataReader contains one or more rows.

**Syntax: Visual Basic**

```
Public ReadOnly Property HasRows As Boolean
```

**Syntax: C#**

```
public bool HasRows {get;}
```

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.4.1.13.1.1.1.4. IsClosed Property

Gets a value indicating whether the data reader is closed.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property IsClosed As Boolean _  
- Implements IDataReader.IsClosed
```

**Syntax: C#**

```
public bool IsClosed {get;}
```

**Implements**

IDataReader.IsClosed

### See Also

[MySQLDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.1.5. Item Property

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

### Overload List

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

- [public object this\[int\] {get;}](#)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

- [public object this\[string\] {get;}](#)

### See Also

[MySQLDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.1.5.1. Item Property (Int32)

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

### Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _
    ByVal i As Integer _
) _
-
Implements IDataRecord.Item As Object _
-
Implements IDataRecord.Item
```

### Syntax: C#

```
public object this[
    inti
] {get;}
```

### Implements

IDataRecord.Item

### See Also

[MySQLDataReader Class](#), [MySql.Data.MySqlClient Namespace](#), [MySQLDataReader.Item Overload List](#)

#### 21.2.7.1.4.1.13.1.1.1.5.2. Item Property (String)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

### Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _
    ByVal name As String _
```

```
) _  
- Implements IDataRecord.Item As Object _  
- Implements IDataRecord.Item
```

**Syntax: C#**

```
public object this[  
stringname  
] {get;}
```

**Implements**

IDataRecord.Item

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLDataReader.Item Overload List](#)

## 21.2.7.1.4.1.13.1.1.1.6. RecordsAffected Property

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property RecordsAffected As Integer _  
- Implements IDataReader.RecordsAffected
```

**Syntax: C#**

```
public int RecordsAffected {get;}
```

**Implements**

IDataReader.RecordsAffected

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.7. [MySQLDataReader.Close](#) Method

Closes the MySQLDataReader object.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Close() _  
- Implements IDataReader.Close
```

**Syntax: C#**

```
public void Close();
```

**Implements**

IDataReader.Close

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.8. [MySQLDataReader.GetBoolean](#) Method

Gets the value of the specified column as a Boolean.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetBoolean( _  
    ByVal i As Integer _  
) As Boolean _  
-  
    Implements IDataRecord.GetBoolean
```

**Syntax: C#**

```
public bool GetBoolean(  
    inti  
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.GetBoolean

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

**21.2.7.1.4.1.13.1.1.1.9. MySQLDataReader.GetByte Method**

Gets the value of the specified column as a byte.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetByte( _  
    ByVal i As Integer _  
) As Byte _  
-  
    Implements IDataRecord.GetByte
```

**Syntax: C#**

```
public byte GetByte(  
    inti  
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.GetByte

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

**21.2.7.1.4.1.13.1.1.1.10. MySQLDataReader.GetBytes Method**

Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.

**Syntax: Visual Basic**

```

NotOverridable Public Function GetBytes( _
    ByVal i As Integer, _
    ByVal dataIndex As Long, _
    ByVal buffer As Byte(), _
    ByVal bufferIndex As Integer, _
    ByVal length As Integer _
) As Long _
-
    Implements IDataRecord.GetBytes

```

**Syntax: C#**

```

public long GetBytes(
    inti,
    longdataIndex,
    byte[]buffer,
    intbufferIndex,
    intlength
);

```

**Parameters**

- **i**: The zero-based column ordinal.
- **dataIndex**: The index within the field from which to begin the read operation.
- **buffer**: The buffer into which to read the stream of bytes.
- **bufferIndex**: The index for buffer to begin the read operation.
- **length**: The maximum length to copy into the buffer.

**Return Value**

The actual number of bytes read.

**Implements**

IDataRecord.GetBytes

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.11. [MySqlDataReader.GetChar](#) Method

Gets the value of the specified column as a single character.

**Syntax: Visual Basic**

```

NotOverridable Public Function GetChar( _
    ByVal i As Integer _
) As Char _
-
    Implements IDataRecord.GetChar

```

**Syntax: C#**

```

public char GetChar(
    inti
);

```

**Parameters**

- **i**:

**Return Value**

**Implements**

IDataRecord.GetChar

**See Also**[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)21.2.7.1.4.1.13.1.1.12. [MySQLDataReader.GetChars](#) Method

Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetChars( _  
    ByVal i As Integer, _  
    ByVal fieldOffset As Long, _  
    ByVal buffer As Char(), _  
    ByVal bufferoffset As Integer, _  
    ByVal length As Integer _  
) As Long _  
-  
    Implements IDataRecord.GetChars
```

**Syntax: C#**

```
public long GetChars(  
    inti,  
    longfieldOffset,  
    char[]buffer,  
    intbufferoffset,  
    intlength  
);
```

**Parameters**

- `i`:
- `fieldOffset`:
- `buffer`:
- `bufferoffset`:
- `length`:

**Return Value****Implements**

IDataRecord.GetChars

**See Also**[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)21.2.7.1.4.1.13.1.1.13. [MySQLDataReader.GetDataTypeName](#) Method

Gets the name of the source data type.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetDataTypeName( _  
    ByVal i As Integer _  
) As String _  
-
```

Implements `IDataRecord.GetDataTypeName`

**Syntax: C#**

```
public string GetDataTypeName(  
    inti  
);
```

**Parameters**

- `i`:

**Return Value****Implements**

`IDataRecord.GetDataTypeName`

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.14. `MySqlDataReader.GetDateTime` Method

**Syntax: Visual Basic**

```
NotOverridable Public Function GetDateTime( _  
    ByVal index As Integer _  
) As Date _  
—  
Implements IDataRecord.GetDateTime
```

**Syntax: C#**

```
public DateTime GetDateTime(  
    int index  
);
```

**Implements**

`IDataRecord.GetDateTime`

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.15. `MySqlDataReader.GetDecimal` Method

**Syntax: Visual Basic**

```
NotOverridable Public Function GetDecimal( _  
    ByVal index As Integer _  
) As Decimal _  
—  
Implements IDataRecord.GetDecimal
```

**Syntax: C#**

```
public decimal GetDecimal(  
    int index  
);
```

**Implements**

`IDataRecord.GetDecimal`

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.16. [MySQLDataReader.GetDouble](#) Method

##### Syntax: Visual Basic

```
NotOverridable Public Function GetDouble( _  
    ByVal index As Integer _  
) As Double _  
-  
    Implements IDataRecord.GetDouble
```

##### Syntax: C#

```
public double GetDouble(  
    int index  
);
```

##### Implements

IDataRecord.GetDouble

##### See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.17. [MySQLDataReader.GetFieldType](#) Method

Gets the Type that is the data type of the object.

##### Syntax: Visual Basic

```
NotOverridable Public Function GetFieldType( _  
    ByVal i As Integer _  
) As Type _  
-  
    Implements IDataRecord.GetFieldType
```

##### Syntax: C#

```
public Type GetFieldType(  
    inti  
);
```

##### Parameters

- `i`:

##### Return Value

##### Implements

IDataRecord.GetFieldType

##### See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.18. [MySQLDataReader.GetFloat](#) Method

##### Syntax: Visual Basic

```
NotOverridable Public Function GetFloat( _  
    ByVal index As Integer _  
) As Single _  
-  
    Implements IDataRecord.GetFloat
```

**Syntax: C#**

```
public float GetFloat(  
    int index  
);
```

**Implements**

IDataRecord.GetFloat

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.19. [MySqlDataReader.GetGuid](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetGuid( _  
    ByVal index As Integer _  
) As Guid _  
—  
    Implements IDataRecord.GetGuid
```

**Syntax: C#**

```
public Guid GetGuid(  
    int index  
);
```

**Implements**

IDataRecord.GetGuid

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.20. [MySqlDataReader.GetInt16](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetInt16( _  
    ByVal index As Integer _  
) As Short _  
—  
    Implements IDataRecord.GetInt16
```

**Syntax: C#**

```
public short GetInt16(  
    int index  
);
```

**Implements**

IDataRecord.GetInt16

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.21. [MySqlDataReader.GetInt32](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetInt32( _
```

```
    ByVal index As Integer _  
) As Integer _  
-  
    Implements IDataRecord.GetInt32
```

**Syntax: C#**

```
public int GetInt32(  
    int index  
);
```

**Implements**

IDataRecord.GetInt32

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.22. [MySQLDataReader.GetInt64](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetInt64( _  
    ByVal index As Integer _  
) As Long _  
-  
    Implements IDataRecord.GetInt64
```

**Syntax: C#**

```
public long GetInt64(  
    int index  
);
```

**Implements**

IDataRecord.GetInt64

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.23. [MySQLDataReader.GetMySqlDateTime](#) Method**Syntax: Visual Basic**

```
Public Function GetMySqlDateTime( _  
    ByVal index As Integer _  
) As MySqlDateTime
```

**Syntax: C#**

```
public MySqlDateTime GetMySqlDateTime(  
    int index  
);
```

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.24. [MySQLDataReader.GetName](#) Method

Gets the name of the specified column.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetName( _  
    ByVal i As Integer _  
    ) As String _  
-  
    Implements IDataRecord.GetName
```

**Syntax: C#**

```
public string GetName(  
    inti  
    );
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.GetName

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.1.25. [MySqlDataReader.GetOrdinal](#) Method

Gets the column ordinal, given the name of the column.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetOrdinal( _  
    ByVal name As String _  
    ) As Integer _  
-  
    Implements IDataRecord.GetOrdinal
```

**Syntax: C#**

```
public int GetOrdinal(  
    stringname  
    );
```

**Parameters**

- `name`:

**Return Value****Implements**

IDataRecord.GetOrdinal

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.13.1.1.1.26. [MySqlDataReader.GetSchemaTable](#) Method

Returns a DataTable that describes the column metadata of the MySqlDataReader.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetSchemaTable() As DataTable _  
-
```

---

```
Implements IDataReader.GetSchemaTable
```

**Syntax: C#**

```
public DataTable GetSchemaTable();
```

**Return Value****Implements**

IDataReader.GetSchemaTable

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.27. [MySQLDataReader.GetString](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetString( _  
    ByVal index As Integer _  
) As String _  
—  
Implements IDataRecord.GetString
```

**Syntax: C#**

```
public string GetString(  
    int index  
);
```

**Implements**

IDataRecord.GetString

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.28. [MySQLDataReader.GetTimeSpan](#) Method**Syntax: Visual Basic**

```
Public Function GetTimeSpan( _  
    ByVal index As Integer _  
) As TimeSpan
```

**Syntax: C#**

```
public TimeSpan GetTimeSpan(  
    int index  
);
```

**See Also**

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.29. [MySQLDataReader.GetUInt16](#) Method**Syntax: Visual Basic**

```
Public Function GetUInt16( _  
    ByVal index As Integer _  
) As UInt16
```

**Syntax: C#**

```
public ushort GetUInt16(  
    int index  
);
```

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.30. [MySqlDataReader.GetUInt32](#) Method**Syntax: Visual Basic**

```
Public Function GetUInt32( _  
    ByVal index As Integer _  
    ) As UInt32
```

**Syntax: C#**

```
public uint GetUInt32(  
    int index  
);
```

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.31. [MySqlDataReader.GetUInt64](#) Method**Syntax: Visual Basic**

```
Public Function GetUInt64( _  
    ByVal index As Integer _  
    ) As UInt64
```

**Syntax: C#**

```
public ulong GetUInt64(  
    int index  
);
```

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.32. [MySqlDataReader.GetValue](#) Method

Gets the value of the specified column in its native format.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetValue( _  
    ByVal i As Integer _  
    ) As Object _  
    Implements IDataRecord.GetValue
```

**Syntax: C#**

```
public object GetValue(  
    int i  
);
```

**Parameters**

- *i*:

**Return Value**

**Implements**

IDataRecord.GetValue

**See Also**[MySQLDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)21.2.7.1.4.1.13.1.1.1.33. [MySQLDataReader.GetValue](#) Method

Gets all attribute columns in the collection for the current row.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetValue( _  
    ByVal values As Object() _  
) As Integer _  
-  
    Implements IDataRecord.GetValue
```

**Syntax: C#**

```
public int GetValue(  
    object[] values  
);
```

**Parameters**

- `values`:

**Return Value****Implements**

IDataRecord.GetValue

**See Also**[MySQLDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)21.2.7.1.4.1.13.1.1.1.34. [MySQLDataReader.IsDBNull](#) Method

Gets a value indicating whether the column contains non-existent or missing values.

**Syntax: Visual Basic**

```
NotOverridable Public Function IsDBNull( _  
    ByVal i As Integer _  
) As Boolean _  
-  
    Implements IDataRecord.IsDBNull
```

**Syntax: C#**

```
public bool IsDBNull(  
    int i  
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.IsDBNull

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.35. [MySqlDataReader.NextResult](#) Method

Advances the data reader to the next result, when reading the results of batch SQL statements.

**Syntax: Visual Basic**

```
NotOverridable Public Function NextResult() As Boolean _  
-  
    Implements IDataReader.NextResult
```

**Syntax: C#**

```
public bool NextResult();
```

**Return Value**

**Implements**

IDataReader.NextResult

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.1.1.1.36. [MySqlDataReader.Read](#) Method

Advances the MySqlDataReader to the next record.

**Syntax: Visual Basic**

```
NotOverridable Public Function Read() As Boolean _  
-  
    Implements IDataReader.Read
```

**Syntax: C#**

```
public bool Read();
```

**Return Value**

**Implements**

IDataReader.Read

**See Also**

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.4.1.13.2. [MySqlCommand.ExecuteReader](#) Method

**Syntax: Visual Basic**

```
Overloads Public Function ExecuteReader( _  
    ByVal behavior As CommandBehavior _  
) As MySqlDataReader
```

**Syntax: C#**

```
public MySqlDataReader ExecuteReader(  
    CommandBehaviorbehavior
```

```
);
```

**See Also**

[MySQLCommand Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLCommand.ExecuteReader Overload List](#)

21.2.7.1.4.1.14. [MySQLCommand.ExecuteScalar](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function ExecuteScalar() As Object _  
- Implements IDbCommand.ExecuteScalar
```

**Syntax: C#**

```
public object ExecuteScalar();
```

**Implements**

IDbCommand.ExecuteScalar

#### 21.2.7.1.5.1. MySqlCommandBuilder Members

[MySqlCommandBuilder overview](#)

#### Public Static (Shared) Methods

<a href="#">DeriveParameters</a>	Overloaded. Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.
----------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

#### Public Instance Constructors

<a href="#">MySqlCommandBuilder</a>	Overloaded. Initializes a new instance of the MySqlCommandBuilder class.
-------------------------------------	--------------------------------------------------------------------------

#### Public Instance Properties

Container (inherited from Component)	Gets the IContainer that contains the Component.
<a href="#">DataAdapter</a>	
<a href="#">QuotePrefix</a>	
<a href="#">QuoteSuffix</a>	
Site (inherited from Component)	Gets or sets the ISite of the Component.

#### Public Instance Methods

CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose (inherited from Component)	Releases all resources used by the Component.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
<a href="#">GetDeleteCommand</a>	
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetInsertCommand</a>	
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
<a href="#">GetUpdateCommand</a>	
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.

<a href="#">RefreshSchema</a>	
ToString (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.

### Public Instance Events

Disposed (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
-------------------------------------	-------------------------------------------------------------------------

### See Also

[MySQLCommandBuilder Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.5.1.1. DeriveParameters Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

### Overload List

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

- [public static void DeriveParameters\(MySqlCommand\);](#)
- [public static void DeriveParameters\(MySqlCommand,bool\);](#)

### See Also

[MySQLCommandBuilder Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.5.1.1.1. [MySQLCommandBuilder.DeriveParameters](#) Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

### Syntax: Visual Basic

```
Overloads Public Shared Sub DeriveParameters( _
    ByVal command As MySqlCommand _
)
```

### Syntax: C#

```
public static void DeriveParameters(
    MySqlCommand command
);
```

### Parameters

- [command](#): The MySqlCommand referencing the stored procedure from which the parameter information is to be derived. The derived parameters are added to the Parameters collection of the MySqlCommand.

### Exceptions

Exception Type	Condition
----------------	-----------

InvalidOperationException	The command text is not a valid stored procedure name.
---------------------------	--------------------------------------------------------

21.2.7.1.5.1.2.2.1.1. [MySQLDataAdapter](#) Members

[MySQLDataAdapter overview](#)

**Public Instance Constructors**

<a href="#">MySQLDataAdapter</a>	Overloaded. Initializes a new instance of the <a href="#">MySQLDataAdapter</a> class.
----------------------------------	---------------------------------------------------------------------------------------

**Public Instance Properties**

<a href="#">AcceptChangesDuringFill</a> (inherited from <a href="#">DataAdapter</a> )	Gets or sets a value indicating whether <a href="#">AcceptChanges</a> is called on a <a href="#">DataRow</a> after it is added to the <a href="#">DataTable</a> during any of the Fill operations.
---------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

AcceptChangesDuringUpdate (inherited from DataAdapter)	Gets or sets whether AcceptChanges is called during a Update.
Container (inherited from Component)	Gets the IContainer that contains the Component.
ContinueUpdateOnError (inherited from DataAdapter)	Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update.
<a href="#">DeleteCommand</a>	Overloaded.
FillLoadOption (inherited from DataAdapter)	Gets or sets the LoadOption that determines how the adapter fills the DataTable from the DbDataReader.
<a href="#">InsertCommand</a>	Overloaded.
MissingMappingAction (inherited from DataAdapter)	Determines the action to take when incoming data does not have a matching table or column.
MissingSchemaAction (inherited from DataAdapter)	Determines the action to take when existing DataSet schema does not match incoming data.
ReturnProviderSpecificTypes (inherited from DataAdapter)	Gets or sets whether the Fill method should return provider-specific values or common CLS-compliant values.
<a href="#">SelectCommand</a>	Overloaded.
Site (inherited from Component)	Gets or sets the ISite of the Component.
TableMappings (inherited from DataAdapter)	Gets a collection that provides the master mapping between a source table and a DataTable.
UpdateBatchSize (inherited from DbDataAdapter)	Gets or sets a value that enables or disables batch processing support, and specifies the number of commands that can be executed in a batch.
<a href="#">UpdateCommand</a>	Overloaded.

### Public Instance Methods

CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose (inherited from Component)	Releases all resources used by the Component.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
Fill (inherited from DbDataAdapter)	Overloaded. Adds or refreshes rows in the DataSet to match those in the data source using the DataSet name, and creates a DataTable named "Table."
FillSchema (inherited from DbDataAdapter)	Overloaded. Configures the schema of the specified DataTable based on the specified SchemaType.
GetFillParameters (inherited from DbDataAdapter)	Gets the parameters set by the user when executing an SQL <code>SELECT</code> statement.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.

GetType (inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
ResetFillLoadOption (inherited from DataAdapter)	Resets FillLoadOption to its default state and causes Fill to honor AcceptChangesDuringFill.
ShouldSerializeAcceptChangesDuringFill (inherited from DataAdapter)	Determines whether the AcceptChangesDuringFill property should be persisted.
ShouldSerializeFillLoadOption (inherited from DataAdapter)	Determines whether the FillLoadOption property should be persisted.
ToString (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.
Update (inherited from DbDataAdapter)	Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the specified DataSet.

### Public Instance Events

Disposed (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
FillError (inherited from DataAdapter)	Returned when an error occurs during a fill operation.
<a href="#">RowUpdated</a>	Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.
<a href="#">RowUpdating</a>	Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

### Protected Internal Instance Properties

FillCommandBehavior (inherited from DbDataAdapter)	Gets or sets the behavior of the command used to fill the data adapter.
----------------------------------------------------	-------------------------------------------------------------------------

21.2.7.1.5.1.2.2.1.1.6. [MySqlDataAdapter.RowUpdated](#) Event

Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.

**Syntax: Visual Basic**

```
Public Event RowUpdated As MySqlRowUpdatedEventHandler
```

**Syntax: C#**

```
public event MySqlRowUpdatedEventHandler RowUpdated;
```

**Event Data**

The event handler receives an argument of type [MySqlRowUpdatedEventArgs](#) containing data related to this event. The following [MySqlRowUpdatedEventArgsproperties](#) provide information specific to this event.

Property	Description
<a href="#">Command</a>	Gets or sets the MySqlCommand executed when Update is called.
Errors	Gets any errors generated by the .NET Framework data provider when the Commandwas executed.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row	Gets the DataRow sent through an Update.
RowCount	Gets the number of rows processed in a batch of updated records.
StatementType	Gets the type of SQL statement executed.
Status	Gets the UpdateStatus of the Commandproperty.
TableMapping	Gets the DataTableMapping sent through an Update.

<a href="#">MySqlRowUpdatedEventArgs Constructor</a>	Initializes a new instance of the <a href="#">MySqlRowUpdatedEventArgs</a> class.
------------------------------------------------------	-----------------------------------------------------------------------------------

**Public Instance Properties**

<a href="#">Command</a>	Overloaded. Gets or sets the <a href="#">MySqlCommand</a> executed when Update is called.
Errors (inherited from <a href="#">RowUpdatedEventArgs</a> )	Gets any errors generated by the .NET Framework data provider when the <a href="#">Command</a> was executed.
RecordsAffected (inherited from <a href="#">RowUpdatedEventArgs</a> )	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row (inherited from <a href="#">RowUpdatedEventArgs</a> )	Gets the <a href="#">DataRow</a> sent through an Update.

RowCount (inherited from RowUpdatedEventArgs)	Gets the number of rows processed in a batch of updated records.
StatementType (inherited from RowUpdatedEventArgs)	Gets the type of SQL statement executed.
Status (inherited from RowUpdatedEventArgs)	Gets the UpdateStatus of the Commandproperty.
TableMapping (inherited from RowUpdatedEventArgs)	Gets the DataTableMappingsent through an Update.

### Public Instance Methods

CopyToRows (inherited from RowUpdatedEventArgs)	Overloaded. Copies references to the modified rows into the provided array.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

#### 21.2.7.1.5.1.2.2.1.1.6.1.1.1.1. MySQLRowUpdatedEventArgs Constructor

Initializes a new instance of the MySQLRowUpdatedEventArgs class.

#### Syntax: Visual Basic

```
Public Sub New( _
    ByVal row As DataRow, _
    ByVal command As IDbCommand, _
    ByVal statementType As StatementType, _
    ByVal tableMapping As DataTableMapping _
)
```

#### Syntax: C#

```
public MySQLRowUpdatedEventArgs(
    DataRow row,
    IDbCommand command,
    StatementType statementType,
    DataTableMapping tableMapping
);
```

#### Parameters

- `row`: The DataRow sent through an Update.
- `command`: The IDbCommand executed when Update is called.
- `statementType`: One of the StatementType values that specifies the type of query executed.
- `tableMapping`: The DataTableMapping sent through an Update.

21.2.7.1.5.1.2.2.1.1.7. [MySqlDataAdapter.RowUpdating](#) Event

Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

**Syntax: Visual Basic**

```
Public Event RowUpdating As MySqlRowUpdatingEventHandler
```

**Syntax: C#**

```
public event MySqlRowUpdatingEventHandler RowUpdating;
```

**Event Data**

The event handler receives an argument of type [MySqlRowUpdatingEventArgs](#) containing data related to this event. The following [MySqlRowUpdatingEventArgsproperties](#) provide information specific to this event.

Property	Description
<a href="#">Command</a>	Gets or sets the MySqlCommand to execute when performing the Update.
Errors	Gets any errors generated by the .NET Framework data provider when the Command executes.
Row	Gets the DataRow that will be sent to the server as part of an insert, update, or delete operation.
StatementType	Gets the type of SQL statement to execute.
Status	Gets or sets the UpdateStatus of the Commandproperty.
TableMapping	Gets the DataTableMapping to send through the Update.

#### 21.2.7.1.5.1.2.2.1.1.7.1.1.1.1. MySQLRowUpdatingEventArgs Constructor

Initializes a new instance of the MySQLRowUpdatingEventArgs class.

### Syntax: Visual Basic

```
Public Sub New( _
    ByVal row As DataRow, _
    ByVal command As IDbCommand, _
    ByVal statementType As StatementType, _
    ByVal tableMapping As DataTableMapping _
)
```

### Syntax: C#

```
public MySQLRowUpdatingEventArgs(
    DataRowrow,
    IDbCommandcommand,
    StatementTypestatementType,
    DataTableMappingtableMapping
);
```

### Parameters

- `row`: The DataRowto Update.
- `command`: The IDbCommandto execute during Update.
- `statementType`: One of the StatementTypevalues that specifies the type of query executed.
- `tableMapping`: The DataTableMappingssent through an Update.

## 21.2.7.1.5.1.4. QuotePrefix Property

**Syntax: Visual Basic**

```
Public Property QuotePrefix As String
```

**Syntax: C#**

```
public string QuotePrefix {get; set;}
```

**See Also**

[MySqlCommandBuilder Class](#),  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.5.1.5. QuoteSuffix Property

**Syntax: Visual Basic**

```
Public Property QuoteSuffix As String
```

**Syntax: C#**

```
public string QuoteSuffix {get; set;}
```

**See Also**

[MySqlCommandBuilder Class](#),  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.5.1.6. MySqlCommandBuilder.GetDeleteCommand Method

**Syntax: Visual Basic**

```
Public Function GetDeleteCommand() As MySqlCommand
```

**Syntax: C#**

```
public MySqlCommand GetDeleteCommand();
```

**See Also**

[MySqlCommandBuilder Class](#),  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.5.1.7. MySqlCommandBuilder.GetInsertCommand Method

**Syntax: Visual Basic**

```
Public Function GetInsertCommand() As MySqlCommand
```

**Syntax: C#**

```
public MySqlCommand GetInsertCommand();
```

**See Also**

[MySqlCommandBuilder Class](#),  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.5.1.8. MySqlCommandBuilder.GetUpdateCommand Method

**Syntax: Visual Basic**

```
Public Function GetUpdateCommand() As MySqlCommand
```

**Syntax: C#**

```
public MySqlCommand GetUpdateCommand();
```

**See Also**

[MySqlCommandBuilder Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.5.1.9. [MySqlCommandBuilder.RefreshSchema](#) Method**Syntax: Visual Basic**

```
Public Sub RefreshSchema()
```

**Syntax: C#**

```
public void RefreshSchema();
```

**See Also**

[MySqlCommandBuilder Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.6. [MySqlException](#) Class

The exception that is thrown when MySQL returns an error. This class cannot be inherited.

For a list of all members of this type, see [MySqlException Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlException_  
    Inherits SystemException
```

**Syntax: C#**

```
public sealed class MySqlException : SystemException
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

[MySqlException Members](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.6.1. [MySqlException](#) Members

[MySqlException overview](#)

**Public Instance Properties**

Data (inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.

InnerException (inherited from Exception)	Gets the <a href="#">Exceptioninstance</a> that caused the current exception.
Message (inherited from Exception)	Gets a message that describes the current exception.
<a href="#">Number</a>	Gets a number that identifies the type of error. This number corresponds to the error numbers given in <a href="#">Section C.3, "Server Error Codes and Messages"</a> .
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

### Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Exception)	Gets the runtime type of the current instance.
ToString (inherited from Exception)	Creates and returns a string representation of the current exception.

#### 21.2.7.1.6.1.1. Number Property

Gets a number that identifies the type of error.

#### Syntax: Visual Basic

```
Public ReadOnly Property Number As Integer
```

#### Syntax: C#

```
public int Number {get;}
```

### See Also

[MySQLException Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 21.2.7.1.7. MySQLHelper Class

Helper class that makes it easier to work with the provider.

For a list of all members of this type, see [MySqlHelper Members](#) .

### Syntax: Visual Basic

```
NotInheritable Public Class MySqlHelper
```

### Syntax: C#

```
public sealed class MySqlHelper
```

### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

### Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

### See Also

[MySqlHelper Members](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.7.1. [MySqlHelper](#) Members

[MySqlHelper overview](#)

#### Public Static (Shared) Methods

<a href="#">ExecuteDataRow</a>	Executes a single SQL statement and returns the first row of the resultset. A new <a href="#">MySqlConnection</a> object is created, opened, and closed during this method.
<a href="#">ExecuteDataset</a>	Overloaded. Executes a single SQL statement and returns the resultset in a <a href="#">DataSet</a> . A new <a href="#">MySqlConnection</a> object is created, opened, and closed during this method.
<a href="#">ExecuteNonQuery</a>	Overloaded. Executes a single command against a MySQL database. The <a href="#">MySqlConnection</a> is assumed to be open when the method is called and remains open after the method completes.
<a href="#">ExecuteReader</a>	Overloaded. Executes a single command against a MySQL database.
<a href="#">ExecuteScalar</a>	Overloaded. Execute a single command against a MySQL database.
<a href="#">UpdateDataSet</a>	Updates the given table with data from the given <a href="#">DataSet</a>

#### Public Instance Methods

<a href="#">Equals</a> (inherited from <a href="#">Object</a> )	Determines whether the specified <a href="#">Object</a> is equal to the current <a href="#">Object</a> .
<a href="#">GetHashCode</a> (inherited from <a href="#">Object</a> )	Serves as a hash function for a particular type. <a href="#">GetHashCode</a> is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetType</a> (inherited from <a href="#">Object</a> )	Gets the <a href="#">Type</a> of the current instance.

ToString (inherited from Object)

Returns a String that represents the current Object.

**See Also**[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#)21.2.7.1.7.1.1. [MySQLHelper.ExecuteDataRow](#) Method

Executes a single SQL statement and returns the first row of the resultset. A new [MySQLConnection](#) object is created, opened, and closed during this method.

**Syntax: Visual Basic**

```
Public Shared Function ExecuteDataRow( _
    ByVal connectionString As String, _
    ByVal commandText As String, _
    ParamArray parms As MySqlParameter() _
) As DataRow
```

**Syntax: C#**

```
public static DataRow ExecuteDataRow(
    string connectionString,
    string commandText,
    params MySqlParameter[] parms
);
```

**Parameters**

- [connectionString](#): Settings to be used for the connection
- [commandText](#): Command to execute
- [parms](#): Parameters to use for the command

**Return Value**

DataRow containing the first row of the resultset

**See Also**[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#)21.2.7.1.7.1.2. [ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

**Overload List**

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

- [public static DataSet ExecuteDataset\(MySqlConnection,string\);](#)

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

- [public static DataSet ExecuteDataset\(MySqlConnection,string,params MySqlParameter\[\]\);](#)

Executes a single SQL statement and returns the resultset in a DataSet. A new [MySQLConnection](#) object is created, opened, and closed during this method.

- [public static DataSet ExecuteDataset\(string,string\);](#)

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

- [public static DataSet ExecuteDataset\(string, string, params MySqlParameter\[\]\)](#);

#### See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.7.1.2.1. [MySqlHelper.ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String _  
) As DataSet
```

#### Syntax: C#

```
public static DataSet ExecuteDataset(  
    MySqlConnection connection,  
    string commandText  
);
```

#### Parameters

- `connection`: [MySqlConnection](#) object to use
- `commandText`: Command to execute

#### Return Value

DataSet containing the resultset

#### See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteDataset Overload List](#)

#### 21.2.7.1.7.1.2.2. [MySqlHelper.ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As DataSet
```

#### Syntax: C#

```
public static DataSet ExecuteDataset(  
    MySqlConnection connection,  
    string commandText,  
    params MySqlParameter[] commandParameters  
);
```

#### Parameters

- `connection`: [MySqlConnection](#) object to use

- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

**Return Value**

DataSet containing the resultset

**See Also**

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteDataset Overload List](#)

**21.2.7.1.7.1.2.3. MySQLHelper.ExecuteDataset Method**

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connectionString As String, _  
    ByVal commandText As String _  
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(  
    string connectionString,  
    string commandText  
);
```

**Parameters**

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute

**Return Value**

DataSet containing the resultset

**See Also**

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteDataset Overload List](#)

**21.2.7.1.7.1.2.4. MySQLHelper.ExecuteDataset Method**

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(  
    string connectionString,  
    string commandText,  
    params MySqlParameter[] commandParameters  
);
```

**Parameters**

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

**Return Value**

DataSet containing the resultset

**See Also**

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteDataset Overload List](#)

## 21.2.7.1.7.1.3. ExecuteNonQuery Method

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

**Overload List**

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

- `public static int ExecuteNonQuery(MySqlConnection, string, params MySqlParameter[]);`

Executes a single command against a MySQL database. A new [MySqlConnection](#) is created using the [ConnectionString](#) given.

- `public static int ExecuteNonQuery(string, string, params MySqlParameter[]);`

**See Also**

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#)

21.2.7.1.7.1.3.1. [MySqlHelper.ExecuteNonQuery](#) Method

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteNonQuery( _
    ByVal connection As MySqlConnection, _
    ByVal commandText As String, _
    ParamArray commandParameters As MySqlParameter() _
) As Integer
```

**Syntax: C#**

```
public static int ExecuteNonQuery(
    MySqlConnection connection,
    string commandText,
    params MySqlParameter[] commandParameters
);
```

**Parameters**

- `connection`: [MySqlConnection](#) object to use
- `commandText`: SQL statement to be executed
- `commandParameters`: Array of [MySqlParameter](#) objects to use with the command.

## Return Value

## See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteNonQuery Overload List](#)

### 21.2.7.1.7.1.3.2. [MySQLHelper.ExecuteNonQuery](#) Method

Executes a single command against a MySQL database. A new [MySQLConnection](#) is created using the [ConnectionString](#) given.

## Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ParamArray parms As MySqlParameter() _  
    ) As Integer
```

## Syntax: C#

```
public static int ExecuteNonQuery(  
    string connectionString,  
    string commandText,  
    params MySqlParameter[] parms  
);
```

## Parameters

- `connectionString`: [ConnectionString](#) to use
- `commandText`: SQL statement to be executed
- `parms`: Array of [MySqlParameter](#) objects to use with the command.

## Return Value

## See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteNonQuery Overload List](#)

### 21.2.7.1.7.1.4. [ExecuteReader](#) Method

Executes a single command against a MySQL database.

## Overload List

Executes a single command against a MySQL database.

- [public static MySqlDataReader ExecuteReader\(string,string\);](#)

Executes a single command against a MySQL database.

- [public static MySqlDataReader ExecuteReader\(string,string,params MySqlParameter\[\]\);](#)

## See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#)

### 21.2.7.1.7.1.4.1. [MySQLHelper.ExecuteReader](#) Method

Executes a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteReader( _
    ByVal connectionString As String, _
    ByVal commandText As String _
) As MySqlDataReader
```

**Syntax: C#**

```
public static MySqlDataReader ExecuteReader(
    string connectionString,
    string commandText
);
```

**Parameters**

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use

**Return Value**

[MySqlDataReader](#) object ready to read the results of the command

**See Also**

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteReader Overload List](#)

21.2.7.1.7.1.4.2. [MySqlHelper.ExecuteReader](#) Method

Executes a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteReader( _
    ByVal connectionString As String, _
    ByVal commandText As String, _
    ParamArray commandParameters As MySqlParameter() _
) As MySqlDataReader
```

**Syntax: C#**

```
public static MySqlDataReader ExecuteReader(
    string connectionString,
    string commandText,
    params MySqlParameter[] commandParameters
);
```

**Parameters**

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use
- `commandParameters`: Array of [MySqlParameter](#) objects to use with the command

**Return Value**

[MySqlDataReader](#) object ready to read the results of the command

**See Also**

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteReader Overload List](#)

21.2.7.1.7.1.5. [ExecuteScalar](#) Method

Execute a single command against a MySQL database.

## Overload List

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(MySqlConnection,string\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(MySqlConnection,string,params MySqlParameter\[\]\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string,params MySqlParameter\[\]\);](#)

## See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.7.1.5.1. [MySqlHelper.ExecuteScalar](#) Method

Execute a single command against a MySQL database.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String _  
) As Object
```

#### Syntax: C#

```
public static object ExecuteScalar(  
    MySqlConnectionconnection,  
    stringcommandText  
);
```

#### Parameters

- `connection`: [MySqlConnection](#) object to use
- `commandText`: Command text to use for the command

#### Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

## See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteScalar Overload List](#)

### 21.2.7.1.7.1.5.2. [MySqlHelper.ExecuteScalar](#) Method

Execute a single command against a MySQL database.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(
    MySqlConnection connection,
    string commandText,
    params MySqlParameter[] commandParameters
);
```

**Parameters**

- `connection`: [MySqlConnection](#) object to use
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteScalar Overload List](#)

21.2.7.1.7.1.5.3. [MySqlHelper.ExecuteScalar](#) Method

Execute a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteScalar( _
    ByVal connectionString As String, _
    ByVal commandText As String _
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(
    string connectionString,
    string commandText
);
```

**Parameters**

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteScalar Overload List](#)

21.2.7.1.7.1.5.4. [MySqlHelper.ExecuteScalar](#) Method

Execute a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteScalar( _
    ByVal connectionString As String, _
    ByVal commandText As String, _
    ParamArray commandParameters As MySqlParameter() _
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(  
    string connectionString,  
    string commandText,  
    params MySqlParameter[] commandParameters  
);
```

**Parameters**

- `connectionString`: Settings to use for the command
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteScalar Overload List](#)

**21.2.7.1.7.1.6. `MySqlHelper.UpdateDataSet` Method**

Updates the given table with data from the given DataSet

**Syntax: Visual Basic**

```
Public Shared Sub UpdateDataSet( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ByVal ds As DataSet, _  
    ByVal tablename As String _  
)
```

**Syntax: C#**

```
public static void UpdateDataSet(  
    string connectionString,  
    string commandText,  
    DataSet ds,  
    string tablename  
);
```

**Parameters**

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update
- `ds`: DataSet containing the new data to use in the update
- `tablename`: Tablename in the data set to update

**See Also**

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.8. `MySqlErrorCode` Enumeration****Syntax: Visual Basic**

```
Public Enum MySqlErrorCode
```

**Syntax: C#**

```
public enum MySQLErrorCode
```

**Public Instance Constructors**

<a href="#">MySqlConversionException Constructor</a>	Ctor
------------------------------------------------------	------

**Public Instance Properties**

Data (inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the <a href="#">Exceptioninstance</a> that caused the current exception.
Message (inherited from Exception)	Gets a message that describes the current exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

**Public Instance Methods**

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Exception)	Gets the runtime type of the current instance.

ToString (inherited from Exception)	Creates and returns a string representation of the current exception.
-------------------------------------	-----------------------------------------------------------------------

**Protected Instance Properties**

HResult (inherited from Exception)	Gets or sets <a href="#">HRESULT</a> , a coded numeric value that is assigned to a specific exception.
------------------------------------	--------------------------------------------------------------------------------------------------------

**Protected Instance Methods**

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

**Public Static (Shared) Type Conversions**

<a href="#">Explicit MySqlDateTime to DateTime Conversion</a>	
---------------------------------------------------------------	--

**Public Instance Properties**

<a href="#">Day</a>	Returns the day portion of this datetime
<a href="#">Hour</a>	Returns the hour portion of this datetime
<a href="#">IsNull</a> (inherited from MySqlValue)	
<a href="#">IsValidDateTime</a>	Indicates if this object contains a value that can be represented as a DateTime
<a href="#">Minute</a>	Returns the minute portion of this datetime
<a href="#">Month</a>	Returns the month portion of this datetime
<a href="#">Second</a>	Returns the second portion of this datetime
<a href="#">Millisecond</a>	Returns the millisecond portion of this datetime
<a href="#">ValueAsObject</a> (inherited from MySqlValue)	Returns the value of this field as an object
<a href="#">Year</a>	Returns the year portion of this datetime

**Public Instance Methods**

<a href="#">Equals</a> (inherited from Object)	Determines whether the specified Object is equal to the current Object.
<a href="#">GetDateTime</a>	Returns this value as a DateTime
<a href="#">GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetType</a> (inherited from Object)	Gets the Type of the current instance.
<a href="#">ToString</a>	Returns a MySQL-specific string representation of this value

**Protected Instance Fields**

<a href="#">classType</a> (inherited from MySqlValue)	The system type represented by this value
<a href="#">dbType</a> (inherited from MySqlValue)	The generic dbtype of this value
<a href="#">isNull</a> (inherited from MySqlValue)	Is this value null
<a href="#">mysqlDbType</a> (inherited from MySqlValue)	The specific MySQL db type
<a href="#">mysqlTypeName</a> (inherited from MySqlValue)	The MySQL-specific typename of this value
<a href="#">objectValue</a> (inherited from MySqlValue)	

**Protected Instance Methods**

<a href="#">Finalize</a> (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
--------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------

MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.
-----------------------------------------	-----------------------------------------------

## 21.2.8. Connector/Net Support

The developers of Connector/Net greatly value the input of our users in the software development process. If you find Connector/Net lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in [Section 1.7, "How to Report Bugs or Problems"](#).

### 21.2.8.1. Connector/Net Community Support

- Community support for Connector/Net can be found through the forums at <http://forums.mysql.com>.
- Community support for Connector/Net can also be found through the mailing lists at <http://lists.mysql.com>.
- Paid support is available from Oracle. Additional information is available at <http://dev.mysql.com/support/>.

### 21.2.8.2. How to Report Connector/Net Problems or Bugs

If you encounter difficulties or problems with Connector/Net, contact the Connector/Net community, as explained in [Section 21.2.8.1, "Connector/Net Community Support"](#).

First try to execute the same SQL statements and commands from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in Connector/Net or MySQL.

If reporting a problem, ideally include the following information with the email:

- Operating system and version.
- Connector/Net version.
- MySQL server version.
- Copies of error messages or other unexpected output.
- Simple reproducible sample.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through <http://bugs.mysql.com/>.

## 21.2.9. Connector/Net FAQ

### Questions

- [22.2.9.1: \[2634\]](#) How do I obtain the value of an auto-incremented column?

### Questions and Answers

#### 22.2.9.1: How do I obtain the value of an auto-incremented column?

When using `CommandBuilder`, setting `ReturnGeneratedIdentifiers` property to `true` no longer works, as `CommandBuilder` does not add `last_insert_id()` by default.

`CommandBuilder` hooks up to the `DataAdapter.RowUpdating` event handler, which means it will get called for every row. It examines the command object and, if it is the same referenced object, it essentially rebuilds the object, thereby destroying your command text changes.

One approach to solving this problem is to clone the command object so you have a different actual reference:

```
dataAdapter.InsertCommand = cb.GetInsertCommand().Clone()
```

This will work, but since the `CommandBuilder` is still connected to the `DataAdapter`, the `RowUpdating` event will still fire and performance will be hit. To stop that, once all your commands have been added you need to disconnect the `CommandBuilder` from the `DataAdapter`:

```
cb.DataAdapter = null;
```

The last requirement is to make sure the `id` that is returned by `last_insert_id()` has the correct name. For example:

```
SELECT last_insert_id() AS id
```

A complete working example is shown here:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace GetAutoIncId
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "SELECT * FROM TestTable";

                MySqlDataAdapter da = new MySqlDataAdapter(sql, conn);
```

```

MySQLCommandBuilder cb = new MySQLCommandBuilder(da);

MySQLCommand cmd = new MySQLCommand();
cmd.Connection = conn;
cmd.CommandText = sql;
// use Cloned object to avoid .NET rebuilding the object, and
// thereby throwing away our command text additions.
MySQLCommand insertCmd = cb.GetInsertCommand().Clone();
insertCmd.CommandText = insertCmd.CommandText + ";SELECT last_insert_id() AS id";
insertCmd.UpdatedRowSource = UpdateRowSource.FirstReturnedRecord;
da.InsertCommand = insertCmd;
cb.DataAdapter = null; // Unhook RowUpdating event handler

DataTable dt = new DataTable();
da.Fill(dt);

DataRow row = dt.NewRow();
row["name"] = "Joe Smith";

dt.Rows.Add(row);
da.Update(dt);

System.Console.WriteLine("ID after update: " + row["id"]);
}
catch (Exception ex)
{
    Console.WriteLine(ex.ToString());
}

conn.Close();
Console.WriteLine("Done.");
}
}
}

```

## 21.3. MySQL Connector/J

This section explains how to configure and develop Java applications with MySQL Connector/J, the JDBC driver that is integrated with MySQL.

For release notes detailing the changes in each release of Connector/J, see [MySQL Connector/J Release Notes](#).

### 21.3.1. Overview of MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language through a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC Type 4 driver. Different versions are available that are compatible with the JDBC 3.0 and JDBC 4.0 specifications. The Type 4 designation means that the driver is a pure Java implementation of the MySQL protocol and does not rely on the MySQL client libraries.

For large-scale programs that use common design patterns of data access, consider using one of the popular persistence frameworks such as [Hibernate](#), [Spring's JDBC templates](#) or [Ibatis SQL Maps](#) to reduce the amount of JDBC code for you to debug, tune, secure, and maintain.

#### Key Topics

- For help with connection strings, connection options, and setting up your connection through JDBC, see [Section 21.3.5.1, "Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J"](#).

### 21.3.2. Connector/J Versions

There are currently four versions of MySQL Connector/J available:

- Connector/J 5.1 is the Type 4 pure Java JDBC driver, which conforms to the JDBC 3.0 and JDBC 4.0 specifications. It provides compatibility with all the functionality of MySQL, including 4.1, 5.0, 5.1, 5.4 and 5.5. Connector/J 5.1 provides ease of development features, including auto-registration with the Driver Manager, standardized validity checks, categorized SQLExceptions, support for the JDBC-4.0 XML processing, per connection client information, [NCHAR](#), [NVARCHAR](#) and [NCLOB](#) types. This release also includes all bug fixes up to and including Connector/J 5.0.6.
- Connector/J 5.0 provides support for all the functionality offered by Connector/J 3.1 and includes distributed transaction (XA) support.
- Connector/J 3.1 was designed for connectivity to MySQL 4.1 and MySQL 5.0 servers and provides support for all the functionality in MySQL 5.0 except distributed transaction (XA) support.
- Connector/J 3.0 provides core functionality and was designed for connectivity to MySQL 3.x or MySQL 4.1 servers, although it provides basic compatibility with later versions of MySQL. Connector/J 3.0 does not support server-side prepared statements, and does not support any of the features in versions of MySQL later than 4.1.

The following table summarizes the Connector/J versions available, along with the details of JDBC driver type, what version of the JDBC API it supports, what versions of MySQL Server it works with, and whether it is currently supported or not:

**Table 21.22. Summary of Connector/J Versions**

Connector/J version	Driver Type	JDBC version	MySQL Server version	Status
5.1	4	3.0, 4.0	4.1, 5.0, 5.1, 5.4, 5.5	Recommended version
5.0	4	3.0	4.1, 5.0	Released version
3.1	4	3.0	4.1, 5.0	Obsolete
3.0	4	3.0	3.x, 4.1	Obsolete

The current recommended version for Connector/J is 5.1. This guide covers all four connector versions, with specific notes given where a setting applies to a specific option.

### 21.3.2.1. Connector/J Release Notes and Change History

For details of new features and bug fixes in each Connector/J release, see the [MySQL Connector/J Release Notes](#).

### 21.3.2.2. Java Versions Supported

The following table summarizes what version of Java RTE is required to use Connector/J with Java applications, and what version of JDK is required to build Connector/J source code:

**Table 21.23. Summary of Java Versions Required by Connector/J**

Connector/J version	Java RTE required	JDK required (to build source code)
5.1	1.5.x, 1.6.x, 1.7.x	1.6.x and 1.5.x
5.0	1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.1	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.0	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x

If you are building Connector/J from source code using the source distribution (see [Section 21.3.3.4, "Installing from the Development Source Tree"](#)), you must use JDK 1.4.2 or newer to compile the Connector package. For Connector/J 5.1, you must have both JDK-1.6.x and JDK-1.5.x installed to be able to build the source code.

Java 1.7 support requires Connector/J 5.1.21 and higher. Several JDBC 4.1 methods were implemented for the first time in Connector/J 5.1.21.

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on a Java runtime older than 1.4 unless the class verifier is turned off (by setting the `-Xverify:none` option to the Java runtime). This is because the class verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use savepoint functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x.

### 21.3.3. Connector/J Installation

You can install the Connector/J package using either the binary or source distribution. The binary distribution provides the easiest method for installation; the source distribution lets you customize your installation further. With either solution, you manually add the Connector/J location to your Java `CLASSPATH`.

If you are upgrading from a previous version, read the upgrade information in [Section 21.3.3.3, “Upgrading from an Older Version”](#) before continuing.

Connector/J is also available as part of the Maven project. For more information, and to download the Connector/J JAR files, see the [Maven repository](#).

#### 21.3.3.1. Installing Connector/J from a Binary Distribution

For the easiest method of installation, use the binary distribution of the Connector/J package. The binary distribution is available either as a tar/gzip or zip file. Extract it to a suitable location, then optionally make the information about the package available by changing your `CLASSPATH` (see [Section 21.3.3.2, “Installing the Driver and Configuring the CLASSPATH”](#)).

MySQL Connector/J is distributed as a `.zip` or `.tar.gz` archive containing the sources, the class files, and the JAR archive named `mysql-connector-java-version-bin.jar`.

Starting with Connector/J 3.1.9, the `.class` files that constitute the JAR files are only included as part of the driver JAR file.

Starting with Connector/J 3.1.8, the archive also includes a debug build of the driver in a file named `mysql-connector-java-version-bin-g.jar`. Do not use the debug build of the driver unless instructed to do so when reporting a problem or a bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

Use the appropriate graphical or command-line utility to extract the distribution (for example, WinZip for the `.zip` archive, and `tar` for the `.tar.gz` archive). Because there are potentially long file names in the distribution, we use the GNU tar archive format. Use GNU tar (or an application that understands the GNU tar archive format) to unpack the `.tar.gz` variant of the distribution.

#### 21.3.3.2. Installing the Driver and Configuring the CLASSPATH

Once you have extracted the distribution archive, you can install the driver by placing `mysql-connector-java-version-bin.jar` in your classpath, either by adding the full path to it to your `CLASSPATH` environment variable, or by directly specifying it with the command line switch `-cp` when starting the JVM.

To use the driver with the JDBC `DriverManager`, use `com.mysql.jdbc.Driver` as the class that implements `java.sql.Driver`.

You can set the `CLASSPATH` environment variable under UNIX, Linux or Mac OS X either locally for a user within their `.profile`, `.login` or other login file. You can also set it globally by editing the global `/etc/profile` file.

For example, add the Connector/J driver to your `CLASSPATH` using one of the following forms, depending on your command shell:

```
# Bourne-compatible shell (sh, ksh, bash, zsh):
shell> export CLASSPATH=/path/mysql-connector-java-ver-bin.jar:$CLASSPATH

# C shell (csh, tcsh):
shell> setenv CLASSPATH /path/mysql-connector-java-ver-bin.jar:$CLASSPATH
```

Within Windows 2000, Windows XP, Windows Server 2003 and Windows Vista, you set the environment variable through the System Control Panel.

To use MySQL Connector/J with an application server such as GlassFish, Tomcat or JBoss, read your vendor's documentation for more information on how to configure third-party class libraries, as most application servers ignore the `CLASSPATH` environment variable. For configuration examples for some J2EE application servers, see [Section 21.3.7, "Connection Pooling with Connector/J"](#) [Section 21.3.8, "Load Balancing with Connector/J"](#), and [Section 21.3.9, "Failover with Connector/J"](#). However, the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's `.jar` file in the `WEB-INF/lib` subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the `MysqlDataSource` or `MysqlConnectionPoolDataSource` classes in the `com.mysql.jdbc.jdbc2.optional` package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the `javax.sql.XADataSource` interface is implemented using the `com.mysql.jdbc.jdbc2.optional.MysqlXADataSource` class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various `MysqlDataSource` classes support the following parameters (through standard set mutators):

- `user`
- `password`
- `serverName` (see the previous section about fail-over hosts)
- `databaseName`
- `port`

### 21.3.3.3. Upgrading from an Older Version

This section has information for users who are upgrading from one version of Connector/J to another, or to a new version of the MySQL server that supports a more recent level of JDBC. A newer version of Connector/J might include changes to support new features, improve existing functionality, or comply with new standards.

#### 21.3.3.3.1. Upgrading to MySQL Connector/J 5.1.x

- In Connector/J 5.0.x and earlier, the alias for a table in a `SELECT` statement is returned when accessing the result set metadata using `ResultSetMetaData.getColumnName()`. This behavior however is not JDBC compliant, and in Connector/J 5.1 this behavior was changed so that the original table name, rather than the alias, is returned.

The JDBC-compliant behavior is designed to let API users reconstruct the DML statement based on the metadata within `ResultSet` and `ResultSetMetaData`.

You can get the alias for a column in a result set by calling `ResultSetMetaData.getColumnLabel()`. To use the old noncompliant behavior with `ResultSetMetaData.getColumnName()`, use the `useOldAliasMetadataBehavior` option and set the value to `true`.

In Connector/J 5.0.x, the default value of `useOldAliasMetadataBehavior` was `true`, but in Connector/J 5.1 this was changed to a default value of `false`.

### 21.3.3.3.2. JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in `latin1` tables on the server.

Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in MySQL server version 4.1 or newer, add the following property to your connection URL:

```
useOldUTF8Behavior=true
```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

```
useServerPrepStmts=false
```

### 21.3.3.3.3. Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, `SQLState` codes returned in error messages by the server and various performance enhancements that can be enabled or disabled using configuration properties.

- **Unicode Character Sets:** See the next section, as well as [Section 10.1, "Character Set Support"](#), for information on this MySQL feature. If you have something misconfigured, it will usually show up as an error with a message similar to `Illegal mix of collations`.
- **Server-side Prepared Statements:** Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

Starting with version 3.1.7, the driver scans SQL you are preparing using all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing `emulateUnsupportedPstmts=false` in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the connection property `useServerPrepStmts=false`.

- **Datetimes** with all-zero components (`0000-00-00 ...`): These values cannot be represented reliably in Java. Connector/J 3.0.x always converted them to `NULL` when being read from a `ResultSet`.

Connector/J 3.1 throws an exception by default when these values are encountered, as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the `zeroDateTimeBehavior` configuration property. The permissible values are:

- `exception` (the default), which throws an `SQLException` with an `SQLState` of `S1009`.
- `convertToNull`, which returns `NULL` instead of the date.
- `round`, which rounds the date to the nearest closest value which is `0001-01-01`.

Starting with Connector/J 3.1.7, `ResultSet.getString()` can be decoupled from this behavior using `noDatetimeStringSync=true` (the default value is `false`) so that you can retrieve the unaltered all-zero value as a `String`. Note that this also precludes using any time zone conversions, therefore the driver will not allow you to enable `noDatetimeStringSync` and `useTimezone` at the same time.

- **New SQLState Codes:** Connector/J 3.1 uses SQL:1999 `SQLState` codes returned by the MySQL server (if supported), which are different from the legacy X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return `SQLStates` as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the configuration property `useSqlStateCodes=false`.
- **`ResultSet.getString()`:** Calling `ResultSet.getString()` on a `BLOB` column will now return the address of the `byte[]` array that represents it, instead of a `String` representation of the `BLOB`. `BLOB` values have no character set, so they cannot be converted to `java.lang.Strings` without data loss or corruption.

To store strings in MySQL with LOB behavior, use one of the `TEXT` types, which the driver will treat as a `java.sql.Clob`.

- **Debug builds:** Starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-version-bin-g.jar` is shipped alongside the normal binary jar file that is named `mysql-connector-java-version-bin.jar`.

Starting with Connector/J 3.1.9, we do not ship the `.class` files unbundled, they are only available in the JAR archives that ship with the driver.

Do not use the debug build of the driver unless instructed to do so when reporting a problem or bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

#### 21.3.3.4. Installing from the Development Source Tree

##### Caution

Read this section only if you are interested in helping us test our new code. To just get MySQL Connector/J up and running on your system, use a standard binary release distribution.

To install MySQL Connector/J from the development source tree, make sure that you have the following prerequisites:

- A Bazaar client, to check out the sources from our Launchpad repository (available from <http://bazaar-vcs.org/>).
- Apache Ant version 1.7 or newer (available from <http://ant.apache.org/>).
- JDK 1.4.2 or later. Although MySQL Connector/J can be used with older JDKs, compiling it from source requires at least JDK 1.4.2. To build Connector/J 5.1 requires JDK 1.6.x *and* an older JDK such as JDK 1.5.x; point your `JAVA_HOME` environment variable at the older installation.

To check out and compile a specific branch of MySQL Connector/J, follow these steps:

1. Check out the latest code from the branch that you want with one of the following commands.

The source code repository for MySQL Connector/J is located on Launchpad at <https://code.launchpad.net/connectorj>. To check out the latest development branch, use:

```
shell> bazaar branch lp:connectorj
```

This creates a `connectorj` subdirectory in the current directory that contains the latest sources for the requested branch.

To check out the latest 5.1 code, use:

```
shell> bazaar branch lp:connectorj/5.1
```

This creates a `5.1` subdirectory in the current directory containing the latest 5.1 code.

2. To build Connector/J 5.1, make sure that you have both JDK 1.6.x installed and an older JDK such as JDK 1.5.x. This is because Connector/J supports both JDBC 3.0 (which was prior to JDK 1.6.x) and JDBC 4.0. Set your `JAVA_HOME` environment variable to the path of the older JDK installation.
3. Change your current working directory to either the `connectorj` or `5.1` directory, depending on which branch you intend to build.
4. To build Connector/J 5.1, edit the `build.xml` to reflect the location of your JDK 1.6.x installation. The lines to change are:

```
<property name="com.mysql.jdbc.java6.javac" value="C:\jvms\jdk1.6.0\bin\javac.exe" />
<property name="com.mysql.jdbc.java6.rtar" value="C:\jvms\jdk1.6.0\jre\lib\rt.jar" />
```

Alternatively, you can set the value of these property names through the Ant `-D` option.

5. Issue the following command to compile the driver and create a `.jar` file suitable for installation:

```
shell> ant dist
```

This creates a `build` directory in the current directory, where all build output will go. A directory is created in the `build` directory that includes the version number of the sources you are building from. This directory contains the sources, compiled `.class` files, and a `.jar` file suitable for deployment. For other possible targets, including ones that will create a fully packaged distribution, issue the following command:

```
shell> ant -projecthelp
```

6. A newly created `.jar` file containing the JDBC driver will be placed in the directory `build/mysql-connector-java-version`.

Install the newly created JDBC driver as you would a binary `.jar` file that you download from MySQL, by following the instructions in [Section 21.3.3.2, "Installing the Driver and Configuring the CLASSPATH"](#).

A package containing both the binary and source code for Connector/J 5.1 can also be found at the following location: [Connector/J 5.1 Download](#)

## 21.3.4. Connector/J Examples

Examples of using Connector/J are located throughout this document. This section provides a summary and links to these examples.

- [Example 21.1, "Connector/J: Obtaining a connection from the DriverManager"](#)
- [Example 21.2, "Connector/J: Using java.sql.Statement to execute a SELECT query"](#)
- [Example 21.3, "Connector/J: Calling Stored Procedures"](#)
- [Example 21.4, "Connector/J: Using Connection.prepareCall\(\)"](#)

- [Example 21.5, “Connector/J: Registering output parameters”](#)
- [Example 21.6, “Connector/J: Setting `CallableStatement` input parameters”](#)
- [Example 21.7, “Connector/J: Retrieving results and output parameter values”](#)
- [Example 21.8, “Connector/J: Retrieving `AUTO\_INCREMENT` column values using `Statement.getGeneratedKeys\(\)`”](#)
- [Example 21.9, “Connector/J: Retrieving `AUTO\_INCREMENT` column values using `SELECT LAST\_INSERT\_ID\(\)`”](#)
- [Example 21.10, “Connector/J: Retrieving `AUTO\_INCREMENT` column values in `Updatable ResultSets`”](#)
- [Example 21.11, “Connector/J: Using a connection pool with a J2EE application server”](#)
- [Example 21.12, “Connector/J: Example of transaction with retry logic”](#)

## 21.3.5. Connector/J (JDBC) Reference

This section of the manual contains reference material for MySQL Connector/J.

### 21.3.5.1. Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements `java.sql.Driver` in MySQL Connector/J is `com.mysql.jdbc.Driver`. The `org.gjt.mm.mysql.Driver` class name is also usable for backward compatibility with MM.MySQL, the predecessor of Connector/J. Use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

#### JDBC URL Format

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets ([, ]) being optional:

```
jdbc:mysql://[host][,failoverhost...][:port]/[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

If the host name is not specified, it defaults to `127.0.0.1`. If the port is not specified, it defaults to `3306`, the default port number for MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

Here is a sample connection URL:

```
jdbc:mysql://localhost:3306/sakila?profileSQL=true
```

#### IPv6 Connections

For IPv6 connections, use this alternative syntax to specify hosts in the URL, `address=(key=value)`. Supported keys are:

- `(protocol=tcp)`, or `(protocol=pipe)` for named pipes on Windows.
- `(path=path_to_pipe)` for named pipes.
- `(host=hostname)` for TCP connections.
- `(port=port_number)` for TCP connections.

For example:

```
jdbc:mysql://address=(protocol=tcp)(host=localhost)(port=3306)(user=test)/db
```

Any other parameters are treated as host-specific properties that follow the conventions of the JDBC URL properties. This now allows per-host overrides of any configuration property for multi-host connections (that is, when using failover, load balancing, or replication). Limit the overrides to user, password, network timeouts and statement and metadata cache sizes; the results of other per-host overrides are not defined.

## Initial Database for Connection

If the database is not specified, the connection is made with no default database. In this case, either call the `setCatalog()` method on the Connection instance, or fully specify table names using the database name (that is, `SELECT dbname.tablename.colname FROM dbname.tablename...`) in your SQL. Opening a connection without specifying the database to use is generally only useful when building tools that work with multiple databases, such as GUI database managers.

### Note

Always use the `Connection.setCatalog()` method to specify the desired database in JDBC applications, rather than the `USE database` statement.

## Failover Support

MySQL Connector/J has failover support. This enables the driver to fail over to any number of slave hosts and still perform read-only queries. Failover only happens when the connection is in an `autoCommit(true)` state, because failover cannot happen reliably when a `transaction` is in progress. Most application servers and connection pools set `autoCommit` to `true` at the end of every transaction/connection use.

The failover functionality has the following behavior:

- If the URL property `autoReconnect` is `false`: Failover only happens at connection initialization, and fallback occurs when the driver determines that the first host has become available again.
- If the URL property `autoReconnect` is `true`: Failover happens when the driver determines that the connection has failed (checked before every query), and falls back to the first host when it determines that the host has become available again (after `queriesBeforeRetryMaster` queries have been issued).

In either case, whenever you are connected to a “failed-over” server, the connection is set to read-only state, so queries that attempt to modify data will throw exceptions (the query will **never** be processed by the MySQL server).

## Setting Configuration Properties

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a `DataSource` object or for a `Connection` object.

Configuration properties can be set in one of the following ways:

- Using the `set*()` methods on MySQL implementations of `java.sql.DataSource` (which is the preferred method when using implementations of `java.sql.DataSource`):
  - `com.mysql.jdbc.jdbc2.optional.MysqlDataSource`
  - `com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource`
- As a key/value pair in the `java.util.Properties` instance passed to `DriverManager.getConnection()` or `Driver.connect()`
- As a JDBC URL parameter in the URL given to `java.sql.DriverManager.getConnection()`, `java.sql.Driver.connect()` or the MySQL implementations of the `javax.sql.DataSource.setURL()` method.

**Note**

If the mechanism you use to configure a JDBC URL is XML-based, use the XML character literal `&amp;` to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following tables.

**Connection/Authentication.**

Property Name	Definition	Default Value	Since Version
user	The user to connect as		all versions
password	The password to use when connecting		all versions
socketFactory	The name of the class that the driver should use for creating socket connections to the server. This class must implement the interface 'com.mysql.jdbc.SocketFactory' and have public no-args constructor.	com.mysql.jdbc.StandardSocketFactory	
connectTimeout	Timeout for socket connect (in milliseconds), with 0 being no timeout. Only works on JDK-1.4 or newer. Defaults to '0'.	0	3.0.1
socketTimeout	Timeout on network socket operations (0, the default means no timeout).	0	3.0.1
connectionLifecycleInterceptors	A comma-delimited list of classes that implement "com.mysql.jdbc.ConnectionLifecycleInterceptor" that should notified of connection lifecycle events (creation, destruction, commit, rollback, setCatalog and setAutoCommit) and potentially alter the execution of these commands. ConnectionLifecycleInterceptors are "stackable", more than one interceptor may be specified via the configuration property as a comma-delimited list, with the interceptors executed in order from left to right.		5.1.4
useConfigs	Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation.		3.1.5
authenticationPlugins	Comma-delimited list of classes that implement com.mysql.jdbc.AuthenticationPlugin and which will be used for authentication unless disabled by "disabledAuthenticationPlugins" property.		5.1.19
defaultAuthenticationPlugin	Name of a class implementing com.mysql.jdbc.AuthenticationPlugin which will be used as the default authentication plugin (see below). It is an error to use a class which is not listed in "authenticationPlugins" nor it is one of the built-in plugins. It is an error to set as default a plugin which was disabled with "disabledAuthenticationPlugins" property. It is an error to set this value to null or the empty	com.mysql.jdbc.AuthenticationPlugin	5.1.19

	string (i.e. there must be at least a valid default authentication plugin specified for the connection, meeting all constraints listed above).		
disabledAuthenticationPlugins	Comma-delimited list of classes implementing com.mysql.jdbc.AuthenticationPlugin or mechanisms, i.e. "mysql_native_password". The authentication plugins or mechanisms listed will not be used for authentication which will fail if it requires one of them. It is an error to disable the default authentication plugin (either the one named by "defaultAuthenticationPlugin" property or the hard-coded one if "defaultAuthenticationPlugin" property is not set).		5.1.19
disconnectOnExpiredPasswords	If "disconnectOnExpiredPasswords" is set to "false" and password is expired then server enters "sandbox" mode and sends ERR(08001, ER_MUST_CHANGE_PASSWORD) for all commands that are not needed to set a new password until a new password is set.	true	5.1.23
interactiveClient	Set the CLIENT_INTERACTIVE flag, which tells MySQL to timeout connections based on INTERACTIVE_TIMEOUT instead of WAIT_TIMEOUT	false	3.1.0
localSocketAddress	Hostname or IP address given to explicitly configure the interface that the driver will bind the client side of the TCP/IP connection to when connecting.		5.0.5
propertiesTransform	An implementation of com.mysql.jdbc.ConnectionPropertiesTransform that the driver will use to modify URL properties passed to the driver before attempting a connection		3.1.4
useCompression	Use zlib compression when communicating with the server (true/false)? Defaults to 'false'.	false	3.0.17

**Networking.**

Property Name	Definition	Default Value	Since Version
maxAllowedPacket	Maximum allowed packet size to send to server. If not set, the value of system variable 'max_allowed_packet' will be used to initialize this upon connecting. This value will not take effect if set larger than the value of 'max_allowed_packet'.	-1	5.1.8
tcpKeepAlive	If connecting using TCP/IP, should the driver set SO_KEEPALIVE?	true	5.0.7
tcpNoDelay	If connecting using TCP/IP, should the driver set SO_TCP_NODELAY (disabling the Nagle Algorithm)?	true	5.0.7
tcpRcvBuf	If connecting using TCP/IP, should the driver set SO_RCV_BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7

tcpSndBuf	If connecting using TCP/IP, should the driver set SO_SND_BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7
tcpTrafficClass	If connecting using TCP/IP, should the driver set traffic class or type-of-service fields ?See the documentation for java.net.Socket.setTrafficClass() for more information.	0	5.0.7

**High Availability and Clustering.**

Property Name	Definition	Default Value	Since Version
autoReconnect	Should the driver try to re-establish stale and/or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connection, which belong to the current transaction, but will attempt reconnect before the next query issued on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to session state and data consistency when applications don't handle SQLExceptions properly, and is only designed to be used when you are unable to configure your application to handle SQLExceptions resulting from dead and stale connections properly. Alternatively, as a last option, investigate setting the MySQL server variable "wait_timeout" to a high value, rather than the default of 8 hours.	false	1.1
autoReconnectForPools	Use a reconnection strategy appropriate for connection pools (defaults to 'false')	false	3.1.3
failOverReadOnly	When failing over in autoReconnect mode, should the connection be set to 'read-only'?	true	3.0.12
maxReconnects	Maximum number of reconnects to attempt if autoReconnect is true, default is '3'.	3	1.1
reconnectAtTxEnd	If autoReconnect is set to true, should the driver attempt reconnections at the end of every transaction?	false	3.0.10
retriesAllDown	When using loadbalancing, the number of times the driver should cycle through available hosts, attempting to connect. Between cycles, the driver will pause for 250ms if no servers are available.	120	5.1.6
initialTimeout	If autoReconnect is enabled, the initial time to wait between re-connect attempts (in seconds, defaults to '2').	2	1.1
roundRobinLoadBalance	When autoReconnect is enabled, and failoverReadOnly is false, should we pick hosts to connect to on a round-robin basis?	false	3.1.2
queriesBeforeRetryMaster	Number of queries to issue before falling back to master when failed over (when using multi-host failover). Whichever condition is met first, 'queriesBeforeRetryMaster' or	50	3.0.2

	'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50.		
secondsBeforeRetryMaster	How long should the driver wait, when failed over, before attempting	30	3.0.2
selfDestructOnPingMaxOperations	If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connection's count of commands sent to the server exceeds this value.	0	5.1.6
selfDestructOnPingSecondsLifetime	If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connection's lifetime exceeds this value.	0	5.1.6
resourceId	A globally unique name that identifies the resource that this datasource or connection is connected to, used for XAResource.isSameRM() when the driver can't determine this value based on hostnames used in the URL		5.0.1

**Security.**

Property Name	Definition	Default Value	Since Version
allowMultiQueries	Allow the use of ';' to delimit multiple queries during one statement (true/false), defaults to 'false', and does not affect the addBatch() and executeBatch() methods, which instead rely on rewriteBatchStatements.	false	3.1.1
useSSL	Use SSL when communicating with the server (true/false), defaults to 'false'	false	3.0.2
requireSSL	Require SSL connection if useSSL=true? (defaults to 'false').	false	3.1.0
verifyServerCertificate	If "useSSL" is set to "true", should the driver verify the server's certificate? When using this feature, the keystore parameters should be specified by the "clientCertificateKeyStore*" properties, rather than system properties.	true	5.1.6
clientCertificateKeyStoreUrl	URL to the client certificate KeyStore (if not specified, use defaults)		5.1.0
clientCertificateKeyStoreType	KeyStore type for client certificates (NULL or empty means use the default, which is "JKS". Standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.	JKS	5.1.0
clientCertificateKeyStorePassword	Password for the client certificates KeyStore		5.1.0
trustCertificateKeyStoreUrl	URL to the trusted root certificate KeyStore (if not specified, use defaults)		5.1.0
trustCertificateKeyStoreType	KeyStore type for trusted root certificates (NULL or empty means use the default, which is "JKS". Standard keystore types supported by the JVM	JKS	5.1.0

	are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.		
trustCertificateKeyStorePassword	Password for the trusted root certificates KeyStore		5.1.0
allowLoadLocalInfile	Should the driver allow use of 'LOAD DATA LOCAL INFILE...' (defaults to 'true').	true	3.0.3
allowUrlInLocalInfile	Should the driver allow URLs in 'LOAD DATA LOCAL INFILE' statements?	false	3.1.4
paranoid	Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false')	false	3.0.1
passwordCharacterEncoding	What character encoding is used for passwords? Leaving this set to the default value (null), uses the platform character set, which works for ISO8859_1 (i.e. "latin1") passwords. For passwords in other character encodings, the encoding will have to be specified with this property, as it's not possible for the driver to auto-detect this.		5.1.7

**Performance Extensions.**

Property Name	Definition	Default Value	Since Version
callableStmtCacheSize	If 'cacheCallableStmts' is enabled, how many callable statements should be cached?	100	3.1.2
metadataCacheSize	The number of queries to cache ResultSetMetadata for if cacheResultSetMetaData is set to 'true' (default 50)	50	3.1.1
useLocalSessionState	Should the driver refer to the internal values of autocommit and transaction isolation that are set by Connection.setAutoCommit() and Connection.setTransactionIsolation() and transaction state as maintained by the protocol, rather than querying the database or blindly sending commands to the database for commit() or rollback() method calls?	false	3.1.7
useLocalTransactionState	Should the driver use the in-transaction state provided by the MySQL protocol to determine if a commit() or rollback() should actually be sent to the database?	false	5.1.7
prepStmtCacheSize	If prepared statement caching is enabled, how many prepared statements should be cached?	25	3.0.10
prepStmtCacheSqlLimit	If prepared statement caching is enabled, what's the largest SQL the driver will cache the parsing for?	256	3.0.10
parseInfoCacheFactory	Name of a class implementing com.mysql.jdbc.CacheAdapterFactory, which will be used to create caches for the parsed representation of client-side prepared statements.	com.mysql.jdbc.PerConnectionL	
serverConfigCacheFactory	Name of a class implementing com.mysql.jdbc.CacheAdapterFactory<String,	com.mysql.jdbc.PerVmServerCo	

	Map<String, String>>, which will be used to create caches for MySQL server configuration values		
alwaysSendSetIsolation	Should the driver always communicate with the database when Connection.setTransactionIsolation() is called? If set to false, the driver will only communicate with the database when the requested transaction isolation is different than the whichever is newer, the last value that was set via Connection.setTransactionIsolation(), or the value that was read from the server when the connection was established. Note that useLocalSessionState=true will force the same behavior as alwaysSendSetIsolation=false, regardless of how alwaysSendSetIsolation is set.	true	3.1.7
maintainTimeStats	Should the driver maintain various internal timers to enable idle time calculations as well as more verbose error messages when the connection to the server fails? Setting this property to false removes at least two calls to System.getCurrentTimeMillis() per query.	true	3.1.9
useCursorFetch	If connected to MySQL > 5.0.2, and setFetchSize() > 0 on a statement, should that statement use cursor-based fetching to retrieve rows?	false	5.0.0
blobSendChunkSize	Chunk to use when sending BLOB/CLOBs via ServerPreparedStatements	1048576	3.1.9
cacheCallableStmts	Should the driver cache the parsing stage of CallableStatements	false	3.1.2
cachePrepStmts	Should the driver cache the parsing stage of PreparedStatements of client-side prepared statements, the "check" for suitability of server-side prepared and server-side prepared statements themselves?	false	3.0.10
cacheResultSetMetadata	Should the driver cache ResultSetMetaData for Statements and PreparedStatements? (Req. JDK-1.4+, true/false, default 'false')	false	3.1.1
cacheServerConfiguration	Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis?	false	3.1.5
defaultFetchSize	The driver will call setFetchSize(n) with this value on all newly-created Statements	0	3.1.9
dontTrackOpenResources	The JDBC specification requires the driver to automatically track and close resources, however if your application doesn't do a good job of explicitly calling close() on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications.	false	3.1.7
dynamicCalendars	Should the driver retrieve the default calendar when required, or cache it per connection/session?	false	3.1.5

elideSetAutoCommits	If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state doesn't match the requested state by Connection.setAutoCommit(boolean)?	false	3.1.3
enableQueryTimeouts	When enabled, query timeouts set via Statement.setQueryTimeout() use a shared java.util.Timer instance for scheduling. Even if the timeout doesn't expire before the query is processed, there will be memory used by the TimerTask for the given timeout which won't be reclaimed until the time the timeout would have expired if it hadn't been cancelled by the driver. High-load environments might want to consider disabling this functionality.	true	5.0.6
holdResultsOpenOverStatementClose	Should the driver close result sets on Statement.close() as required by the JDBC specification?	false	3.1.7
largeRowSizeThreshold	What size result set row should the JDBC driver consider "large", and thus use a more memory-efficient way of representing the row internally?	2048	5.1.1
loadBalanceStrategy	If using a load-balanced connection to connect to SQL nodes in a MySQL Cluster/ NDB configuration (by using the URL prefix "jdbc:mysql:loadbalance://"), which load balancing algorithm should the driver use: (1) "random" - the driver will pick a random host for each request. This tends to work better than round-robin, as the randomness will somewhat account for spreading loads where requests vary in response time, while round-robin can sometimes lead to overloaded nodes if there are variations in response times across the workload. (2) "bestResponseTime" - the driver will route the request to the host that had the best response time for the previous transaction.	random	5.0.6
locatorFetchBufferSize	If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for getBinaryInputStream?	1048576	3.2.1
rewriteBatchedStatements	Should the driver use multiqueries (irregardless of the setting of "allowMultiQueries") as well as rewriting of prepared statements for INSERT into multi-value inserts when executeBatch() is called? Notice that this has the potential for SQL injection if using plain java.sql.Statements and your code doesn't sanitize input correctly. Notice that for prepared statements, server-side prepared statements can not currently take advantage of this rewrite option, and that if you don't specify stream lengths when using PreparedStatement.set*Stream(), the driver won't be able to determine the optimum number of parameters per batch and you might receive an error from the driver that the resultant packet is too large. Statement.getGeneratedKeys() for	false	3.1.13

	these rewritten statements only works when the entire batch includes INSERT statements.		
useDirectRowUnpack	Use newer result set row unpacking code that skips a copy from network buffers to a MySQL packet instance and instead reads directly into the result set row data buffers.	true	5.1.1
useDynamicCharsetInfo	Should the driver use a per-connection cache of character set information queried from the server when necessary, or use a built-in static mapping that is more efficient, but isn't aware of custom character sets or character sets implemented after the release of the JDBC driver?	true	5.0.6
useFastDateParsing	Use internal String->Date/Time/Timestamp conversion routines to avoid excessive object creation?	true	5.0.5
useFastIntParsing	Use internal String->Integer conversion routines to avoid excessive object creation?	true	3.1.4
useJvmCharsetConverters	Always use the character encoding routines built into the JVM, rather than using lookup tables for single-byte character sets?	false	5.0.1
useReadAheadInput	Use newer, optimized non-blocking, buffered input stream when reading from the server?	true	3.1.5

**Debugging/Profiling.**

Property Name	Definition	Default Value	Since Version
logger	The name of a class that implements "com.mysql.jdbc.log.Log" that will be used to log messages to. (default is "com.mysql.jdbc.log.StandardLogger", which logs to STDERR)	com.mysql.jdbc.log.Standard	
gatherPerfMetrics	Should the driver gather performance metrics, and report them via the configured logger every 'reportMetricsIntervalMillis' milliseconds?	false	3.1.2
profileSQL	Trace queries and their execution/fetch times to the configured logger (true/false) defaults to 'false'	false	3.1.0
profileSql	Deprecated, use 'profileSQL' instead. Trace queries and their execution/fetch times on STDERR (true/false) defaults to 'false'		2.0.14
reportMetricsIntervalMillis	If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)?	30000	3.1.2
maxQuerySizeToLog	Controls the maximum length/size of a query that will get logged when profiling or tracing	2048	3.1.3
packetDebugBufferSize	The maximum number of packets to retain when 'enablePacketDebug' is true	20	3.1.3
slowQueryThresholdMillis	If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'?	2000	3.1.2
slowQueryThresholdNanos	If 'useNanosForElapsedTime' is set to true, and this property is set to a non-zero value, the driver will use this threshold (in nanosecond units) to determine if a query was slow.	0	5.0.7

useUsageAdvisor	Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')?	false	3.1.1	
autoGenerateTestcaseScript	Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR?	false	3.1.9	
autoSlowLog	Instead of using slowQueryThreshold* to determine if a query is slow enough to be logged, maintain statistics that allow the driver to determine queries that are outside the 99th percentile?	true	5.1.4	
clientInfoProvider	The name of a class that implements the com.mysql.jdbc.JDBC4ClientInfoProvider interface in order to support JDBC-4.0's Connection.get/setClientInfo() methods	com.mysql.jdbc.JDBC4ClientInfoProvider		JDBC4Comments
dumpMetadataOnColumnNotFoundException	Should the driver dump the field-level metadata of a result set into the exception message when ResultSet.findColumn() fails?	false	3.1.13	
dumpQueriesOnException	Should the driver dump the contents of the query sent to the server in the message for SQLExceptions?	false	3.1.3	
enablePacketDebug	When enabled, a ring-buffer of 'packetDebugBufferSize' packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code	false	3.1.3	
explainSlowQueries	If 'logSlowQueries' is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level?	false	3.1.2	
includeInnodbStatusInDeadlockExceptions	Should the output of "SHOW ENGINE INNODB STATUS" in exception messages when deadlock exceptions are detected?	false	5.0.7	
includeThreadDumpInDeadlockExceptions	Should the current Java thread dump in exception messages when deadlock exceptions are detected?	false	5.1.15	
includeThreadNamesAsStatementComments	Should the name of the current thread as a comment visible in "SHOW PROCESSLIST", or in Innodb deadlock dumps, useful in correlation with "includeInnodbStatusInDeadlockExceptions=true" and "includeThreadDumpInDeadlockExceptions=true".	false	5.1.15	
logSlowQueries	Should queries that take longer than 'slowQueryThresholdMillis' be logged?	false	3.1.2	
logXaCommands	Should the driver log XA commands sent by MySQLXaConnection to the server, at the DEBUG level of logging?	false	5.0.5	
profilerEventHandler	Name of a class that implements the interface com.mysql.jdbc.profiler.ProfilerEventHandler that will be used to handle profiling/tracing events.	com.mysql.jdbc.profiler.LoggingProfilerEventHandler		Logging

resultSetSizeThreshold	If the usage advisor is enabled, how many rows should a result set contain before the driver warns that it is suspiciously large?	100	5.0.5
traceProtocol	Should trace-level network protocol be logged?	false	3.1.2
useNanosForElapsedTime	For profiling/debugging functionality that measures elapsed time, should the driver try to use nanoseconds resolution if available (JDK >= 1.5)?	false	5.0.7

**Miscellaneous.**

Property Name	Definition	Default Value	Since Version
useUnicode	Should the driver use Unicode character encodings when handling strings? Should only be used when the driver can't determine the character set mapping, or you are trying to 'force' the driver to use a character set that MySQL either doesn't natively support (such as UTF-8), true/false, defaults to 'true'	true	1.1g
characterEncoding	If 'useUnicode' is set to true, what character encoding should the driver use when dealing with strings? (defaults is to 'autodetect')		1.1g
characterSetResults	Character set to tell the server to return results as.		3.0.13
connectionAttributes	A comma-delimited list of user-defined key:value pairs (in addition to standard MySQL-defined key:value pairs) to be passed to MySQL Server for display as connection attributes in the PERFORMANCE_SCHEMA.SESSION_CONNECT_ATTRS table. Example usage: connectionAttributes=key1:value1,key2:value2 This functionality is available for use with MySQL Server version 5.6 or later only. Earlier versions of MySQL Server do not support connection attributes, causing this configuration option will be ignored. Setting connectionAttributes=none will cause connection attribute processing to be bypassed, for situations where Connection creation/initialization speed is critical.		5.1.25
connectionCollation	If set, tells the server to use this collation via 'set collation_connection'		3.0.13
useBlobToStoreUTF8OutsideBMP	Tells the driver to treat [MEDIUM/LONG]BLOB columns as [LONG]VARCHAR columns holding text encoded in UTF-8 that has characters outside the BMP (4-byte encodings), which MySQL server can't handle natively.	false	5.1.3
utf8OutsideBmpExcludedColumnNamePattern	When useBlobToStoreUTF8OutsideBMP is set to "true", column names matching the given regex will still be treated as BLOBs unless they match the regex specified for "utf8OutsideBmpIncludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.		5.1.3
utf8OutsideBmpIncludedColumnNamePattern	Used to specify exclusion rules to "utf8OutsideBmpExcludedColumnNamePattern".		5.1.3

	The regex must follow the patterns used for the java.util.regex package.		
loadBalanceEnableJMX	Enables JMX-based management of load-balanced connection groups, including live addition/removal of hosts from load-balancing pool.	false	5.1.13
sessionVariables	A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects.		3.1.8
useColumnNamesInFindColumn	Prior to JDBC-4.0, the JDBC specification had a bug related to what could be given as a "column name" to ResultSet methods like findColumn(), or getters that took a String property. JDBC-4.0 clarified "column name" to mean the label, as given in an "AS" clause and returned by ResultSetMetaData.getColumnLabel(), and if no AS clause, the column name. Setting this property to "true" will give behavior that is congruent to JDBC-3.0 and earlier versions of the JDBC specification, but which because of the specification bug could give unexpected results. This property is preferred over "useOldAliasMetadataBehavior" unless you need the specific behavior that it provides with respect to ResultSetMetadata.	false	5.1.7
allowNanAndInf	Should the driver allow NaN or +/- INF values in PreparedStatement.setDouble()?	false	3.1.5
autoClosePstmtStreams	Should the driver automatically call .close() on streams/readers passed as arguments via set*() methods?	false	3.1.12
autoDeserialize	Should the driver automatically detect and de-serialize objects stored in BLOB fields?	false	3.1.5
blobsAreStrings	Should the driver always treat BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
capitalizeTypeNames	Capitalize type names in DatabaseMetaData? (usually only useful when using WebObjects, true/false, defaults to 'false')	true	2.0.7
clobCharacterEncoding	The character encoding to use for sending and retrieving TEXT, MEDIUMTEXT and LONGTEXT values instead of the configured connection characterEncoding		5.0.0
clobberStreamingResults	This will cause a 'streaming' ResultSet to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.	false	3.0.9
compensateOnDuplicateKeyUpdateCounts	Should the driver compensate for the update counts of "ON DUPLICATE KEY" INSERT statements (2 = 1, 0 = 1) when using prepared statements?	false	5.1.7

continueBatchOnError	Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true').	true	3.0.3
createDatabaseIfNotExist	Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases.	false	3.1.9
emptyStringsConvertToZero	Should the driver allow conversions from empty string fields to numeric values of '0'?	true	3.1.8
emulateLocators	Should the driver emulate java.sql.Blobs with locators? With this feature enabled, the driver will delay loading the actual Blob data until the one of the retrieval methods (getInputStream(), getBytes(), and so forth) on the blob data stream has been accessed. For this to work, you must use a column alias with the value of the column to the actual name of the Blob. The feature also has the following restrictions: The SELECT that created the result set must reference only one table, the table must have a primary key; the SELECT must alias the original blob column name, specified as a string, to an alternate name; the SELECT must cover all columns that make up the primary key.	false	3.1.0
emulateUnsupportedPstmts	Should the driver detect prepared statements that are not supported by the server, and replace them with client-side emulated versions?	true	3.1.7
exceptionInterceptors	Comma-delimited list of classes that implement com.mysql.jdbc.ExceptionInterceptor. These classes will be instantiated one per Connection instance, and all SQLExceptions thrown by the driver will be allowed to be intercepted by these interceptors, in a chained fashion, with the first class listed as the head of the chain.		5.1.8
functionsNeverReturnBlobs	Should the driver always treat data from functions returning BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
generateSimpleParameterMetadata	Should the driver generate simplified parameter metadata for PreparedStatement when no metadata is available either because the server couldn't support preparing the statement, or server-side prepared statements are disabled?	false	5.0.5
ignoreNonTxTables	Ignore non-transactional table warning for rollback? (defaults to 'false').	false	3.0.9
jdbcCompliantTruncation	Should the driver throw java.sql.DataTruncation exceptions when data is truncated as is required by the JDBC specification when connected to a server that supports warnings (MySQL 4.1.0 and newer)? This property has no effect if the server sql-mode includes STRICT_TRANS_TABLES.	true	3.1.2
loadBalanceAutoCommitStatements	When load-balancing is enabled for auto-commit statements (via loadBalanceAutoCommitStatementThreshold), the statement counter will only increment when the		5.1.15

Connector/J (JDBC) Reference

	SQL matches the regular expression. By default, every statement issued matches.		
loadBalanceAutoCommitStatementThreshold	When the auto-commit is enabled, the number of statements which should be executed before triggering load-balancing to rebalance. Default value of 0 causes load-balanced connections to only rebalance when exceptions are encountered, or auto-commit is disabled and transactions are explicitly committed or rolled back.	0	5.1.15
loadBalanceBlacklistTimeout	Time in milliseconds between checks of servers which are unavailable, by controlling how long a server lives in the global blacklist.	0	5.1.0
loadBalanceConnectionGroup	Logical group of load-balanced connections within a classloader, used to manage different groups independently. If not specified, live management of load-balanced connections is disabled.		5.1.13
loadBalanceExceptionChecker	Fully-qualified class name of custom exception checker. The class must implement com.mysql.jdbc.LoadBalanceExceptionChecker interface, and is used to inspect SQLExceptions and determine whether they should trigger fail-over to another host in a load-balanced deployment.	com.mysql.jdbc.StandardLoadBalanceExceptionChecker	
loadBalancePingTimeout	Time in milliseconds to wait for ping response from each of load-balanced physical connections when using load-balanced Connection.	0	5.1.13
loadBalanceSQLExceptionSubClassFailover	Comma-delimited list of classes/interfaces used by default load-balanced exception checker to determine whether a given SQLException should trigger failover. The comparison is done using Class.isInstance(SQLException) using the thrown SQLException.		5.1.13
loadBalanceSQLStateFailover	Comma-delimited list of SQLState codes used by default load-balanced exception checker to determine whether a given SQLException should trigger failover. The SQLState of a given SQLException is evaluated to determine whether it begins with any value in the comma-delimited list.		5.1.13
loadBalanceValidateConnectionOnSwapStatement	Should a load-balanced Connection explicitly check whether the connection is live when swapping to a new physical connection at commit/rollback?	false	5.1.13
maxRows	The maximum number of rows to return (0, the default means return all rows).	-1	all versions
netTimeoutForStreamingResults	What value should the driver automatically set the server setting 'net_write_timeout' to when the streaming result sets feature is in use? (value has unit of seconds, the value '0' means the driver will not try and adjust this value)	600	5.1.0
noAccessToProcedureBodies	When determining procedure parameter types for CallableStatements, and the connected user can't access procedure bodies through "SHOW CREATE PROCEDURE" or select on mysql.proc	false	5.0.3

	should the driver instead create basic metadata (all parameters reported as IN VARCHARs, but allowing registerOutParameter() to be called on them anyway) instead of throwing an exception?		
noDatetimeStringSync	Don't ensure that ResultSet.getDatetimeType().toString().equals(ResultSet.getString())	false	3.1.7
noTimezoneConversionForTimeType	Do not convert TIME values using the server timezone if 'useTimezone'='true'	false	5.0.0
nullCatalogMeansCurrent	When DatabaseMetadataMethods ask for a 'catalog' parameter, does the value null mean use the current catalog? (this is not JDBC-compliant, but follows legacy behavior from earlier versions of the driver)	true	3.1.8
nullNamePatternMatchesAll	Should DatabaseMetaData methods that accept *pattern parameters treat null the same as '%' (this is not JDBC-compliant, however older versions of the driver accepted this departure from the specification)	true	3.1.8
overrideSupportsIntegrityEnhancementFacility	Should the driver return "true" for DatabaseMeta-data.supportsIntegrityEnhancementFacility() even if the database doesn't support it to workaround applications that require this method to return "true" to signal support of foreign keys, even though the SQL specification states that this facility contains much more than just foreign key support (one such application being OpenOffice)?	false	3.1.12
padCharsWithSpace	If a result set column has the CHAR type and the value does not fill the amount of characters specified in the DDL for the column, should the driver pad the remaining characters with space (for ANSI compliance)?	false	5.0.6
pedantic	Follow the JDBC spec to the letter.	false	3.0.0
pinGlobalTxToPhysicalConnection	When using XAConnections, should the driver ensure that operations on a given XID are always routed to the same physical connection? This allows the XAConnection to support "XA START ... JOIN" after "XA END" has been called	false	5.0.1
populateInsertRowWithDefaultValues	When using ResultSets that are CONCUR_UPDATABLE, should the driver pre-populate the "insert" row with default values from the DDL for the table used in the query so those values are immediately available for ResultSet accessors? This functionality requires a call to the database for metadata each time a result set of this type is created. If disabled (the default), the default values will be populated by the an internal call to refreshRow() which pulls back default values and/or values changed by triggers.	false	5.0.5
processEscapeCodesForPreparedStatements	Should the driver process escape codes in queries that are prepared?	true	3.1.12
queryTimeoutKillsConnection	If the timeout given in Statement.setQueryTimeout() expires, should	false	5.1.9

## Connector/J (JDBC) Reference

	the driver forcibly abort the Connection instead of attempting to abort the query?		
relaxAutoCommit	If the version of MySQL the driver connects to does not support transactions, still allow calls to commit(), rollback() and setAutoCommit() (true/false, defaults to 'false')?	false	2.0.13
retainStatementAfterResultSetClose	Should the driver retain the Statement reference in a ResultSet after ResultSet.close() has been called. This is not JDBC-compliant after JDBC-4.0.	false	3.1.11
rollbackOnPooledClose	Should the driver issue a rollback() when the logical connection in a pool is closed?	true	3.0.15
runningCTS13	Enables workarounds for bugs in Sun's JDBC compliance testsuite version 1.3	false	3.1.7
serverTimezone	Override detection/mapping of timezone. Used when timezone from server doesn't map to Java timezone		3.0.2
statementInterceptors	A comma-delimited list of classes that implement "com.mysql.jdbc.StatementInterceptor" that should be placed "in between" query execution to influence the results. StatementInterceptors are "chainable", the results returned by the "current" interceptor will be passed on to the next in the chain, from left-to-right order, as specified in this property.		5.1.1
strictFloatingPoint	Used only in older versions of compliance test	false	3.0.0
strictUpdates	Should the driver do strict checking (all primary keys selected) of updatable result sets (true, false, defaults to 'true')?	true	3.0.4
tinyInt1isBit	Should the driver treat the datatype TINYINT(1) as the BIT type (because the server silently converts BIT -> TINYINT(1) when creating tables)?	true	3.0.16
transformedBitsIsBoolean	If the driver converts TINYINT(1) to a different type, should it use BOOLEAN instead of BIT for future compatibility with MySQL-5.0, as MySQL-5.0 has a BIT type?	false	3.1.9
treatUtilDateAsTimestamp	Should the driver treat java.util.Date as a TIMESTAMP for the purposes of PreparedStatement.setObject()?	true	5.0.5
ultraDevHack	Create PreparedStatements for prepareCall() when required, because UltraDev is broken and issues a prepareCall() for _all_ statements? (true/false, defaults to 'false')	false	2.0.3
useAffectedRows	Don't set the CLIENT_FOUND_ROWS flag when connecting to the server (not JDBC-compliant, will break most applications that rely on "found" rows vs. "affected rows" for DML statements), but does cause "correct" update counts from "INSERT ... ON DUPLICATE KEY UPDATE" statements to be returned by the server.	false	5.1.7
useGmtMillisForDatetimes	Convert between session timezone and GMT before creating Date and Timestamp instances	false	3.1.12

	(value of "false" is legacy behavior, "true" leads to more JDBC-compliant behavior.		
useHostsInPrivileges	Add '@hostname' to users in DatabaseMetaData.getColumn/TablePrivileges() (true/false), defaults to 'true'.	true	3.0.2
useInformationSchema	When connected to MySQL-5.0.7 or newer, should the driver use the INFORMATION_SCHEMA to derive information used by DatabaseMetaData?	false	5.0.0
useJDBCCompliantTimezoneShift	Should the driver use JDBC-compliant rules when converting TIME/TIMESTAMP/DATETIME values' timezone information for those JDBC arguments which take a java.util.Calendar argument? (Notice that this option is exclusive of the "useTimezone=true" configuration option.)	false	5.0.0
useLegacyDatetimeCode	Use code for DATE/TIME/DATETIME/TIMESTAMP handling in result sets and statements that consistently handles timezone conversions from client to server and back again, or use the legacy code for these datatypes that has been in the driver for backwards-compatibility?	true	5.1.6
useOldAliasMetadataBehavior	Should the driver use the legacy behavior for "AS" clauses on columns and tables, and only return aliases (if any) for ResultSetMetaData.getColumn() or ResultSetMetaData.getTable() rather than the original column/table name? In 5.0.x, the default value was true.	false	5.0.4
useOldUTF8Behavior	Use the UTF-8 behavior the driver did when communicating with 4.0 and older servers	false	3.1.6
useOnlyServerErrorMessages	Don't prepend 'standard' SQLState error messages to error messages returned by the server.	true	3.0.15
useSSPSCompatibleTimezoneShift	When migrating from an environment that was using server-side prepared statements, and the configuration property "useJDBCCompliantTimezoneShift" set to "true", use compatible behavior when not using server-side prepared statements when sending TIMESTAMP values to the MySQL server.	false	5.0.5
useServerPrepStmts	Use server-side prepared statements if the server supports them?	false	3.1.0
useSqlStateCodes	Use SQL Standard state codes instead of 'legacy' X/Open/SQL state codes (true/false), default is 'true'	true	3.1.3
useStreamLengthsInPrepStmts	Honor stream length parameter in PreparedStatement/ResultSet.setXXXStream() method calls (true/false, defaults to 'true')?	true	3.0.2
useTimezone	Convert time/date types between client and server timezones (true/false, defaults to 'false')?	false	3.0.2
useUnbufferedInput	Don't use BufferedInputStream for reading data from the server	true	3.0.11

yearIsDateType	Should the JDBC driver treat the MySQL type "YEAR" as a java.sql.Date, or as a SHORT?	true	3.1.9
zeroDateTimeBehavior	What should happen when the driver encounters DATETIME values that are composed entirely of zeros (used by MySQL to represent invalid dates)? Valid values are "exception", "round" and "convertToNull".	exception	3.1.4

Connector/J also supports access to MySQL using named pipes on Windows NT, Windows 2000, or Windows XP using the `NamedPipeSocketFactory` as a plugin-socket factory using the `socketFactory` property. If you do not use a `namedPipePath` property, the default of `'\\.\pipe\MySQL'` is used. If you use the `NamedPipeSocketFactory`, the host name and port number values in the JDBC url are ignored. To enable this feature, use:

```
socketFactory=com.mysql.jdbc.NamedPipeSocketFactory
```

Named pipes only work when connecting to a MySQL server on the same physical machine where the JDBC driver is running. In simple performance tests, named pipe access is between 30%-50% faster than the standard TCP/IP access. However, this varies per system, and named pipes are slower than TCP/IP in many Windows configurations.

To create your own socket factories, follow the example code in `com.mysql.jdbc.NamedPipeSocketFactory`, or `com.mysql.jdbc.StandardSocketFactory`.

### 21.3.5.1.1. Properties Files for the `useConfigs` Option

The `useConfigs` connection option is a convenient shorthand for specifying combinations of options for particular scenarios. The argument values you can use with this option correspond to the names of `.properties` files within the Connector/J `mysql-connector-java-version-bin.jar` JAR file. For example, the Connector/J 5.1.9 driver includes the following configuration properties files:

```
$ unzip mysql-connector-java-5.1.19-bin.jar '*/configs/*'
Archive:  mysql-connector-java-5.1.19-bin.jar
  creating:  com/mysql/jdbc/configs/
  inflating:  com/mysql/jdbc/configs/3-0-Compat.properties
  inflating:  com/mysql/jdbc/configs/5-0-Compat.properties
  inflating:  com/mysql/jdbc/configs/clusterBase.properties
  inflating:  com/mysql/jdbc/configs/coldFusion.properties
  inflating:  com/mysql/jdbc/configs/fullDebug.properties
  inflating:  com/mysql/jdbc/configs/maxPerformance.properties
  inflating:  com/mysql/jdbc/configs/solarisMaxPerformance.properties
```

To specify one of these combinations of options, specify `useConfigs=3-0-Compat`, `useConfigs=maxPerformance`, and so on. The following sections show the options that are part of each `useConfigs` setting. For the details of why each one is included, see the comments in the `.properties` files.

#### 3-0-Compat

```
emptyStringsConvertToZero=true
jdbcCompliantTruncation=false
noDatetimeStringSync=true
nullCatalogMeansCurrent=true
nullNamePatternMatchesAll=true
transformedBitIsBoolean=false
dontTrackOpenResources=true
zeroDateTimeBehavior=convertToNull
useServerPrepStmts=false
autoClosePstmtStreams=true
processEscapeCodesForPrepStmts=false
useFastDateParsing=false
populateInsertRowWithDefaultValues=false
useDirectRowUnpack=false
```

## 5-0-Compat

```
useDirectRowUnpack=false
```

## clusterBase

```
autoReconnect=true
failOverReadOnly=false
roundRobinLoadBalance=true
```

## coldFusion

```
useDynamicCharsetInfo=false
alwaysSendSetIsolation=false
useLocalSessionState=true
autoReconnect=true
```

## fullDebug

```
profileSQL=true
gatherPerMetrics=true
useUsageAdvisor=true
logSlowQueries=true
explainSlowQueries=true
```

## maxPerformance

```
cachePrepStmts=true
cacheCallableStmts=true
cacheServerConfiguration=true
useLocalSessionState=true
elideSetAutoCommits=true
alwaysSendSetIsolation=false
enableQueryTimeouts=false
```

## solarisMaxPerformance

```
useUnbufferedInput=false
useReadAheadInput=false
maintainTimeStats=false
```

## 21.3.5.2. JDBC API Implementation Notes

MySQL Connector/J passes all of the tests in the publicly available version of Sun's JDBC compliance test suite. This section gives details on a interface-by-interface level about implementation decisions that might affect how you code applications with MySQL Connector/J. The JDBC specification is vague about how certain functionality should be implemented, or the specification enables leeway in implementation.

### • BLOB

Starting with Connector/J version 3.1.0, you can emulate BLOBs with locators by adding the property `emulateLocators=true` to your JDBC URL. Using this method, the driver will delay loading the actual BLOB data until you retrieve the other data and then use retrieval methods (`getInputStream()`, `getBytes()`, and so forth) on the BLOB data stream.

You must use a column alias with the value of the column to the actual name of the BLOB, for example:

```
SELECT id, 'data' as blob_data from blobtable
```

You must also follow these rules:

- The `SELECT` must reference only one table. The table must have a [primary key](#).
- The `SELECT` must alias the original BLOB column name, specified as a string, to an alternate name.

- The `SELECT` must cover all columns that make up the primary key.

The BLOB implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, use the corresponding `PreparedStatement.setBlob()` or `ResultSet.updateBlob()` (in the case of updatable result sets) methods to save changes back to the database.

- **CallableStatement**

Starting with Connector/J 3.1.1, stored procedures are supported when connecting to MySQL version 5.0 or newer using the `CallableStatement` interface. Currently, the `getParameterMetaData()` method of `CallableStatement` is not supported.

- **CLOB**

The CLOB implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, use the `PreparedStatement.setClob()` method to save changes back to the database. The JDBC API does not have a `ResultSet.updateClob()` method.

- **Connection**

Unlike the pre-Connector/J JDBC driver (`MM.MySQL`), the `isClosed()` method does not ping the server to determine if it is available. In accordance with the JDBC specification, it only returns true if `closed()` has been called on the connection. If you need to determine if the connection is still valid, issue a simple query, such as `SELECT 1`. The driver will throw an exception if the connection is no longer valid.

- **DatabaseMetaData**

**Foreign key** information (`getImportedKeys()`/`getExportedKeys()` and `getCrossReference()`) is only available from `InnoDB` tables. The driver uses `SHOW CREATE TABLE` to retrieve this information, so if any other storage engines add support for foreign keys, the driver would transparently support them as well.

- **PreparedStatement**

`PreparedStatement`s are implemented by the driver, as MySQL does not have a prepared statement feature. Because of this, the driver does not implement `getParameterMetaData()` or `getMetaData()` as it would require the driver to have a complete SQL parser in the client.

Starting with version 3.1.0 MySQL Connector/J, server-side prepared statements and binary-encoded result sets are used when the server supports them.

Take care when using a server-side prepared statement with **large** parameters that are set using `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()`, or `setClob()`. To re-execute the statement with any large parameter changed to a nonlarge parameter, call `clearParameters()` and set all parameters again. The reason for this is as follows:

- During both server-side prepared statements and client-side emulation, large data is exchanged only when `PreparedStatement.execute()` is called.
- Once that has been done, the stream used to read the data on the client side is closed (as per the JDBC spec), and cannot be read from again.
- If a parameter changes from large to nonlarge, the driver must reset the server-side state of the prepared statement to allow the parameter that is being changed to take the place of the prior large value. This removes all of the large data that has already been sent to the server,

thus requiring the data to be re-sent, using the `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()` or `setClob()` method.

Consequently, to change the type of a parameter to a nonlarge one, you must call `clearParameters()` and set all parameters of the prepared statement again before it can be re-executed.

- **ResultSet**

By default, ResultSets are completely retrieved and stored in memory. In most cases this is the most efficient way to operate, and due to the design of the MySQL network protocol is easier to implement. If you are working with ResultSets that have a large number of rows or large values, and cannot allocate heap space in your JVM for the memory required, you can tell the driver to stream the results back one row at a time.

To enable this functionality, create a `Statement` instance in the following manner:

```
stmt = conn.createStatement( java.sql.ResultSet.TYPE_FORWARD_ONLY,
                             java.sql.ResultSet.CONCUR_READ_ONLY );
stmt.setFetchSize( Integer.MIN_VALUE );
```

The combination of a forward-only, read-only result set, with a fetch size of `Integer.MIN_VALUE` serves as a signal to the driver to stream result sets row-by-row. After this, any result sets created with the statement will be retrieved row-by-row.

There are some caveats with this approach. You must read all of the rows in the result set (or close it) before you can issue any other queries on the connection, or an exception will be thrown.

The earliest the locks these statements hold can be released (whether they be `MyISAM` table-level locks or row-level locks in some other storage engine such as `InnoDB`) is when the statement completes.

If the statement is within scope of a transaction, then locks are released when the transaction completes (which implies that the statement needs to complete first). As with most other databases, statements are not complete until all the results pending on the statement are read or the active result set for the statement is closed.

Therefore, if using streaming results, process them as quickly as possible if you want to maintain concurrent access to the tables referenced by the statement producing the result set.

- **ResultSetMetaData**

The `isAutoIncrement()` method only works when using MySQL servers 4.0 and newer.

- **Statement**

When using versions of the JDBC driver earlier than 3.2.1, and connected to server versions earlier than 5.0.3, the `setFetchSize()` method has no effect, other than to toggle result set streaming as described above.

Connector/J 5.0.0 and later include support for both `Statement.cancel()` and `Statement.setQueryTimeout()`. Both require MySQL 5.0.0 or newer server, and require a separate connection to issue the `KILL QUERY` statement. In the case of `setQueryTimeout()`, the implementation creates an additional thread to handle the timeout functionality.

**Note**

Failures to cancel the statement for `setQueryTimeout()` may manifest themselves as `RuntimeException` rather than failing silently, as there is currently no way to unblock the thread that is executing the query being cancelled due to timeout expiration and have it throw the exception instead.

**Note**

The MySQL statement `KILL QUERY` (which is what the driver uses to implement `Statement.cancel()`) is non-deterministic; thus, avoid the use of `Statement.cancel()` if possible. If no query is in process, the next query issued will be killed by the server. This race condition is guarded against as of Connector/J 5.1.18.

MySQL does not support SQL cursors, and the JDBC driver doesn't emulate them, so `setCursorName()` has no effect.

Connector/J 5.1.3 and later include two additional methods:

- `setLocalInfileInputStream()` sets an `InputStream` instance that will be used to send data to the MySQL server for a `LOAD DATA LOCAL INFILE` statement rather than a `FileInputStream` or `URLInputStream` that represents the path given as an argument to the statement.

This stream will be read to completion upon execution of a `LOAD DATA LOCAL INFILE` statement, and will automatically be closed by the driver, so it needs to be reset before each call to `execute*()` that would cause the MySQL server to request data to fulfill the request for `LOAD DATA LOCAL INFILE`.

If this value is set to `NULL`, the driver will revert to using a `FileInputStream` or `URLInputStream` as required.

- `getLocalInfileInputStream()` returns the `InputStream` instance that will be used to send data in response to a `LOAD DATA LOCAL INFILE` statement.

This method returns `NULL` if no such stream has been set using `setLocalInfileInputStream()`.

### 21.3.5.3. Java, JDBC and MySQL Types

MySQL Connector/J is flexible in the way it handles conversions between MySQL data types and Java data types.

In general, any MySQL data type can be converted to a `java.lang.String`, and any numeric type can be converted to any of the Java numeric types, although round-off, overflow, or loss of precision may occur.

**Note**

All `TEXT` types return `Types.LONGVARCHAR` with different `getPrecision()` values (65535, 255, 16777215, and 2147483647 respectively) with `getColumnType()` returning `-1`. This behavior is intentional even though `TINYTEXT` does not fall, regarding to its size, within the `LONGVARCHAR` category. This is to avoid different handling inside the same base type. And `getColumnType()` returns `-1` because the internal server handling is of type `TEXT`, which is similar to `BLOB`.

Also note that `getColumnTypeName()` will return `VARCHAR` even though `getColumnType()` returns `Types.LONGVARCHAR`, because `VARCHAR` is the designated column database-specific name for this type.

Starting with Connector/J 3.1.0, the JDBC driver issues warnings or throws `DataTruncation` exceptions as is required by the JDBC specification unless the connection was configured not to do so by using the property `jdbcCompliantTruncation` and setting it to `false`.

The conversions that are always guaranteed to work are listed in the following table. The first column lists one or more MySQL data types, and the second column lists one or more Java types to which the MySQL types can be converted.

**Table 21.24. Connection Properties - Miscellaneous**

These MySQL Data Types	Can always be converted to these Java types
CHAR, VARCHAR, BLOB, TEXT, ENUM, and SET	java.lang.String, java.io.InputStream, java.io.Reader, java.sql.Blob, java.sql.Clob
FLOAT, REAL, DOUBLE PRECISION, NUMERIC, DECIMAL, TINYINT, SMALLINT, MEDIUMINT, INTEGER, BIGINT	java.lang.String, java.lang.Short, java.lang.Integer, java.lang.Long, java.lang.Double, java.math.BigDecimal
DATE, TIME, DATETIME, TIMESTAMP	java.lang.String, java.sql.Date, java.sql.Timestamp

**Note**

Round-off, overflow or loss of precision may occur if you choose a Java numeric data type that has less precision or capacity than the MySQL data type you are converting to/from.

The `ResultSet.getObject()` method uses the type conversions between MySQL and Java types, following the JDBC specification where appropriate. The value returned by `ResultSetMetaData.GetColumnName()` is also shown below. For more information on the `java.sql.Types` classes see [Java 2 Platform Types](#).

**Table 21.25. MySQL Types to Java Types for ResultSet.getObject()**

MySQL Type Name	Return value of <code>GetColumnName</code>	Returned as Java Class
BIT(1) (new in MySQL-5.0)	BIT	java.lang.Boolean
BIT( > 1) (new in MySQL-5.0)	BIT	byte[]
TINYINT	TINYINT	java.lang.Boolean if the configuration property <code>tinyInt1isBit</code> is set to <code>true</code> (the default) and the storage size is 1, or java.lang.Integer if not.
BOOL, BOOLEAN	TINYINT	See TINYINT, above as these are aliases for TINYINT(1), currently.
SMALLINT[ (M) ] [UNSIGNED]	SMALLINT [UNSIGNED]	java.lang.Integer (regardless if UNSIGNED or not)
MEDIUMINT[ (M) ] [UNSIGNED]	MEDIUMINT [UNSIGNED]	java.lang.Integer, if UNSIGNED java.lang.Long (C/J 3.1 and earlier), or java.lang.Integer for C/J 5.0 and later
INT, INTEGER[ (M) ] [UNSIGNED]	INTEGER [UNSIGNED]	java.lang.Integer, if UNSIGNED java.lang.Long
BIGINT[ (M) ] [UNSIGNED]	BIGINT [UNSIGNED]	java.lang.Long, if UNSIGNED java.math.BigInteger
FLOAT[ (M,D) ]	FLOAT	java.lang.Float
DOUBLE[ (M,B) ]	DOUBLE	java.lang.Double
DECIMAL[ (M[,D) ] ]	DECIMAL	java.math.BigDecimal

MySQL Type Name	Return value of <code>GetColumnName</code>	Returned as Java Class
DATE	DATE	<code>java.sql.Date</code>
DATETIME	DATETIME	<code>java.sql.Timestamp</code>
TIMESTAMP[ (M) ]	TIMESTAMP	<code>java.sql.Timestamp</code>
TIME	TIME	<code>java.sql.Time</code>
YEAR[ ( 2   4 ) ]	YEAR	If <code>yearIsDateType</code> configuration property is set to <code>false</code> , then the returned object type is <code>java.sql.Short</code> . If set to <code>true</code> (the default), then the returned object is of type <code>java.sql.Date</code> with the date set to January 1st, at midnight.
CHAR(M)	CHAR	<code>java.lang.String</code> (unless the character set for the column is <code>BINARY</code> , then <code>byte[]</code> is returned.
VARCHAR(M) [BINARY]	VARCHAR	<code>java.lang.String</code> (unless the character set for the column is <code>BINARY</code> , then <code>byte[]</code> is returned.
BINARY(M)	BINARY	<code>byte[]</code>
VARBINARY(M)	VARBINARY	<code>byte[]</code>
TINYBLOB	TINYBLOB	<code>byte[]</code>
TINYTEXT	VARCHAR	<code>java.lang.String</code>
BLOB	BLOB	<code>byte[]</code>
TEXT	VARCHAR	<code>java.lang.String</code>
MEDIUMBLOB	MEDIUMBLOB	<code>byte[]</code>
MEDIUMTEXT	VARCHAR	<code>java.lang.String</code>
LOBLOB	LOBLOB	<code>byte[]</code>
LONGTEXT	VARCHAR	<code>java.lang.String</code>
ENUM('value1', 'value2', ...)	CHAR...	<code>java.lang.String</code>
SET('value1', 'value2', ...)	CHAR..	<code>java.lang.String</code>

#### 21.3.5.4. Using Character Sets and Unicode

All strings sent from the JDBC driver to the server are converted automatically from native Java Unicode form to the client character encoding, including all queries sent using `Statement.execute()`, `Statement.executeUpdate()`, `Statement.executeQuery()` as well as all `PreparedStatement` and `CallableStatement` parameters with the exclusion of parameters set using `setBytes()`, `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()` and `setBlob()`.

#### Number of Encodings Per Connection

In MySQL Server 4.1 and higher, Connector/J supports a single character encoding between client and server, and any number of character encodings for data returned by the server to the client in `ResultSets`.

Prior to MySQL Server 4.1, Connector/J supported a single character encoding per connection, which could either be automatically detected from the server configuration, or could be configured by the user through the `useUnicode` and `characterEncoding` properties.

#### Setting the Character Encoding

The character encoding between client and server is automatically detected upon connection. You specify the encoding on the server using the `character_set_server` [468] for server versions 4.1.0

and newer, and `character_set` system variable for server versions older than 4.1.0. The driver automatically uses the encoding specified by the server. For more information, see [Section 10.1.3.1, “Server Character Set and Collation”](#).

For example, to use 4-byte UTF-8 character sets with Connector/J, configure the MySQL server with `character_set_server=utf8mb4` [468], and leave `characterEncoding` out of the Connector/J connection string. Connector/J will then autodetect the UTF-8 setting.

To override the automatically detected encoding on the client side, use the `characterEncoding` property in the URL used to connect to the server.

To allow multiple character sets to be sent from the client, use the UTF-8 encoding, either by configuring `utf8` as the default server character set, or by configuring the JDBC driver to use UTF-8 through the `characterEncoding` property.

When specifying character encodings on the client side, use Java-style names. The following table lists MySQL character set names and the corresponding Java-style names:

**Table 21.26. MySQL to Java Encoding Name Translations**

MySQL Character Set Name	Java-Style Character Encoding Name
<code>ascii</code>	<code>US-ASCII</code>
<code>big5</code>	<code>Big5</code>
<code>gbk</code>	<code>GBK</code>
<code>sjis</code>	<code>SJIS</code> (or <code>Cp932</code> or <code>MS932</code> for MySQL Server < 4.1.11)
<code>cp932</code>	<code>Cp932</code> or <code>MS932</code> (MySQL Server > 4.1.11)
<code>gb2312</code>	<code>EUC_CN</code>
<code>ujis</code>	<code>EUC_JP</code>
<code>euckr</code>	<code>EUC_KR</code>
<code>latin1</code>	<code>Cp1252</code>
<code>latin2</code>	<code>ISO8859_2</code>
<code>greek</code>	<code>ISO8859_7</code>
<code>hebrew</code>	<code>ISO8859_8</code>
<code>cp866</code>	<code>Cp866</code>
<code>tis620</code>	<code>TIS620</code>
<code>cp1250</code>	<code>Cp1250</code>
<code>cp1251</code>	<code>Cp1251</code>
<code>cp1257</code>	<code>Cp1257</code>
<code>macroman</code>	<code>MacRoman</code>
<code>macce</code>	<code>MacCentralEurope</code>
<code>utf8</code>	<code>UTF-8</code>
<code>ucs2</code>	<code>UnicodeBig</code>

#### Warning

Do not issue the query `set names` with Connector/J, as the driver will not detect that the character set has changed, and will continue to use the character set detected during the initial connection setup.

### 21.3.5.5. Connecting Securely Using SSL

SSL in MySQL Connector/J encrypts all data (other than the initial handshake) between the JDBC driver and the server. The performance penalty for enabling SSL is an increase in query processing time between 35% and 50%, depending on the size of the query, and the amount of data it returns.

For SSL support to work, you must have the following:

- A JDK that includes JSSE (Java Secure Sockets Extension), like JDK-1.4.1 or newer. SSL does not currently work with a JDK that you can add JSSE to, like JDK-1.2.x or JDK-1.3.x due to the following JSSE bug: <http://developer.java.sun.com/developer/bugParade/bugs/4273544.html>
- A MySQL server that supports SSL and has been compiled and configured to do so, which is MySQL 4.0.4 or later. For more information, see [Section 6.3.9.2, “Configuring MySQL for SSL”](#).
- A client certificate (covered later in this section)

The system works through two Java truststore files, one file contains the certificate information for the server (`truststore` in the examples below). The other file contains the certificate for the client (`keystore` in the examples below). All Java truststore files are password protected by supplying a suitable password to the `keytool` when you create the files. You need the file names and associated passwords to create an SSL connection.

You will first need to import the MySQL server CA Certificate into a Java truststore. A sample MySQL server CA Certificate is located in the [SSL](#) subdirectory of the MySQL source distribution. This is what SSL will use to determine if you are communicating with a secure MySQL server. Alternatively, use the CA Certificate that you have generated or been provided with by your SSL provider.

To use Java's `keytool` to create a truststore in the current directory, and import the server's CA certificate (`cacert.pem`), you can do the following (assuming that `keytool` is in your path. The `keytool` is typically located in the `bin` subdirectory of your JDK or JRE):

```
shell> keytool -import -alias mysqlServerCACert \
  -file cacert.pem -keystore truststore
```

Enter the password when prompted for the keystore file. Interaction with `keytool` looks like this:

```
Enter keystore password: *****
Owner: EMAILADDRESS=walrus@example.com, CN=Walrus,
  O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Issuer: EMAILADDRESS=walrus@example.com, CN=Walrus,
  O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Serial number: 0
Valid from:
  Fri Aug 02 16:55:53 CDT 2002 until: Sat Aug 02 16:55:53 CDT 2003
Certificate fingerprints:
  MD5: 61:91:A0:F2:03:07:61:7A:81:38:66:DA:19:C4:8D:AB
  SHA1: 25:77:41:05:D5:AD:99:8C:14:8C:CA:68:9C:2F:B8:89:C3:34:4D:6C
Trust this certificate? [no]: yes
Certificate was added to keystore
```

You then have two options: either import the client certificate that matches the CA certificate you just imported, or create a new client certificate.

Importing an existing certificate requires the certificate to be in DER format. You can use `openssl` to convert an existing certificate into the new format. For example:

```
shell> openssl x509 -outform DER -in client-cert.pem -out client.cert
```

Now import the converted certificate into your keystore using `keytool`:

```
shell> keytool -import -file client.cert -keystore keystore -alias mysqlClientCertificate
```

To generate your own client certificate, use `keytool` to create a suitable certificate and add it to the `keystore` file:

```
shell> keytool -genkey -keyalg rsa \
  -alias mysqlClientCertificate -keystore keystore
```

Keytool will prompt you for the following information, and create a keystore named `keystore` in the current directory.

Respond with information that is appropriate for your situation:

```
Enter keystore password: *****
What is your first and last name?
  [Unknown]: Matthews
What is the name of your organizational unit?
  [Unknown]: Software Development
What is the name of your organization?
  [Unknown]: MySQL AB
What is the name of your City or Locality?
  [Unknown]: Flossmoor
What is the name of your State or Province?
  [Unknown]: IL
What is the two-letter country code for this unit?
  [Unknown]: US
Is <CN=Matthews, OU=Software Development, O=MySQL AB,
L=Flossmoor, ST=IL, C=US> correct?
  [no]: y

Enter key password for <mysqlClientCertificate>
  (RETURN if same as keystore password):
```

Finally, to get JSSE to use the keystore and truststore that you have generated, you need to set the following system properties when you start your JVM, replacing `path_to_keystore_file` with the full path to the keystore file you created, `path_to_truststore_file` with the path to the truststore file you created, and using the appropriate password values for each property. You can do this either on the command line:

```
-Djavax.net.ssl.keyStore=path_to_keystore_file
-Djavax.net.ssl.keyStorePassword=password
-Djavax.net.ssl.trustStore=path_to_truststore_file
-Djavax.net.ssl.trustStorePassword=password
```

Or you can set the values directly within the application:

```
System.setProperty("javax.net.ssl.keyStore", "path_to_keystore_file");
System.setProperty("javax.net.ssl.keyStorePassword", "password");
System.setProperty("javax.net.ssl.trustStore", "path_to_truststore_file");
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

You will also need to set `useSSL` to `true` in your connection parameters for MySQL Connector/J, either by adding `useSSL=true` to your URL, or by setting the property `useSSL` to `true` in the `java.util.Properties` instance you pass to `DriverManager.getConnection()`.

You can test that SSL is working by turning on JSSE debugging (as detailed below), and look for the following key events:

```
...

```

JSSSE provides debugging (to `stdout`) when you set the following system property: - `Djavax.net.debug=all` This will tell you what keystores and truststores are being used, as well as what is going on during the SSL handshake and certificate exchange. It will be helpful when trying to determine what is not working when trying to get an SSL connection to happen.

### 21.3.5.6. Connecting Using PAM Authentication

Java applications using Connector/J 5.1.21 and higher can connect to MySQL servers that use the pluggable authentication module (PAM) authentication scheme.

For PAM authentication to work, you must have the following:

- A MySQL server that supports PAM authentication: a commercial distribution of MySQL 5.5.16 or higher. See [Section 6.3.7.3, “The PAM Authentication Plugin”](#) for more information. Connector/J implements the same cleartext authentication method as in [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).
- SSL capability, as explained in [Section 21.3.5.5, “Connecting Securely Using SSL”](#). Because the PAM authentication scheme sends the original password to the server, the connection to the server must be encrypted.

PAM authentication support is enabled by default in Connector/J 5.1.21 and up, so no extra configuration is needed.

To disable the PAM authentication feature, specify `mysql_clear_password` (the method) or `com.mysql.jdbc.authentication.MySqlClearPasswordPlugin` (the class name) in the comma-separated list of arguments for the `disabledAuthenticationPlugins` connection option. See [Section 21.3.5.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”](#) for details about that connection option.

### 21.3.5.7. Using Master/Slave Replication with ReplicationConnection

Connector/J 3.1.7 and higher includes a variant of the driver that will automatically send queries to a read/write master, or a failover or round-robin loadbalanced set of slaves based on the state of `Connection.getReadOnly()`.

An application signals that it wants a transaction to be read-only by calling `Connection.setReadOnly(true)`, this replication-aware connection will use one of the slave connections, which are load-balanced per-vm using a round-robin scheme (a given connection is sticky to a slave unless that slave is removed from service). If you have a write transaction, or if you have a read that is time-sensitive (remember, replication in MySQL is asynchronous), set the connection to be not read-only, by calling `Connection.setReadOnly(false)` and the driver will ensure that further calls are sent to the master MySQL server. The driver takes care of propagating the current state of autocommit, isolation level, and catalog between all of the connections that it uses to accomplish this load balancing functionality.

To enable this functionality, use the `com.mysql.jdbc.ReplicationDriver` class when configuring your application server's connection pool or when creating an instance of a JDBC driver for your standalone application. Because it accepts the same URL format as the standard MySQL JDBC driver, `ReplicationDriver` does not currently work with `java.sql.DriverManager`-based connection creation unless it is the only MySQL JDBC driver registered with the `DriverManager`.

Here is a short example of how `ReplicationDriver` might be used in a standalone application:

```
import java.sql.Connection;
import java.sql.ResultSet;
import java.util.Properties;

import com.mysql.jdbc.ReplicationDriver;

public class ReplicationDriverDemo {

    public static void main(String[] args) throws Exception {
        ReplicationDriver driver = new ReplicationDriver();

        Properties props = new Properties();

        // We want this for failover on the slaves
        props.put("autoReconnect", "true");

        // We want to load balance between the slaves
        props.put("roundRobinLoadBalance", "true");

        props.put("user", "foo");
        props.put("password", "bar");

        //
        // Looks like a normal MySQL JDBC url, with a
        // comma-separated list of hosts, the first
        // being the 'master', the rest being any number
        // of slaves that the driver will load balance against
        //

        Connection conn =
            driver.connect("jdbc:mysql:replication://master,slave1,slave2,slave3/test",
                props);

        //
        // Perform read/write work on the master
        // by setting the read-only flag to "false"
        //

        conn.setReadOnly(false);
        conn.setAutoCommit(false);
        conn.createStatement().executeUpdate("UPDATE some_table ...");
        conn.commit();

        //
        // Now, do a query from a slave, the driver automatically picks one
        // from the list
        //

        conn.setReadOnly(true);

        ResultSet rs =
            conn.createStatement().executeQuery("SELECT a,b FROM alt_table");

        .....
    }
}
```

Consider investigating the Load Balancing JDBC Pool (`lbpool`) tool, which provides a wrapper around the standard JDBC driver and enables you to use DB connection pools that includes checks for system failures and uneven load distribution. For more information, see [Load Balancing JDBC Pool \(lbpool\)](#).

### 21.3.5.8. Mapping MySQL Error Numbers to JDBC SQLState Codes

The table below provides a mapping of the MySQL error numbers to JDBC `SQLState` values.

**Table 21.27. Mapping of MySQL Error Numbers to SQLStates**

MySQL Error Number	MySQL Error Name	Legal (X/Open) SQLState	Standard SQLState
1022	ER_DUPSCHEMA	23000	23000
1037	ER_OUT_OF_MEMORY	SF001	SF001
1038	ER_OUT_OF_SORTMEMORY	SF001	SF001
1040	ER_COND_COUNT_ERROR	23004	23004
1042	ER_BAD_DB_ERROR	42000	42000
1043	ER_HANDSHAKE_ERROR	08S01	08S01
1044	ER_DBACCESS_DENIED_ERROR	42000	42000
1045	ER_ACCESS_DENIED_ERROR	28S01	28S01
1047	ER_UNKNOWN_COOM_ERROR	08S01	08S01
1050	ER_TABLE_EXISTS_ERROR	42000	42000
1051	ER_BAD_TABLE_ERROR	42000	42000
1052	ER_NON_UNIQUE_ERROR	23000	23000
1053	ER_SERVER_SHUTDOWN	08S01	08S01
1054	ER_BAD_FIELD_ERROR	42000	42000
1055	ER_WRONG_FIELD_WITH_GROUP	42000	42000
1056	ER_WRONG_GROUP_FIELD	42000	42000
1057	ER_WRONG_SELECT	42000	42000
1058	ER_WRONG_COUNT	42000	42000
1059	ER_TOO_LONG_IDENT	42000	42000
1060	ER_DUPSCHEMA	23000	23000

### 21.3.6. JDBC Concepts

This section provides some general JDBC background.

#### 21.3.6.1. Connecting to MySQL Using the JDBC `DriverManager` Interface

When you are using JDBC outside of an application server, the `DriverManager` class manages the establishment of Connections.

Specify to the `DriverManager` which JDBC drivers to try to make Connections with. The easiest way to do this is to use `Class.forName()` on the class that implements the `java.sql.Driver` interface. With MySQL Connector/J, the name of this class is `com.mysql.jdbc.Driver`. With this method, you could use an external configuration file to supply the driver class name and driver parameters to use when connecting to a database.

The following section of Java code shows how you might register MySQL Connector/J from the `main()` method of your application. If testing this code, first read the installation section at [Section 21.3.3, “Connector/J Installation”](#), to make sure you have connector installed correctly and the `CLASSPATH` set up. Also, ensure that MySQL is configured to accept external TCP/IP connections.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

// Notice, do not import com.mysql.jdbc.*
// or you will have problems!

public class LoadDriver {
    public static void main(String[] args) {
        try {
            // The newInstance() call is a work around for some
```

```

        // broken Java implementations

        Class.forName("com.mysql.jdbc.Driver").newInstance();
    } catch (Exception ex) {
        // handle the error
    }
}

```

After the driver has been registered with the `DriverManager`, you can obtain a `Connection` instance that is connected to a particular database by calling `DriverManager.getConnection()`:

#### Example 21.1. Connector/J: Obtaining a connection from the `DriverManager`

If you have not already done so, please review the section [Section 21.3.6.1, "Connecting to MySQL Using the JDBC `DriverManager` Interface"](#) before working with these examples.

This example shows how you can obtain a `Connection` instance from the `DriverManager`. There are a few different signatures for the `getConnection()` method. Consult the API documentation that comes with your JDK for more specific information on how to use them.

```

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

Connection conn = null;
...
try {
    conn =
        DriverManager.getConnection("jdbc:mysql://localhost/test?" +
                                   "user=monty&password=greatsqldb");

    // Do something with the Connection

    ...
} catch (SQLException ex) {
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}

```

Once a `Connection` is established, it can be used to create `Statement` and `PreparedStatement` objects, as well as retrieve metadata about the database. This is explained in the following sections.

### 21.3.6.2. Using JDBC `Statement` Objects to Execute SQL

`Statement` objects allow you to execute basic SQL queries and retrieve the results through the `ResultSet` class, which is described later.

To create a `Statement` instance, you call the `createStatement()` method on the `Connection` object you have retrieved using one of the `DriverManager.getConnection()` or `DataSource.getConnection()` methods described earlier.

Once you have a `Statement` instance, you can execute a `SELECT` query by calling the `executeQuery(String)` method with the SQL you want to use.

To update data in the database, use the `executeUpdate(String SQL)` method. This method returns the number of rows matched by the update statement, not the number of rows that were modified.

If you do not know ahead of time whether the SQL statement will be a `SELECT` or an `UPDATE/INSERT`, then you can use the `execute(String SQL)` method. This method will return true if the SQL query was a `SELECT`, or false if it was an `UPDATE`, `INSERT`, or `DELETE` statement. If the statement was a `SELECT` query, you can retrieve the results by calling the `getResultSet()` method. If the statement was an `UPDATE`, `INSERT`, or `DELETE` statement, you can retrieve the affected rows count by calling `getUpdateCount()` on the `Statement` instance.

**Example 21.2. Connector/J: Using `java.sql.Statement` to execute a `SELECT` query**

```

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;

// assume that conn is an already created JDBC connection (see previous examples)

Statement stmt = null;
ResultSet rs = null;

try {
    stmt = conn.createStatement();
    rs = stmt.executeQuery("SELECT foo FROM bar");

    // or alternatively, if you don't know ahead of time that
    // the query will be a SELECT...

    if (stmt.execute("SELECT foo FROM bar")) {
        rs = stmt.getResultSet();
    }

    // Now do something with the ResultSet ....
}
catch (SQLException ex){
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
finally {
    // it is a good idea to release
    // resources in a finally{} block
    // in reverse-order of their creation
    // if they are no-longer needed

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) { } // ignore

        rs = null;
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) { } // ignore

        stmt = null;
    }
}

```

**21.3.6.3. Using JDBC `CallableStatements` to Execute Stored Procedures**

Starting with MySQL server version 5.0 when used with Connector/J 3.1.1 or newer, the `java.sql.CallableStatement` interface is fully implemented with the exception of the `getParameterMetaData()` method.

For more information on MySQL stored procedures, please refer to <http://dev.mysql.com/doc/mysql/en/stored-routines.html>.

Connector/J exposes stored procedure functionality through JDBC's `CallableStatement` interface.

**Note**

Current versions of MySQL server do not return enough information for the JDBC driver to provide result set metadata for callable statements. This means

that when using `CallableStatement`, `ResultSetMetaData` may return `NULL`.

The following example shows a stored procedure that returns the value of `inOutParam` incremented by 1, and the string passed in using `inputParam` as a `ResultSet`:

### Example 21.3. Connector/J: Calling Stored Procedures

```
CREATE PROCEDURE demoSp(IN inputParam VARCHAR(255), \
                        INOUT inOutParam INT)
BEGIN
  DECLARE z INT;
  SET z = inOutParam + 1;
  SET inOutParam = z;

  SELECT inputParam;

  SELECT CONCAT('zyxw', inputParam);
END
```

To use the `demoSp` procedure with Connector/J, follow these steps:

1. Prepare the callable statement by using `Connection.prepareCall()`.

Notice that you have to use JDBC escape syntax, and that the parentheses surrounding the parameter placeholders are not optional:

### Example 21.4. Connector/J: Using `Connection.prepareCall()`

```
import java.sql.CallableStatement;

...

//
// Prepare a call to the stored procedure 'demoSp'
// with two parameters
//
// Notice the use of JDBC-escape syntax ({call ...})
//

CallableStatement cStmt = conn.prepareCall("{call demoSp(?, ?)}");

cStmt.setString(1, "abcdefg");
```

#### Note

`Connection.prepareCall()` is an expensive method, due to the metadata retrieval that the driver performs to support output parameters. For performance reasons, minimize unnecessary calls to `Connection.prepareCall()` by reusing `CallableStatement` instances in your code.

2. Register the output parameters (if any exist)

To retrieve the values of output parameters (parameters specified as `OUT` or `INOUT` when you created the stored procedure), JDBC requires that they be specified before statement execution using the various `registerOutputParameter()` methods in the `CallableStatement` interface:

### Example 21.5. Connector/J: Registering output parameters

```
import java.sql.Types;

...
//
// Connector/J supports both named and indexed
// output parameters. You can register output
```

```

// parameters using either method, as well
// as retrieve output parameters using either
// method, regardless of what method was
// used to register them.
//
// The following examples show how to use
// the various methods of registering
// output parameters (you should of course
// use only one registration per parameter).
//
//
// Registers the second parameter as output, and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter(2, Types.INTEGER);
//
// Registers the named parameter 'inOutParam', and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter("inOutParam", Types.INTEGER);
...

```

### 3. Set the input parameters (if any exist)

Input and in/out parameters are set as for [PreparedStatement](#) objects. However, [CallableStatement](#) also supports setting parameters by name:

#### Example 21.6. Connector/J: Setting [CallableStatement](#) input parameters

```

...
//
// Set a parameter by index
//
cStmt.setString(1, "abcdefg");
//
// Alternatively, set a parameter using
// the parameter name
//
cStmt.setString("inputParameter", "abcdefg");
//
// Set the 'in/out' parameter using an index
//
cStmt.setInt(2, 1);
//
// Alternatively, set the 'in/out' parameter
// by name
//
cStmt.setInt("inOutParam", 1);
...

```

### 4. Execute the [CallableStatement](#), and retrieve any result sets or output parameters.

Although [CallableStatement](#) supports calling any of the [Statement](#) execute methods ([executeUpdate\(\)](#), [executeQuery\(\)](#) or [execute\(\)](#)), the most flexible method to call is [execute\(\)](#), as you do not need to know ahead of time if the stored procedure returns result sets:

**Example 21.7. Connector/J: Retrieving results and output parameter values**

```

...

boolean hadResults = cStmt.execute();

//
// Process all returned result sets
//

while (hadResults) {
    ResultSet rs = cStmt.getResultSet();

    // process result set
    ...

    hadResults = cStmt.getMoreResults();
}

//
// Retrieve output parameters
//
// Connector/J supports both index-based and
// name-based retrieval
//

int outputValue = cStmt.getInt(2); // index-based

outputValue = cStmt.getInt("inOutParam"); // name-based

...

```

**21.3.6.4. Retrieving `AUTO_INCREMENT` Column Values through JDBC**

Before version 3.0 of the JDBC API, there was no standard way of retrieving key values from databases that supported auto increment or identity columns. With older JDBC drivers for MySQL, you could always use a MySQL-specific method on the `Statement` interface, or issue the query `SELECT LAST_INSERT_ID()` after issuing an `INSERT` to a table that had an `AUTO_INCREMENT` key. Using the MySQL-specific method call isn't portable, and issuing a `SELECT` to get the `AUTO_INCREMENT` key's value requires another round-trip to the database, which isn't as efficient as possible. The following code snippets demonstrate the three different ways to retrieve `AUTO_INCREMENT` values. First, we demonstrate the use of the new JDBC 3.0 method `getGeneratedKeys()` which is now the preferred method to use if you need to retrieve `AUTO_INCREMENT` keys and have access to JDBC 3.0. The second example shows how you can retrieve the same value using a standard `SELECT LAST_INSERT_ID()` query. The final example shows how updatable result sets can retrieve the `AUTO_INCREMENT` value when using the `insertRow()` method.

**Example 21.8. Connector/J: Retrieving `AUTO_INCREMENT` column values using `Statement.getGeneratedKeys()`**

```

Statement stmt = null;
ResultSet rs = null;

try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets assuming you have a
    // Connection 'conn' to a MySQL database already
    // available

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                                java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example

```

```

//

stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
stmt.executeUpdate(
    "CREATE TABLE autoIncTutorial ("
    + "priKey INT NOT NULL AUTO_INCREMENT, "
    + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

//
// Insert one row that will generate an AUTO INCREMENT
// key in the 'priKey' field
//
stmt.executeUpdate(
    "INSERT INTO autoIncTutorial (dataField) "
    + "values ('Can I Get the Auto Increment Field?')",
    Statement.RETURN_GENERATED_KEYS);

//
// Example of using Statement.getGeneratedKeys()
// to retrieve the value of an auto-increment
// value
//

int autoIncKeyFromApi = -1;

rs = stmt.getGeneratedKeys();

if (rs.next()) {
    autoIncKeyFromApi = rs.getInt(1);
} else {

    // throw an exception from here
}

rs.close();

rs = null;

System.out.println("Key returned from getGeneratedKeys():"
    + autoIncKeyFromApi);
} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}

```

### Example 21.9. Connector/J: Retrieving `AUTO_INCREMENT` column values using `SELECT LAST_INSERT_ID()`

```

Statement stmt = null;
ResultSet rs = null;

try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets.

```

```

stmt = conn.createStatement();

//
// Issue the DDL queries for the table for this example
//

stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
stmt.executeUpdate(
    "CREATE TABLE autoIncTutorial ("
    + "priKey INT NOT NULL AUTO_INCREMENT, "
    + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

//
// Insert one row that will generate an AUTO INCREMENT
// key in the 'priKey' field
//

stmt.executeUpdate(
    "INSERT INTO autoIncTutorial (dataField) "
    + "values ('Can I Get the Auto Increment Field?')");

//
// Use the MySQL LAST_INSERT_ID()
// function to do the same thing as getGeneratedKeys()
//

int autoIncKeyFromFunc = -1;
rs = stmt.executeQuery("SELECT LAST_INSERT_ID()");

if (rs.next()) {
    autoIncKeyFromFunc = rs.getInt(1);
} else {
    // throw an exception from here
}

rs.close();

System.out.println("Key returned from " +
    "'SELECT LAST_INSERT_ID()': " +
    autoIncKeyFromFunc);
} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}

```

### Example 21.10. Connector/J: Retrieving `AUTO_INCREMENT` column values in `Updatable ResultSets`

```

Statement stmt = null;
ResultSet rs = null;

try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets as well as an 'updatable'

```

```

// one, assuming you have a Connection 'conn' to
// a MySQL database already available
//

stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                             java.sql.ResultSet.CONCUR_UPDATABLE);

//
// Issue the DDL queries for the table for this example
//

stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
stmt.executeUpdate(
    "CREATE TABLE autoIncTutorial ( "
    + "priKey INT NOT NULL AUTO_INCREMENT, "
    + "dataField VARCHAR(64), PRIMARY KEY (priKey)");

//
// Example of retrieving an AUTO INCREMENT key
// from an updatable result set
//

rs = stmt.executeQuery("SELECT priKey, dataField "
    + "FROM autoIncTutorial");

rs.moveToInsertRow();

rs.updateString("dataField", "AUTO INCREMENT here?");
rs.insertRow();

//
// the driver adds rows at the end
//

rs.last();

//
// We should now be on the row we just inserted
//

int autoIncKeyFromRS = rs.getInt("priKey");

rs.close();

rs = null;

System.out.println("Key returned for inserted row: "
    + autoIncKeyFromRS);
} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}

```

Running the preceding example code should produce the following output:

```

Key returned from getGeneratedKeys(): 1
Key returned from SELECT LAST_INSERT_ID(): 1

```

```
Key returned for inserted row: 2
```

At times, it can be tricky to use the `SELECT LAST_INSERT_ID()` query, as that function's value is scoped to a connection. So, if some other query happens on the same connection, the value is overwritten. On the other hand, the `getGeneratedKeys()` method is scoped by the `Statement` instance, so it can be used even if other queries happen on the same connection, but not on the same `Statement` instance.

### 21.3.7. Connection Pooling with Connector/J

Connection pooling is a technique of creating and managing a pool of connections that are ready for use by any `thread` that needs them. Connection pooling can greatly increase the performance of your Java application, while reducing overall resource usage.

#### How Connection Pooling Works

Most applications only need a thread to have access to a JDBC connection when they are actively processing a `transaction`, which often takes only milliseconds to complete. When not processing a transaction, the connection sits idle. Connection pooling enables the idle connection to be used by some other thread to do useful work.

In practice, when a thread needs to do work against a MySQL or other database with JDBC, it requests a connection from the pool. When the thread is finished using the connection, it returns it to the pool, so that it can be used by any other threads.

When the connection is loaned out from the pool, it is used exclusively by the thread that requested it. From a programming point of view, it is the same as if your thread called `DriverManager.getConnection()` every time it needed a JDBC connection. With connection pooling, your thread may end up using either a new connection or an already-existing connection.

#### Benefits of Connection Pooling

The main benefits to connection pooling are:

- Reduced connection creation time.

Although this is not usually an issue with the quick connection setup that MySQL offers compared to other databases, creating new JDBC connections still incurs networking and JDBC driver overhead that will be avoided if connections are recycled.

- Simplified programming model.

When using connection pooling, each individual thread can act as though it has created its own JDBC connection, allowing you to use straightforward JDBC programming techniques.

- Controlled resource usage.

If you create a new connection every time a thread needs one, rather than using connection pooling, your application's resource usage can be wasteful and lead to unpredictable behavior under load.

#### Using Connection Pooling with Connector/J

Sun has standardized the concept of connection pooling in JDBC through the JDBC 2.0 Optional interfaces, and all major application servers have implementations of these APIs that work with MySQL Connector/J.

Generally, you configure a connection pool in your application server configuration files, and access it through the Java Naming and Directory Interface (JNDI). The following code shows how you might use a connection pool from an application deployed in a J2EE application server:

**Example 21.11. Connector/J: Using a connection pool with a J2EE application server**

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;

import javax.naming.InitialContext;
import javax.sql.DataSource;

public class MyServletJspOrEjb {

    public void doSomething() throws Exception {
        /*
         * Create a JNDI Initial context to be able to
         * lookup the DataSource
         *
         * In production-level code, this should be cached as
         * an instance or static variable, as it can
         * be quite expensive to create a JNDI context.
         *
         * Note: This code only works when you are using servlets
         * or EJBs in a J2EE application server. If you are
         * using connection pooling in standalone Java code, you
         * will have to create/configure datasources using whatever
         * mechanisms your particular connection pooling library
         * provides.
         */

        InitialContext ctx = new InitialContext();

        /*
         * Lookup the DataSource, which will be backed by a pool
         * that the application server provides. DataSource instances
         * are also a good candidate for caching as an instance
         * variable, as JNDI lookups can be expensive as well.
         */

        DataSource ds =
            (DataSource)ctx.lookup("java:comp/env/jdbc/MySQLDB");

        /*
         * The following code is what would actually be in your
         * Servlet, JSP or EJB 'service' method...where you need
         * to work with a JDBC connection.
         */

        Connection conn = null;
        Statement stmt = null;

        try {
            conn = ds.getConnection();

            /*
             * Now, use normal JDBC programming to work with
             * MySQL, making sure to close each resource when you're
             * finished with it, which permits the connection pool
             * resources to be recovered as quickly as possible
             */

            stmt = conn.createStatement();
            stmt.execute("SOME SQL QUERY");

            stmt.close();
            stmt = null;

            conn.close();
            conn = null;
        } finally {
            /*
             * close any jdbc instances here that weren't
             * explicitly closed during normal code path, so

```

```
    * that we don't 'leak' resources...
    */

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) {
            // ignore, as we can't do anything about it here
        }

        stmt = null;
    }

    if (conn != null) {
        try {
            conn.close();
        } catch (SQLException sqlEx) {
            // ignore, as we can't do anything about it here
        }

        conn = null;
    }
}
}
```

As shown in the example above, after obtaining the JNDI `InitialContext`, and looking up the `DataSource`, the rest of the code follows familiar JDBC conventions.

When using connection pooling, always make sure that connections, and anything created by them (such as statements or result sets) are closed. This rule applies no matter what happens in your code (exceptions, flow-of-control, and so forth). When these objects are closed, they can be re-used; otherwise, they will be stranded, which means that the MySQL server resources they represent (such as buffers, locks, or sockets) are tied up for some time, or in the worst case can be tied up forever.

## Sizing the Connection Pool

Each connection to MySQL has overhead (memory, CPU, context switches, and so forth) on both the client and server side. Every connection limits how many resources there are available to your application as well as the MySQL server. Many of these resources will be used whether or not the connection is actually doing any useful work! Connection pools can be tuned to maximize performance, while keeping resource utilization below the point where your application will start to fail rather than just run slower.

The optimal size for the connection pool depends on anticipated load and average database transaction time. In practice, the optimal connection pool size can be smaller than you might expect. If you take Sun's Java Petstore blueprint application for example, a connection pool of 15-20 connections can serve a relatively moderate load (600 concurrent users) using MySQL and Tomcat with acceptable response times.

To correctly size a connection pool for your application, create load test scripts with tools such as Apache JMeter or The Grinder, and load test your application.

An easy way to determine a starting point is to configure your connection pool's maximum number of connections to be unbounded, run a load test, and measure the largest amount of concurrently used connections. You can then work backward from there to determine what values of minimum and maximum pooled connections give the best performance for your particular application.

## Validating Connections

MySQL Connector/J can validate the connection by executing a lightweight ping against a server. In the case of load-balanced connections, this is performed against all active pooled internal connections that are retained. This is beneficial to Java applications using connection pools, as the pool can

use this feature to validate connections. Depending on your connection pool and configuration, this validation can be carried out at different times:

1. Before the pool returns a connection to the application.
2. When the application returns a connection to the pool.
3. During periodic checks of idle connections.

To use this feature, specify a validation query in your connection pool that starts with `/* ping */`. Note that the syntax must be exactly as specified. This will cause the driver send a ping to the server and return a dummy lightweight result set. When using a [ReplicationConnection](#) or [LoadBalancedConnection](#), the ping will be sent across all active connections.

It is critical that the syntax be specified correctly. The syntax needs to be exact for reasons of efficiency, as this test is done for every statement that is executed:

```
protected static final String PING_MARKER = "/* ping */";
...
if (sql.charAt(0) == '/') {
if (sql.startsWith(PING_MARKER)) {
doPingInstead();
...
}
```

None of the following snippets will work, because the ping syntax is sensitive to whitespace, capitalization, and placement:

```
sql = "/* PING */ SELECT 1";
sql = "SELECT 1 /* ping*/";
sql = "/*ping*/ SELECT 1";
sql = " /* ping */ SELECT 1";
sql = "/*to ping or not to ping*/ SELECT 1";
```

All of the previous statements will issue a normal [SELECT](#) statement and will **not** be transformed into the lightweight ping. Further, for load-balanced connections, the statement will be executed against one connection in the internal pool, rather than validating each underlying physical connection. This results in the non-active physical connections assuming a stale state, and they may die. If Connector/J then re-balances, it might select a dead connection, resulting in an exception being passed to the application. To help prevent this, you can use [loadBalanceValidateConnectionOnSwapServer](#) to validate the connection before use.

If your Connector/J deployment uses a connection pool that allows you to specify a validation query, take advantage of it, but ensure that the query starts *exactly* with `/* ping */`. This is particularly important if you are using the load-balancing or replication-aware features of Connector/J, as it will help keep alive connections which otherwise will go stale and die, causing problems later.

### 21.3.8. Load Balancing with Connector/J

Connector/J has long provided an effective means to distribute read/write load across multiple MySQL server instances for Cluster or master-master replication deployments. Starting with Connector/J 5.1.3, you can now dynamically configure load-balanced connections, with no service outage. In-process transactions are not lost, and no application exceptions are generated if any application is trying to use that particular server instance.

There are two connection string options associated with this functionality:

- [loadBalanceConnectionGroup](#) – This provides the ability to group connections from different sources. This allows you to manage these JDBC sources within a single class loader in any combination you choose. If they use the same configuration, and you want to manage them as a logical single group, give them the same name. This is the key property for management: if you do not define a name (string) for [loadBalanceConnectionGroup](#), you cannot manage the

connections. All load-balanced connections sharing the same `loadBalanceConnectionGroup` value, regardless of how the application creates them, will be managed together.

- `loadBalanceEnableJMX` – The ability to manage the connections is exposed when you define a `loadBalanceConnectionGroup`, but if you want to manage this externally, enable JMX by setting this property to `true`. This enables a JMX implementation, which exposes the management and monitoring operations of a connection group. Further, start your application with the `-Dcom.sun.management.jmxremote` JVM flag. You can then perform connect and perform operations using a JMX client such as `jconsole`.

Once a connection has been made using the correct connection string options, a number of monitoring properties are available:

- Current active host count.
- Current active physical connection count.
- Current active logical connection count.
- Total logical connections created.
- Total transaction count.

The following management operations can also be performed:

- Add host.
- Remove host.

The JMX interface, `com.mysql.jdbc.jmx.LoadBalanceConnectionGroupManagerMBean`, has the following methods:

- `int getActiveHostCount(String group);`
- `int getTotalHostCount(String group);`
- `long getTotalLogicalConnectionCount(String group);`
- `long getActiveLogicalConnectionCount(String group);`
- `long getActivePhysicalConnectionCount(String group);`
- `long getTotalPhysicalConnectionCount(String group);`
- `long getTotalTransactionCount(String group);`
- `void removeHost(String group, String host) throws SQLException;`
- `void stopNewConnectionsToHost(String group, String host) throws SQLException;`
- `void addHost(String group, String host, boolean forExisting);`
- `String getActiveHostsList(String group);`
- `String getRegisteredConnectionGroups();`

The `getRegisteredConnectionGroups()` method returns the names of all connection groups defined in that class loader.

You can test this setup with the following code:

---

```

public class Test {

    private static String URL = "jdbc:mysql:loadbalance://" +
        "localhost:3306,localhost:3310/test?" +
        "loadBalanceConnectionGroup=first&loadBalanceEnableJMX=true";

    public static void main(String[] args) throws Exception {
        new Thread(new Repeater()).start();
        new Thread(new Repeater()).start();
        new Thread(new Repeater()).start();
    }

    static Connection getNewConnection() throws SQLException, ClassNotFoundException {
        Class.forName("com.mysql.jdbc.Driver");
        return DriverManager.getConnection(URL, "root", "");
    }

    static void executeSimpleTransaction(Connection c, int conn, int trans){
        try {
            c.setAutoCommit(false);
            Statement s = c.createStatement();
            s.executeQuery("SELECT SLEEP(1) /* Connection: " + conn + ", transaction: " + trans + " */");
            c.commit();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }

    public static class Repeater implements Runnable {
        public void run() {
            for(int i=0; i < 100; i++){
                try {
                    Connection c = getNewConnection();
                    for(int j=0; j < 10; j++){
                        executeSimpleTransaction(c, i, j);
                        Thread.sleep(Math.round(100 * Math.random()));
                    }
                    c.close();
                    Thread.sleep(100);
                } catch (Exception e) {
                    e.printStackTrace();
                }
            }
        }
    }
}

```

After compiling, the application can be started with the `-Dcom.sun.management.jmxremote` flag, to enable remote management. `jconsole` can then be started. The `Test` main class will be listed by `jconsole`. Select this and click **Connect**. You can then navigate to the `com.mysql.jdbc.jmx.LoadBalanceConnectionGroupManager` bean. At this point, you can click on various operations and examine the returned result.

If you now had an additional instance of MySQL running on port 3309, you could ensure that Connector/J starts using it by using the `addHost()`, which is exposed in `jconsole`. Note that these operations can be performed dynamically without having to stop the application running.

For further information on the combination of load balancing and failover, see [Section 21.3.9, “Failover with Connector/J”](#).

### 21.3.9. Failover with Connector/J

Connector/J provides a useful load-balancing implementation for Cluster or multi-master deployments, as explained in [Section 21.3.8, “Load Balancing with Connector/J”](#). As of Connector/J 5.1.12, this same implementation is used for balancing load between read-only slaves with `ReplicationDriver`. When trying to balance workload between multiple servers, the driver has to determine when it is safe to swap servers, doing so in the middle of a transaction, for example, could cause problems. It is

important not to lose state information. For this reason, Connector/J will only try to pick a new server when one of the following happens:

1. At transaction boundaries (transactions are explicitly committed or rolled back).
2. A communication exception (SQL State starting with "08") is encountered.
3. When a `SQLException` matches conditions defined by user, using the extension points defined by the `loadBalanceSQLStateFailover`, `loadBalanceSQLExceptionSubclassFailover` or `loadBalanceExceptionChecker` properties.

The third condition revolves around three new properties introduced with Connector/J 5.1.13. It allows you to control which `SQLExceptions` trigger failover.

- `loadBalanceExceptionChecker` - The `loadBalanceExceptionChecker` property is really the key. This takes a fully-qualified class name which implements the new `com.mysql.jdbc.LoadBalanceExceptionChecker` interface. This interface is very simple, and you only need to implement the following method:

```
public boolean shouldExceptionTriggerFailover(SQLException ex)
```

A `SQLException` is passed in, and a boolean returned. A value of `true` triggers a failover, `false` does not.

You can use this to implement your own custom logic. An example where this might be useful is when dealing with transient errors when using MySQL Cluster, where certain buffers may become overloaded. The following code snippet illustrates this:

```
public class NdbLoadBalanceExceptionChecker
    extends StandardLoadBalanceExceptionChecker {

    public boolean shouldExceptionTriggerFailover(SQLException ex) {
        return super.shouldExceptionTriggerFailover(ex)
            || checkNdbException(ex);
    }

    private boolean checkNdbException(SQLException ex){
        // Have to parse the message since most NDB errors
        // are mapped to the same DEMC.
        return (ex.getMessage().startsWith("Lock wait timeout exceeded") ||
            (ex.getMessage().startsWith("Got temporary error")
            && ex.getMessage().endsWith("from NDB")));
    }
}
```

The code above extends `com.mysql.jdbc.StandardLoadBalanceExceptionChecker`, which is the default implementation. There are a few convenient shortcuts built into this, for those who want to have some level of control using properties, without writing Java code. This default implementation uses the two remaining properties: `loadBalanceSQLStateFailover` and `loadBalanceSQLExceptionSubclassFailover`.

- `loadBalanceSQLStateFailover` - allows you to define a comma-delimited list of `SQLState` code prefixes, against which a `SQLException` is compared. If the prefix matches, failover is triggered. So, for example, the following would trigger a failover if a given `SQLException` starts with "00", or is "12345":

```
loadBalanceSQLStateFailover=00,12345
```

- `loadBalanceSQLExceptionSubclassFailover` - can be used in conjunction with `loadBalanceSQLStateFailover` or on its own. If you want certain subclasses of `SQLException` to trigger failover, simply provide a comma-delimited list of fully-qualified class or interface names to check against. For example, if you want all `SQLTransientConnectionExceptions` to trigger failover, you would specify:

```
loadBalanceSQLExceptionSubclassFailover=java.sql.SQLException
```

While the three fail-over conditions enumerated earlier suit most situations, if `autoCommit` is enabled, Connector/J never re-balances, and continues using the same physical connection. This can be problematic, particularly when load-balancing is being used to distribute read-only load across multiple slaves. However, Connector/J can be configured to re-balance after a certain number of statements are executed, when `autoCommit` is enabled. This functionality is dependent upon the following properties:

- `loadBalanceAutoCommitStatementThreshold` – defines the number of matching statements which will trigger the driver to potentially swap physical server connections. The default value, 0, retains the behavior that connections with `autoCommit` enabled are never balanced.
- `loadBalanceAutoCommitStatementRegex` – the regular expression against which statements must match. The default value, blank, matches all statements. So, for example, using the following properties will cause Connector/J to re-balance after every third statement that contains the string “test”:

```
loadBalanceAutoCommitStatementThreshold=3
loadBalanceAutoCommitStatementRegex=.*test.*
```

`loadBalanceAutoCommitStatementRegex` can prove useful in a number of situations. Your application may use temporary tables, server-side session state variables, or connection state, where letting the driver arbitrarily swap physical connections before processing is complete could cause data loss or other problems. This allows you to identify a trigger statement that is only executed when it is safe to swap physical connections.

### 21.3.10. Using the Connector/J Interceptor Classes

An interceptor is a software design pattern that provides a transparent way to extend or modify some aspect of a program, similar to a user exit. No recompiling is required. With Connector/J, the interceptors are enabled and disabled by updating the connection string to refer to different sets of interceptor classes that you instantiate.

The connection properties that control the interceptors are explained in [Section 21.3.5.1, “Driver/ Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”](#):

- `connectionLifecycleInterceptors`, where you specify the fully qualified names of classes that implement the `com.mysql.jdbc.ConnectionLifecycleInterceptor` interface. In these kinds of interceptor classes, you might log events such as rollbacks, measure the time between transaction start and end, or count events such as calls to `setAutoCommit()`.
- `exceptionInterceptors`, where you specify the fully qualified names of classes that implement the `com.mysql.jdbc.ExceptionInterceptor` interface. In these kinds of interceptor classes, you might add extra diagnostic information to exceptions that can have multiple causes or indicate a problem with server settings. Because `exceptionInterceptors` classes are only called when handling a `SQLException` thrown from Connector/J code, they can be used even in production deployments without substantial performance overhead.
- `statementInterceptors`, where you specify the fully qualified names of classes that implement the `com.mysql.jdbc.StatementInterceptorV2` interface. In these kinds of interceptor classes, you might change or augment the processing done by certain kinds of statements, such as automatically checking for queried data in a `memcached` server, rewriting slow queries, logging information about statement execution, or route requests to remote servers.

### 21.3.11. Using Connector/J with Tomcat

The following instructions are based on the instructions for Tomcat-5.x, available at <http://tomcat.apache.org/tomcat-5.5-doc/jndi-datasource-examples-howto.html> which is current at the time this document was written.

First, install the `.jar` file that comes with Connector/J in `$(CATALINA_HOME)/common/lib` so that it is available to all applications installed in the container.

Next, configure the JNDI DataSource by adding a declaration resource to `$(CATALINA_HOME)/conf/server.xml` in the context that defines your web application:

```
<Context ....>

...

<Resource name="jdbc/MySQLDB"
          auth="Container"
          type="javax.sql.DataSource"/>

<ResourceParams name="jdbc/MySQLDB">
  <parameter>
    <name>factory</name>
    <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
  </parameter>

  <parameter>
    <name>maxActive</name>
    <value>10</value>
  </parameter>

  <parameter>
    <name>maxIdle</name>
    <value>5</value>
  </parameter>

  <parameter>
    <name>validationQuery</name>
    <value>SELECT 1</value>
  </parameter>

  <parameter>
    <name>testOnBorrow</name>
    <value>true</value>
  </parameter>

  <parameter>
    <name>testWhileIdle</name>
    <value>true</value>
  </parameter>

  <parameter>
    <name>timeBetweenEvictionRunsMillis</name>
    <value>10000</value>
  </parameter>

  <parameter>
    <name>minEvictableIdleTimeMillis</name>
    <value>60000</value>
  </parameter>

  <parameter>
    <name>username</name>
    <value>someuser</value>
  </parameter>

  <parameter>
    <name>password</name>
    <value>somepass</value>
  </parameter>

  <parameter>
    <name>driverClassName</name>
    <value>com.mysql.jdbc.Driver</value>
  </parameter>

  <parameter>
    <name>url</name>
```

```

    <value>jdbc:mysql://localhost:3306/test</value>
  </parameter>

</ResourceParams>
</Context>

```

Note that Connector/J 5.1.3 introduced a facility whereby, rather than use a `validationQuery` value of `SELECT 1`, it is possible to use `validationQuery` with a value set to `/* ping */`. This sends a ping to the server which then returns a fake result set. This is a lighter weight solution. It also has the advantage that if using `ReplicationConnection` or `LoadBalancedConnection` type connections, the ping will be sent across all active connections. The following XML snippet illustrates how to select this option:

```

<parameter>
  <name>validationQuery</name>
  <value>/* ping */</value>
</parameter>

```

Note that `/* ping */` has to be specified exactly.

In general, follow the installation instructions that come with your version of Tomcat, as the way you configure datasources in Tomcat changes from time to time, and if you use the wrong syntax in your XML file, you will most likely end up with an exception similar to the following:

```

Error: java.sql.SQLException: Cannot load JDBC driver class 'null ' SQL
state: null

```

Note that the auto-loading of drivers having the `META-INF/service/java.sql.Driver` class in JDBC 4.0 causes an improper undeployment of the Connector/J driver in Tomcat on Windows. Namely, the Connector/J jar remains locked. This is an initialization problem that is not related to the driver. The possible workarounds, if viable, are as follows: use `antiResourceLocking=true` as a Tomcat Context attribute, or remove the `META-INF/` directory.

## 21.3.12. Using Connector/J with JBoss

These instructions cover JBoss-4.x. To make the JDBC driver classes available to the application server, copy the `.jar` file that comes with Connector/J to the `lib` directory for your server configuration (which is usually called `default`). Then, in the same configuration directory, in the subdirectory named `deploy`, create a datasource configuration file that ends with `-ds.xml`, which tells JBoss to deploy this file as a JDBC Datasource. The file should have the following contents:

```

<datasources>
  <local-tx-datasource>

    <jndi-name>MySQLDB</jndi-name>
    <connection-url>jdbc:mysql://localhost:3306/dbname</connection-url>
    <driver-class>com.mysql.jdbc.Driver</driver-class>
    <user-name>user</user-name>
    <password>pass</password>

    <min-pool-size>5</min-pool-size>

    <max-pool-size>20</max-pool-size>

    <idle-timeout-minutes>5</idle-timeout-minutes>

    <exception-sorter-class-name>
com.mysql.jdbc.integration.jboss.ExtendedMysqlExceptionSorter
    </exception-sorter-class-name>
    <valid-connection-checker-class-name>
com.mysql.jdbc.integration.jboss.MysqlValidConnectionChecker
    </valid-connection-checker-class-name>

  </local-tx-datasource>
</datasources>

```

### 21.3.13. Using Connector/J with Spring

The Spring Framework is a Java-based application framework designed for assisting in application design by providing a way to configure components. The technique used by Spring is a well known design pattern called Dependency Injection (see [Inversion of Control Containers and the Dependency Injection pattern](#)). This article will focus on Java-oriented access to MySQL databases with Spring 2.0. For those wondering, there is a .NET port of Spring appropriately named Spring.NET.

Spring is not only a system for configuring components, but also includes support for aspect oriented programming (AOP). This is one of the main benefits and the foundation for Spring's resource and transaction management. Spring also provides utilities for integrating resource management with JDBC and Hibernate.

For the examples in this section the MySQL world sample database will be used. The first task is to set up a MySQL data source through Spring. Components within Spring use the "bean" terminology. For example, to configure a connection to a MySQL server supporting the world sample database, you might use:

```
<util:map id="dbProps">
  <entry key="db.driver" value="com.mysql.jdbc.Driver"/>
  <entry key="db.jdbcurl" value="jdbc:mysql://localhost/world"/>
  <entry key="db.username" value="myuser"/>
  <entry key="db.password" value="mypass"/>
</util:map>
```

In the above example, we are assigning values to properties that will be used in the configuration. For the datasource configuration:

```
<bean id="dataSource"
  class="org.springframework.jdbc.datasource.DriverManagerDataSource">
  <property name="driverClassName" value="${db.driver}"/>
  <property name="url" value="${db.jdbcurl}"/>
  <property name="username" value="${db.username}"/>
  <property name="password" value="${db.password}"/>
</bean>
```

The placeholders are used to provide values for properties of this bean. This means that you can specify all the properties of the configuration in one place instead of entering the values for each property on each bean. We do, however, need one more bean to pull this all together. The last bean is responsible for actually replacing the placeholders with the property values.

```
<bean
  class="org.springframework.beans.factory.config.PropertyPlaceholderConfigurer">
  <property name="properties" ref="dbProps"/>
</bean>
```

Now that we have our MySQL data source configured and ready to go, we write some Java code to access it. The example below will retrieve three random cities and their corresponding country using the data source we configured with Spring.

```
// Create a new application context. this processes the Spring config
ApplicationContext ctx =
  new ClassPathXmlApplicationContext("exlappContext.xml");
// Retrieve the data source from the application context
DataSource ds = (DataSource) ctx.getBean("dataSource");
// Open a database connection using Spring's DataSourceUtils
Connection c = DataSourceUtils.getConnection(ds);
try {
  // retrieve a list of three random cities
  PreparedStatement ps = c.prepareStatement(
    "select City.Name as 'City', Country.Name as 'Country' " +
    "from City inner join Country on City.CountryCode = Country.Code " +
```

```

        "order by rand() limit 3");
    ResultSet rs = ps.executeQuery();
    while(rs.next()) {
        String city = rs.getString("City");
        String country = rs.getString("Country");
        System.out.printf("The city %s is in %s\n", city, country);
    }
} catch (SQLException ex) {
    // something has failed and we print a stack trace to analyse the error
    ex.printStackTrace();
    // ignore failure closing connection
    try { c.close(); } catch (SQLException e) { }
} finally {
    // properly release our connection
    DataSourceUtils.releaseConnection(c, ds);
}

```

This is very similar to normal JDBC access to MySQL with the main difference being that we are using `DataSourceUtils` instead of the `DriverManager` to create the connection.

While it may seem like a small difference, the implications are somewhat far reaching. Spring manages this resource in a way similar to a container managed data source in a J2EE application server. When a connection is opened, it can be subsequently accessed in other parts of the code if it is synchronized with a transaction. This makes it possible to treat different parts of your application as transactional instead of passing around a database connection.

### 21.3.13.1. Using `JdbcTemplate`

Spring makes extensive use of the Template method design pattern (see [Template Method Pattern](#)). Our immediate focus will be on the `JdbcTemplate` and related classes, specifically `NamedParameterJdbcTemplate`. The template classes handle obtaining and releasing a connection for data access when one is needed.

The next example shows how to use `NamedParameterJdbcTemplate` inside of a DAO (Data Access Object) class to retrieve a random city given a country code.

```

public class Ex2JdbcDao {
    /**
     * Data source reference which will be provided by Spring.
     */
    private DataSource dataSource;

    /**
     * Our query to find a random city given a country code. Notice
     * the ":country" parameter toward the end. This is called a
     * named parameter.
     */
    private String queryString = "select Name from City " +
        "where CountryCode = :country order by rand() limit 1";

    /**
     * Retrieve a random city using Spring JDBC access classes.
     */
    public String getRandomCityByCountryCode(String centryCode) {
        // A template that permits using queries with named parameters
        NamedParameterJdbcTemplate template =
            new NamedParameterJdbcTemplate(dataSource);
        // A java.util.Map is used to provide values for the parameters
        Map params = new HashMap();
        params.put("country", centryCode);
        // We query for an Object and specify what class we are expecting
        return (String)template.queryForObject(queryString, params, String.class);
    }

    /**
     * A JavaBean setter-style method to allow Spring to inject the data source.
     * @param dataSource
     */
}

```

```

public void setDataSource(DataSource dataSource) {
    this.dataSource = dataSource;
}
}

```

The focus in the above code is on the `getRandomCityByCountryCode()` method. We pass a country code and use the `NamedParameterJdbcTemplate` to query for a city. The country code is placed in a Map with the key "country", which is the parameter is named in the SQL query.

To access this code, you need to configure it with Spring by providing a reference to the data source.

```

<bean id="dao" class="code.Ex2JdbcDao">
    <property name="dataSource" ref="dataSource"/>
</bean>

```

At this point, we can just grab a reference to the DAO from Spring and call `getRandomCityByCountryCode()`.

```

// Create the application context
ApplicationContext ctx =
new ClassPathXmlApplicationContext("ex2appContext.xml");
// Obtain a reference to our DAO
Ex2JdbcDao dao = (Ex2JdbcDao) ctx.getBean("dao");

String countryCode = "USA";

// Find a few random cities in the US
for(int i = 0; i < 4; ++i)
    System.out.printf("A random city in %s is %s%n", countryCode,
        dao.getRandomCityByCountryCode(countryCode));

```

This example shows how to use Spring's JDBC classes to completely abstract away the use of traditional JDBC classes including `Connection` and `PreparedStatement`.

### 21.3.13.2. Transactional JDBC Access

You might be wondering how we can add transactions into our code if we do not deal directly with the JDBC classes. Spring provides a transaction management package that not only replaces JDBC transaction management, but also enables declarative transaction management (configuration instead of code).

To use transactional database access, we will need to change the storage engine of the tables in the world database. The downloaded script explicitly creates MyISAM tables which do not support transactional semantics. The InnoDB storage engine does support transactions and this is what we will be using. We can change the storage engine with the following statements.

```

ALTER TABLE City ENGINE=InnoDB;
ALTER TABLE Country ENGINE=InnoDB;
ALTER TABLE CountryLanguage ENGINE=InnoDB;

```

A good programming practice emphasized by Spring is separating interfaces and implementations. What this means is that we can create a Java interface and only use the operations on this interface without any internal knowledge of what the actual implementation is. We will let Spring manage the implementation and with this it will manage the transactions for our implementation.

First you create a simple interface:

```

public interface Ex3Dao {
    Integer createCity(String name, String countryCode,
        String district, Integer population);
}

```

This interface contains one method that will create a new city record in the database and return the id of the new record. Next you need to create an implementation of this interface.

```

public class Ex3DaoImpl implements Ex3Dao {
    protected DataSource dataSource;
    protected SqlUpdate updateQuery;
    protected SqlFunction idQuery;

    public Integer createCity(String name, String countryCode,
        String district, Integer population) {
        updateQuery.update(new Object[] { name, countryCode,
            district, population });
        return getLastId();
    }

    protected Integer getLastId() {
        return idQuery.run();
    }
}

```

You can see that we only operate on abstract query objects here and do not deal directly with the JDBC API. Also, this is the complete implementation. All of our transaction management will be dealt with in the configuration. To get the configuration started, we need to create the DAO.

```

<bean id="dao" class="code.Ex3DaoImpl">
    <property name="dataSource" ref="dataSource"/>
    <property name="updateQuery">...</property>
    <property name="idQuery">...</property>
</bean>

```

Now you need to set up the transaction configuration. The first thing you must do is create transaction manager to manage the data source and a specification of what transaction properties are required for the `dao` methods.

```

<bean id="transactionManager"
    class="org.springframework.jdbc.datasource.DataSourceTransactionManager">
    <property name="dataSource" ref="dataSource"/>
</bean>

<tx:advice id="txAdvice" transaction-manager="transactionManager">
    <tx:attributes>
        <tx:method name="*" />
    </tx:attributes>
</tx:advice>

```

The preceding code creates a transaction manager that handles transactions for the data source provided to it. The `txAdvice` uses this transaction manager and the attributes specify to create a transaction for all methods. Finally you need to apply this advice with an AOP pointcut.

```

<aop:config>
    <aop:pointcut id="daoMethods"
        expression="execution(* code.Ex3Dao.*(..))"/>
    <aop:advisor advice-ref="txAdvice" pointcut-ref="daoMethods"/>
</aop:config>

```

This basically says that all methods called on the `Ex3Dao` interface will be wrapped in a transaction. To make use of this, you only have to retrieve the `dao` from the application context and call a method on the `dao` instance.

```

Ex3Dao dao = (Ex3Dao) ctx.getBean("dao");
Integer id = dao.createCity(name, countryCode, district, pop);

```

We can verify from this that there is no transaction management happening in our Java code and it is all configured with Spring. This is a very powerful notion and regarded as one of the most beneficial features of Spring.

### 21.3.13.3. Connection Pooling with Spring

In many situations, such as web applications, there will be a large number of small database transactions. When this is the case, it usually makes sense to create a pool of database connections available for web requests as needed. Although MySQL does not spawn an extra process when a connection is made, there is still a small amount of overhead to create and set up the connection. Pooling of connections also alleviates problems such as collecting large amounts of sockets in the `TIME_WAIT` state.

Setting up pooling of MySQL connections with Spring is as simple as changing the data source configuration in the application context. There are a number of configurations that we can use. The first example is based on the [Jakarta Commons DBCP library](#). The example below replaces the source configuration that was based on `DriverManagerDataSource` with DBCP's `BasicDataSource`.

```
<bean id="dataSource" destroy-method="close"
  class="org.apache.commons.dbcp.BasicDataSource">
  <property name="driverClassName" value="${db.driver}"/>
  <property name="url" value="${db.jdbcurl}"/>
  <property name="username" value="${db.username}"/>
  <property name="password" value="${db.password}"/>
  <property name="initialSize" value="3"/>
</bean>
```

The configuration of the two solutions is very similar. The difference is that DBCP will pool connections to the database instead of creating a new connection every time one is requested. We have also set a parameter here called `initialSize`. This tells DBCP that we want three connections in the pool when it is created.

Another way to configure connection pooling is to configure a data source in our J2EE application server. Using JBoss as an example, you can set up the MySQL connection pool by creating a file called `mysql-local-ds.xml` and placing it in the `server/default/deploy` directory in JBoss. Once we have this setup, we can use JNDI to look it up. With Spring, this lookup is very simple. The data source configuration looks like this.

```
<jee:jndi-lookup id="dataSource" jndi-name="java:MySQL_DS"/>
```

## 21.3.14. Using Connector/J with GlassFish

This section explains how to use MySQL Connector/J with Glassfish™ Server Open Source Edition 3.0.1. Glassfish can be downloaded from the [Glassfish website](#).

Once Glassfish is installed you will need to make sure it can access MySQL Connector/J. To do this copy the MySQL Connector/J JAR file to the directory `GLASSFISH_INSTALL/glassfish/lib`. For example, copy `mysql-connector-java-5.1.12-bin.jar` to `C:\glassfishv3\glassfish\lib`. Restart the Glassfish Application Server.

You are now ready to create JDBC Connection Pools and JDBC Resources.

### Creating a Connection Pool

1. In the Glassfish Administration Console, using the navigation tree navigate to **Resources, JDBC, Connection Pools**.
2. In the **JDBC Connection Pools** frame click **New**. You will enter a two step wizard.
3. In the **Name** field under **General Settings** enter the name for the connection pool, for example enter `MySQLConnPool`.
4. In the **Resource Type** field, select `javax.sql.DataSource` from the drop-down listbox.
5. In the **Database Vendor** field, select `MySQL` from the drop-down listbox. Click **Next** to go to the next page of the wizard.

6. You can accept the default settings for General Settings, Pool Settings and Transactions for this example. Scroll down to Additional Properties.
7. In Additional Properties you will need to ensure the following properties are set:
  - **ServerName** - The server to connect to. For local testing this will be `localhost`.
  - **User** - The user name with which to connect to MySQL.
  - **Password** - The corresponding password for the user.
  - **DatabaseName** - The database to connect to, for example the sample MySQL database `world`.
8. Click **Finish** to exit the wizard. You will be taken to the **JDBC Connection Pools** page where all current connection pools, including the one you just created, will be displayed.
9. In the **JDBC Connection Pools** frame click on the connection pool you just created. Here you can review and edit information about the connection pool.
10. To test your connection pool click the **Ping** button at the top of the frame. A message will be displayed confirming correct operation or otherwise. If an error message is received recheck the previous steps, and ensure that MySQL Connector/J has been correctly copied into the previously specified location.

Now that you have created a connection pool you will also need to create a JDBC Resource (data source) for use by your application.

### Creating a JDBC Resource

Your Java application will usually reference a data source object to establish a connection with the database. This needs to be created first using the following procedure.

- Using the navigation tree in the Glassfish Administration Console, navigate to **Resources**, **JDBC**, **JDBC Resources**. A list of resources will be displayed in the **JDBC Resources** frame.
- Click **New**. The **New JDBC Resource** frame will be displayed.
- In the **JNDI Name** field, enter the JNDI name that will be used to access this resource, for example enter `jdbc/MySQLDataSource`.
- In the **Pool Name** field, select a connection pool you want this resource to use from the drop-down listbox.
- Optionally, you can enter a description into the **Description** field.
- Additional properties can be added if required.
- Click **OK** to create the new JDBC resource. The **JDBC Resources** frame will list all available JDBC Resources.

#### 21.3.14.1. A Simple JSP Application with Glassfish, Connector/J and MySQL

This section shows how to deploy a simple JSP application on Glassfish, that connects to a MySQL database.

This example assumes you have already set up a suitable Connection Pool and JDBC Resource, as explained in the preceding sections. It is also assumed you have a sample database installed, such as `world`.

The main application code, `index.jsp` is presented here:

```

<%@ page import="java.sql.*, javax.sql.*, java.io.*, javax.naming.*" %>
<html>
<head><title>Hello world from JSP</title></head>
<body>
<%
    InitialContext ctx;
    DataSource ds;
    Connection conn;
    Statement stmt;
    ResultSet rs;

    try {
        ctx = new InitialContext();
        ds = (DataSource) ctx.lookup("java:comp/env/jdbc/MySQLDataSource");
        //ds = (DataSource) ctx.lookup("jdbc/MySQLDataSource");
        conn = ds.getConnection();
        stmt = conn.createStatement();
        rs = stmt.executeQuery("SELECT * FROM Country");

        while(rs.next()) {
%>
            <h3>Name: <%= rs.getString("Name") %></h3>
            <h3>Population: <%= rs.getString("Population") %></h3>
<%
        }
    }
    catch (SQLException se) {
%>
        <%= se.getMessage() %>
<%
    }
    catch (NamingException ne) {
%>
        <%= ne.getMessage() %>
<%
    }
%>
</body>
</html>

```

In addition two XML files are required: [web.xml](#), and [sun-web.xml](#). There may be other files present, such as classes and images. These files are organized into the directory structure as follows:

```

index.jsp
WEB-INF
|
- web.xml
- sun-web.xml

```

The code for [web.xml](#) is:

```

<?xml version="1.0" encoding="UTF-8"?>
<web-app version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
<display-name>HelloWebApp</display-name>
<distributable/>
<resource-ref>
    <res-ref-name>jdbc/MySQLDataSource</res-ref-name>
    <res-type>javax.sql.DataSource</res-type>
    <res-auth>Container</res-auth>
    <res-sharing-scope>Shareable</res-sharing-scope>
</resource-ref>
</web-app>

```

The code for [sun-web.xml](#) is:

```

<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE sun-web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Application Server 8.1 Servlet 2.4//EN" "http:
<sun-web-app>
    <context-root>HelloWebApp</context-root>

```

```
<resource-ref>
  <res-ref-name>jdbc/MySQLDataSource</res-ref-name>
  <jndi-name>jdbc/MySQLDataSource</jndi-name>
</resource-ref>
</sun-web-app>
```

These XML files illustrate a very important aspect of running JDBC applications on Glassfish. On Glassfish it is important to map the string specified for a JDBC resource to its JNDI name, as set up in the Glassfish administration console. In this example, the JNDI name for the JDBC resource, as specified in the Glassfish Administration console when creating the JDBC Resource, was `jdbc/MySQLDataSource`. This must be mapped to the name given in the application. In this example the name specified in the application, `jdbc/MySQLDataSource`, and the JNDI name, happen to be the same, but this does not necessarily have to be the case. Note that the XML element `<res-ref-name>` is used to specify the name as used in the application source code, and this is mapped to the JNDI name specified using the `<jndi-name>` element, in the file `sun-web.xml`. The resource also has to be created in the `web.xml` file, although the mapping of the resource to a JNDI name takes place in the `sun-web.xml` file.

If you do not have this mapping set up correctly in the XML files you will not be able to lookup the data source using a JNDI lookup string such as:

```
ds = (DataSource) ctx.lookup("java:comp/env/jdbc/MySQLDataSource");
```

You will still be able to access the data source directly using:

```
ds = (DataSource) ctx.lookup("jdbc/MySQLDataSource");
```

With the source files in place, in the correct directory structure, you are ready to deploy the application:

1. In the navigation tree, navigate to **Applications** - the **Applications** frame will be displayed. Click **Deploy**.
2. You can now deploy an application packaged into a single WAR file from a remote client, or you can choose a packaged file or directory that is locally accessible to the server. If you are simply testing an application locally you can simply point Glassfish at the directory that contains your application, without needing to package the application into a WAR file.
3. Now select the application type from the **Type** drop-down listbox, which in this example is `Web application`.
4. Click OK.

Now, when you navigate to the **Applications** frame, you will have the option to **Launch**, **Redeploy**, or **Restart** your application. You can test your application by clicking **Launch**. The application will connection to the MySQL database and display the Name and Population of countries in the `Country` table.

### 21.3.14.2. A Simple Servlet with Glassfish, Connector/J and MySQL

This section describes a simple servlet that can be used in the Glassfish environment to access a MySQL database. As with the previous section, this example assumes the sample database `world` is installed.

The project is set up with the following directory structure:

```
index.html
WEB-INF
|
- web.xml
- sun-web.xml
- classes
|
- HelloWorldServlet.java
```

```
- HelloWebServlet.class
```

The code for the servlet, located in `HelloWebServlet.java`, is as follows:

```
import javax.servlet.http.*;
import javax.servlet.*;
import java.io.*;
import java.sql.*;
import javax.sql.*;
import javax.naming.*;

public class HelloWebServlet extends HttpServlet {

    InitialContext ctx = null;
    DataSource ds = null;
    Connection conn = null;
    PreparedStatement ps = null;
    ResultSet rs = null;

    String sql = "SELECT Name, Population FROM Country WHERE Name=?";

    public void init () throws ServletException {
        try {
            ctx = new InitialContext();
            ds = (DataSource) ctx.lookup("java:comp/env/jdbc/MySQLDataSource");
            conn = ds.getConnection();
            ps = conn.prepareStatement(sql);
        }
        catch (SQLException se) {
            System.out.println("SQLException: "+se.getMessage());
        }
        catch (NamingException ne) {
            System.out.println("NamingException: "+ne.getMessage());
        }
    }

    public void destroy () {
        try {
            if (rs != null)
                rs.close();
            if (ps != null)
                ps.close();
            if (conn != null)
                conn.close();
            if (ctx != null)
                ctx.close();
        }
        catch (SQLException se) {
            System.out.println("SQLException: "+se.getMessage());
        }
        catch (NamingException ne) {
            System.out.println("NamingException: "+ne.getMessage());
        }
    }

    public void doPost(HttpServletRequest req, HttpServletResponse resp){
        try {
            String country_name = req.getParameter("country_name");
            resp.setContentType("text/html");
            PrintWriter writer = resp.getWriter();
            writer.println("<html><body>");
            writer.println("<p>Country: "+country_name+"</p>");
            ps.setString(1, country_name);
            rs = ps.executeQuery();
            if (!rs.next()){
                writer.println("<p>Country does not exist!</p>");
            }
            else {
                rs.beforeFirst();
                while(rs.next()) {
                    writer.println("<p>Name: "+rs.getString("Name")+"</p>");
                }
            }
        }
    }
}
```

```

        writer.println("<p>Population: "+rs.getString("Population")+ "</p>");
    }
}
writer.println("</body></html>");
writer.close();
}
catch (Exception e) {
    e.printStackTrace();
}
}

public void doGet(HttpServletRequest req, HttpServletResponse resp){
    try {
        resp.setContentType("text/html");
        PrintWriter writer = resp.getWriter();
        writer.println("<html><body>");
        writer.println("<p>Hello from servlet doGet()</p>");
        writer.println("</body></html>");
        writer.close();
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}
}
}

```

In the preceding code a basic `doGet()` method is implemented, but is not used in the example. The code to establish the connection with the database is as shown in the previous example, [Section 21.3.14.1, “A Simple JSP Application with Glassfish, Connector/J and MySQL”](#), and is most conveniently located in the servlet `init()` method. The corresponding freeing of resources is located in the destroy method. The main functionality of the servlet is located in the `doPost()` method. If the user enters into the input form a country name that can be located in the database, the population of the country is returned. The code is invoked using a POST action associated with the input form. The form is defined in the file `index.html`:

```

<html>
  <head><title>HelloWebServlet</title></head>

  <body>
    <h1>HelloWebServlet</h1>

    <p>Please enter country name:</p>

    <form action="HelloWebServlet" method="POST">
      <input type="text" name="country_name" length="50" />
      <input type="submit" value="Submit" />
    </form>

  </body>
</html>

```

The XML files `web.xml` and `sun-web.xml` are as for the example in the preceding section, [Section 21.3.14.1, “A Simple JSP Application with Glassfish, Connector/J and MySQL”](#), no additional changes are required.

When compiling the Java source code, you will need to specify the path to the file `javaee.jar`. On Windows, this can be done as follows:

```
shell> javac -classpath c:\glassfishv3\glassfish\lib\javaee.jar HelloWebServlet.java
```

Once the code is correctly located within its directory structure, and compiled, the application can be deployed in Glassfish. This is done in exactly the same way as described in the preceding section, [Section 21.3.14.1, “A Simple JSP Application with Glassfish, Connector/J and MySQL”](#).

Once deployed the application can be launched from within the Glassfish Administration Console. Enter a country name such as “England”, and the application will return “Country does not exist!”. Enter “France”, and the application will return a population of 59225700.

## 21.3.15. Troubleshooting Connector/J Applications

This section explains the symptoms and resolutions for the most commonly encountered issues with applications using MySQL Connector/J.

### Questions

- [22.3.15.1: \[2705\]](#) When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

What is going on? I can connect just fine with the MySQL command-line client.

- [22.3.15.2: \[2705\]](#) My application throws an SQLException 'No Suitable Driver'. Why is this happening?
- [22.3.15.3: \[2705\]](#) I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

- [22.3.15.4: \[2706\]](#) I have a servlet/application that works fine for a day, and then stops working overnight
- [22.3.15.5: \[2708\]](#) I'm trying to use JDBC 2.0 updatable result sets, and I get an exception saying my result set is not updatable.
- [22.3.15.6: \[2708\]](#) I cannot connect to the MySQL server using Connector/J, and I'm sure the connection parameters are correct.
- [22.3.15.7: \[2708\]](#) I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```
java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)
at com.mysql.jdbc.MysqlIO.readFully(MysqlIO.java:1392)
at com.mysql.jdbc.MysqlIO.readPacket(MysqlIO.java:1414)
at com.mysql.jdbc.MysqlIO.doHandshake(MysqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)
```

- [22.3.15.8: \[2709\]](#) My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads, I am getting an error and stack trace, but these only occur after a fixed period of heavy activity.
- [22.3.15.9: \[2709\]](#) When using `gcj`, a `java.io.CharConversionException` exception is raised when working with certain character sequences.
- [22.3.15.10: \[2709\]](#) Updating a table that contains a `primary key` that is either `FLOAT` or compound primary key that uses `FLOAT` fails to update the table and raises an exception.

- [22.3.15.11: \[2709\]](#) You get an `ER_NET_PACKET_TOO_LARGE [3670]` exception, even though the binary blob size you want to insert using JDBC is safely below the `max_allowed_packet [502]` size.
- [22.3.15.12: \[2709\]](#) What should you do if you receive error messages similar to the following: “Communications link failure – Last packet sent to the server was X ms ago”?
- [22.3.15.13: \[2710\]](#) Why does Connector/J not reconnect to MySQL and re-issue the statement after a communication failure, instead of throwing an Exception, even though I use the `autoReconnect` connection string option?
- [22.3.15.14: \[2711\]](#) How can I use 3-byte UTF8 with Connector/J?
- [22.3.15.15: \[2711\]](#) How can I use 4-byte UTF8, `utf8mb4` with Connector/J?
- [22.3.15.16: \[2711\]](#) Using `useServerPrepStmts=false` and certain character encodings can lead to corruption when inserting BLOBs. How can this be avoided?

## Questions and Answers

### 22.3.15.1: When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

#### What is going on? I can connect just fine with the MySQL command-line client.

MySQL Connector/J must use TCP/IP sockets to connect to MySQL, as Java does not support Unix Domain Sockets. Therefore, when MySQL Connector/J connects to MySQL, the security manager in MySQL server will use its grant tables to determine whether the connection is permitted.

You must add the necessary security credentials to the MySQL server for this to happen, using the `GRANT` statement to your MySQL Server. See [Section 13.7.1.4, “GRANT Syntax”](#), for more information.

#### Note

Testing your connectivity with the `mysql` command-line client will not work unless you add the "host" flag, and use something other than `localhost` for the host. The `mysql` command-line client will use Unix domain sockets if you use the special host name `localhost`. If you are testing connectivity to `localhost`, use `127.0.0.1` as the host name instead.

#### Warning

Changing privileges and permissions improperly in MySQL can potentially cause your server installation to not have optimal security properties.

### 22.3.15.2: My application throws an SQLException 'No Suitable Driver'. Why is this happening?

There are three possible causes for this error:

- The Connector/J driver is not in your `CLASSPATH`, see [Section 21.3.3, “Connector/J Installation”](#).
- The format of your connection URL is incorrect, or you are referencing the wrong JDBC driver.
- When using DriverManager, the `jdbc.drivers` system property has not been populated with the location of the Connector/J driver.

### 22.3.15.3: I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?
```

```
(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

Either you're running an Applet, your MySQL server has been installed with the "skip-networking" option set, or your MySQL server has a firewall sitting in front of it.

Applets can only make network connections back to the machine that runs the web server that served the .class files for the applet. This means that MySQL must run on the same machine (or you must have some sort of port re-direction) for this to work. This also means that you will not be able to test applets from your local file system, you must always deploy them to a web server.

MySQL Connector/J can only communicate with MySQL using TCP/IP, as Java does not support Unix domain sockets. TCP/IP communication with MySQL might be affected if MySQL was started with the "skip-networking" flag, or if it is firewalled.

If MySQL has been started with the "skip-networking" option set (the Debian Linux package of MySQL server does this for example), you need to comment it out in the file `/etc/mysql/my.cnf` or `/etc/my.cnf`. Of course your `my.cnf` file might also exist in the `data` directory of your MySQL server, or anywhere else (depending on how MySQL was compiled for your system). Binaries created by us always look in `/etc/my.cnf` and `datadir/my.cnf`. If your MySQL server has been firewalled, you will need to have the firewall configured to allow TCP/IP connections from the host where your Java code is running to the MySQL server on the port that MySQL is listening to (by default, 3306).

#### 22.3.15.4: I have a servlet/application that works fine for a day, and then stops working overnight

MySQL closes connections after 8 hours of inactivity. You either need to use a connection pool that handles stale connections or use the `autoReconnect` parameter (see [Section 21.3.5.1, "Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J"](#)).

Also, catch `SQLExceptions` in your application and deal with them, rather than propagating them all the way until your application exits. This is just good programming practice. MySQL Connector/J will set the `SQLState` (see `java.sql.SQLException.getSQLState()` in your API docs) to `08S01` when it encounters network-connectivity issues during the processing of a query. Attempt to reconnect to MySQL at this point.

The following (simplistic) example shows what code that can handle these exceptions might look like:

#### Example 21.12. Connector/J: Example of transaction with retry logic

```
public void doBusinessOp() throws SQLException {
    Connection conn = null;
    Statement stmt = null;
    ResultSet rs = null;

    //
    // How many times do you want to retry the transaction
    // (or at least _getting_ a connection)?
    //
    int retryCount = 5;

    boolean transactionCompleted = false;

    do {
        try {
            conn = getConnection(); // assume getting this from a
                                   // javax.sql.DataSource, or the
                                   // java.sql.DriverManager

            conn.setAutoCommit(false);

            //
            // Okay, at this point, the 'retry-ability' of the
            // transaction really depends on your application logic,
            // whether or not you're using autocommit (in this case
```

```

// not), and whether you're using transactional storage
// engines
//
// For this example, we'll assume that it's _not_ safe
// to retry the entire transaction, so we set retry
// count to 0 at this point
//
// If you were using exclusively transaction-safe tables,
// or your application could recover from a connection going
// bad in the middle of an operation, then you would not
// touch 'retryCount' here, and just let the loop repeat
// until retryCount == 0.
//
retryCount = 0;

stmt = conn.createStatement();

String query = "SELECT foo FROM bar ORDER BY baz";

rs = stmt.executeQuery(query);

while (rs.next()) {
}

rs.close();
rs = null;

stmt.close();
stmt = null;

conn.commit();
conn.close();
conn = null;

transactionCompleted = true;
} catch (SQLException sqlEx) {

//
// The two SQL states that are 'retry-able' are 08S01
// for a communications error, and 40001 for deadlock.
//
// Only retry if the error was due to a stale connection,
// communications problem or deadlock
//

String sqlState = sqlEx.getSQLState();

if ("08S01".equals(sqlState) || "40001".equals(sqlState)) {
    retryCount -= 1;
} else {
    retryCount = 0;
}
} finally {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) {
            // You'd probably want to log this...
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) {
            // You'd probably want to log this as well...
        }
    }

    if (conn != null) {
        try {
            //

```

```

        // If we got here, and conn is not null, the
        // transaction should be rolled back, as not
        // all work has been done

        try {
            conn.rollback();
        } finally {
            conn.close();
        }
    } catch (SQLException sqlEx) {
        //
        // If we got an exception here, something
        // pretty serious is going on, so we better
        // pass it up the stack, rather than just
        // logging it...

        throw sqlEx;
    }
}
} while (!transactionCompleted && (retryCount > 0));
}
}

```

### Note

Use of the `autoReconnect` option is not recommended because there is no safe method of reconnecting to the MySQL server without risking some corruption of the connection state or database state information. Instead, use a connection pool, which will enable your application to connect to the MySQL server using an available connection from the pool. The `autoReconnect` facility is deprecated, and may be removed in a future release.

#### 22.3.15.5: I'm trying to use JDBC 2.0 updatable result sets, and I get an exception saying my result set is not updatable.

Because MySQL does not have row identifiers, MySQL Connector/J can only update result sets that have come from queries on tables that have at least one [primary key](#), the query must select every primary key column, and the query can only span one table (that is, no joins). This is outlined in the JDBC specification.

Note that this issue only occurs when using updatable result sets, and is caused because Connector/J is unable to guarantee that it can identify the correct rows within the result set to be updated without having a unique reference to each row. There is no requirement to have a unique field on a table if you are using `UPDATE` or `DELETE` statements on a table where you can individually specify the criteria to be matched using a `WHERE` clause.

#### 22.3.15.6: I cannot connect to the MySQL server using Connector/J, and I'm sure the connection parameters are correct.

Make sure that the `skip-networking` [440] option has not been enabled on your server. Connector/J must be able to communicate with your server over TCP/IP; named sockets are not supported. Also ensure that you are not filtering connections through a firewall or other network security system. For more information, see [Section C.5.2.2, "Can't connect to \[local\] MySQL server"](#).

#### 22.3.15.7: I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```

java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)

```

```
at com.mysql.jdbc.MySqlIO.readFully(MySqlIO.java:1392)
at com.mysql.jdbc.MySqlIO.readPacket(MySqlIO.java:1414)
at com.mysql.jdbc.MySqlIO.doHandshake(MySqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)
```

The error probably indicates that you are using a older version of the Connector/J JDBC driver (2.0.14 or 3.0.x) and you are trying to connect to a MySQL server with version 4.1x or newer. The older drivers are not compatible with 4.1 or newer of MySQL as they do not support the newer authentication mechanisms.

It is likely that the older version of the Connector/J driver exists within your application directory or your `CLASSPATH` includes the older Connector/J package.

**22.3.15.8: My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads, I am getting an error and stack trace, but these only occur after a fixed period of heavy activity.**

This is a JBoss, not Connector/J, issue and is connected to the use of transactions. Under heavy loads the time taken for transactions to complete can increase, and the error is caused because you have exceeded the predefined timeout.

You can increase the timeout value by setting the `TransactionTimeout` attribute to the `TransactionManagerService` within the `/conf/jboss-service.xml` file (pre-4.0.3) or `/deploy/jta-service.xml` for JBoss 4.0.3 or later. See `TransactionTimeout` within the JBoss wiki for more information.

**22.3.15.9: When using gcj, a java.io.CharConversionException exception is raised when working with certain character sequences.**

This is a known issue with `gcj` which raises an exception when it reaches an unknown character or one it cannot convert. Add `useJvmCharsetConverters=true` to your connection string to force character conversion outside of the `gcj` libraries, or try a different JDK.

**22.3.15.10: Updating a table that contains a primary key that is either FLOAT or compound primary key that uses FLOAT fails to update the table and raises an exception.**

Connector/J adds conditions to the `WHERE` clause during an `UPDATE` to check the old values of the primary key. If there is no match, then Connector/J considers this a failure condition and raises an exception.

The problem is that rounding differences between supplied values and the values stored in the database may mean that the values never match, and hence the update fails. The issue will affect all queries, not just those from Connector/J.

To prevent this issue, use a primary key that does not use `FLOAT`. If you have to use a floating point column in your primary key, use `DOUBLE` or `DECIMAL` types in place of `FLOAT`.

**22.3.15.11: You get an ER\_NET\_PACKET\_TOO\_LARGE [3670] exception, even though the binary blob size you want to insert using JDBC is safely below the max\_allowed\_packet [502] size.**

This is because the `hexEscapeBlock()` method in `com.mysql.jdbc.PreparedStatement.streamToBytes()` may almost double the size of your data.

**22.3.15.12: What should you do if you receive error messages similar to the following: “Communications link failure – Last packet sent to the server was X ms ago”?**

Generally speaking, this error suggests that the network connection has been closed. There can be several root causes:

- Firewalls or routers may clamp down on idle connections (the MySQL client/server protocol does not ping).
- The MySQL Server may be closing idle connections that exceed the `wait_timeout` or `interactive_timeout` threshold.

To help troubleshoot these issues, the following tips can be used. If a recent (5.1.13+) version of Connector/J is used, you will see an improved level of information compared to earlier versions. Older versions simply display the last time a packet was sent to the server, which is frequently 0 ms ago. This is of limited use, as it may be that a packet was just sent, while a packet from the server has not been received for several hours. Knowing the period of time since Connector/J last received a packet from the server is useful information, so if this is not displayed in your exception message, it is recommended that you update Connector/J.

Further, if the time a packet was last sent/received exceeds the `wait_timeout` or `interactive_timeout` threshold, this is noted in the exception message.

Although network connections can be volatile, the following can be helpful in avoiding problems:

- Ensure connections are valid when used from the connection pool. Use a query that starts with `/* ping */` to execute a lightweight ping instead of full query. Note, the syntax of the ping needs to be exactly as specified here.
- Minimize the duration a connection object is left idle while other application logic is executed.
- Explicitly validate the connection before using it if the connection has been left idle for an extended period of time.
- Ensure that `wait_timeout` and `interactive_timeout` are set sufficiently high.
- Ensure that `tcpKeepalive` is enabled.
- Ensure that any configurable firewall or router timeout settings allow for the maximum expected connection idle time.

#### Note

Do not expect to be able to reuse a connection without problems, if it has been lying idle for a period. If a connection is to be reused after being idle for any length of time, ensure that you explicitly test it before reusing it.

#### 22.3.15.13: Why does Connector/J not reconnect to MySQL and re-issue the statement after a communication failure, instead of throwing an Exception, even though I use the `autoReconnect` connection string option?

There are several reasons for this. The first is transactional integrity. The MySQL Reference Manual states that “there is no safe method of reconnecting to the MySQL server without risking some corruption of the connection state or database state information”. Consider the following series of statements for example:

```
conn.createStatement().execute(
    "UPDATE checking_account SET balance = balance - 1000.00 WHERE customer='Smith'");
conn.createStatement().execute(
    "UPDATE savings_account SET balance = balance + 1000.00 WHERE customer='Smith'");
conn.commit();
```

Consider the case where the connection to the server fails after the `UPDATE` to `checking_account`. If no exception is thrown, and the application never learns about the problem, it will continue executing. However, the server did not commit the first transaction in this case, so that will get rolled back. But execution continues with the next transaction, and increases the `savings_account` balance by 1000. The application did not receive an exception, so it continued regardless, eventually committing the

second transaction, as the commit only applies to the changes made in the new connection. Rather than a transfer taking place, a deposit was made in this example.

Note that running with `autocommit` enabled does not solve this problem. When Connector/J encounters a communication problem, there is no means to determine whether the server processed the currently executing statement or not. The following theoretical states are equally possible:

- The server never received the statement, and therefore no related processing occurred on the server.
- The server received the statement, executed it in full, but the response was not received by the client.

If you are running with `autocommit` enabled, it is not possible to guarantee the state of data on the server when a communication exception is encountered. The statement may have reached the server, or it may not. All you know is that communication failed at some point, before the client received confirmation (or data) from the server. This does not only affect `autocommit` statements though. If the communication problem occurred during `Connection.commit()`, the question arises of whether the transaction was committed on the server before the communication failed, or whether the server received the commit request at all.

The second reason for the generation of exceptions is that transaction-scoped contextual data may be vulnerable, for example:

- Temporary tables.
- User-defined variables.
- Server-side prepared statements.

These items are lost when a connection fails, and if the connection silently reconnects without generating an exception, this could be detrimental to the correct execution of your application.

In summary, communication errors generate conditions that may well be unsafe for Connector/J to simply ignore by silently reconnecting. It is necessary for the application to be notified. It is then for the application developer to decide how to proceed in the event of connection errors and failures.

#### **22.3.15.14: How can I use 3-byte UTF8 with Connector/J?**

To use 3-byte UTF8 with Connector/J set `characterEncoding=utf8` and set `useUnicode=true` in the connection string.

#### **22.3.15.15: How can I use 4-byte UTF8, `utf8mb4` with Connector/J?**

To use 4-byte UTF8 with Connector/J configure the MySQL server with `character_set_server=utf8mb4`. Connector/J will then use that setting as long as `characterEncoding` has not been set in the connection string. This is equivalent to autodetection of the character set.

#### **22.3.15.16: Using `useServerPrepStmts=false` and certain character encodings can lead to corruption when inserting BLOBs. How can this be avoided?**

When using certain character encodings, such as SJIS, CP932, and BIG5, it is possible that BLOB data contains characters that can be interpreted as control characters, for example, backslash, '\'. This can lead to corrupted data when inserting BLOBs into the database. There are two things that need to be done to avoid this:

1. Set the connection string option `useServerPrepStmts` to `true`.
2. Set `SQL_MODE` to `NO_BACKSLASH_ESCAPES`.

---

## 21.3.16. Connector/J Support

### 21.3.16.1. Connector/J Community Support

Oracle provides assistance to the user community by means of its mailing lists. For Connector/J related issues, you can get help from experienced users by using the MySQL and Java mailing list. Archives and subscription information is available online at <http://lists.mysql.com/java>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.6.1, "MySQL Mailing Lists"](#).

Community support from experienced users is also available through the [JDBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.6.2, "MySQL Community Support at the MySQL Forums"](#).

### 21.3.16.2. How to Report Connector/J Bugs or Problems

The normal place to report bugs is <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public, and can be browsed and searched by anyone. If you log in to the system, you will also be able to enter new reports.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert\\_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support at <http://support.oracle.com/>.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release.

This section will help you write your report correctly so that you do not waste your time doing things that may not help us much or at all.

If you have a repeatable bug report, please report it to the bugs database at <http://bugs.mysql.com/>. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

To report other problems, you can use one of the MySQL mailing lists.

Remember that it is possible for us to respond to a message containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter.

A good principle is this: If you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of Connector/J or MySQL used, and (b) not fully describing the platform on which Connector/J is installed (including the JVM version, and the platform type and version number that MySQL itself is installed on).

This is highly relevant information, and in 99 cases out of 100, the bug report is useless without it. Very often we get questions like, "Why doesn't this work for me?" Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has already been fixed in newer MySQL versions.

Sometimes the error is platform-dependent; in such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If at all possible, create a repeatable, standalone testcase that doesn't involve any third-party classes.

To streamline this process, we ship a base class for testcases with Connector/J, named `'com.mysql.jdbc.util.BaseBugReport'`. To create a testcase for Connector/J using this class,

create your own class that inherits from `com.mysql.jdbc.util.BaseBugReport` and override the methods `setUp()`, `tearDown()` and `runTest()`.

In the `setUp()` method, create code that creates your tables, and populates them with any data needed to demonstrate the bug.

In the `runTest()` method, create code that demonstrates the bug using the tables and data you created in the `setUp` method.

In the `tearDown()` method, drop any tables you created in the `setUp()` method.

In any of the above three methods, use one of the variants of the `getConnection()` method to create a JDBC connection to MySQL:

- `getConnection()` - Provides a connection to the JDBC URL specified in `getUrl()`. If a connection already exists, that connection is returned, otherwise a new connection is created.
- `getNewConnection()` - Use this if you need to get a new connection for your bug report (that is, there is more than one connection involved).
- `getConnection(String url)` - Returns a connection using the given URL.
- `getConnection(String url, Properties props)` - Returns a connection using the given URL and properties.

If you need to use a JDBC URL that is different from 'jdbc:mysql:///test', override the method `getUrl()` as well.

Use the `assertTrue(boolean expression)` and `assertTrue(String failureMessage, boolean expression)` methods to create conditions that must be met in your testcase demonstrating the behavior you are expecting (vs. the behavior you are observing, which is why you are most likely filing a bug report).

Finally, create a `main()` method that creates a new instance of your testcase, and calls the `run` method:

```
public static void main(String[] args) throws Exception {
    new MyBugReport().run();
}
```

Once you have finished your testcase, and have verified that it demonstrates the bug you are reporting, upload it with your bug report to <http://bugs.mysql.com/>.

## 21.4. MySQL Connector/C++

MySQL Connector/C++ is a MySQL database connector for C++. It lets you develop C++ applications that connect to the MySQL Server.

For release notes detailing the changes in each release of MySQL Connector/C++, see [MySQL Connector/C++ Release Notes](#).

### MySQL Connector/C++ Benefits

MySQL Connector/C++ offers the following benefits for C++ users compared to the MySQL C API (MySQL client library):

- Convenience of pure C++; no C function calls required
- Supports JDBC 4.0, an industry standard API
- Supports the object-oriented programming paradigm
- Reduces development time

- Licensed under the GPL with the FLOSS License Exception
- Available under a commercial license upon request

## JDBC Compatibility

MySQL Connector/C++ is compatible with the JDBC 4.0 API. MySQL Connector/C++ does not implement the entire JDBC 4.0 API, but does feature the following classes:

- `Connection`
- `DatabaseMetaData`
- `Driver`
- `PreparedStatement`
- `ResultSet`
- `ResultSetMetaData`
- `Savepoint`
- `Statement`

The JDBC 4.0 API defines approximately 450 methods for the classes just mentioned. MySQL Connector/C++ implements approximately 80% of these.

## Platform Support and Prerequisites

MySQL Connector/C++ requires:

- MySQL 5.1 or later
- Microsoft Visual Studio 2003 or later on Windows

The release has been successfully compiled and tested on the following platforms:

### AIX

- 5.2 (PPC32, PPC64)
- 5.3 (PPC32, PPC64)

### FreeBSD

- 6.0 (x86, x86\_64)

### HPUX

- 11.11 (PA-RISC 32bit, PA-RISC 64bit)

### Linux

- Debian 3.1 (PPC32, x86)
- FC4 (x86)
- RHEL 3 (ia64, x86, x86\_64)
- RHEL 4 (ia64, x86, x86\_64)
- RHEL 5 (ia64, x86, x86\_64)

- SLES 9 (ia64, x86, x86\_64)
- SLES 10 (ia64, x86\_64)
- SuSE 10.3, (x86\_64)
- Ubuntu 8.04 (x86)
- Ubuntu 8.10 (x86\_64)

#### **Mac OS X**

- Mac OS X 10.3 (PPC32, PPC64)
- Mac OS X 10.4 (PPC32, PPC64, x86)
- Mac OS X 10.5 (PPC32, PPC64, x86, x86\_64)

#### **SunOS**

- Solaris 8 (SPARC32, SPARC64, x86)
- Solaris 9 (SPARC32, SPARC64, x86)
- Solaris 10 (SPARC32, SPARC64, x86, x86\_64)

#### **Windows**

- XP Professional (32bit)
- 2003 (64bit)

## **Release Status**

MySQL Connector/C++ is available as a Generally Available (GA) version. We ask users and developers to try it out and provide feedback.

Note that MySQL Workbench is successfully using MySQL Connector/C++.

If you have any queries, please [contact us](#).

## **Licensing**

MySQL Connector/C++ is licensed under the terms of the GPL, like most MySQL Connectors. There are special exceptions to the terms and conditions of the GPL as applied to this software; see FLOSS License Exception. If you need a non-GPL license for commercial distribution, please contact us.

### **21.4.1. How to Get MySQL Connector/C++**

Binary and source packages can be obtained from [MySQL Connector/C++ downloads](#).

#### **MySQL Connector/C++ Binary Distributions**

Binary distributions are available for these platforms:

Microsoft Windows:

- MSI installer package
- Without installer (a Zip file)

Other platforms:

- Compressed GNU TAR archive ([tar.gz](#))

## MySQL Connector/C++ Source Distributions

Source packages use compressed GNU TAR file (`tar.gz`) format and can be used on any supported platform.

## MySQL Connector/C++ Source Repository

The latest development sources are available through [Launchpad](#).

The MySQL Connector/C++ code repository uses Bazaar. To check out the latest source code, use the `bzr` command-line tool:

```
shell> bzr branch lp:~mysql/mysql-connector-cpp/trunk .
```

### 21.4.2. Installing MySQL Connector/C++ from a Binary Distribution

#### Caution

One problem that can occur is when the tools you use to build your application are not compatible with the tools used to build the binary versions of MySQL Connector/C++. Ideally, build your application with the same tools that were used to build the MySQL Connector/C++ binaries. To help with this, the following resources are provided.

All distributions include a [README](#) file that contains platform-specific notes. At the end of the [README](#) file contained in the binary distribution, you will find the settings used to build the binaries. If you experience build-related issues on a platform, it may help to check the settings used on the platform to build the binary.

Developers using Microsoft Windows must satisfy the following requirements:

1. Use a supported version of Visual Studio, either Visual Studio 2005 or Visual Studio 2008.
2. Ensure that your application uses the same runtime library as that used to build MySQL Connector/C++. Visual Studio 2005 builds use `Microsoft.VC80.CRT (8.0.50727.762)`, and Visual Studio 2008 builds use `Microsoft.VC90.CRT (9.0.21022.8)`.
3. Your application should use the same linker configuration as MySQL Connector/C++. For example, use one of `/MD`, `/MDd`, `/MT`, or `/MTd`.

To use a variation of the requirements previously listed, such as a different compiler version, release configuration, or runtime library, compile MySQL Connector/C++ from source using your desired settings and ensure that your application is built using these same settings. To avoid issues, ensure that the three variables of compiler version, runtime library, and runtime linker configuration settings are the same for both application and MySQL Connector/C++ itself.

A better solution that ensures compatibility is to build your MySQL Connector/C++ libraries from the source code using the same tools that you use to build your application.

#### Downloading MySQL Connector/C++

Binary packages can be obtained from [MySQL Connector/C++ downloads](#).

#### Archive Package

Unpack the distribution archive into an appropriate directory. If you plan to use a dynamically linked version of MySQL Connector/C++, make sure that your system can reference the MySQL client library (MySQL Connector/C++ is linked against and thus requires the MySQL client library). Consult your operating system documentation on how to modify and expand the search path for libraries. If you cannot modify the library search path, it may help to copy your application, the MySQL Connector/C++ library and the MySQL client library into the same directory. Most systems search for libraries in the current directory.

Windows users can choose between two binary packaging formats:

- Windows MSI Installer (.msi file): To use the MSI Installer, launch it and follow the prompts in the screens it presents to install MySQL Connector/C in the location of your choosing.
- Zip archive without installer (.zip file): To use a Zip archive, unpack it in the directory where you intend to install it using WinZip or another tool that can read .zip files.

### Windows MSI Installer

Using the MSI Installer may be the easiest solution. The MSI Installer does not require any administrative permissions as it simply copies files.

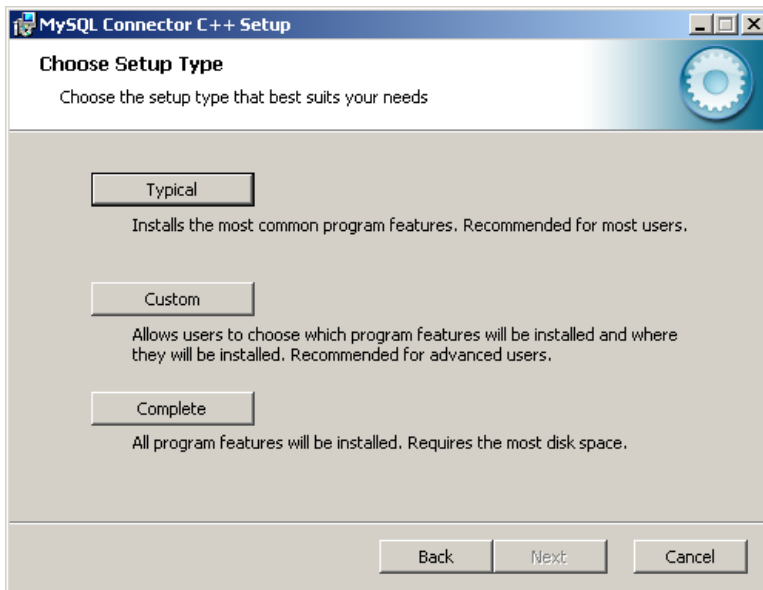

The MSI Installer begins by presenting a welcome screen.

**Figure 21.70. MSI Installer Welcome Screen**

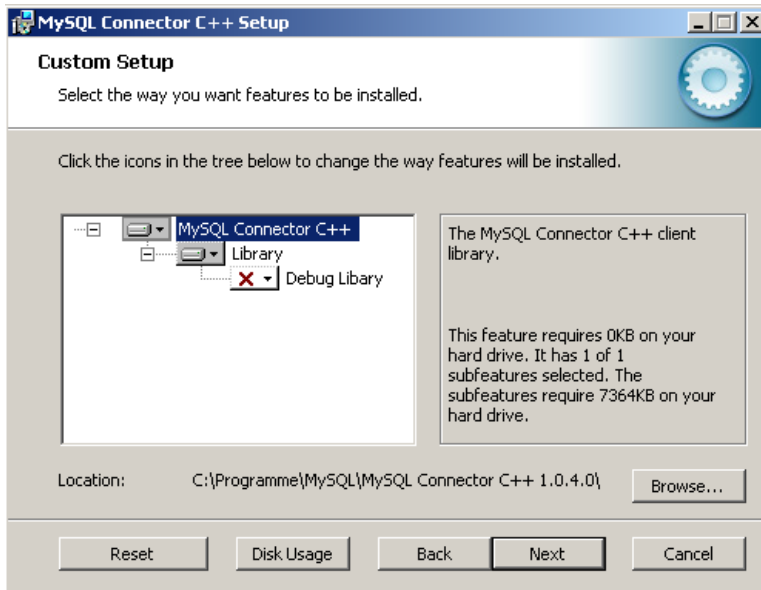

The MSI Installer overview screen enables you to select the type of installation you want to perform. The "Typical" installation consists of all required header files and the Release libraries. The "Custom" installation enables you to install additional Debug versions of the connector libraries.

**Figure 21.71. MSI Installer Overview Screen**

If you select a “Custom” installation, the MSI Installer presents a Custom Setup screen that enables you to select which features to install and where to install them.

**Figure 21.72. MSI Installer Custom Setup Screen**

### 21.4.3. Installing MySQL Connector/C++ from Source

MySQL Connector/C++ is based on the MySQL client library (MySQL C API) and is linked against it. Thus, to compile MySQL Connector/C++, the MySQL Client Library must be installed.

You also need the cross-platform build tool [CMake](#) 2.4, or newer, and [GLib](#) 2.2.3 or newer. Check the [README](#) file included with the distribution for platform-specific notes on building for Windows and SunOS.

Typically, the MySQL client library is installed when the MySQL Server is installed. However, check your operating system documentation for other installation options.

As of MySQL Connector/C++ 1.1.0, the Boost C++ libraries 1.34.0 or newer must be installed. Boost is required only to build the connector, required to use the connector. You can obtain Boost and its installation instructions from [the official site](#). Once Boost is installed, tell the build system where the Boost files are by defining the `BOOST_ROOT:STRING` option. This can be done when you invoke [CMake](#). For example:

```
shell> cmake . -DBOOST_ROOT:STRING=/usr/local/boost_1_40_0
```

Change `/usr/local/boost_1_40_0/` as necessary to match your installation. For further details, see [Section 21.4.3.1, “Building MySQL Connector/C++ from Source on Unix, Solaris, and Mac OS X”](#) and [Section 21.4.3.2, “Building MySQL Connector/C++ from Source on Windows”](#).

#### 21.4.3.1. Building MySQL Connector/C++ from Source on Unix, Solaris, and Mac OS X

1. Change location to the top-level directory of the source distribution:

```
shell> cd /path/to/mysql-connector-cpp
```

2. Run [CMake](#) to build a [Makefile](#):

```
shell> cmake .
-- Check for working C compiler: /usr/local/bin/gcc
-- Check for working C compiler: /usr/local/bin/gcc -- works
[...]
-- Generating done
-- Build files have been written to: /path/to/mysql-connector-cpp/
```

On non-Windows systems, `CMake` first checks to see if the `CMake` variable `MYSQL_CONFIG_EXECUTABLE` is set. If it is not found, `CMake` tries to locate `mysql_config` in the default locations.

If you have any problems with the configuration process, check the troubleshooting instructions given later.

- Use `make` to build the libraries. First make sure you have a clean build:

```
shell> make clean
```

Then build the connector:

```
shell> make
[ 1%] Building CXX object »
driver/CMakeFiles/mysqlcppconn.dir/mysql_connection.o
[ 3%] Building CXX object »
driver/CMakeFiles/mysqlcppconn.dir/mysql_constructed_resultset.o
[...]
[100%] Building CXX object examples/CMakeFiles/statement.dir/statement.o
Linking CXX executable statement
```

If all goes well, you will find the MySQL Connector/C++ library in the `driver` directory.

- Install the header and library files:

```
shell> make install
```

Unless you have changed the location in the configuration step, `make install` copies the header files to the directory `/usr/local/include`. The header files copied are `mysql_connection.h` and `mysql_driver.h`.

Again, unless you have specified otherwise, `make install` copies the library files to `/usr/local/lib`. The files copied are the dynamic library `libmysqlcppconn.so`, and the static library `libmysqlcppconn-static.a`. The extension of the dynamic library might be different on your system (for example, `.dylib` on Mac OS X).

If you encounter any errors, please first carry out these checks:

- `CMake` options: MySQL installation path, debug version and more

In case of configuration or compilation problems, check the list of `CMake` options:

```
shell> cmake -L
[...]
CMAKE_BACKWARDS_COMPATIBILITY:STRING=2.4
CMAKE_BUILD_TYPE:STRING=
CMAKE_INSTALL_PREFIX:PATH=/usr/local
EXECUTABLE_OUTPUT_PATH:PATH=
LIBRARY_OUTPUT_PATH:PATH=
MYSQLCPPCONN_GCOV_ENABLE:BOOL=0
MYSQLCPPCONN_TRACE_ENABLE:BOOL=0
MYSQL_CONFIG_EXECUTABLE:FILEPATH=/usr/bin/mysql_config
```

For example, if your MySQL Server installation path is not `/usr/local/mysql` and you want to build a debug version of the MySQL Connector/C++, use this command:

```
shell> cmake \
  -D CMAKE_BUILD_TYPE:STRING=Debug \
  -D MYSQL_CONFIG_EXECUTABLE=/path/to/my/mysql/server/bin/mysql_config .
```

- Verify your settings with `cmake -L`:

```
shell> cmake -L
[...]
CMAKE_BACKWARDS_COMPATIBILITY:STRING=2.4
```

```

CMAKE_BUILD_TYPE:STRING=
CMAKE_INSTALL_PREFIX:PATH=/usr/local
EXECUTABLE_OUTPUT_PATH:PATH=
LIBRARY_OUTPUT_PATH:PATH=
MYSQLCPPCONN_GCOV_ENABLE:BOOL=0
MYSQLCPPCONN_TRACE_ENABLE:BOOL=0
MYSQL_CONFIG_EXECUTABLE=/path/to/my/mysql/server/bin/mysql_config

```

Proceed by executing a `make clean` command followed by a `make` command, as described previously.

Once you have installed MySQL Connector/C++, you can carry out a quick test to check the installation. To do this, compile and run one of the example programs, such as `examples/standalone_example.cpp`. This example is discussed in more detail later, but for now, you can use it to test whether the connector has been correctly installed. This procedure assumes that you have a working MySQL Server to which you can connect. It also assumes header and library locations of `/usr/local/include` and `/usr/local/lib`, respectively; adjust these as necessary for your system.

1. Compile the example program. To do this, change location to the `examples` directory and enter this command:

```

shell> g++ -o test_install \
-I/usr/local/include -I/usr/local/include/cppconn \
-Wl,-Bdynamic -lmysqlcppconn standalone_example.cpp

```

2. Make sure the dynamic library which is used in this case can be found at runtime:

```

shell> export LD_LIBRARY_PATH=/usr/local/lib

```

3. Now run the program to test your installation, substituting the appropriate host, user, password, and database names for your system:

```

shell> ./test_install localhost root password database

```

You should see output similar to the following:

```

Connector/C++ standalone program example...

... running 'SELECT 'Welcome to Connector/C++' AS _message'
... MySQL replies: Welcome to Connector/C++
... say it again, MySQL
...MySQL replies: Welcome to Connector/C++

... find more at http://www.mysql.com

```

If you see any errors, take note of them and go through the troubleshooting procedures discussed earlier.

### 21.4.3.2. Building MySQL Connector/C++ from Source on Windows

#### Note

The only compiler formally supported for Windows is Microsoft Visual Studio 2003 and above.

The basic steps for building the connector on Windows are the same as for Unix. It is important to use `CMake` 2.6.2 or newer to generate build files for your compiler and to invoke the compiler.

#### Note

On Windows, `mysql_config` is not present, so `CMake` attempts to retrieve the location of MySQL from the environment variable `$ENV{MYSQL_DIR}`. If `MYSQL_DIR` is not set, `CMake` then proceeds to check for MySQL in the following locations: `$ENV{ProgramFiles}/MySQL/*/include`, and `$ENV{SystemDrive}/MySQL/*/include`.

**CMake** makes it easy for you to try other compilers. However, you may experience compile warnings, compile errors or linking issues not detected by Visual Studio. Patches are gratefully accepted to fix issues with other compilers.

Consult the **CMake** manual or check `cmake --help` to find out which build systems are supported by your **CMake** version:

```
C:\>cmake --help
cmake version 2.6-patch 2
Usage
[...]
Generators

The following generators are available on this platform:
  Borland Makefiles           = Generates Borland makefiles.
  MSYS Makefiles              = Generates MSYS makefiles.
  MinGW Makefiles             = Generates a make file for use with
                               mingw32-make.
  NMake Makefiles             = Generates NMake makefiles.
  Unix Makefiles              = Generates standard UNIX makefiles.
  Visual Studio 6              = Generates Visual Studio 6 project files.
  Visual Studio 7              = Generates Visual Studio .NET 2002 project
                               files.
  Visual Studio 7 .NET 2003    = Generates Visual Studio .NET 2003 project
                               files.
  Visual Studio 8 2005         = Generates Visual Studio .NET 2005 project
                               files.
  Visual Studio 8 2005 Win64   = Generates Visual Studio .NET 2005 Win64
                               project files.
  Visual Studio 9 2008         = Generates Visual Studio 9 2008 project fil
  Visual Studio 9 2008 Win64   = Generates Visual Studio 9 2008 Win64 proje
                               files.
[...]
```

It is likely that your **CMake** binary supports more compilers, known by **CMake** as *generators*, than can actually be used to build MySQL Connector/C++. We have built the connector using the following generators:

- Microsoft Visual Studio 8 (Visual Studio 2005)
- Microsoft Visual Studio 9 (Visual Studio 2008, Visual Studio 2008 Express)
- NMake

Please see the building instructions for Unix, Solaris and Mac OS X for troubleshooting and configuration hints.

Use these steps to build the connector:

1. Change location to the top-level directory of the source distribution:

```
shell> cd C:\path_to_mysql_cpp
```

2. Run **CMake** to generate build files for your generator:

### Visual Studio

```
C:\>cmake -G "Visual Studio 9 2008"
-- Check for working C compiler: cl
-- Check for working C compiler: cl -- works
-- Detecting C compiler ABI info
-- Detecting C compiler ABI info - done

Linking CXX executable statement.exe
[100%] Built target statement

```

## 21.4.3.3. Dynamically Linking MySQL Connector/C++ Against the MySQL Client Library

### Note

This section refers to dynamic linking of MySQL Connector/C++ with the client library, not dynamic linking of the application to MySQL Connector/C++.

Precompiled binaries of MySQL Connector/C++ use static binding with the client library by default.

An application that uses MySQL Connector/C++ can be either statically or dynamically linked to the MySQL Connector/C++ libraries. MySQL Connector/C++ is usually statically linked to the underlying MySQL client library (or Connector/C). Note that, unless otherwise stated, reference to the MySQL client library is also taken to include Connector/C, which is a separately packaged, standalone version of the MySQL client library. From MySQL Connector/C++ 1.1.0 on, it is possible to also dynamically link to the underlying MySQL client library. The ability of MySQL Connector/C++ to dynamically link to MySQL client library is not enabled by default. Enabling this feature is done through a compile-time option when compiling the MySQL Connector/C++ source code.

To use the ability to dynamically link the client library to MySQL Connector/C++, define the `MYSQLCLIENT_STATIC_BINDING:BOOL` when building the MySQL Connector/C++ source code:

```
shell> rm CMakeCache.txt
shell> cmake -DMYSQLCLIENT_STATIC_BINDING:BOOL=1 .
shell> make clean
shell> make
shell> make install
```

Now, in your application, when creating a connection, MySQL Connector/C++ will select and load a client library at runtime. It will choose the client library by searching defined locations and environment variables depending on the host operating system. It is also possible when creating a connection in an application to define an absolute path to the client library to be loaded at runtime. This can be convenient if you have defined a standard location from which you want the client library to be loaded. This is sometimes done to circumvent possible conflicts with other versions of the client library that may be located on the system.

## 21.4.4. Building MySQL Connector/C++ Windows Applications with Microsoft Visual Studio

MySQL Connector/C++ is available as a static or dynamic library to use with your application. This section describes how to link the library to your application.

### Note

To avoid potential crashes, the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

### Static Library

The MySQL Connector/C++ static library file is `mysqlcppconn-static.lib`. You link this library statically with your application. Also link against the files `libmysql.dll` and `libmysql.lib`. At runtime, the application will require access to `libmysql.dll`.

### Dynamic Library

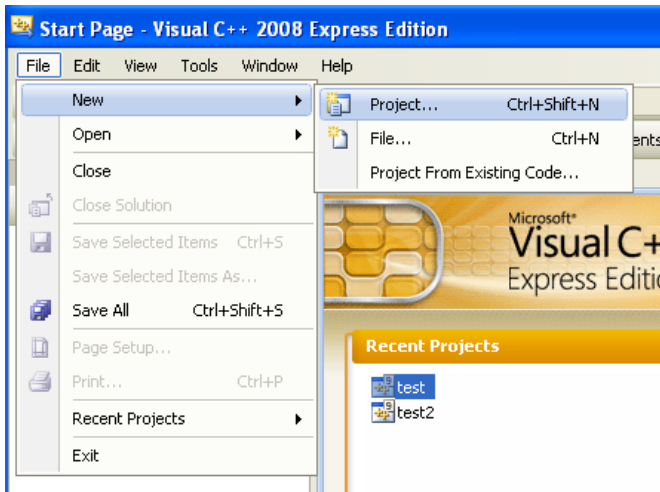

The MySQL Connector/C++ dynamic library file is `mysqlcppconn.dll`. To build your client application, link it with the file `mysqlcppconn.lib`. At runtime, the application will require access to the files `mysqlcppconn.dll` and `libmysql.dll`.

### Building a MySQL Connector/C++ Application with Microsoft Visual Studio

The initial steps for building an application to use either the static or dynamic library are the same. Some additional steps vary, depend on whether you are building your application to use the [static \[2729\]](#) or [dynamic \[2730\]](#) library.

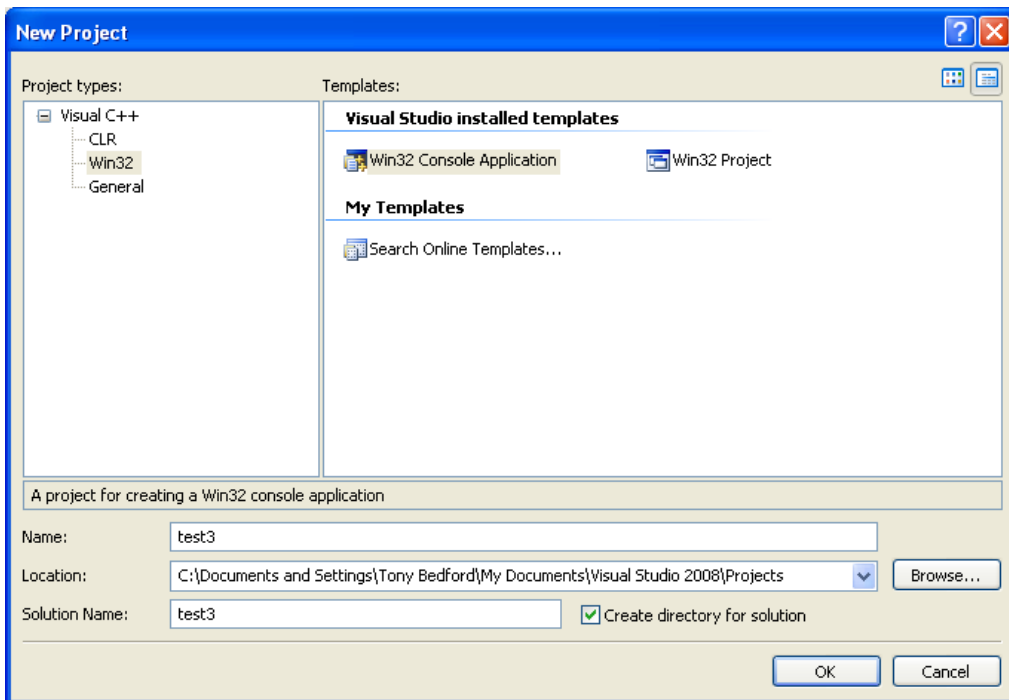

1. Select **File**, **New**, **Project** from the main menu.

**Figure 21.73. Creating a New Project**

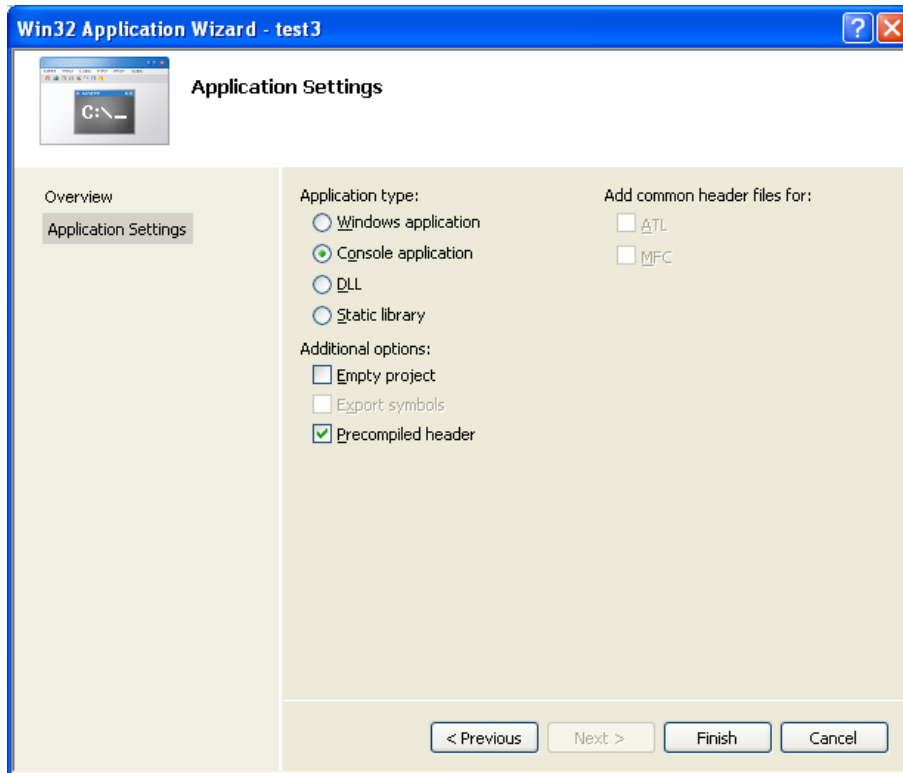

2. In the wizard, select **Visual C++**, **Win32**. From **Visual Studio Installed Templates**, select the application type **Win32 Console Application**. Enter a name for the application, then click **OK**, to move to the Win32 Application Wizard.

**Figure 21.74. The New Project Dialog Box**

3. In the Win32 Application Wizard, click **Application Settings** and ensure the defaults are selected. The radio button **Console application** and the check box **Precompiled headers** are selected. Click **Finish** to close the wizard.

**Figure 21.75. The Win32 Application Wizard**

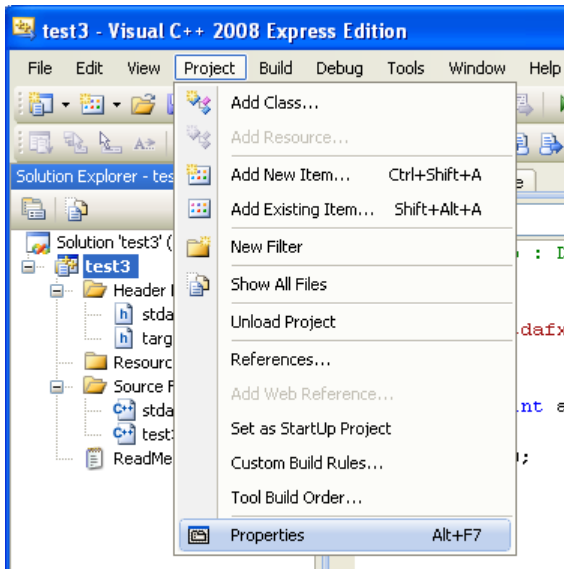

4. From the drop down list box on the toolbar, change from the default **Debug** build to the **Release** build.

**Figure 21.76. Selecting the Release Build**

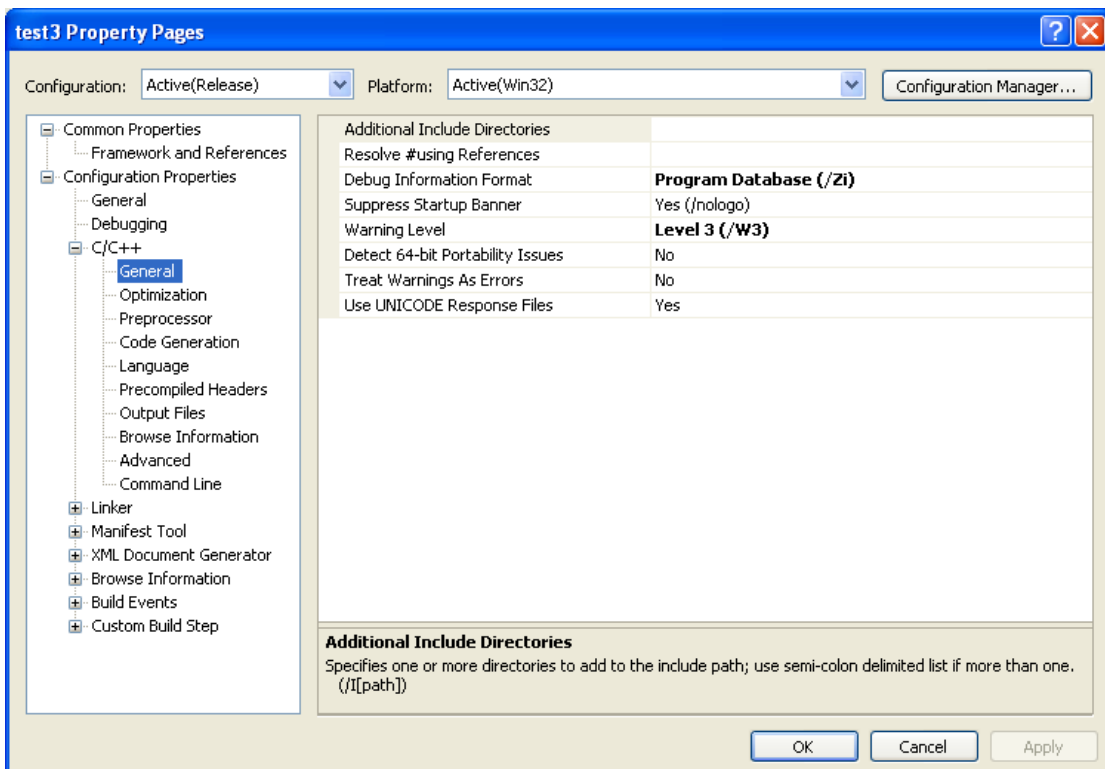

5. From the main menu select **Project**, **Properties**. This can also be accessed using the hot key **ALT + F7**.

**Figure 21.77. Selecting Project Properties from the Main Menu**

6. Under **Configuration Properties**, open the tree view.
7. Select **C++**, **General** in the tree view.

**Figure 21.78. Setting Properties**

8. Ensure that Visual Studio can find the MySQL include directory. This directory includes header files that can optionally be installed when installing MySQL Server.

Figure 21.79. MySQL Include Directory

```

C:\mysql\include>dir
Volume in drive C has no label.
Volume Serial Number is 9484-B7C3

Directory of C:\mysql\include

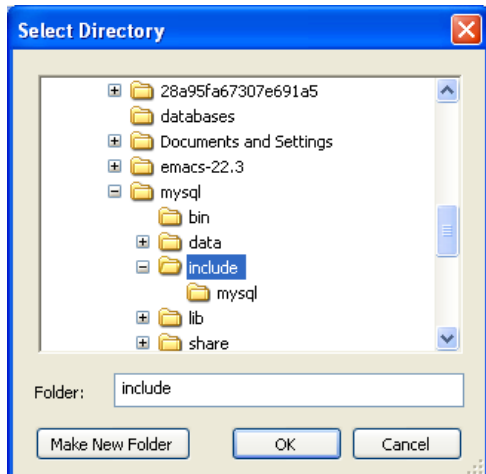

10/12/2008  13:56    <DIR>          .
10/12/2008  13:56    <DIR>          ..

C:\mysql\include>

```

- In the **Additional Include Directories** text field, add the MySQL `include/` directory.

Figure 21.80. Select Directory Dialog

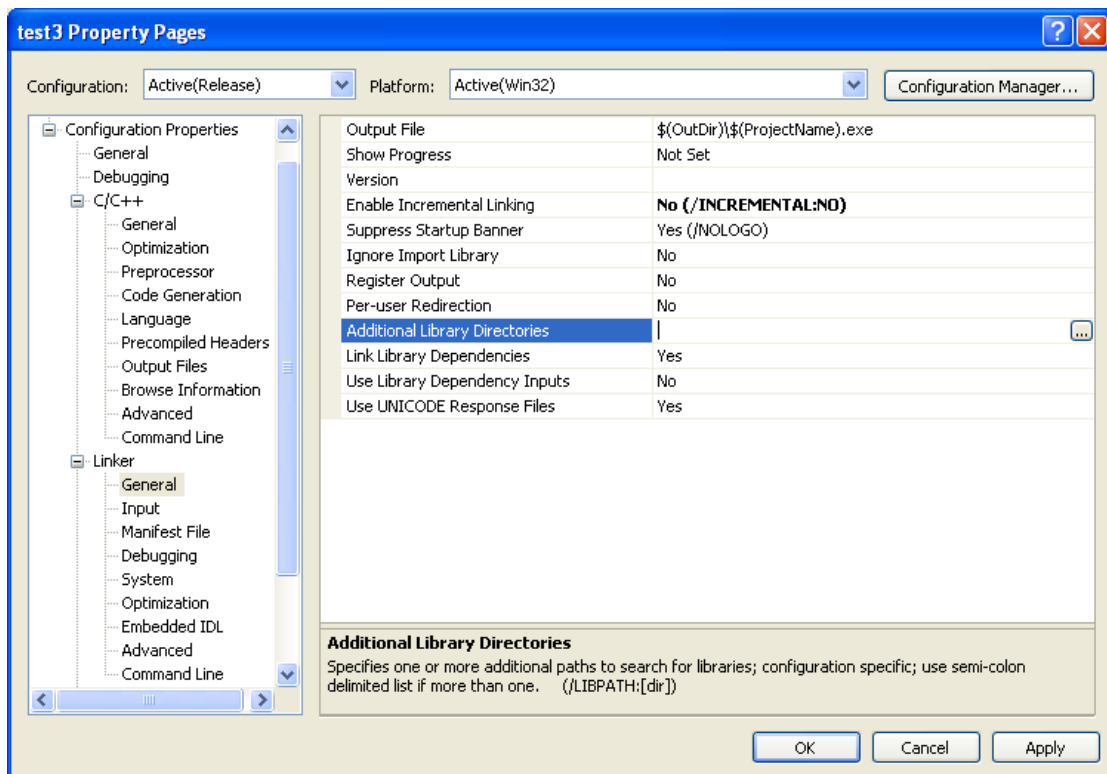

- Also set the location of additional libraries that Visual Studio needs to build the application. These are located in the MySQL `lib/opt` directory, a subdirectory of the MySQL Server installation directory.

Figure 21.81. Typical Contents of MySQL lib/opt Directory

11. In the tree view, open **Linker, General, Additional Library Directories**.

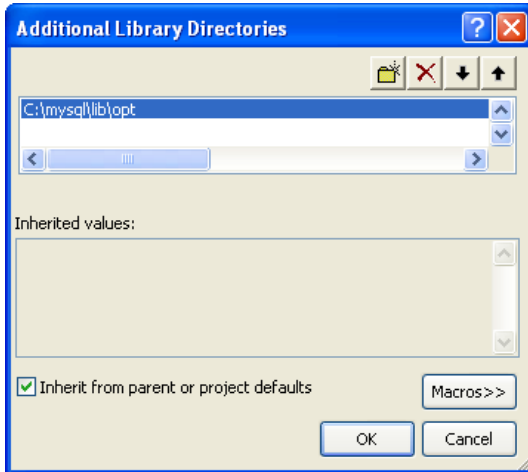

Figure 21.82. Additional Library Directories

12. Add the `lib/opt` directory into the **Additional Library Directories** text field. This enables the library file `libmysql.lib` to be found.

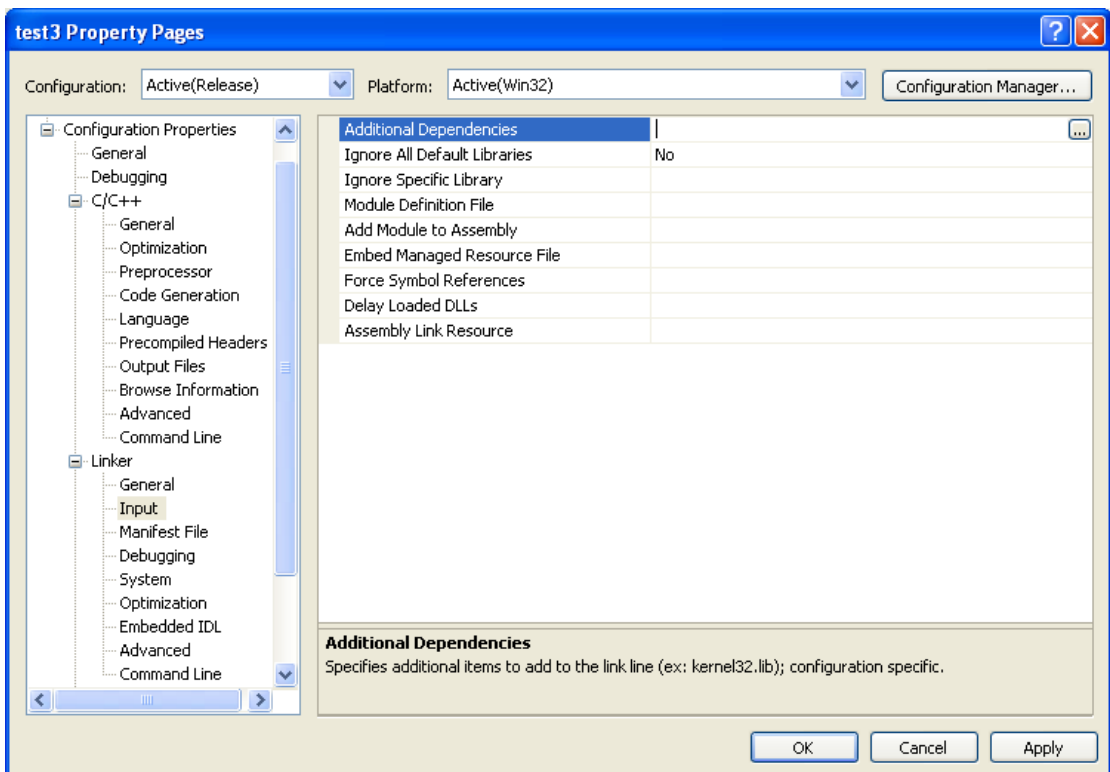

**Figure 21.83. Additional Library Directories Dialog**

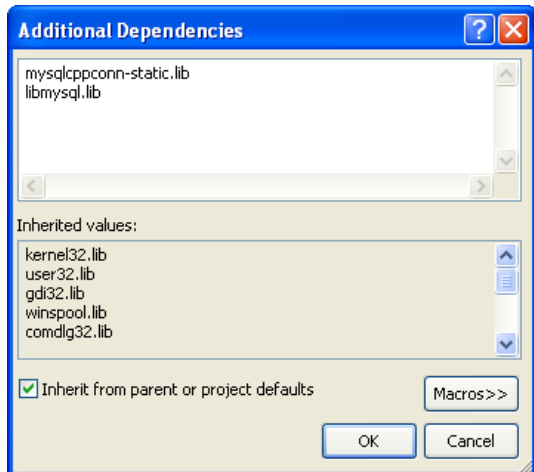

The remaining steps depend on whether you are building an application to use the MySQL Connector/C++ static or dynamic library. If you are building your application to use the dynamic library, see [Section 21.4.4, “Building MySQL Connector/C++ Windows Applications with Microsoft Visual Studio” \[2730\]](#). If you are building your application to use the static library, carry out the following steps:

1. Open **Linker, Input, Additional Dependencies**.

**Figure 21.84. Additional Dependencies**

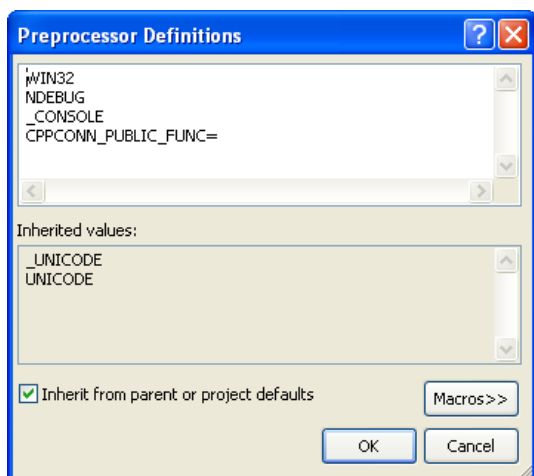

2. Enter `mysqlcppconn-static.lib` and `libmysql.lib`.

**Figure 21.85. Adding Additional Dependencies**

- By default `CPPCONN_PUBLIC_FUNC` is defined to declare functions to be compatible with an application that calls a DLL. If you are building an application to call the static library, ensure that function prototypes are compatible with this. In this case, define `CPPCONN_PUBLIC_FUNC` to be an empty string, so that functions are declared with the correct prototype.

In the **Project, Properties** tree view, under **C++**, **Preprocessor**, enter `CPPCONN_PUBLIC_FUNC=` into the **Preprocessor Definitions** text field.

**Figure 21.86. Setting the CPPCONN\_PUBLIC\_FUNC Define****Note**

Make sure you enter `CPPCONN_PUBLIC_FUNC=` and not `CPPCONN_PUBLIC_FUNC`, so that it is defined as an empty string.

If you are building an application to use the MySQL Connector/C++ dynamically linked library, carry out these steps:

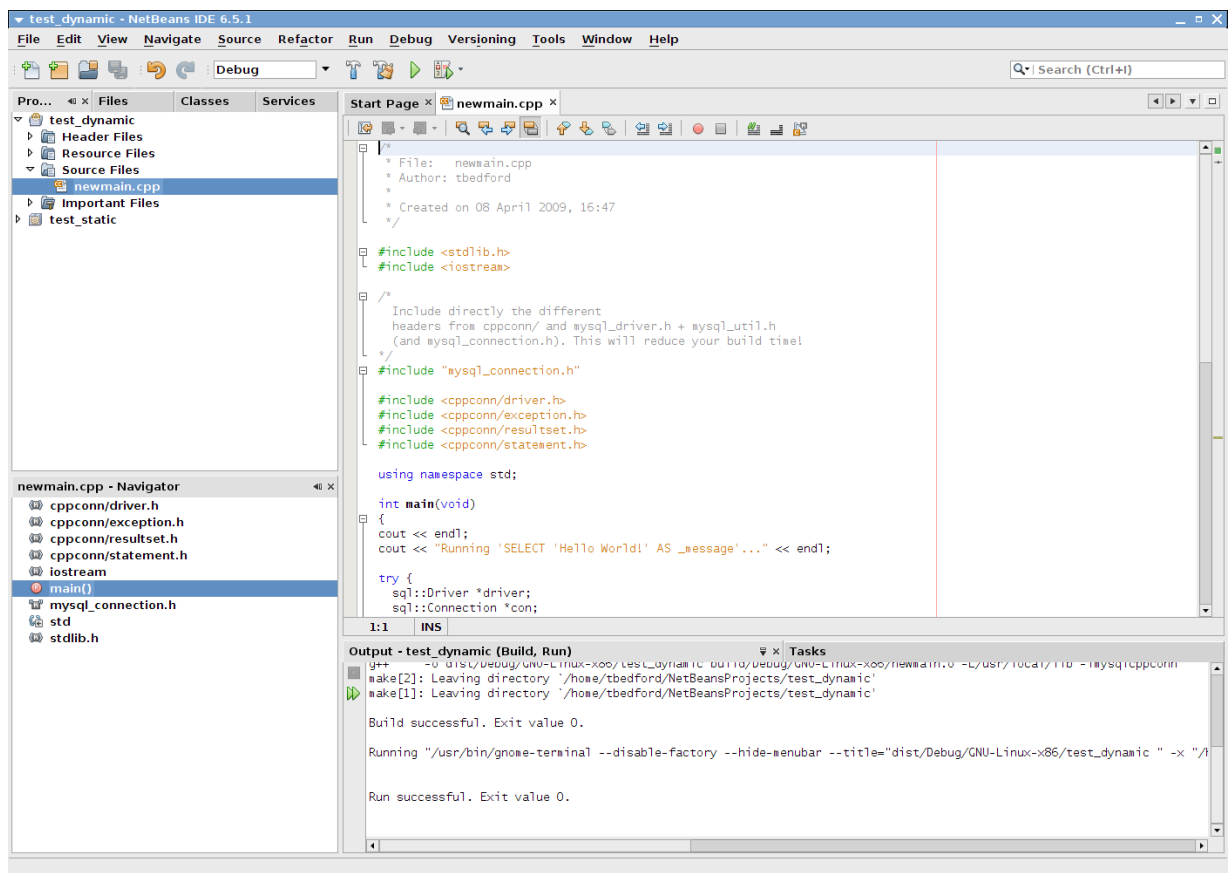

- Under **Linker, Input**, add `mysqlcppconn.lib` into the **Additional Dependencies** text field.
- `mysqlcppconn.dll` must be in the same directory as the application executable, or somewhere on the system's path, so that the application can access the MySQL Connector/C++ Dynamic Linked Library at runtime.

Copy `mysqlcppconn.dll` to the same directory as the application. Alternatively, extend the `PATH` environment variable using `SET PATH=%PATH%;C:\path\to\cpp`. Alternatively, you can copy `mysqlcppconn.dll` to the Windows installation Directory, typically `c:\windows`.

## 21.4.5. Building MySQL Connector/C++ Linux Applications with NetBeans

This section describes how to build MySQL Connector/C++ applications for Linux using the NetBeans IDE.

Figure 21.87. The NetBeans IDE

### Note

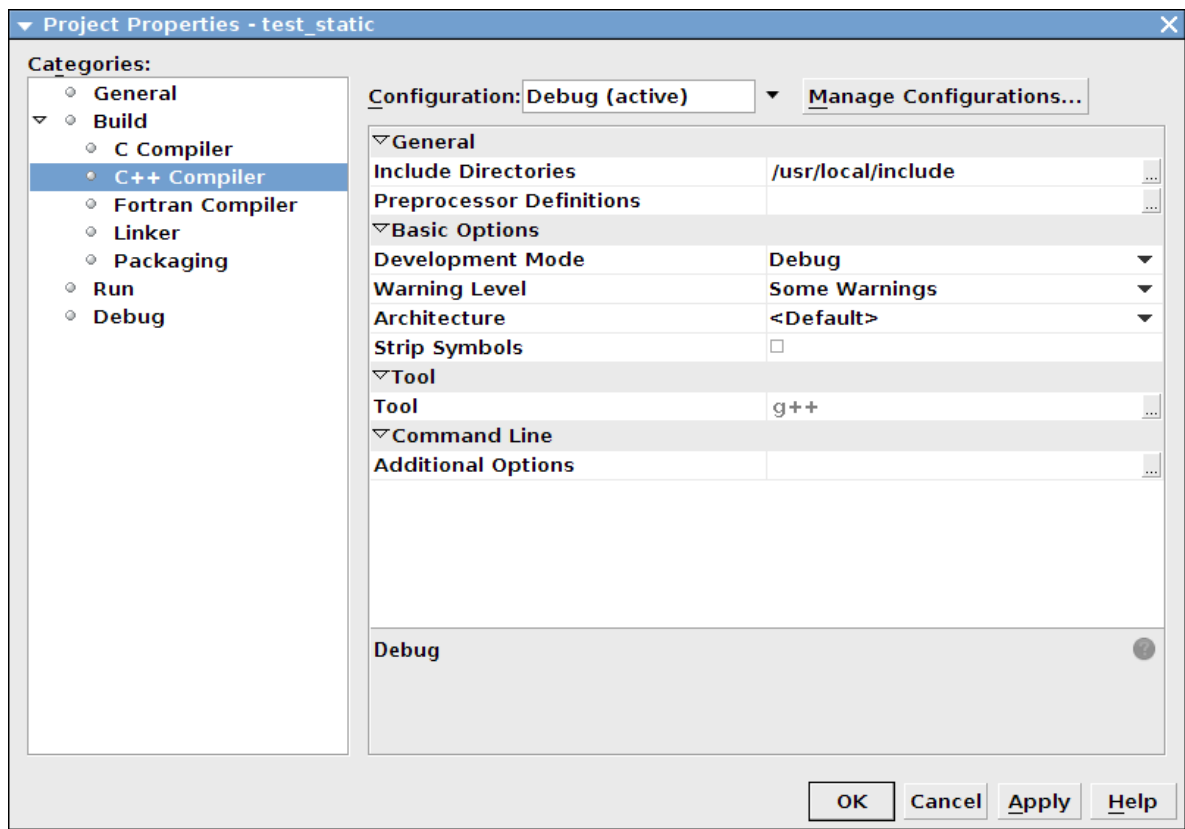

To avoid potential crashes, the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

1. Create a new project. Select **File**, **New Project**. Choose a **C/C++ Application** and click **Next**.
2. Give the project a name and click **Finish**. A new project is created.
3. In the **Projects** tab, right-click **Source Files** and select **New**, then **Main C++ File...**
4. Change the filename, or simply select the defaults and click **Finish** to add the new file to the project.
5. Now add some working code to your main source file. Explore your MySQL Connector/C++ installation and navigate to the `examples` directory.
6. Select a suitable example, such as `standalone_example_docs1.cpp`. Copy all the code in this file, and use it to replace the code in your existing main source file. Amend the code to reflect the

connection properties required for your test database. You now have a working example that will access a MySQL database using MySQL Connector/C++.

7. At this point, NetBeans shows some errors in the source code. Direct NetBeans to the necessary header files to include. Select **File, Project Properties** from the main menu.
8. In the **Categories:** tree view panel, navigate to **Build, C++ Compiler**.
9. In the **General** panel, select **Include Directories**.
10. Click the **...** button.
11. Click **Add**, then navigate to the directory where the MySQL Connector/C++ header files are located. This is `/usr/local/include` unless you have installed the files to a different location. Click **Select**. Click **OK**.

**Figure 21.88. Setting the Header Include Directory**

12. Click **OK** again to close the **Project Properties** dialog.

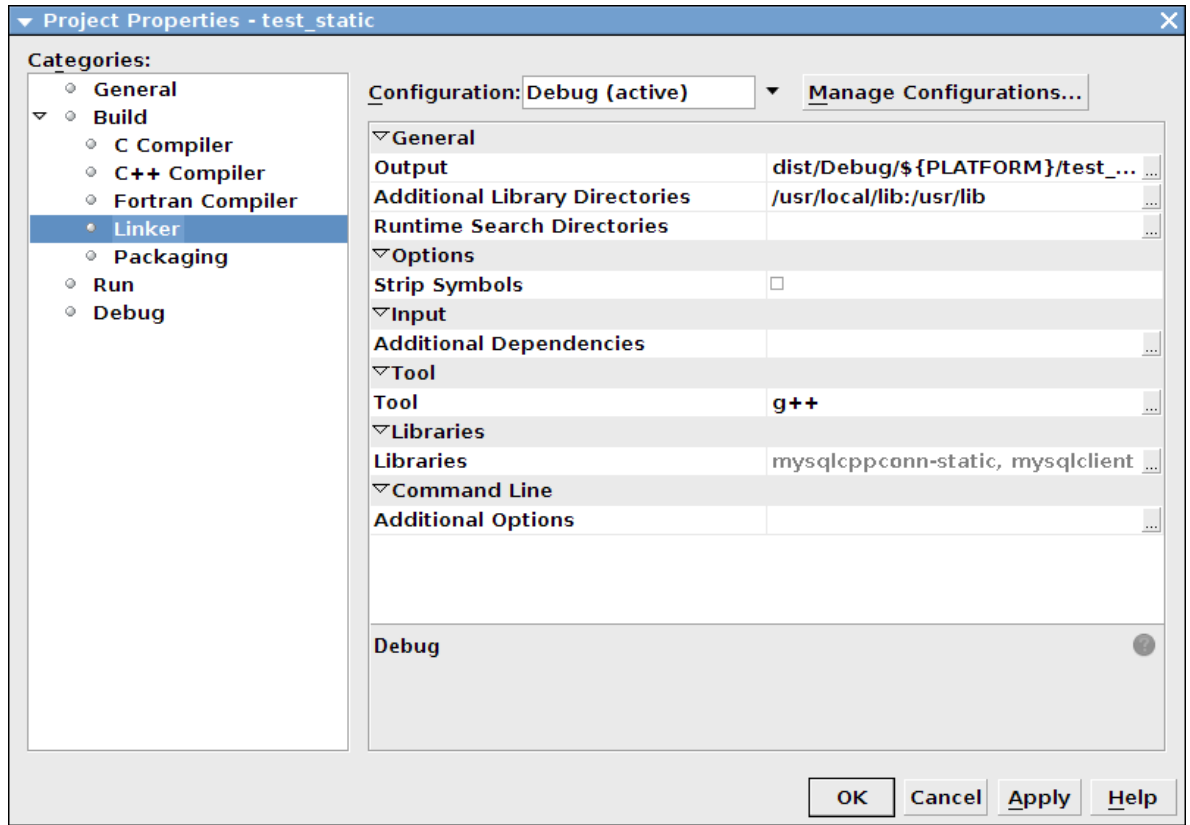

At this point, you have created a NetBeans project containing a single C++ source file. You have also ensured that the necessary include files are accessible. Before continuing, decide whether your project is to use the MySQL Connector/C++ static or dynamic library. The project settings are slightly different in each case, because you link against a different library.

### Using the Static Library

To use the static MySQL Connector/C++ library, link against two library files, `libmysqlcppconn-static.a` and `libmysqlclient.a`. The locations of the files depend on your setup, but typically the former are in `/usr/local/lib` and the latter in `/usr/lib`. The file `libmysqlclient.a` is not part of MySQL Connector/C++, but is the MySQL client library file distributed with MySQL Server. (Remember, the MySQL client library is an optional component as part of the MySQL Server installation process.) The MySQL Client Library is also available as part of the MySQL Connector/C distribution.

1. Set the project to link the necessary library files. Select **File**, **Project Properties** from the main menu.
2. In the **Categories:** tree view, navigate to **Linker**.
3. In the **General** panel, select **Additional Library Directories**. Click the **...** button.
4. Select and add the `/usr/lib` and `/usr/local/lib` directories.
5. In the same panel, add the two library files required for static linking as discussed earlier. The properties panel should then look similar to the following screenshot.

**Figure 21.89. Setting the Static Library Directories and File Names**

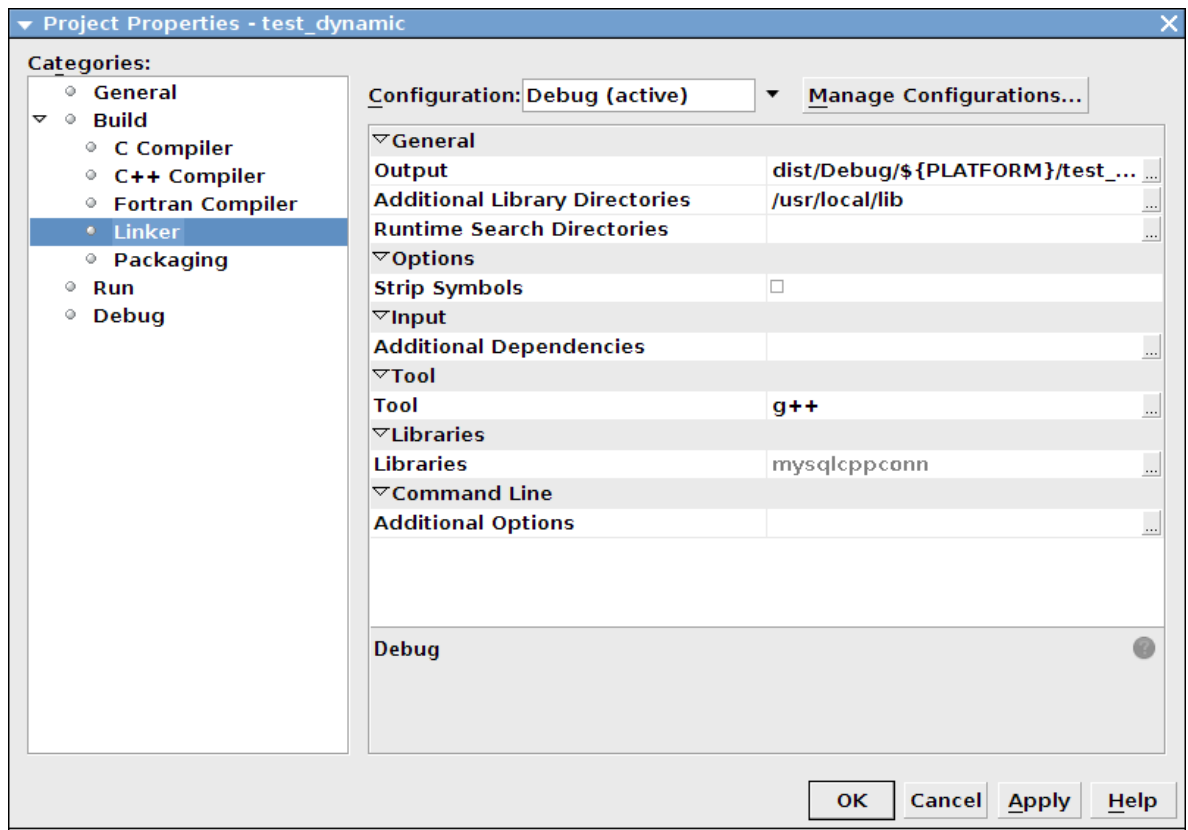

6. Click OK to close the **Project Properties** dialog.

### Using the Dynamic Library

To use the MySQL Connector/C++ dynamic library, link your project with a single library file, `libmysqlcppconn.so`. The location of this file depends on how you configured your installation of MySQL Connector/C++, but typically is `/usr/local/lib`.

1. Set the project to link the necessary library file. Select **File**, **Project Properties** from the main menu.
2. In the **Categories:** tree view, navigate to **Linker**.
3. In the **General** panel, select **Additional Library Directories**. Click the **...** button.
4. Select and add the `/usr/local/lib` directories.
5. In the same panel, add the library file required for static linking as discussed earlier. The properties panel should look similar to the following screenshot.

**Figure 21.90. Setting the Dynamic Library Directory and File Name**

6. Click OK to close the Project Properties dialog.

After configuring your project, build it by selecting **Run, Build Main Project** from the main menu. You then run the project using **Run, Run Main Project**.

On running the application, you should see a screen similar to the following (this is actually the static version of the application shown):

**Figure 21.91. The Example Application Running**A screenshot of a terminal window titled "dist/Debug/GNU-Linux-x86/test\_static". The window contains the following text:

```
Running 'SELECT 'Hello World!' AS _message'...  
... MySQL replies: Hello World!  
... MySQL says it again: Hello World!  
[Press Enter to close window]
```

**Note**

The preceding settings and procedures were carried out for the default [Debug](#) configuration. To create a [Release](#) configuration, select that configuration before setting the Project Properties.

## 21.4.6. MySQL Connector/C++ Getting Started: Usage Examples

The download package contains usage examples in the directory [examples/](#). These examples explain how to use the following classes:

- [Connection](#)
- [Driver](#)
- [PreparedStatement](#)
- [ResultSet](#)
- [ResultSetMetaData](#)
- [Statement](#)

The examples cover:

- Using the [Driver](#) class to connect to MySQL
- Creating tables, inserting rows, fetching rows using (simple) statements
- Creating tables, inserting rows, fetching rows using prepared statements
- Hints for working around prepared statement limitations
- Accessing result set metadata

The examples in this document are only code snippets, not complete programs. The code snippets provide a brief overview on the API. For complete programs, check the [examples/](#) directory of your MySQL Connector/C++ installation. Please also read the [README](#) file in that directory. To test

the example code, edit the `examples.h` file in the `examples/` directory to add your connection information, then rebuild the code by issuing a `make` command.

The examples in the `examples/` directory include:

- `examples/connect.cpp`:

How to create a connection, insert data into MySQL and handle exceptions.

- `examples/connection_meta_schemaobj.cpp`:

How to obtain metadata associated with a connection object, for example, a list of tables, databases, MySQL version, connector version.

- `examples/debug_output.cpp`:

How to activate and deactivate the MySQL Connector/C++ debug protocol.

- `examples/exceptions.cpp`:

A closer look at the exceptions thrown by the connector and how to fetch error information.

- `examples/prepared_statements.cpp`:

How to run Prepared Statements including an example how to handle SQL statements that cannot be prepared by the MySQL Server.

- `examples/resultset.cpp`:

How to use a cursor to fetch data and iterate over a result set.

- `examples/resultset_meta.cpp`:

How to obtain metadata associated with a result set, for example, number of columns and column types.

- `examples/resultset_types.cpp`:

Result sets returned from metadata methods. (This is more a test than an example.)

- `examples/standalone_example.cpp`:

Simple standalone program not integrated into regular `CMake` builds.

- `examples/statements.cpp`:

How to execute SQL statements without using Prepared Statements.

- `examples/cpp_trace_analyzer.cpp`:

This example shows how to filter the output of the `debug trace`. Please see the inline comments for further documentation. This script is unsupported.

### 21.4.6.1. MySQL Connector/C++ Connecting to MySQL

To establish a connection to MySQL Server, retrieve an instance of `sql::Connection` from a `sql::mysql::MySQL_Driver` object. A `sql::mysql::MySQL_Driver` object is returned by `sql::mysql::MySQL_Driver::get_mysql_driver_instance()`.

```
sql::mysql::MySQL_Driver *driver;
sql::Connection *con;

driver = sql::mysql::MySQL_Driver::get_mysql_driver_instance();
con = driver->connect("tcp://127.0.0.1:3306", "user", "password");
```

```
delete con;
```

Make sure that you free, `con`, the `sql::Connection` object as soon as you do not need it any more. But do not explicitly free `driver`, the connector object! The connector will take care of freeing that.

### 21.4.6.2. MySQL Connector/C++ Running a Simple Query

For running simple queries, you can use the methods `sql::Statement::execute()`, `sql::Statement::executeQuery()` and `sql::Statement::executeUpdate()`. Use the method `sql::Statement::execute()` if your query does not return a result set or if your query returns more than one result set. See the `examples/` directory for more information.

```
sql::mysql::MySQL_Driver *driver;
sql::Connection *con;
sql::Statement *stmt;

driver = sql::mysql::get_mysql_driver_instance();
con = driver->connect("tcp://127.0.0.1:3306", "user", "password");

stmt = con->createStatement();
stmt->execute("USE " EXAMPLE_DB);
stmt->execute("DROP TABLE IF EXISTS test");
stmt->execute("CREATE TABLE test(id INT, label CHAR(1))");
stmt->execute("INSERT INTO test(id, label) VALUES (1, 'a')");

delete stmt;
delete con;
```

Note that you must free `sql::Statement` and `sql::Connection` objects explicitly using `delete`.

### 21.4.6.3. MySQL Connector/C++ Fetching Results

The API for fetching result sets is identical for (simple) statements and prepared statements. If your query returns one result set, use `sql::Statement::executeQuery()` or `sql::PreparedStatement::executeQuery()` to run your query. Both methods return `sql::ResultSet` objects. The preview version does buffer all result sets on the client to support cursors.

```
// ...
sql::Connection *con;
sql::Statement *stmt;
sql::ResultSet *res;
// ...
stmt = con->createStatement();
// ...

res = stmt->executeQuery("SELECT id, label FROM test ORDER BY id ASC");
while (res->next()) {
    // You can use either numeric offsets...
    cout << "id = " << res->getInt(1); // getInt(1) returns the first column
    // ... or column names for accessing results.
    // The latter is recommended.
    cout << ", label = '" << res->getString("label") << "' << endl;
}

delete res;
delete stmt;
delete con;
```

#### Note

In the preceding code snippet, column indexing starts from 1.

Note that you must free `sql::Statement`, `sql::Connection` and `sql::ResultSet` objects explicitly using `delete`.

Cursor usage is demonstrated in the examples contained in the download package.

### 21.4.6.4. MySQL Connector/C++ Using Prepared Statements

If you are not familiar with Prepared Statements on MySQL, take a look at the source code comments and explanations in the file [examples/prepared\\_statement.cpp](#).

`sql::PreparedStatement` is created by passing an SQL query to `sql::Connection::prepareStatement()`. As `sql::PreparedStatement` is derived from `sql::Statement`, you will feel familiar with the API once you have learned how to use (simple) statements (`sql::Statement`). For example, the syntax for fetching results is identical.

```
// ...
sql::Connection *con;
sql::PreparedStatement *prep_stmt
// ...

prep_stmt = con->prepareStatement("INSERT INTO test(id, label) VALUES (?, ?)");

prep_stmt->setInt(1, 1);
prep_stmt->setString(2, "a");
prep_stmt->execute();

prep_stmt->setInt(1, 2);
prep_stmt->setString(2, "b");
prep_stmt->execute();

delete prep_stmt;
delete con;
```

As usual, you must free `sql::PreparedStatement` and `sql::Connection` objects explicitly.

### 21.4.6.5. MySQL Connector/C++ Complete Example 1

The following code shows a complete example of how to use MySQL Connector/C++:

```
/* Copyright 2008, 2010, Oracle and/or its affiliates. All rights reserved.

*/

/* Standard C++ includes */
#include <stdlib.h>
#include <iostream>

/*
   Include directly the different
   headers from cppconn/ and mysql_driver.h + mysql_util.h
   (and mysql_connection.h). This will reduce your build time!
*/
#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
```

```

using namespace std;

int main(void)
{
cout << endl;
cout << "Running 'SELECT 'Hello World!' »
    AS _message'..." << endl;

try {
    sql::Driver *driver;
    sql::Connection *con;
    sql::Statement *stmt;
    sql::ResultSet *res;

    /* Create a connection */
    driver = get_driver_instance();
    con = driver->connect("tcp://127.0.0.1:3306", "root", "root");
    /* Connect to the MySQL test database */
    con->setSchema("test");

    stmt = con->createStatement();
    res = stmt->executeQuery("SELECT 'Hello World!' AS _message");
    while (res->next()) {
        cout << "\t... MySQL replies: ";
        /* Access column data by alias or column name */
        cout << res->getString("_message") << endl;
        cout << "\t... MySQL says it again: ";
        /* Access column data by numeric offset, 1 is the first column */
        cout << res->getString(1) << endl;
    }
    delete res;
    delete stmt;
    delete con;

} catch (sql::SQLException &e) {
    cout << "# ERR: SQLException in " << __FILE__;
    cout << "(" << __FUNCTION__ << " on line " <<
        << __LINE__ << endl;
    cout << "# ERR: " << e.what();
    cout << " (MySQL error code: " << e.getErrorCode();
    cout << ", SQLState: " << e.getSQLState() << " )" << endl;
}

cout << endl;

return EXIT_SUCCESS;
}

```

### 21.4.6.6. MySQL Connector/C++ Complete Example 2

The following code shows a complete example of how to use MySQL Connector/C++:

```

/* Copyright 2008, 2010, Oracle and/or its affiliates. All rights reserved.

This program is free software; you can redistribute it and/or modify
it under the terms of the GNU General Public License as published by

Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA

```

```

*/

/* Standard C++ includes */
#include <stdlib.h>
#include <iostream>

/*
   Include directly the different
   headers from cppconn/ and mysql_driver.h + mysql_util.h
   (and mysql_connection.h). This will reduce your build time!
*/
#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
#include <cppconn/prepared_statement.h>

using namespace std;

int main(void)
{
    cout << endl;
    cout << "Let's have MySQL count from 10 to 1..." << endl;

    try {
        sql::Driver *driver;
        sql::Connection *con;
        sql::Statement *stmt;
        sql::ResultSet *res;
        sql::PreparedStatement *pstmt;

        /* Create a connection */
        driver = get_driver_instance();
        con = driver->connect("tcp://127.0.0.1:3306", "root", "root");
        /* Connect to the MySQL test database */
        con->setSchema("test");

        stmt = con->createStatement();
        stmt->execute("DROP TABLE IF EXISTS test");
        stmt->execute("CREATE TABLE test(id INT)");
        delete stmt;

        /* '?' is the supported placeholder syntax */
        pstmt = con->prepareStatement("INSERT INTO test(id) VALUES (?)");
        for (int i = 1; i <= 10; i++) {
            pstmt->setInt(1, i);
            pstmt->executeUpdate();
        }
        delete pstmt;

        /* Select in ascending order */
        pstmt = con->prepareStatement("SELECT id FROM test ORDER BY id ASC");
        res = pstmt->executeQuery();

        /* Fetch in reverse = descending order! */
        res->afterLast();
        while (res->previous())
            cout << "\t... MySQL counts: " << res->getInt("id") << endl;
        delete res;

        delete pstmt;
        delete con;
    } catch (sql::SQLException &e) {
        cout << "# ERR: SQLException in " << __FILE__;
        cout << "(" << __FUNCTION__ << " on line " <<
            << __LINE__ << endl;
        cout << "# ERR: " << e.what();
        cout << " (MySQL error code: " << e.getErrorCode();
        cout << ", SQLState: " << e.getSQLState() << >

```

```

    " )" << endl;
}

cout << endl;

return EXIT_SUCCESS;
}

```

## 21.4.7. MySQL Connector/C++ Tutorials

The following tutorials illustrate various aspects of using MySQL Connector/C++. Also consult the examples in [Section 21.4.6, “MySQL Connector/C++ Getting Started: Usage Examples”](#).

### 21.4.7.1. Prerequisites and Background Information

This section describes the prerequisites that must be satisfied before you work through the remaining tutorial sections, and shows how to set up the framework code that serves as the basis for the tutorial applications.

These tutorials refer to tables and sample data from the `world` database, which you can download from the “Example Databases” section of the [MySQL Documentation](#) page.

Each tutorial application uses a framework consisting of the following code. The examples vary at the line that says `/* INSERT TUTORIAL CODE HERE! */` within the `try` block, which is replaced for each application with the application-specific code.

```

#include <stdlib.h>
#include <iostream>
#include <sstream>
#include <stdexcept>
/* uncomment for applications that use vectors */
/*#include <vector>*/

#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
#include <cppconn/prepared_statement.h>

#define EXAMPLE_HOST "localhost"
#define EXAMPLE_USER "worlduser"
#define EXAMPLE_PASS "worldpass"
#define EXAMPLE_DB "world"

using namespace std;

int main(int argc, const char **argv)
{
    string url(argc >= 2 ? argv[1] : EXAMPLE_HOST);
    const string user(argc >= 3 ? argv[2] : EXAMPLE_USER);
    const string pass(argc >= 4 ? argv[3] : EXAMPLE_PASS);
    const string database(argc >= 5 ? argv[4] : EXAMPLE_DB);

    cout << "Connector/C++ tutorial framework..." << endl;
    cout << endl;

    try {

        /* INSERT TUTORIAL CODE HERE! */

    } catch (sql::SQLException &e) {
        /*
         * MySQL Connector/C++ throws three different exceptions:
         *
         * - sql::MethodNotImplementedException (derived from sql::SQLException)
         * - sql::InvalidArgumentException (derived from sql::SQLException)
         */
    }
}

```

```

- sql::SQLException (derived from std::runtime_error)
*/
cout << "# ERR: SQLException in " << __FILE__;
cout << "(" << __FUNCTION__ << ") on line " << __LINE__ << endl;
/* what() (derived from std::runtime_error) fetches error message */
cout << "# ERR: " << e.what();
cout << " (MySQL error code: " << e.getErrorCode();
cout << ", SQLState: " << e.getSQLState() << " )" << endl;

return EXIT_FAILURE;
}

cout << "Done." << endl;
return EXIT_SUCCESS;
}

```

Try the framework code as a standalone program using this procedure:

1. Copy and paste the framework code to a file such as `framework.cpp`. Edit the `#define` statements to reflect your connection parameters (server, user, password, database). Also, because the file contains those parameters, set its access mode to be readable only to yourself.
2. Compile the framework. For example, on Mac OS X, the command might look like this (enter the command on one line):

```

shell> g++ -o framework
-I/usr/local/include -I/usr/local/include/cppconn
-lmysqlcppconn framework.cpp

```

Adapt the command as necessary for your system. A similar command is needed for the tutorial applications that follow.

3. To run the framework, enter the following:

```

shell> ./framework

```

You will see a simple message:

```

Connector/C++ tutorial framework...
Done.

```

You are now ready to continue to the tutorials.

### 21.4.7.2. Calling Stored Procedures with `Statement` Objects

A stored procedure can be called using a `Statement` or `PreparedStatement` object. This section shows how to call stored procedures using `Statement` objects. To see how to use `PreparedStatement` objects, see [Section 21.4.7.3, "Calling Stored Procedures with PreparedStatement Objects"](#).

You can construct and call different types of stored procedures:

1. A stored procedure that returns no result. For example, such a stored procedure can log non-critical information, or change database data in a straightforward way.
2. A stored procedure that returns one or more values using output parameters. For example, such a procedure can indicate success or failure, or retrieve and return data items.
3. A stored procedure that returns one or more result sets. The procedure can execute one or more queries, each of which returns an arbitrary number of rows. Your application loops through each result set to display, transform, or otherwise process each row in it.

The following stored procedures illustrate each of these scenarios.

The following procedure adds a country to the `world` database, but does not return a result. This corresponds to Scenario 1 described earlier.

```
CREATE PROCEDURE add_country (IN country_code CHAR(3),
                             IN country_name CHAR(52),
                             IN continent_name CHAR(30))
BEGIN
  INSERT INTO Country(Code, Name, Continent)
    VALUES (country_code, country_name, continent_name);
END;
```

The next procedures use an output parameter to return the population of a specified country or continent, or the entire world. These correspond to Scenario 2 described earlier.

```
CREATE PROCEDURE get_pop (IN country_name CHAR(52),
                          OUT country_pop BIGINT)
BEGIN
  SELECT Population INTO country_pop FROM Country
    WHERE Name = country_name;
END;
```

```
CREATE PROCEDURE get_pop_continent (IN continent_name CHAR(30),
                                     OUT continent_pop BIGINT)
BEGIN
  SELECT SUM(Population) INTO continent_pop FROM Country
    WHERE Continent = continent_name;
END;
```

```
CREATE PROCEDURE get_pop_world (OUT world_pop BIGINT)
BEGIN
  SELECT SUM(Population) INTO world_pop FROM Country;
END;
```

The next procedure returns several result sets. This corresponds to Scenario 3 described earlier.

```
CREATE PROCEDURE get_data ()
BEGIN
  SELECT Code, Name, Population, Continent FROM Country
    WHERE Continent = 'Oceania' AND Population < 10000;
  SELECT Code, Name, Population, Continent FROM Country
    WHERE Continent = 'Europe' AND Population < 10000;
  SELECT Code, Name, Population, Continent FROM Country
    WHERE Continent = 'North America' AND Population < 10000;
END;
```

Enter and test the stored procedures manually to ensure that they will be available to your C++ applications. (Select `world` as the default database before you create them.) You are now ready to start writing applications using Connector/C++ that call stored procedures.

### Scenario 1: Using a [Statement](#) for a Stored Procedure That Returns No Result

This example shows how to call a stored procedure that returns no result set.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp sp_scenario1.cpp
```

2. Add the following code to the `try` block of the tutorial framework:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

// We need not check the return value explicitly. If it indicates
// an error, Connector/C++ generates an exception.
stmt->execute("CALL add_country('ATL', 'Atlantis', 'North America')");
```

3. Compile the program as described in [Section 21.4.7.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./sp_scenario1
```

- Using the `mysql` command-line client or other suitable program, check the `world` database to determine that it has been updated correctly. You can use this query:

```
mysql> SELECT Code, Name, Continent FROM Country WHERE Code='ATL';
+-----+-----+-----+
| Code | Name      | Continent |
+-----+-----+-----+
| ATL  | Atlantis | North America |
+-----+-----+-----+
```

The code in this application simply invokes the `execute` method, passing to it a statement that calls the stored procedure. The procedure itself returns no value, although it is important to note there is always a return value from the `CALL` statement; this is the `execute` status. MySQL Connector/C++ handles this status for you, so you need not handle it explicitly. If the `execute` call fails for some reason, it raises an exception that the `catch` block handles.

## Scenario 2: Using a `Statement` for a Stored Procedure That Returns an Output Parameter

This example shows how to handle a stored procedure that returns an output parameter.

- Make a copy of the tutorial framework code:

```
shell> cp framework.cpp sp_scenario2.cpp
```

- Add the following code to the `try` block of the tutorial framework:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

stmt->execute("CALL get_pop('Uganda', @pop)");

std::auto_ptr<sql::ResultSet> res(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of Uganda: " << res->getString("_reply") << endl;

stmt->execute("CALL get_pop_continent('Asia', @pop)");

res.reset(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of Asia: " << res->getString("_reply") << endl;

stmt->execute("CALL get_pop_world(@pop)");

res.reset(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of World: " << res->getString("_reply") << endl;
```

- Compile the program as described in [Section 21.4.7.1, "Prerequisites and Background Information"](#).
- Run the program:

```
shell> ./sp_scenario2
Connector/C++ tutorial framework...

Population of Uganda: 21778000
Population of Asia: 3705025700
Population of World: 6078749450
Done.
```

In this scenario, each stored procedure sets the value of an output parameter. This is not returned directly to the `execute` method, but needs to be obtained using a subsequent query. If you were executing the SQL statements directly, you might use statements similar to these:

```
CALL get_pop('Uganda', @pop);
SELECT @pop;
CALL get_pop_continent('Asia', @pop);
SELECT @pop;
CALL get_pop_world(@pop);
SELECT @pop;
```

In the C++ code, a similar sequence is carried out for each procedure call:

- Execute the `CALL` statement.
- Obtain the output parameter by executing an additional query. The query produces a `ResultSet` object.
- Retrieve the data using a `while` loop. The simplest way to do this is to use a `getString` method on the `ResultSet`, passing the name of the variable to access. In this example `_reply` is used as a placeholder for the variable and therefore is used as the key to access the correct element of the result dictionary.

Although the query used to obtain the output parameter returns only a single row, it is important to use the `while` loop to catch more than one row, to avoid the possibility of the connection becoming unstable.

### Scenario 3: Using a `Statement` for a Stored Procedure That Returns a Result Set

This example shows how to handle result sets produced by a stored procedure.

#### Note

This scenario requires MySQL 5.5.3 or higher. The client/server protocol does not support fetching multiple result sets from stored procedures prior to 5.5.3.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp sp_scenario3.cpp
```

2. Add the following code to the `try` block of the tutorial framework:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

stmt->execute("CALL get_data()");
std::auto_ptr< sql::ResultSet > res;
do {
    res.reset(stmt->getResultSet());
    while (res->next()) {
        cout << "Name: " << res->getString("Name")
            << " Population: " << res->getInt("Population")
            << endl;
    }
} while (stmt->getMoreResults());
```

3. Compile the program as described in [Section 21.4.7.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./sp_scenario3
Connector/C++ tutorial framework...

Name: Cocos (Keeling) Islands Population: 600
Name: Christmas Island Population: 2500
Name: Norfolk Island Population: 2000
Name: Niue Population: 2000
Name: Pitcairn Population: 50
```

```
Name: Tokelau Population: 2000
Name: United States Minor Outlying Islands Population: 0
Name: Svalbard and Jan Mayen Population: 3200
Name: Holy See (Vatican City State) Population: 1000
Name: Anguilla Population: 8000
Name: Atlantis Population: 0
Name: Saint Pierre and Miquelon Population: 7000
Done.
```

The code is similar to the examples shown previously. The code of particular interest here is:

```
do {
    res.reset(stmt->getResultSet());
    while (res->next()) {
        cout << "Name: " << res->getString("Name")
            << " Population: " << res->getInt("Population")
            << endl;
    }
} while (stmt->getMoreResults());
```

The `CALL` is executed as before, but this time the results are returned into multiple `ResultSet` objects because the stored procedure executes multiple `SELECT` statements. In this example, the output shows that three result sets are processed, because there are three `SELECT` statements in the stored procedure. Each result set returns more than one row.

The results are processed using this code pattern:

```
do {
    Get Result Set
    while (Get Result) {
        Process Result
    }
} while (Get More Result Sets);
```

#### Note

Use this pattern even if the stored procedure executes only a single `SELECT` and produces only one result set. This is a requirement of the underlying protocol.

### 21.4.7.3. Calling Stored Procedures with `PreparedStatement` Objects

This section shows how to call stored procedures using prepared statements. It is recommended that, before working through it, you first work through the previous tutorial [Section 21.4.7.2, "Calling Stored Procedures with `Statement` Objects"](#). That section shows the stored procedures required by the applications in this section.

#### Scenario 1: Using a `PreparedStatement` for a Stored Procedure That Returns No Result

This example shows how to call a stored procedure that returns no result set.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp ps_scenario1.cpp
```

2. Add the following code to the `try` block of the tutorial framework:

```
vector<string> code_vector;
code_vector.push_back("SLD");
code_vector.push_back("DSN");
code_vector.push_back("ATL");

vector<string> name_vector;
name_vector.push_back("Sealand");
```

```

name_vector.push_back("Disneyland");
name_vector.push_back("Atlantis");

vector<string> cont_vector;
cont_vector.push_back("Europe");
cont_vector.push_back("North America");
cont_vector.push_back("Oceania");

sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::PreparedStatement > pstmt;

pstmt.reset(con->prepareStatement("CALL add_country(?,?,?)"));
for (int i=0; i<3; i++)
{
    pstmt->setString(1,code_vector[i]);
    pstmt->setString(2,name_vector[i]);
    pstmt->setString(3,cont_vector[i]);

    pstmt->execute();
}

```

Also, uncomment `#include <vector>` near the top of the code, because vectors are used to store sample data.

3. Compile the program as described in [Section 21.4.7.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./ps_scenario1
```

5. You can check whether the database has been updated correctly by using this query:

```

mysql> SELECT Code, Name, Continent FROM Country
       -> WHERE Code IN('DSN','ATL','SLD');
+-----+-----+-----+
| Code | Name       | Continent |
+-----+-----+-----+
| ATL  | Atlantis  | Oceania   |
| DSN  | Disneyland| North America |
| SLD  | Sealand   | Europe    |
+-----+-----+-----+

```

The code is relatively simple, as no processing is required to handle result sets. The procedure call, `CALL add_country(?,?,?)`, is made using placeholders for input parameters denoted by '?'. These placeholders are replaced by the appropriate data values using the `PreparedStatement` object's `setString` method. The `for` loop is set up to iterate 3 times, as there are three data sets in this example. The same `PreparedStatement` is executed three times, each time with different input parameters.

## Scenario 2: Using a `PreparedStatement` for a Stored Procedure That Returns an Output Parameter

This example shows how to handle a stored procedure that returns an output parameter.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp ps_scenario2.cpp
```

2. Add the following code to the `try` block of the tutorial framework:

```

vector<string> cont_vector;
cont_vector.push_back("Europe");
cont_vector.push_back("North America");

```

```

cont_vector.push_back("Oceania");

sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::Statement > stmt(con->createStatement());
std::auto_ptr< sql::PreparedStatement > pstmt;
std::auto_ptr< sql::ResultSet > res;

pstmt.reset(con->prepareStatement("CALL get_pop_continent(?,@pop)"));

for (int i=0; i<3; i++)
{
    pstmt->setString(1,cont_vector[i]);
    pstmt->execute();
    res.reset(stmt->executeQuery("SELECT @pop AS _population"));
    while (res->next())
        cout << "Population of "
            << cont_vector[i]
            << " is "
            << res->getString("_population") << endl;
}

```

Also, uncomment `#include <vector>` near the top of the code, because vectors are used to store sample data.

3. Compile the program as described in [Section 21.4.7.1, "Prerequisites and Background Information"](#).
4. Run the program:

```

shell> ./ps_scenario2
Connector/C++ tutorial framework...

Population of Europe is 730074600
Population of North America is 482993000
Population of Oceania is 30401150
Done.

```

In this scenario a `PreparedStatement` object is created that calls the `get_pop_continent` stored procedure. This procedure takes an input parameter, and also returns an output parameter. The approach used is to create another statement that can be used to fetch the output parameter using a `SELECT` query. Note that when the `PreparedStatement` is created, the input parameter to the stored procedure is denoted by '?'. Prior to execution of the prepared statement, it is necessary to replace this placeholder by an actual value. This is done using the `setString` method:

```
pstmt->setString(1,cont_vector[i]);
```

Although the query used to obtain the output parameter returns only a single row, it is important to use the `while` loop to catch more than one row, to avoid the possibility of the connection becoming unstable.

### Scenario 3: Using a `PreparedStatement` for a Stored Procedure That Returns a Result Set

This example shows how to handle result sets produced by a stored procedure.

#### Note

This scenario requires MySQL 5.5.3 or higher. The client/server protocol does not support fetching multiple result sets from stored procedures prior to 5.5.3.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp ps_scenario3.cpp
```

2. Add the following code to the `try` block of the tutorial framework:

```

sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::PreparedStatement > pstmt;
std::auto_ptr< sql::ResultSet > res;

pstmt.reset(con->prepareStatement("CALL get_data()"));
res.reset(pstmt->executeQuery());

do {
    res.reset(pstmt->getResultSet());
    while (res->next()) {
        cout << "Name: " << res->getString("Name")
              << " Population: " << res->getInt("Population")
              << endl;
    }
} while (pstmt->getMoreResults());

```

3. Compile the program as described in [Section 21.4.7.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./ps_scenario3
```

5. Make a note of the output generated.

The code executes the stored procedure using a [PreparedStatement](#) object. The standard [do/while](#) construct is used to ensure that all result sets are fetched. The returned values are fetched from the result sets using the [getInt](#) and [getString](#) methods.

## 21.4.8. MySQL Connector/C++ Debug Tracing

Although a debugger can be used to debug your application, you may find it beneficial to turn on the debug traces of the connector. Some problems happen randomly which makes them difficult to debug using a debugger. In such cases, debug traces and protocol files are more useful because they allow you to trace the activities of all instances of your program.

DTrace is a very powerful technology to trace any application without having to develop an extra trace module for your application. Unfortunately, DTrace is currently only available on Solaris, Mac OS X 10.5, and FreeBSD.

MySQL Connector/C++ can write two trace files:

1. Trace file generated by the MySQL client library
2. Trace file generated internally by MySQL Connector/C++

The first trace file can be generated by the underlying MySQL client library ([libmysqlclient](#)). To enable this trace, the connector will call the [mysql\\_debug\(\)](#) C API function internally. Because only debug versions of the MySQL client library are capable of writing a trace file, compile MySQL Connector/C++ against a debug version of the library to use this trace. The trace shows the internal function calls and the addresses of internal objects as shown here:

```

>mysql_stmt_init
| >_mymalloc
| | enter: Size: 816
| | exit: ptr: 0x68e7b8
| <_mymalloc | >init_alloc_root
| | enter: root: 0x68e7b8
| | >_mymalloc
| | | enter: Size: 2064
| | | exit: ptr: 0x68eb28
[...]
```

The second trace is the MySQL Connector/C++ internal trace. It is available with debug and nondebug builds of the connector as long as you have enabled the tracing module at compile time using `cmake -DMYSQLCPPCONN_TRACE_ENABLE:BOOL=1`. By default, tracing functionality is not available and calls to trace functions are removed by the preprocessor.

Compiling the connector with tracing functionality enabled causes two additional tracing function calls per each connector function call. For example:

```
| INF: Tracing enabled
| <MySQL_Connection::setClientOption
| >MySQL_Prepared_Statement::setInt
| INF: this=0x69a2e0
| >MySQL_Prepared_Statement::checkClosed
| <MySQL_Prepared_Statement::checkClosed
| <MySQL_Prepared_Statement::setInt
| [...]

```

Run your own benchmark to find out how much this will impact the performance of your application.

A simple test using a loop running 30,000 `INSERT` SQL statements showed no significant real-time impact. The two variants of this application using a trace enabled and trace disabled version of the connector performed equally well. The runtime measured in real time was not significantly impacted as long as writing a debug trace was not enabled. However, there will be a difference in the time spent in the application. When writing a debug trace, the I/O subsystem may become a bottleneck.

In summary, use connector builds with tracing enabled carefully. Trace-enabled versions may cause higher CPU usage even if the overall runtime of your application is not impacted significantly.

The example from `examples/debug_output.cpp` demonstrates how to activate the debug traces in your program. Currently they can only be activated through API calls. The traces are controlled on a per-connection basis. You can use the `setClientOptions()` method of a connection object to activate and deactivate trace generation. The MySQL client library trace is always written to a file, whereas the connector's protocol messages are printed to the standard output.

```
sql::Driver *driver;
int on_off = 1;

/* Using the Driver to create a connection */
driver = get_driver_instance();
std::auto_ptr< sql::Connection > con(driver->connect(host, user, pass));

/*
Activate debug trace of the MySQL client library (C API)
Only available with a debug build of the MySQL client library!
*/
con->setClientOption("libmysql_debug", "d:t:O,client.trace");

/*
Connector/C++ tracing is available if you have compiled the
driver using cmake -DMYSQLCPPCONN_TRACE_ENABLE:BOOL=1
*/
con->setClientOption("client_trace", &on_off);

```

## 21.4.9. MySQL Connector/C++ Usage Notes

MySQL Connector/C++ is compatible with the JDBC 4.0 API. See the [JDBC overview](#) for information on JDBC 4.0. Please also check the `examples/` directory of the download package.

- The MySQL Connector/C++ `sql::DataType` class defines the following JDBC standard data types: `UNKNOWN`, `BIT`, `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INTEGER`, `BIGINT`, `REAL`, `DOUBLE`, `DECIMAL`, `NUMERIC`, `CHAR`, `BINARY`, `VARCHAR`, `VARBINARY`, `LONGVARCHAR`, `LONGVARBINARY`, `TIMESTAMP`, `DATE`, `TIME`, `GEOMETRY`, `ENUM`, `SET`, `SQLNULL`.

MySQL Connector/C++ does not support the following JDBC standard data types: `ARRAY`, `BLOB`, `CLOB`, `DISTINCT`, `FLOAT`, `OTHER`, `REF`, `STRUCT`.

- `DatabaseMetaData::supportsBatchUpdates()` returns `true` because MySQL supports batch updates in general. However, the MySQL Connector/C++ API provides no API calls for batch updates.
- Two non-JDBC methods let you fetch and set unsigned integers: `getUInt64()` and `getUInt()`. These are available for `ResultSet` and `PreparedStatement`:
  - `ResultSet::getUInt64()`
  - `ResultSet::getUInt()`
  - `PreparedStatement::setUInt64()`
  - `PreparedStatement::setUInt()`

The corresponding `getLong()` and `setLong()` methods have been removed.

- The `DatabaseMetaData::getColumns()` method has 23 columns in its result set, rather than the 22 columns defined by JDBC. The first 22 columns are as described in the JDBC documentation, but column 23 is new:

23. `IS_AUTOINCREMENT`: A string which is “YES” if the column is an auto-increment column, “NO” otherwise.

- MySQL Connector/C++ may return different metadata for the same column, depending on the method you call.

Suppose that you have a column that accepts a character set and a collation in its specification and you specify a binary collation, such as:

```
VARCHAR(20) CHARACTER SET utf8 COLLATE utf8_bin
```

The server sets the `BINARY` flag in the result set metadata of this column. The `ResultSetMetadata::getColumnTypeName()` method uses the metadata and will report, due to the `BINARY` flag, that the column type name is `BINARY`. This is illustrated here:

```
mysql> CREATE TABLE varbin (a VARCHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
Query OK, 0 rows affected (0.00 sec)

mysql> select * from varbin;
Field  1: `a`
Catalog: `def`
Database: `test`
Table: `varbin`
Org_table: `varbin`
Type: VAR_STRING
Collation: latin1_swedish_ci (8)
Length: 20
Max_length: 0
Decimals: 0
Flags: BINARY

0 rows in set (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_NAME='varbin'\G
***** 1. row *****
      TABLE_CATALOG: NULL
      TABLE_SCHEMA: test
      TABLE_NAME: varbin
      COLUMN_NAME: a
      ORDINAL_POSITION: 1
      COLUMN_DEFAULT: NULL
      IS_NULLABLE: YES
      DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 20
CHARACTER_OCTET_LENGTH: 60
```

```

NUMERIC_PRECISION: NULL
NUMERIC_SCALE: NULL
CHARACTER_SET_NAME: utf8
COLLATION_NAME: utf8_bin
COLUMN_TYPE: varchar(20)
COLUMN_KEY:
EXTRA:
PRIVILEGES: select,insert,update,references
COLUMN_COMMENT:
1 row in set (0.01 sec)

```

However, `INFORMATION_SCHEMA` gives no hint in its `COLUMNS` table that metadata will contain the `BINARY` flag. `DatabaseMetaData::getColumns()` uses `INFORMATION_SCHEMA` and will report the type name `VARCHAR` for the same column. It also returns a different type code.

- When inserting or updating `BLOB` or `TEXT` columns, MySQL Connector/C++ developers are advised not to use `setString()`. Instead, use the dedicated `setBlob()` API function.

The use of `setString()` can cause a `Packet too large` error message. The error occurs if the length of the string passed to the connector using `setString()` exceeds `max_allowed_packet [502]` (minus a few bytes reserved in the protocol for control purposes). This situation is not handled in MySQL Connector/C++, because it could lead to security issues, such as extremely large memory allocation requests due to malevolently long strings.

If `setBlob()` is used, this problem does not arise because `setBlob()` takes a streaming approach based on `std::istream`. When sending the data from the stream to MySQL Server, MySQL Connector/C++ splits the stream into chunks appropriate for MySQL Server using the current `max_allowed_packet [502]` setting.

### Caution

When using `setString()`, it is not possible to set `max_allowed_packet [502]` to a value large enough for the string prior to passing it to MySQL Connector/C++. That configuration option cannot be changed within a session.

This difference from the JDBC specification ensures that MySQL Connector/C++ is not vulnerable to memory flooding attacks.

- In general, MySQL Connector/C++ works with MySQL 5.0, but it is not completely supported. Some methods may not be available when connecting to MySQL 5.0. This is because the Information Schema is used to obtain the requested information. There are no plans to improve the support for 5.0 because the current GA version of MySQL Server is 5.6. MySQL Connector/C++ is primarily targeted at the MySQL Server GA version that is available on its release.

The following methods throw a `sql::MethodNotImplemented` exception when you connect to a MySQL server earlier than 5.1:

- `DatabaseMetaData::getCrossReference()`
- `DatabaseMetaData::getExportedKeys()`
- MySQL Connector/C++ includes a `Connection::getClientOption()` method that is not included in the JDBC API specification. The prototype is:

```
void getClientOption(const std::string & optionName, void * optionValue)
```

The method can be used to check the value of connection properties set when establishing a database connection. The values are returned through the `optionValue` argument passed to the method with the type `void *`.

Currently, `getClientOption()` supports fetching the `optionValue` of the following options:

- `metadataUseInfoSchema`
- `defaultStatementResultType`
- `defaultPreparedStatementResultType`

The `metadataUseInfoSchema` connection option controls whether to use the `Information_Schemata` for returning the metadata of `SHOW` statements:

- For `metadataUseInfoSchema`, interpret the `optionValue` argument as a boolean upon return.
- For `defaultStatementResultType` and `defaultPreparedStatementResultType`, interpret the `optionValue` argument as an integer upon return.

The connection property can be set either when establishing the connection through the connection property map, or using `void Connection::setClientOption(const std::string & optionName, const void * optionValue)` where `optionName` is assigned the value `metadataUseInfoSchema`.

Some examples:

```
bool isInfoSchemaUsed;
conn->getClientOption("metadataUseInfoSchema", (void *) &isInfoSchemaUsed);

int defaultStmtResType;
int defaultPStmtResType;
conn->getClientOption("defaultStatementResultType", (void *) &defaultStmtResType);
conn->getClientOption("defaultPreparedStatementResultType", (void *) &defaultPStmtResType);
```

- MySQL Connector/C++ supports the following methods not found in the JDBC API standard:

```
std::string MySQL_Connection::getSessionVariable(const std::string & varname)
```

```
void MySQL_Connection::setSessionVariable(const std::string & varname, const std::string & value)
```

These methods get and set MySQL session variables. Both are members of the `MySQL_Connection` class.

`getSessionVariable()` is equivalent to executing the following and fetching the first return value:

```
SHOW SESSION VARIABLES LIKE "<varname>"
```

You can use the “%” and “\_” SQL pattern characters in `<varname>`.

`setSessionVariable()` is equivalent to executing:

```
SET SESSION <varname> = <value>
```

- Fetching the value of a column can sometimes return different values depending on whether the call is made from a Statement or Prepared Statement. This is because the protocol used to communicate with the server differs depending on whether a Statement or Prepared Statement is used.

To illustrate this, consider the case where a column has been defined as type `BIGINT`. The most negative `BIGINT` value is then inserted into the column. If a Statement and Prepared Statement are created that perform a `GetUInt64()` call, then the results will be different in each case. The Statement returns the maximum positive value for `BIGINT`. The Prepared Statement returns 0.

The difference results from the fact that Statements use a text protocol, and Prepared Statements use a binary protocol. With the binary protocol in this case, a binary value is returned from the server that can be interpreted as an `int64`. In the preceding scenario, a very large negative value is fetched with `GetUInt64()`, which fetches unsigned integers. Because the large negative value cannot be sensibly converted to an unsigned value, 0 is returned.

In the case of the Statement, which uses the text protocol, values are returned from the server as strings, and then converted as required. When a string value is returned from the server in the preceding scenario, the large negative value must be converted by the runtime library function `strtoul()`, which `GetUInt64()` calls. The behavior of `strtoul()` is dependent upon the specific runtime and host operating system, so the results can be platform dependent. In the case, given a large positive value was actually returned.

Although it is very rare, there are some cases where Statements and Prepared Statements can return different values unexpectedly, but this usually only happens in extreme cases such as the one mentioned.

- The JDBC documentation [lists many fields](#) for the `DatabaseMetaData` class. JDBC also appears to [define certain values](#) for those fields. However, MySQL Connector/C++ does not define certain values for those fields. Internally enumerations are used and the compiler determines the values to assign to a field.

To compare a value with the field, use code such as the following, rather than making assumptions about specific values for the attribute:

```
// dbmeta is an instance of DatabaseMetaData
if (myvalue == dbmeta->attributeNoNulls) {
    ...
}
```

Usually `myvalue` will be a column from a result set holding metadata information. MySQL Connector/C++ does not guarantee that `attributeNoNulls` is 0. It can be any value.

- When programming stored procedures, JDBC has available an extra class, an extra abstraction layer for callable statements, the `CallableStatement` class. As this class is not present in MySQL Connector/C++, use the methods from the `Statement` and `PreparedStatement` classes to execute a stored procedure using `CALL`.

## 21.4.10. MySQL Connector/C++ Known Bugs and Issues

Please report bugs through the MySQL Bug System. See [Section 1.7, “How to Report Bugs or Problems”](#).

For release notes detailing the changes in each release of Connector/C++, see [MySQL Connector/C++ Release Notes](#).

- When linking against a static library for 1.0.3 on Windows, define `CPPDBC_PUBLIC_FUNC` either in the compiler options (preferable) or with `/D "CPPCONN_PUBLIC_FUNC="`. You can also explicitly define it in your code by placing `#define CPPCONN_PUBLIC_FUNC` before the header inclusions.
- Generally speaking, C++ library binaries are less portable than C library binaries. Issues can be caused by name mangling, different Standard Template Library (STL) versions, and using different compilers and linkers for linking against the libraries than were used for building the library itself.

Even a small change in the compiler version can cause problems. If you obtain error messages that you suspect are related to binary incompatibilities, build MySQL Connector/C++ from source, using the same compiler and linker that you will use to build and link your application.

Due to the variations between Linux distributions, compiler and linker versions and STL versions, it is not possible to provide binaries for each and every possible configuration. However, the MySQL Connector/C++ binary distributions contain a [README](#) file that describes the environment and settings used to build the binary versions of the libraries.

- To avoid potential crashes, the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

## 21.4.11. MySQL Connector/C++ Support

For general discussion of the MySQL Connector/C++ please use the [C/C++ community forum](#) or join the [MySQL Connector/C++ mailing list](#).

Bugs can be reported at the [MySQL bug Web site](#).

For release notes detailing the changes in each release of MySQL Connector/C++, see [MySQL Connector/C++ Release Notes](#).

For Licensing questions, and to purchase MySQL Products and Services, please see <http://www.mysql.com/buy-mysql/>

## 21.5. MySQL Connector/C

MySQL Connector/C is a client library that implements the C API for client/server communication. It is a standalone replacement for the MySQL client library shipped with MySQL Server distributions. See [Section 21.8.1, “MySQL C API Implementations”](#).

Reasons to use MySQL Connector/C:

- If you need only the client library, MySQL Connector/C provides everything required. There is no need to compile or install the MySQL Server package, which is much larger.
- MySQL Connector/C does not rely on the MySQL Server release cycle, so bug fixes and new features can be distributed independently of MySQL Server releases.

For documentation of the C API implemented by MySQL Connector/C, see [Section 21.8, “MySQL C API”](#).

For release notes detailing the changes in each release of MySQL Connector/C, see [MySQL Connector/C Release Notes](#).

The following discussion covers these topics:

- MySQL Connector/C supported platforms
- MySQL Connector/C distribution contents
- Obtaining and installing MySQL Connector/C
- Building client programs that use MySQL Connector/C

### 21.5.1. MySQL Connector/C Supported Platforms

The following table indicates the platforms on which MySQL Connector/C has been tested.

**Table 21.28. Supported Platforms for MySQL Connector/C 6.0.2**

Platform	Versions
Windows	Windows 2000, XP, Vista, Server 2003, Server 2008
Linux	RHEL 4, 5; SuSE LES 9, 10; generic <code>glibc</code> 2-based Linux systems
Solaris	8, 9, 10
Mac OS X	10.4, 10.5
FreeBSD	6, 7
HP-UX	11.11, 11.23, 11.31
IBM AIX	5.3

## 21.5.2. MySQL Connector/C Distribution Contents

A MySQL Connector/C distribution contains the header, library, and utility files necessary to build MySQL client applications that communicate with MySQL Server using the C API.

Distributions are available in binary and source formats. A binary distribution contains the header, library, and utility components discussed following, compiled and ready for use in writing client programs. A source distribution contains the source files required to produce the same headers, libraries, and utilities included in a binary distribution, but you compile them yourself.

MySQL Connector/C distributions include these components:

- A set of `.h` header files that C applications include at compile time. These files are located in the `include` directory.
- Static and dynamic libraries that C applications link to at link time. These libraries are located in the `lib` directory. The library names depend on the library type and platform for which a distribution is built:
  - On Unix (and Unix-like) systems, the static library is `libmysqlclient.a`. The dynamic library is `libmysqlclient.so` on most Unix systems and `libmysqlclient.dylib` on Mac OS X.
  - On Windows, the static library is `mysqlclient.lib` and the dynamic library is `libmysql.dll`. Windows distributions also include `libmysql.lib`, a static import library needed for using the dynamic library.
- Utilities. MySQL Connector/C includes the `mysql_config` utility, located in the `bin` directory.

## 21.5.3. Obtaining MySQL Connector/C

To obtain a distribution, visit [MySQL Connector/C downloads](#). For a list of supported platforms, see [Section 21.5.1, “MySQL Connector/C Supported Platforms”](#).

## 21.5.4. Installing MySQL Connector/C from a Binary Distribution

On Unix and Unix-like systems, a MySQL Connector/C binary distribution is packaged as a compressed `tar` file, denoted here as `PACKAGE.tar.gz`. Download the distribution file and unpack it in the intended installation directory using this command:

```
shell> tar zxvf PACKAGE.tar.gz
```

Windows users can choose between two binary packaging formats:

- Windows MSI Installer (`.msi` file): To use the MSI Installer, launch it and follow the prompts in the screens it presents to install MySQL Connector/C in the location of your choosing.
- Zip archive without installer (`.zip` file): To use a Zip archive, unpack it in the intended installation directory using `WinZip` or another tool that can read `.zip` files.

`.tar.gz` and `.zip` packages unpack into a directory named `PACKAGE`, which is a value such as `mysql-connector-c-6.0.2-linux-rhel5-x86-64bit`. If you want a simpler name to work with, rename the directory. On Unix, an alternative is to create a symbolic link with a simpler name:

```
shell> ln -s mysql-connector-c-6.0.2-linux-rhel5-x86-64bit connector-c
```

## 21.5.5. Installing MySQL Connector/C from Source

A MySQL Connector/C source distribution is packaged as a compressed `tar` file or Zip archive, denoted here as `PACKAGE.tar.gz` or `PACKAGE.zip`. A source distribution can be used on any supported platform listed in [Section 21.5.1, “MySQL Connector/C Supported Platforms”](#).

Download the distribution file and unpack it in the intended installation directory. To unpack a compressed `tar` file, use this command:

```
shell> tar zxvf PACKAGE.tar.gz
```

To unpack a Zip archive, use [WinZip](#) or another tool that can read `.zip` files.

After unpacking the distribution, build it using the following instructions appropriate for your platform.

### 21.5.5.1. Building MySQL Connector/C from Source on Unix

If the native compiler toolset for the target platform is available (for example, SunStudio for Solaris), you can use that for compilation. Alternatively, the GNU toolset can be used on all platforms.

You also need [CMake](#) 2.6 or newer, which is available from [cmake.org](#).

To build and install the source distribution, use the following procedure:

1. Change location to the top-level directory of the source distribution.
2. Generate the [Makefile](#):

```
shell> cmake -G "Unix Makefiles"
```

Or, for a Debug build:

```
shell> cmake -G "Unix Makefiles" -DCMAKE_BUILD_TYPE=Debug
```

By default, the installation location for MySQL Connector/C is `/usr/local/mysql`. To change this location, use the `CMAKE_INSTALL_PREFIX` option to specify a different directory when generating the [Makefile](#). For example:

```
shell> cmake -G "Unix Makefiles" -DCMAKE_INSTALL_PREFIX=/opt/local/mysql
```

For other [CMake](#) options that you might find useful, see [Section 21.5.5.3, "Other Build Options"](#).

3. Build the project:

```
shell> make
```

4. As `root`, install the MySQL Connector/C headers, libraries, and utilities:

```
root-shell> make install
```

### 21.5.5.2. Building MySQL Connector/C from Source on Microsoft Windows

MySQL Connector/C can be built on several versions of Microsoft Windows, listed in [Section 21.5.1, "MySQL Connector/C Supported Platforms"](#).

Microsoft Visual Studio 8 or 9 is recommended. The Express Edition of Visual Studio and other compilers might work, but are untested.

You also need [CMake](#) 2.6 or newer, which is available from [cmake.org](#).

To build and install the source distribution, use the following procedure:

1. Set the environment variables for the Visual Studio toolchain. Visual Studio includes a batch file to set these for you, and installs a shortcut in the **Start** menu to open a command prompt with these variables set.
2. Change location to the top-level directory of the source distribution.
3. Generate the [Makefile](#) by entering the following command in a command-prompt window:

```
shell> cmake -G "Visual Studio 9 2008"
```

For other [CMake](#) options that you might find useful, see [Section 21.5.5.3, "Other Build Options"](#).

The result of the `cmake` command is a project (solution) file, `libmysql.sln`, that you can open with Visual Studio. Alternatively, build from the command line with either of these commands:

```
shell> devenv.com libmysql.sln /build Release
```

```
shell> devenv.com libmysql.sln /build RelWithDebInfo
```

For other versions of Visual Studio or for an `nmake`-based build, use the following command to check which generators can be specified with the `-G` option:

```
shell> cmake --help
```

To compile a Debug build, you must set the `CMake` build type so the correct external library versions are used, then compile using the `Debug` solution configuration:

```
shell> cmake -G "Visual Studio 9 2008" -DCMAKE_BUILD_TYPE=Debug
shell> devenv.com libmysql.sln /build Debug
```

A normal build builds the C API libraries for the `lib` directory. A Debug build additionally builds debug libraries for the `lib/debug` directory. You must use the debug libraries when compiling clients built using the debug C runtime.

4. Use the install operation provided by your development environment to install the MySQL Connector/C headers, libraries, and utilities. You can also use this `CMake` command:

```
shell> cmake --build . --target INSTALL --config RelWithDebInfo
```

### 21.5.5.3. Other Build Options

The following table shows other options that can be used when building MySQL Connector/C from source.

**Table 21.29. Build Options for MySQL Connector/C**

Build Option	Description
<code>-DWITH_OPENSSL=1</code>	Enable dynamic linking to the system OpenSSL library.
<code>-DWITH_EXTERNAL_ZLIB=1</code>	Enable dynamic linking to the system Zlib library.

### 21.5.6. Testing MySQL Connector/C

To test MySQL Connector/C, a running MySQL server instance must be available. Before you run the test suite, specify the following environment variables:

- `MYSQL_TEST_HOST`: The host where the MySQL server is running (default `localhost`)
- `MYSQL_TEST_USER`: The user name of the MySQL account to use
- `MYSQL_TEST_PASSWD`: The password of the MySQL account to use
- `MYSQL_TEST_PORT`: The TCP/IP port to connect to
- `MYSQL_TEST_SOCKET`: The socket file to connect to
- `MYSQL_TEST_DB`: The default database to use (default `test`)

To run the test suite, execute `ctest` from the command line:

```
shell> ctest
```

### 21.5.7. Building MySQL Connector/C Applications

For instructions on building C applications to use MySQL Connector/C, see [Section 21.8.3.1, "Building C API Client Programs"](#). To enable your compiler to find the header and library files under the directory

where you installed MySQL Connector/C, specify the appropriate compile-time options, as indicated in that section.

## 21.6. MySQL Connector/Python

MySQL Connector/Python allows Python programs to access MySQL databases, using an API that is compliant with the [Python DB API version 2.0](#). It is written in pure Python and does not have any dependencies except for the [Python Standard Library](#).

For release notes detailing the changes in each release of Connector/Python, see [MySQL Connector/Python Release Notes](#).

MySQL Connector/Python includes support for:

- Almost all features provided by MySQL Server up to and including MySQL Server version 5.5.
- Converting parameter values back and forth between Python and MySQL data types, for example Python `datetime` and MySQL `DATETIME`. You can turn automatic conversion on for convenience, or off for optimal performance.
- All MySQL extensions to standard SQL syntax.
- Protocol compression, which enables compressing the data stream between the client and server.
- Connections using TCP/IP sockets and on Unix using Unix sockets.
- Secure TCP/IP connections using SSL.
- Self-contained driver. Connector/Python does not require the MySQL client library or any Python modules outside the standard library.

MySQL Connector/Python supports from Python version 2.4 through 2.7, and Python 3.1 and later. Note that Connector/Python does not support the old MySQL Server authentication methods, which means that MySQL versions prior to 4.1 will not work.

### 21.6.1. Guidelines for Python Developers

The following guidelines cover aspects of developing MySQL applications that might not be immediately obvious to developers coming from a Python background:

- For security, do not hardcode the values needed to connect and log into the database in your main script. Python has the convention of a `config.py` module, where you can keep such values separate from the rest of your code.
- Python scripts often build up and tear down large data structures in memory, up to the limits of available RAM. Because MySQL often deals with data sets that are many times larger than available memory, techniques that optimize storage space and disk I/O are especially important. For example, in MySQL tables, you typically use numeric IDs rather than string-based dictionary keys, so that the key values are compact and have a predictable length. This is especially important for columns that make up the [primary key](#) for an [InnoDB](#) table, because those column values are duplicated within each [secondary index](#).
- Any application that accepts input must expect to handle bad data.

The bad data might be accidental, such as out-of-range values or misformatted strings. The application can use server-side checks such as [unique constraints](#) and [NOT NULL constraints](#), to keep the bad data from ever reaching the database. On the client side, use techniques such as exception handlers to report any problems and take corrective action.

The bad data might also be deliberate, representing a “SQL injection” attack. For example, input values might contain quotation marks, semicolons, `%` and `_` wildcard characters and other characters

significant in SQL statements. Validate input values to make sure they have only the expected characters. Escape any special characters that could change the intended behavior when substituted into a SQL statement. Never concatenate a user input value into a SQL statement without doing validation and escaping first. Even when accepting input generated by some other program, expect that the other program could also be hacked and be sending you incorrect or malicious data.

- Because the result sets from SQL queries can be very large, use the appropriate method to retrieve items from the result set as you loop through them. `fetchone()` retrieves a single item, when you know the result set contains a single row. `fetchall()` retrieves all the items, when you know the result set contains a limited number of rows that can fit comfortably into memory. `fetchmany()` is the general-purpose method when you cannot predict the size of the result set: you keep calling it and looping through the returned items, until there are no more results to process.
- Since Python already has convenient modules such as `pickle` and `cPickle` to read and write data structures on disk, the data that you choose store in MySQL instead is likely to have special characteristics:
  - **Too large to all fit in memory at one time.** You use `SELECT` statements to query only the precise items you need, and `aggregate functions` to perform calculations across multiple items. You configure the `innodb_buffer_pool_size [1708]` option within the MySQL server to dedicate a certain amount of RAM for caching query results.
  - **Too complex to be represented by a single data structure.** You divide the data between different SQL tables. You can recombine data from multiple tables by using a `join` query. You make sure that related data is kept in sync between different tables by setting up `foreign key` relationships.
  - **Updated frequently, perhaps by multiple users simultaneously.** The updates might only affect a small portion of the data, making it wasteful to write the whole structure each time. You use the SQL `INSERT`, `UPDATE`, and `DELETE` statements to update different items concurrently, writing only the changed values to disk. You use `InnoDB` tables and `transactions` to keep write operations from conflicting with each other, and to return consistent query results even as the underlying data is being updated.
- Building in MySQL best practices for performance can help your application to scale without requiring major rewrites and architectural changes. See [Chapter 8, Optimization](#) for best practices for MySQL performance. It offers guidelines and tips for SQL tuning, database design, and server configuration.
- You can avoid reinventing the wheel by learning the MySQL SQL statements for common operations: operators to use in queries, techniques for bulk loading data, and so on. Some statements and clauses are extensions to the basic ones defined by the SQL standard. See [Section 13.2, “Data Manipulation Statements”](#), [Section 13.1, “Data Definition Statements”](#), and [Section 13.2.9, “SELECT Syntax”](#) for the main classes of statements.
- Issuing SQL statements from Python typically involves declaring very long, possibly multi-line string literals. Because string literals within the SQL statements could be enclosed by single quotation, double quotation marks, or contain either of those characters, for simplicity you can use Python's triple-quoting mechanism to enclose the entire statement. For example:

```
'''It doesn't matter if this string contains 'single'
or "double" quotes, as long as there aren't 3 in a
row.'''
```

You can use either of the `'` or `"` characters for triple-quoting multi-line string literals.

- Many of the secrets to a fast, scalable MySQL application involve using the right syntax at the very start of your setup procedure, in the `CREATE TABLE` statements. For example, Oracle recommends the `ENGINE=INNODB` clause for most tables, and makes it the default in MySQL 5.5 and up. Using `InnoDB` tables enables transactional behavior that helps scalability of read-write workloads and offers automatic `crash recovery`. A follow-on recommendation is to declare a numeric `primary key` for each table, which offers the fastest way to look up values and can act as a pointer to associated

values in other tables (a [foreign key](#)). Also within the `CREATE TABLE` statement, using the most compact column data types that meet your application requirements helps performance and scalability, as the database server moves large amounts of data back and forth between memory and disk.

## 21.6.2. Connector/Python Versions

MySQL Connector/Python v1.0.x series went through a series of beta releases, leading to the first generally available (GA) version 1.0.7. Any development releases prior to general availability are not supported now that the GA version is released.

The following table summarizes the available Connector/Python versions:

**Table 21.30. Connector/Python Version Reference**

Connector/Python Version	MySQL Server Versions	Python Versions	Support Status for Connector
1.0	5.6, 5.5 (5.1, 5.0, 4.1)	2.7, 2.6 (2.5, 2.4); 3.1 and later	Recommended version

### Note

MySQL server and Python versions within brackets are known to work with Connector/Python, but are not officially supported. Bugs might not get fixed for those versions.

## 21.6.3. Connector/Python Installation

Connector/Python runs on any platform where Python is installed. Python comes pre-installed on almost any Linux distribution or UNIX-like system such as Apple Mac OS X and FreeBSD. On Microsoft Windows systems, you can install Python using the installer found on the [Python Download website](#).

Connector/Python is a pure Python implementation of the MySQL Client/Server protocol, meaning it does not require any other MySQL client libraries or other components. It also has no third-party dependencies. If you need SSL support, verify that your Python installation has been compiled using the [OpenSSL](#) libraries.

The installation of Connector/Python is similar on every platform and follows the standard [Python Distribution Utilities](#) or [Distutils](#). Some platforms have specific packaging, for example RPM, and, when made available, the installation of these will be covered in this manual.

Python terminology regarding distributions:

- **Source Distribution** is a distribution that contains only source files and is generally platform independent.
- **Built Distribution** can be regarded as a binary package. It contains both sources and platform-independent bytecode.

### 21.6.3.1. Installing Connector/Python Source Distribution on Linux, UNIX, or Mac OS X

On UNIX-like systems such as Linux distributions, Solaris, Apple Mac OS X, and FreeBSD, you can download Connector/Python as a `tar` archive from <http://dev.mysql.com/downloads/connector/python/>.

To install Connector/Python from the `.tar.gz` file, download the latest version and follow these steps:

```
shell> gunzip mysql-connector-python-1.0.6b1.tar.gz
shell> tar xf mysql-connector-python-1.0.6b1.tar
shell> cd mysql-connector-python-1.0.6b1
shell> sudo python setup.py install
```

On UNIX-like systems, Connector/Python gets installed in the default location `/prefix/lib/pythonX.Y/site-packages/`, where `prefix` is the location where Python was installed and `X.Y` is the version of Python. See [How installation works](#) in the Python manual.

If you are not sure where Connector/Python was installed, do the following to retrieve the location:

```
shell> python
>>> from distutils.sysconfig import get_python_lib

>>> print get_python_lib()          # Python v2.x
/Library/Python/2.7/site-packages

>>> print(get_python_lib())        # Python v3.x
/Library/Frameworks/Python.framework/Versions/3.1/lib/python3.1/site-packages
```

#### Note

The above example shows the default installation location on Mac OS X 10.7.

### 21.6.3.2. Installing Connector/Python Source Distribution on Microsoft Windows

On Microsoft Windows systems, you can download Connector/Python as a [zip](http://dev.mysql.com/downloads/connector/python/) archive from <http://dev.mysql.com/downloads/connector/python/>.

Make sure that the Python executable is available in the Windows `%PATH%` setting. For more information about installation and configuration of Python on Windows, see the section [Using Python on Windows](#) in the Python documentation.

To install Connector/Python from the `.zip` file, download the latest version and follow these steps:

1. Unpack the downloaded `zip` archive into a directory of your choice. For example, into the folder `C:\mysql-connector\`. Use the appropriate unzip command for your system, for example, `unzip`, `pkunzip`, and so on.
2. Start a console window (or a DOS window) and change to the folder where you unpacked the Connector/Python `zip` archive.

```
shell> cd C:\mysql-connector\
```

3. Once inside the Connector/Python folder, do the following:

```
shell> python setup.py install
```

On Windows, Connector/Python gets installed in the default location `C:\PythonX.Y\Lib\site-packages\` where `X.Y` is the Python version you used to install the connector.

If you are not sure where Connector/Python ended up, do the following to retrieve the location where packages get installed:

```
shell> python
>>> from distutils.sysconfig import get_python_lib
>>> print get_python_lib()          # Python v2.x
>>> print(get_python_lib())        # Python v3.x
```

### 21.6.3.3. Verifying Your Connector/Python Installation

To test that your Connector/Python installation is working and is able to connect to a MySQL database server, you can run a very simple program where you substitute the login credentials and host information of the MySQL server. See [Section 21.6.4.1, “Connecting to MySQL Using Connector/Python”](#) for an example.

## 21.6.4. Connector/Python Coding Examples

These coding examples illustrate how to develop Python applications and scripts which connect to a MySQL Server using MySQL Connector/Python.

### 21.6.4.1. Connecting to MySQL Using Connector/Python

The `connect()` constructor is used for creating a connection to the MySQL server and returns a `MySQLConnection` object.

The following example shows how to connect to the MySQL server:

```
import mysql.connector

cnx = mysql.connector.connect(user='scott', password='tiger',
                             host='127.0.0.1',
                             database='employees')

cnx.close()
```

See [Section 21.6.6, “Connector/Python Connection Arguments”](#) for all possible connection arguments.

It is also possible to create connection objects using the `connection.MySQLConnection()` class. Both methods, using the `connect()` constructor, or the class directly, are valid and functionally equal, but using `connector()` is preferred and will be used in most examples in this manual.

To handle connection errors, use the `try` statement and catch all errors using the `errors.Error` exception:

```
import mysql.connector
from mysql.connector import errorcode

try:
    cnx = mysql.connector.connect(user='scott',
                                 database='testt')
except mysql.connector.Error as err:
    if err.errno == errorcode.ER_ACCESS_DENIED_ERROR:
        print("Something is wrong your username or password")
    elif err.errno == errorcode.ER_BAD_DB_ERROR:
        print("Database does not exists")
    else:
        print(err)
else:
    cnx.close()
```

If you have lots of connection arguments, it's best to keep them in a dictionary and use the `**`-operator. Here is an example:

```
import mysql.connector

config = {
    'user': 'scott',
    'password': 'tiger',
    'host': '127.0.0.1',
    'database': 'employees',
    'raise_on_warnings': True,
}

cnx = mysql.connector.connect(**config)

cnx.close()
```

### 21.6.4.2. Creating Tables Using Connector/Python

All **DDL** (Data Definition Language) statements are executed using a handle structure known as a cursor. The following examples show how to create the tables of the `employees` database. You will need them for the other examples.

In a MySQL server, tables are very long-lived objects, and are often accessed by multiple applications written in different languages. You might typically work with tables that are already set up, rather than creating them within your own application. Avoid setting up and dropping tables over and over

again, as that is an expensive operation. The exception is [temporary tables](#), which can be created and dropped quickly within an application.

```

from __future__ import print_function

import mysql.connector
from mysql.connector import errorcode

DB_NAME = 'employees'

TABLES = {}
TABLES['employees'] = (
    "CREATE TABLE `employees` ("
    "  `emp_no` int(11) NOT NULL AUTO_INCREMENT,"
    "  `birth_date` date NOT NULL,"
    "  `first_name` varchar(14) NOT NULL,"
    "  `last_name` varchar(16) NOT NULL,"
    "  `gender` enum('M','F') NOT NULL,"
    "  `hire_date` date NOT NULL,"
    "  PRIMARY KEY (`emp_no`)"
    ") ENGINE=InnoDB")

TABLES['departments'] = (
    "CREATE TABLE `departments` ("
    "  `dept_no` char(4) NOT NULL,"
    "  `dept_name` varchar(40) NOT NULL,"
    "  PRIMARY KEY (`dept_no`), UNIQUE KEY `dept_name` (`dept_name`)"
    ") ENGINE=InnoDB")

TABLES['salaries'] = (
    "CREATE TABLE `salaries` ("
    "  `emp_no` int(11) NOT NULL,"
    "  `salary` int(11) NOT NULL,"
    "  `from_date` date NOT NULL,"
    "  `to_date` date NOT NULL,"
    "  PRIMARY KEY (`emp_no`,`from_date`), KEY `emp_no` (`emp_no`),"
    "  CONSTRAINT `salaries_ibfk_1` FOREIGN KEY (`emp_no`) "
    "    REFERENCES `employees` (`emp_no`) ON DELETE CASCADE"
    ") ENGINE=InnoDB")

TABLES['dept_emp'] = (
    "CREATE TABLE `dept_emp` ("
    "  `emp_no` int(11) NOT NULL,"
    "  `dept_no` char(4) NOT NULL,"
    "  `from_date` date NOT NULL,"
    "  `to_date` date NOT NULL,"
    "  PRIMARY KEY (`emp_no`,`dept_no`), KEY `emp_no` (`emp_no`),"
    "  KEY `dept_no` (`dept_no`),"
    "  CONSTRAINT `dept_emp_ibfk_1` FOREIGN KEY (`emp_no`) "
    "    REFERENCES `employees` (`emp_no`) ON DELETE CASCADE,"
    "  CONSTRAINT `dept_emp_ibfk_2` FOREIGN KEY (`dept_no`) "
    "    REFERENCES `departments` (`dept_no`) ON DELETE CASCADE"
    ") ENGINE=InnoDB")

TABLES['dept_manager'] = (
    "CREATE TABLE `dept_manager` ("
    "  `dept_no` char(4) NOT NULL,"
    "  `emp_no` int(11) NOT NULL,"
    "  `from_date` date NOT NULL,"
    "  `to_date` date NOT NULL,"
    "  PRIMARY KEY (`emp_no`,`dept_no`),"
    "  KEY `emp_no` (`emp_no`),"
    "  KEY `dept_no` (`dept_no`),"
    "  CONSTRAINT `dept_manager_ibfk_1` FOREIGN KEY (`emp_no`) "
    "    REFERENCES `employees` (`emp_no`) ON DELETE CASCADE,"
    "  CONSTRAINT `dept_manager_ibfk_2` FOREIGN KEY (`dept_no`) "
    "    REFERENCES `departments` (`dept_no`) ON DELETE CASCADE"
    ") ENGINE=InnoDB")

TABLES['titles'] = (
    "CREATE TABLE `titles` ("
    "  `emp_no` int(11) NOT NULL,"

```

```
" `title` varchar(50) NOT NULL,"
" `from_date` date NOT NULL,"
" `to_date` date DEFAULT NULL,"
" PRIMARY KEY (`emp_no`,`title`,`from_date`), KEY `emp_no` (`emp_no`),"
" CONSTRAINT `titles_ibfk_1` FOREIGN KEY (`emp_no`)
" REFERENCES `employees` (`emp_no`) ON DELETE CASCADE"
") ENGINE=InnoDB")
```

The above code shows how we are storing the `CREATE` statements in a Python dictionary called `TABLES`. We also define the database in a global variable called `DB_NAME`, which allows you to easily use a different schema.

```
cnx = mysql.connector.connect(user='scott')
cursor = cnx.cursor()
```

A single MySQL server can contain multiple `databases`. Typically, you specify the database to switch to when connecting to the MySQL server. This example does not connect to the database upon connection, so that it can make sure the database exists, and create it if not.

```
def create_database(cursor):
    try:
        cursor.execute(
            "CREATE DATABASE {} DEFAULT CHARACTER SET 'utf8'".format(DB_NAME))
    except mysql.connector.Error as err:
        print("Failed creating database: {}".format(err))
        exit(1)

try:
    cnx.database = DB_NAME
except mysql.connector.Error as err:
    if err.errno == errorcode.ER_BAD_DB_ERROR:
        create_database(cursor)
        cnx.database = DB_NAME
    else:
        print(err)
        exit(1)
```

We first try to change to a particular database using the `database` property of the connection object `cnx`. If there is an error, we examine the error number to check if the database does not exist. If so, we call the `create_database` function to create it for us.

On any other error, the application exits and displays the error message.

```
for name, ddl in TABLES.iteritems():
    try:
        print("Creating table {}: ".format(name), end='')
        cursor.execute(ddl)
    except mysql.connector.Error as err:
        if err.errno == errorcode.ER_TABLE_EXISTS_ERROR:
            print("already exists.")
        else:
            print(err.errmsg)
    else:
        print("OK")

cursor.close()
cnx.close()
```

After we successfully created or changed to the target database, we create the tables by iterating over the items of the `TABLES` dictionary.

We handle the error when the table already exists by simply notifying the user that it was already there. Other errors are printed, but we simply continue creating tables. (We show how to handle the “table already exists” condition for illustration purposes. In a real application, we would typically avoid the error condition entirely by using the `IF NOT EXISTS` clause of the `CREATE TABLE` statement.)

The output would be something like this:

```

Creating table employees: already exists.
Creating table salaries: already exists.
Creating table titles: OK
Creating table departments: already exists.
Creating table dept_manager: already exists.
Creating table dept_emp: already exists.

```

To populate the employees tables, use the dump files of the [Employee Sample Database](#). Note that you only need the data dump files that you will find in an archive named like [employees\\_db-dump-files-1.0.5.tar.bz2](#). After downloading the dump files, do the following from the command line, adding connection options to the `mysql` commands if necessary:

```

shell> tar xzf employees_db-dump-files-1.0.5.tar.bz2
shell> cd employees_db
shell> mysql employees < load_employees.dump
shell> mysql employees < load_titles.dump
shell> mysql employees < load_departments.dump
shell> mysql employees < load_salaries.dump
shell> mysql employees < load_dept_emp.dump
shell> mysql employees < load_dept_manager.dump

```

### 21.6.4.3. Inserting Data Using Connector/Python

Inserting or updating data is also done using the handler structure known as a cursor. When you use a transactional storage engine such as [InnoDB](#) (which is the default in MySQL 5.5 and later), you must [commit](#) the data after a sequence of [INSERT](#), [DELETE](#), and [UPDATE](#) statements.

In this example we show how to insert new data. The second [INSERT](#) depends on the value of the newly created [primary key](#) of the first. We are also demonstrating how to use extended formats. The task is to add a new employee starting to work tomorrow with a salary set to 50000.

#### Note

The following example uses tables created in the example [Section 21.6.4.2, “Creating Tables Using Connector/Python”](#). The `AUTO_INCREMENT` column option for the primary key of the `employees` table is important to ensure reliable, easily searchable data.

```

from __future__ import print_function
from datetime import date, datetime, timedelta
import mysql.connector

cnx = mysql.connector.connect(user='scott', database='employees')
cursor = cnx.cursor()

tomorrow = datetime.now().date() + timedelta(days=1)

add_employee = ("INSERT INTO employees "
               "(first_name, last_name, hire_date, gender, birth_date) "
               "VALUES (%s, %s, %s, %s, %s)")
add_salary = ("INSERT INTO salaries "
             "(emp_no, salary, from_date, to_date) "
             "VALUES (%(emp_no)s, %(salary)s, %(from_date)s, %(to_date)s)")

data_employee = ('Geert', 'Vanderkelen', tomorrow, 'M', date(1977, 6, 14))

# Insert new employee
cursor.execute(add_employee, data_employee)
emp_no = cursor.lastrowid

# Insert salary information
data_salary = {
    'emp_no': emp_no,
    'salary': 50000,
    'from_date': tomorrow,
    'to_date': date(9999, 1, 1),
}

```

```

cursor.execute(add_salary, data_salary)

# Make sure data is committed to the database
cnx.commit()

cursor.close()
cnx.close()

```

We first open a connection to the MySQL server and store the [connection object](#) in the variable `cnx`. We then create a new cursor, by default a [MySQLCursor](#) object, using the connection's `cursor()` method.

We could calculate tomorrow by calling a database function, but for clarity we do it in Python using the [datetime](#) module.

Both `INSERT` statements are stored in the variables called `add_employee` and `add_salary`. Note that the second `INSERT` statement uses extended Python format codes.

The information of the new employee is stored in the tuple `data_employee`. The query to insert the new employee is executed and we retrieve the newly inserted value for the column `emp_no` using the `lastrowid` property of the cursor object.

Next, we insert the new salary for the new employee. We are using the `emp_no` variable in the directory holding the data. This directory is passed to the `execute()` method of the cursor object.

Since by default Connector/Python turns [autocommit](#) off, and MySQL 5.5 and later uses transactional [InnoDB](#) tables by default, it is necessary to commit your changes using the connection's `commit()` method. You could also [roll back](#) using the `rollback()` method.

#### 21.6.4.4. Querying Data Using Connector/Python

The following example shows how to [query](#) data using a cursor created using the connection's `cursor()` method. The data returned is formatted and printed on the console.

The task is to select all employees hired in the year 1999 and print their names with their hire date to the console.

```

import datetime
import mysql.connector

cnx = mysql.connector.connect(user='scott', database='employees')
cursor = cnx.cursor()

query = ("SELECT first_name, last_name, hire_date FROM employees "
        "WHERE hire_date BETWEEN %s AND %s")

hire_start = datetime.date(1999, 1, 1)
hire_end = datetime.date(1999, 12, 31)

cursor.execute(query, (hire_start, hire_end))

for (first_name, last_name, hire_date) in cursor:
    print("{} , {} was hired on {:%d %b %Y}".format(
        last_name, first_name, hire_date))

cursor.close()
cnx.close()

```

We first open a connection to the MySQL server and store the [connection object](#) in the variable `cnx`. We then create a new cursor, by default a [MySQLCursor](#) object, using the connection's `cursor()` method.

In the preceding example, we store the `SELECT` statement in the variable `query`. Note that we are using unquoted `%s`-markers where dates should have been. Connector/Python converts `hire_start`

and `hire_end` from Python types to a data type that MySQL understands and adds the required quotes. In this case, it replaces the first `%s` with `'1999-01-01'`, and the second with `'1999-12-31'`.

We then execute the operation stored in the `query` variable using the `execute()` method. The data used to replace the `%s`-markers in the query is passed as a tuple: `(hire_start, hire_end)`.

After executing the query, the MySQL server is ready to send the data. The result set could be zero rows, one row, or 100 million rows. Depending on the expected volume, you can use different techniques to process this result set. In this example, we use the `cursor` object as an iterator. The first column in the row will be stored in the variable `first_name`, the second in `last_name`, and the third in `hire_date`.

We print the result, formatting the output using Python's built-in `format()` function. Note that `hire_date` was converted automatically by Connector/Python to a Python `datetime.date` object. This means that we can easily format the date in a more human-readable form.

The output should be something like this:

```
..
Wilharm, LiMin was hired on 16 Dec 1999
Wielonsky, Lalit was hired on 16 Dec 1999
Kamble, Dannz was hired on 18 Dec 1999
DuBourdieu, Zhongwei was hired on 19 Dec 1999
Fujisawa, Rosita was hired on 20 Dec 1999
..
```

## 21.6.5. Connector/Python Tutorials

These tutorials illustrate how to develop Python applications and scripts that connect to a MySQL database server using MySQL Connector/Python.

### 21.6.5.1. Tutorial: Raise employee's salary using a buffering cursor

The following example script will give a long-overdue raise effective tomorrow to all employees who joined in the year 2000 and are still with the company.

We are using buffered cursors to iterate through the selected employees. This way we do not have to fetch the rows in a new variables, but can instead use the cursor as an iterator.

Note that the script is an example; there are other ways of doing this simple task.

```
from __future__ import print_function

from decimal import Decimal
from datetime import datetime, date, timedelta

import mysql.connector

# Connect with the MySQL Server
cnx = mysql.connector.connect(user='scott', database='employees')

# Get two buffered cursors
curA = cnx.cursor(buffered=True)
curB = cnx.cursor(buffered=True)

# Query to get employees who joined in a period defined by two dates
query = (
    "SELECT s.emp_no, salary, from_date, to_date FROM employees AS e "
    "LEFT JOIN salaries AS s USING (emp_no) "
    "WHERE to_date = DATE('9999-01-01') "
    "AND e.hire_date BETWEEN DATE(%s) AND DATE(%s)"
)

# UPDATE and INSERT statements for the old and new salary
update_old_salary = (
    "UPDATE salaries SET to_date = %s "
    "WHERE emp_no = %s AND from_date = %s"
)
insert_new_salary = (
```

```

"INSERT INTO salaries (emp_no, from_date, to_date, salary) "
"VALUES (%s, %s, %s, %s)"

# Select the employees getting a raise
curA.execute(query, (date(2000, 1, 1), date(2001, 1, 1)))

# Iterate through the result of curA
for (emp_no, salary, from_date, to_date) in curA:

    # Update the old and insert the new salary
    new_salary = int(round(salary * Decimal('1.15')))
    curB.execute(update_old_salary, (tomorrow, emp_no, from_date))
    curB.execute(insert_new_salary,
                  (emp_no, tomorrow, date(9999, 1, 1), new_salary))

# Commit the changes
cnx.commit()

cnx.close()

```

## 21.6.6. Connector/Python Connection Arguments

The following lists the arguments that can be used to initiate a connection with the MySQL server using either:

- Function `mysql.connector.connect()`
- Class `mysql.connector.MySQLConnection()`

**Table 21.31. Connection Arguments for Connector/Python**

Argument Name	Default	Description
<code>user</code> ( <code>username*</code> )		The username used to authenticate with the MySQL Server.
<code>password</code> ( <code>passwd*</code> )		The password to authenticate the user with the MySQL Server.
<code>database</code> ( <code>db*</code> )		Database name to use when connecting with the MySQL Server.
<code>host</code>	127.0.0.1	Hostname or IP address of the MySQL Server.
<code>port</code>	3306	TCP/IP port of the MySQL Server. Must be an integer.
<code>unix_socket</code>		The location of the Unix socket file.
<code>use_unicode</code>	True	Whether to use Unicode or not.
<code>charset</code>	utf8	Which MySQL character set to use.
<code>collation</code>	utf8_general_ci	Which MySQL collation to use.
<code>autocommit</code>	False	Whether to <a href="#">autocommit</a> transactions.
<code>time_zone</code>		Set the <code>time_zone</code> session variable at connection.
<code>sql_mode</code>		Set the <code>sql_mode</code> session variable at connection.
<code>get_warnings</code>	False	Whether to fetch warnings.
<code>raise_on_warnings</code>	False	Whether to raise an exception on warnings.
<code>connection_timeout</code> ( <code>connect_timeout*</code> )		Timeout for the TCP and Unix socket connections.
<code>client_flags</code>		MySQL client flags.
<code>buffered</code>	False	Whether cursor object fetches the result immediately after executing query.
<code>raw</code>	False	Whether MySQL results are returned as-is, rather than converted to Python types.

Argument Name	Default	Description
<code>ssl_ca</code>		File containing the SSL certificate authority.
<code>ssl_cert</code>		File containing the SSL certificate file.
<code>ssl_key</code>		File containing the SSL key.
<code>ssl_verify_cert</code>	False	When set to <code>True</code> , checks the server certificate against the certificate file specified by the <code>ssl_ca</code> option. Any mismatch causes a <code>ValueError</code> exception.
<code>force_ipv6</code>	False	When set to <code>True</code> , uses IPv6 when an address resolves to both IPv4 and IPv6. By default, IPv4 is used in such cases.
<code>dsn</code>		Not supported (raises <code>NotSupportedError</code> when used).

\* Synonymous argument name, available only for compatibility with other Python MySQL drivers. Oracle recommends not to use these alternative names.

## MySQL Authentication

Authentication with MySQL will use `username` and `password`. Note that MySQL Connector/Python does not support the old, insecure password protocols of MySQL versions prior to 4.1.

When the `database` parameter is given, the current database is set to the given value. To later change the database, execute the MySQL `USE` command or set the `database` property of the `MySQLConnection` instance.

By default, Connector/Python tries to connect to a MySQL server running on `localhost` using TCP/IP. The `host` argument defaults to IP address 127.0.0.1 and `port` to 3306. Unix sockets are supported by setting `unix_socket`. Named pipes on the Windows platform are not supported.

## Character Encoding

Strings coming from MySQL are by default returned as Python Unicode literals. To change this behavior, set `use_unicode` to `False`. You can change the character setting for the client connection through the `charset` argument. To change the character set after connecting to MySQL, set the `charset` property of the `MySQLConnection` instance. This technique is preferred over using the MySQL `SET NAMES` statement directly. Similar to the `charset` property, you can set the `collation` for the current MySQL session.

## Transactions

Transactions are not automatically committed; call the `commit()` method of the `MySQLConnection` instance within your application after doing a set of related insert, update, and delete operations. For data consistency and high throughput for write operations, it is best to leave the `autocommit` configuration option turned off when using `InnoDB` or other transactional tables.

## Time Zones

The time zone can be set per connection using the `time_zone` argument. This is useful if the MySQL server is set, for example, to UTC and `TIMESTAMP` values should be returned by MySQL converted to the `PST` time zone.

## SQL Modes

MySQL supports so called SQL Modes, which will change the behavior of the server globally or per connection. For example, to have warnings raised as errors, set `sql_mode` to `TRADITIONAL`. For more information, see [Section 5.1.7, "Server SQL Modes"](#).

## Troubleshooting and Error Handling

Warnings generated by queries are fetched automatically when `get_warnings` is set to `True`. You can also immediately raise an exception by setting `raise_on_warnings` to `True`. Consider using the MySQL `sql_mode` setting for turning warnings into errors.

To set a timeout value for connections, use `connection_timeout`.

## Enabling and Disabling Features through Client Flags

MySQL uses `client flags` to enable or disable features. Using the `client_flags` argument, you have control of what is set. To find out what flags are available, use the following:

```
from mysql.connector.constants import ClientFlag
print '\n'.join(ClientFlag.get_full_info())
```

If `client_flags` is not specified (that is, it is zero), defaults are used for MySQL v4.1 and later. If you specify an integer greater than 0, make sure all flags are set. A better way to set and unset flags is to use a list. For example, to set `FOUND_ROWS`, but disable the default `LONG_FLAG`:

```
flags = [ClientFlag.FOUND_ROWS, -ClientFlag.LONG_FLAG]
mysql.connector.connect(client_flags=flags)
```

## Buffering for Result Sets

By default, MySQL Connector/Python does not buffer or pre-fetch results. This means that after a query is executed, your program is responsible of fetching the data. This avoids using excessive memory when queries return large result sets. If you know that the result set is small enough to handle all at once, fetching the results immediately by setting `buffered` to `True`. It is also possible to set this per cursor (see cursor manual).

## Type Conversions

MySQL types will be converted automatically to Python types. For example, a `DATETIME` column becomes a `datetime.datetime` object. When conversion should be done differently, for example to get better performance, set `raw` to `True`.

## Connecting through SSL

Using SSL connections is possible when your [Python installation supports SSL](#), that is, when it is compiled against the OpenSSL libraries. When you provide the arguments `ssl_ca`, `ssl_key` and `ssl_cert`, the connection switches to SSL, and the `client_flags` option includes the `ClientFlag.SSL` value automatically. You can use this in combination with the `compressed` argument set to `True`.

```
# Note (Example is valid for Python v2 and v3)
from __future__ import print_function

import sys

#sys.path.insert(0, 'python{0}/'.format(sys.version_info[0]))

import mysql.connector
from mysql.connector.constants import ClientFlag

config = {
    'user': 'ssluser',
    'password': 'asecret',
    'host': '127.0.0.1',
    'client_flags': [ClientFlag.SSL],
    'ssl_ca': '/opt/mysql/ssl/ca-cert.pem',
    'ssl_cert': '/opt/mysql/ssl/client-cert.pem',
    'ssl_key': '/opt/mysql/ssl/client-key.pem',
```

```

}

cnx = mysql.connector.connect(**config)
cur = cnx.cursor(buffered=True)
cur.execute("SHOW STATUS LIKE 'Ssl_cipher'")
print(cur.fetchone())
cur.close()
cnx.close()

```

## Compatibility with Other Connection Interfaces

`passwd`, `db` and `connect_timeout` are valid for compatibility with other MySQL interfaces and are respectively the same as `password`, `database` and `connection_timeout`. The latter take precedence. Data source name syntax or `dsn` is not used; if specified, it raises a `NotSupportedError` exception.

## 21.6.7. Connector/Python API Reference

This section contains the public API reference of Connector/Python. Although valid for both Python 2 and Python 3, examples should be considered working for Python 2.7, and Python 3.1 and greater.

The following overview shows the `mysql.connector` package with its modules. Currently, only the most useful modules, classes and functions for end users are documented.

```

mysql.connector
  errorcode
  errors
  connection
  constants
  conversion
  cursor
  dbapi
  locales
    eng
      client_error
  protocol
  utils

```

### 21.6.7.1. Errors and Exceptions

The `mysql.connector.errors` module defines exception classes for errors and warnings raised by MySQL Connector/Python. Most classes defined in this module are available when you import `mysql.connector`.

The exception classes defined in this module follow mostly the Python Database Specification v2.0 (PEP-249). For some MySQL client or server errors it is not always clear which exception to raise. It is good to discuss whether an error should be reclassified by opening a bug report.

MySQL Server errors are mapped with Python exception based on their SQLState (see [Section C.3, “Server Error Codes and Messages”](#)). The following list shows the `SQLState` classes and the exception Connector/Python will raise. It is, however, possible to redefine which exception is raised for each server error. Note that the default exception is `DatabaseError`.

- `02`: `DataError`
- `07`: `DatabaseError`
- `08`: `OperationalError`
- `0A`: `NotSupportedError`
- `21`: `DataError`
- `22`: `DataError`

- [23](#): IntegrityError
- [24](#): ProgrammingError
- [25](#): ProgrammingError
- [26](#): ProgrammingError
- [27](#): ProgrammingError
- [28](#): ProgrammingError
- [2A](#): ProgrammingError
- [2B](#): DatabaseError
- [2C](#): ProgrammingError
- [2D](#): DatabaseError
- [2E](#): DatabaseError
- [33](#): DatabaseError
- [34](#): ProgrammingError
- [35](#): ProgrammingError
- [37](#): ProgrammingError
- [3C](#): ProgrammingError
- [3D](#): ProgrammingError
- [3F](#): ProgrammingError
- [40](#): InternalError
- [42](#): ProgrammingError
- [44](#): InternalError
- [HZ](#): OperationalError
- [XA](#): IntegrityError
- [0K](#): OperationalError
- [HY](#): DatabaseError

#### 21.6.7.1.1. Module `errorcode`

This module contains both MySQL server and client error codes defined as module attributes with the error number as value. Using error codes instead of error numbers could make reading the source code a bit easier.

```
>>> from mysql.connector import errorcode
>>> errorcode.ER_BAD_TABLE_ERROR
1051
```

See [Section C.3](#), “Server Error Codes and Messages” and [Section C.4](#), “Client Error Codes and Messages”.

### 21.6.7.1.2. Exception `errors.Error`

This exception is the base class for all other exceptions in the `errors` module. It can be used to catch all errors in a single `except` statement.

The following example shows how we could catch syntax errors:

```
import mysql.connector
try:
    cnx = mysql.connector.connect(user='scott', database='employees')
    cursor = cnx.cursor()
    cursor.execute("SELECT * FORM employees") # Syntax error in query
    cnx.close()
except mysql.connector.Error as err:
    print("Something went wrong: {}".format(err))
```

Initializing the exception supports a few optional arguments, namely `msg`, `errno`, `values` and `sqlstate`. All of them are optional and default to `None`. `errors.Error` is internally used by Connector/Python to raise MySQL client and server errors and should not be used by your application to raise exceptions.

The following examples show the result when using no or a combination of the arguments:

```
>>> from mysql.connector.errors import Error
>>> str(Error())
'Unknown error'

>>> str(Error("Oops! There was an error. "))
'Oops! There was an error.'

>>> str(Error(errno=2006))
'2006: MySQL server has gone away'

>>> str(Error(errno=2002, values=('/tmp/mysql.sock', 2)))
'2002: Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)'

>>> str(Error(errno=1146, sqlstate='42S02', msg="Table 'test.spam' doesn't exist"))
'1146 (42S02): Table 'test.spam' doesn't exist'
```

The example which uses error number 1146 is used when Connector/Python receives an error packet from the MySQL Server. The information is parsed and passed to the `Error` exception as shown.

Each exception subclassing from `Error` can be initialized using the above mentioned arguments. Additionally, each instance has the attributes `errno`, `msg` and `sqlstate` which can be used in your code.

The following example shows how to handle errors when dropping a table which does not exist (when you do not want to use the `IF EXISTS` clause):

```
import mysql.connector
from mysql.connector import errorcode

cnx = mysql.connector.connect(user='scott', database='test')
try:
    cur.execute("DROP TABLE spam")
except mysql.connector.Error as err:
    if err.errno == errorcode.ER_BAD_TABLE_ERROR:
        print("Creating table spam")
    else:
        raise
```

`errors.Error` is a subclass of the Python `StandardError`.

### 21.6.7.1.3. Exception `errors.Warning`

This exception is used for reporting important warnings, however, Connector/Python does not use it. It is included to be compliant with the Python Database Specification v2.0 (PEP-249).

Consider using either more strict [Server SQL Modes](#) or the [raise\\_on\\_warnings](#) connection argument to make Connector/Python raise errors when your queries produce warnings.

`errors.Warning` is a subclass of the Python `StandardError`.

#### 21.6.7.1.4. Exception `errors.InterfaceError`

This exception is raised for errors originating from Connector/Python itself, not related to the MySQL server.

`errors.InterfaceError` is a subclass of `errors.Error`.

#### 21.6.7.1.5. Exception `errors.DatabaseError`

This exception is the default for any MySQL error which does not fit the other exceptions.

`errors.DatabaseError` is a subclass of `errors.Error`.

#### 21.6.7.1.6. Exception `errors.InternalError`

This exception is raised when the MySQL server encounters an internal error, for example, when a deadlock occurred.

`errors.InternalError` is a subclass of `errors.DatabaseError`.

#### 21.6.7.1.7. Exception `errors.OperationalError`

This exception is raised for errors which are related to MySQL's operations. For example, to many connections, a hostname could not be resolved, bad handshake, server is shutting down, communication errors, and so on.

`errors.OperationalError` is a subclass of `errors.DatabaseError`.

#### 21.6.7.1.8. Exception `errors.ProgrammingError`

This exception is raised on programming errors, for example when you have a syntax error in your SQL or a table was not found.

The following example shows how to handle syntax errors:

```
try:
    cursor.execute("CREATE DESK t1 (id int, PRIMARY KEY (id))")
except mysql.connector.ProgrammingError as err:
    if err.errno == errorcode.ER_SYNTAX_ERROR:
        print("Check your syntax!")
    else:
        print("Error: {}".format(err))
```

`errors.ProgrammingError` is a subclass of `errors.DatabaseError`.

#### 21.6.7.1.9. Exception `errors.IntegrityError`

This exception is raised when the relational integrity of the data is affected. For example, a duplicate key was inserted or a foreign key constraint would fail.

The following example shows a duplicate key error raised as `IntegrityError`:

```
cursor.execute("CREATE TABLE t1 (id int, PRIMARY KEY (id))")
try:
    cursor.execute("INSERT INTO t1 (id) VALUES (1)")
    cursor.execute("INSERT INTO t1 (id) VALUES (1)")
except mysql.connector.IntegrityError as err:
```

```
print("Error: {}".format(err))
```

`errors.IntegrityError` is a subclass of `errors.DatabaseError`.

#### 21.6.7.1.10. Exception `errors.DataError`

This exception is raised when there were problems with the data. Examples are a column set to NULL when it can not, out of range values for a column, division by zero, column count does not match value count, and so on.

`errors.DataError` is a subclass of `errors.DatabaseError`.

#### 21.6.7.1.11. Exception `errors.NotSupportedError`

This exception is raised in case some feature was used but not supported by the version of MySQL which returned the error. It is also raised when using functions or statements which are not supported by stored routines.

`errors.NotSupportedError` is a subclass of `errors.DatabaseError`.

#### 21.6.7.1.12. Function `errors.custom_error_exception(error=None, exception=None)`

This function defines custom exceptions for MySQL server errors and returns current customizations.

If `error` is a MySQL Server error number, then you have to pass also the `exception` class. The `error` argument can also be a dictionary in which case the key is the server error number, and value the class of the exception to be raised.

To reset the customizations, simply supply an empty dictionary.

```
import mysql.connector
from mysql.connector import errorcode

# Server error 1028 should raise a DatabaseError
mysql.connector.custom_error_exception(1028, mysql.connector.DatabaseError)

# Or using a dictionary:
mysql.connector.custom_error_exception({
    1028: mysql.connector.DatabaseError,
    1029: mysql.connector.OperationalError,
})

# To reset, pass an empty dictionary:
mysql.connector.custom_error_exception({})
```

### 21.6.7.2. Class `connection.MySQLConnection`

The `MySQLConnection` class is used to open and manage a connection to a MySQL server. It also used to send commands and SQL queries and read result.

#### 21.6.7.2.1. Constructor `connection.MySQLConnection(**kwargs)`

The `MySQLConnection` constructor initializes the attributes and when at least one argument is passed, it tries to connect with the MySQL server.

For a complete list of arguments, see [Section 21.6.6, “Connector/Python Connection Arguments”](#).

#### 21.6.7.2.2. Method `MySQLConnection.close()`

See [disconnect\(\)](#).

Returns a tuple.

### 21.6.7.2.3. Method `MySQLConnection.config(**kwargs)`

Allows to configure a `MySQLConnection` instance after it was instantiated. See [Section 21.6.6, “Connector/Python Connection Arguments”](#) for a complete list of possible arguments.

You could use the `config()` method to change, for example, the username and call `reconnect()`.

```
cnx = MySQLConnection(user='joe', database='test')
# Connected as 'joe'
cnx.config(user='jane')
cnx.reconnect()
# Now connected as 'jane'
```

### 21.6.7.2.4. Method `MySQLConnection.connect(**kwargs)`

This method sets up the connection to the MySQL server. If no arguments are given, it uses the already configured or default values. See [Section 21.6.6, “Connector/Python Connection Arguments”](#) for a complete list of possible arguments.

### 21.6.7.2.5. Method `MySQLConnection.commit()`

This method sends the `COMMIT` command to the MySQL server, committing the current transaction. Since by default, Connector/Python does not auto commit, it is important to call this method after every transaction which updates data for tables using transactional storage engines.

See the `rollback()` method for rolling back transactions.

```
>>> cursor.execute("INSERT INTO employees (first_name) VALUES (%s)", ('Jane'))
>>> cnx.commit()
```

### 21.6.7.2.6. Method `MySQLConnection.cursor(buffered=None, raw=None, cursor_class=None)`

This method returns a `MySQLCursor()` object, or a subclass of it depending the passed arguments.

When `buffered` is `True`, the cursor will fetch all rows after the operation is executed. This is useful when queries return small result sets. Setting `raw` will skip the conversion from MySQL data types to Python types when fetching rows. Raw is usually used when you want to have more performance and/or you want to do the conversion yourself.

The `cursor_class` argument can be used to pass a class to use for instantiating a new cursor. It has to be a subclass of `cursor.CursorBase`.

The returned object depends on the combination of the `buffered` and `raw` arguments.

- If not buffered and not raw: `cursor.MySQLCursor`
- If buffered and not raw: `cursor.MySQLCursorBuffered`
- If buffered and raw: `cursor.MySQLCursorBufferedRaw`
- If not buffered and raw: `cursor.MySQLCursorRaw`

Returns a `CursorBase` instance.

### 21.6.7.2.7. Method `MySQLConnection.cmd_change_user(username='', password='', database='', charset=33)`

Changes the user using `username` and `password`. It also causes the specified `database` to become the default (current) database. It is also possible to change the character set using the `charset` argument.

Returns a dictionary containing the OK packet information.

#### 21.6.7.2.8. Method `MySQLConnection.cmd_debug()`

Instructs the server to write some debug information to the log. For this to work, the connected user must have the `SUPER` privilege.

Returns a dictionary containing the OK packet information.

#### 21.6.7.2.9. Method `MySQLConnection.cmd_init_db(database)`

This method makes specified database the default (current) database. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

Returns a dictionary containing the OK packet information.

#### 21.6.7.2.10. Method `MySQLConnection.cmd_ping()`

Checks whether the connection to the server is working.

This method is not to be used directly. Use `ping()` or `is_connected()` instead.

Returns a dictionary containing the OK packet information.

#### 21.6.7.2.11. Method `MySQLConnection.cmd_process_info()`

This method raises the `NotSupportedError` exception. Instead, use the `SHOW PROCESSLIST` statement or query the tables found in the database `INFORMATION_SCHEMA`.

#### 21.6.7.2.12. Method `MySQLConnection.cmd_process_kill(mysql_pid)`

Asks the server to kill the thread specified by `mysql_pid`. Although still available, it's better to use the SQL `KILL` command.

Returns a dictionary containing the OK packet information.

The following two lines do the same:

```
>>> cnx.cmd_process_kill(123)
>>> cnx.cmd_query('KILL 123')
```

#### 21.6.7.2.13. Method `MySQLConnection.cmd_quit()`

This method sends the `QUIT` command to the MySQL server, closing the current connection. Since there is no response from the MySQL, the packet that was sent is returned.

#### 21.6.7.2.14. Method `MySQLConnection.cmd_query(statement)`

This method sends the given `statement` to the MySQL server and returns a result. If you need to send multiple statements, you have to use the `cmd_query_iter()` method.

The returned dictionary contains information depending on what kind of query was executed. If the query is a `SELECT` statement, the result contains information about columns. Other statements return a dictionary containing OK or EOF packet information.

Errors received from the MySQL server are raised as exceptions. An `InterfaceError` is raised when multiple results are found.

Returns a dictionary.

### 21.6.7.2.15. Method `MySQLConnection.cmd_query_iter(statement)`

Similar to the `cmd_query()` method, but returns a generator object to iterate through results. Use `cmd_query_iter()` when sending multiple statements, and separate the statements with semicolons.

The following example shows how to iterate through the results after sending multiple statements:

```
statement = 'SELECT 1; INSERT INTO t1 VALUES (); SELECT 2'
for result in cnx.cmd_query(statement, iterate=True):
    if 'columns' in result:
        columns = result['columns']
        rows = cnx.get_rows()
    else:
        # do something useful with INSERT result
```

Returns a generator object.

### 21.6.7.2.16. Method `MySQLConnection.cmd_refresh(options)`

This method flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument should be a bitwise value using constants from the class `constants.RefreshOption`.

See [Section 21.6.7.9, “Class `constants.RefreshOption`”](#) for a list of options.

Example:

```
>>> from mysql.connector import RefreshOption
>>> refresh = RefreshOption.LOG | RefreshOption.THREADS
>>> cnx.cmd_refresh(refresh)
```

### 21.6.7.2.17. Method `MySQLConnection.cmd_shutdown()`

Asks the database server to shut down. The connected user must have the `SHUTDOWN` privilege.

Returns a dictionary containing the OK packet information.

### 21.6.7.2.18. Method `MySQLConnection.cmd_statistics()`

Returns a dictionary containing information about the MySQL server including uptime in seconds and the number of running threads, questions, reloads, and open tables.

### 21.6.7.2.19. Method `MySQLConnection.disconnect()`

This method tries to send the `QUIT` command and close the socket. It does not raise any exceptions.

`MySQLConnection.close()` is a synonymous method name and more commonly used.

### 21.6.7.2.20. Method `MySQLConnection.get_rows(count=None)`

This method retrieves all or remaining rows of a query result set, returning a tuple containing the rows as sequence and the EOF packet information. The `count` argument can be used to get a given amount of rows. If `count` is not specified or is `None`, all rows are retrieved.

The tuple returned by `get_rows()` consists of:

- A list of tuples containing the row data as byte objects, or an empty list when no rows are available.

- EOF packet information as a dictionary containing `status_flag` and `warning_count`.

An `InterfaceError` is raised when all rows have been retrieved.

The `get_rows()` method is used by `MySQLCursor` to fetch rows.

Returns a tuple.

#### 21.6.7.2.21. Method `MySQLConnection.get_row()`

This method retrieves the next row of a query result set, returning a tuple.

The tuple returned by `get_row()` consists of:

- The row as a tuple containing byte objects, or `None` when no more rows are available.
- EOF packet information as a dictionary containing `status_flag` and `warning_count`, or `None` when the row returned is not the last row.

The `get_row()` method is used by `MySQLCursor` to fetch rows.

#### 21.6.7.2.22. Method `MySQLConnection.get_server_info()`

This method returns the MySQL server information verbatim, for example `'5.5.24-log'`, or `None` when not connected.

Returns a string or `None`.

#### 21.6.7.2.23. Method `MySQLConnection.get_server_version()`

This method returns the MySQL server version as a tuple, or `None` when not connected.

Returns a tuple or `None`.

#### 21.6.7.2.24. Method `MySQLConnection.is_connected()`

Reports whether the connection to MySQL Server is available.

This method checks whether the connection to MySQL is available using the `ping()` method, but unlike `ping()`, `is_connected()` returns `True` when the connection is available, `False` otherwise.

Returns `True` or `False`.

#### 21.6.7.2.25. Method `MySQLConnection.isset_client_flag(flag)`

This method returns `True` if the client flag was set, `False` otherwise.

Returns `True` or `False`.

#### 21.6.7.2.26. Method `MySQLConnection.ping(attempts=1, delay=0)`

Check whether the connection to the MySQL server is still available.

When `reconnect` is set to `True`, one or more attempts are made to try to reconnect to the MySQL server using the `reconnect()` method. Use the `delay` argument (seconds) if you want to wait between each retry.

When the connection is not available, an `InterfaceError` is raised. Use the `is_connected()` method to check the connection without raising an error.

Raises `InterfaceError` on errors.

### 21.6.7.2.27. Method `MySQLConnection.reconnect(attempts=1, delay=0)`

Attempt to reconnect with the MySQL server.

The argument `attempts` specifies the number of times a reconnect is tried. The `delay` argument is the number of seconds to wait between each retry.

You might set the number of attempts higher and use a longer delay when you expect the MySQL server to be down for maintenance, or when you expect the network to be temporarily unavailable.

### 21.6.7.2.28. Method `MySQLConnection.rollback()`

This method sends the `ROLLBACK` command to the MySQL server, undoing all data changes from the current `transaction`. Since by default, Connector/Python does not auto commit, it is possible to cancel transactions when using transactional storage engines such as `InnoDB`.

See the `commit()` method for `committing` transactions.

```
>>> cursor.execute("INSERT INTO employees (first_name) VALUES (%s)", ('Jane'))
>>> cnx.rollback()
```

### 21.6.7.2.29. Method `MySQLConnection.set_charset_collation(charset=None, collation=None)`

This method sets the character set and collation to be used for the current connection. The `charset` argument can be either the name of a character set, or the numerical equivalent as defined in `constants.CharacterSet`.

When `collation` is `None`, the default will be looked up and used.

The `charset` argument then be either:

In the following example, we set the character set to `latin1` and the collation will be set to the default `latin1_swedish_ci`:

```
>>> cnx = mysql.connector.connect(user='scott')
>>> cnx.set_charset('latin1')
```

Specify a specific collation as follows:

```
>>> cnx = mysql.connector.connect(user='scott')
>>> cnx.set_charset('latin1', 'latin1_general_ci')
```

### 21.6.7.2.30. Method `MySQLConnection.set_client_flags(flags)`

This method sets the client flags which are used when connecting with the MySQL server and returns the new value. The `flags` argument can be either an integer or a sequence of valid client flag values (see [Section 21.6.7.5, "Class constants.ClientFlag"](#)).

If `flags` is a sequence, each item in the sequence will set the flag when the value is positive or unset it when negative. For example, to unset `LONG_FLAG` and set the `FOUND_ROWS` flags:

```
>>> from mysql.connector.constants import ClientFlag
>>> cnx.set_client_flags([ClientFlag.FOUND_ROWS, -ClientFlag.LONG_FLAG])
>>> cnx.reconnect()
```

Note that client flags are only set or used when connecting with the MySQL server. It is therefore necessary to reconnect after making changes.

Returns an integer.

### 21.6.7.2.31. Property `MySQLConnection.autocommit`

This property is used to toggle the auto commit feature of MySQL and retrieve the current state. When the value evaluates to True, auto commit will be turned, otherwise it is turned off.

Note that auto commit is disabled by default when connecting through Connector/Python. This can be toggled using the [connection parameter](#) `autocommit`.

When the auto commit is turned off, you have to [commit](#) transactions when using transactional storage engines such as InnoDB or NDBCluster.

```
>>> cnx.autocommit
False
>>> cnx.autocommit = True
>>> cnx.autocommit
True
```

Returns True or False.

### 21.6.7.2.32. Property `MySQLConnection.charset_name`

This property returns which character set is used for the connection whether it is connected or not.

Returns a string.

### 21.6.7.2.33. Property `MySQLConnection.collation_name`

This property returns which collation is used for the connection whether it is connected or not.

Returns a string.

### 21.6.7.2.34. Property `MySQLConnection.connection_id`

This property returns the connection ID (thread ID or session ID) for the current connection or None when not connected.

Returns a integer or None.

### 21.6.7.2.35. Property `MySQLConnection.database`

This property is used to set current (active) database executing the [USE](#) command. The property can also be used to retrieve the current database name.

```
>>> cnx.database = 'test'
>>> cnx.database = 'mysql'
>>> cnx.database
u'mysql'
```

Returns a string.

### 21.6.7.2.36. Property `MySQLConnection.get_warnings`

This property is used to toggle whether warnings should be fetched automatically or not. It accepts True or False (default).

Fetching warnings automatically could be useful when debugging queries. Cursors will make warnings available through the method [MySQLCursor.fetchwarnings\(\)](#).

```
>>> cnx.get_warnings = True
>>> cursor.execute('SELECT "a"+1')
```

```
>>> cursor.fetchall()
[(1.0,)]
>>> cursor.fetchwarnings()
[(u'Warning', 1292, u"Truncated incorrect DOUBLE value: 'a'")]
```

Returns True or False.

#### 21.6.7.2.37. Property `MySQLConnection.raise_on_warnings`

This property is used to toggle whether warnings should raise exceptions or not. It accepts True or False (default).

toggling `raise_on_warnings` will also toggle `get_warnings` since warnings need to be fetched so they can be raised as exceptions.

Note that you might always want to check setting SQL Mode if you would like to have the MySQL server directly report warnings as errors. It is also good to use transactional engines so transactions can be rolled back when catching the exception.

Result sets needs to be fetched completely before any exception can be raised. The following example shows the execution of a query which produces a warning

```
>>> cnx.raise_on_warnings = True
>>> cursor.execute('SELECT "a"+1')
>>> cursor.fetchall()
..
mysql.connector.errors.DataError: 1292: Truncated incorrect DOUBLE value: 'a'
```

Returns True or False.

#### 21.6.7.2.38. Property `MySQLConnection.server_host`

This read-only property returns the hostname or IP address used for connecting with the MySQL server.

Returns a string.

#### 21.6.7.2.39. Property `MySQLConnection.server_port`

This read-only property returns the TCP/IP port used for connecting with the MySQL server.

Returns an integer.

#### 21.6.7.2.40. Property `MySQLConnection.sql_mode`

This property is used to retrieve and set the SQL Modes for the current. The value should be list of different modes separated by comma (","), or a sequence of modes, preferably using the constants.SQLMode class.

To unset all modes, pass an empty string or an empty sequence.

```
>>> cnx.sql_mode = 'TRADITIONAL,NO_ENGINE_SUBSTITUTION'
>>> cnx.sql_mode.split(',')
[u'STRICT_TRANS_TABLES', u'STRICT_ALL_TABLES', u'NO_ZERO_IN_DATE',
u'NO_ZERO_DATE', u'ERROR_FOR_DIVISION_BY_ZERO', u'TRADITIONAL',
u'NO_AUTO_CREATE_USER', u'NO_ENGINE_SUBSTITUTION']

>>> from mysql.connector.constants import SQLMode
>>> cnx.sql_mode = [ SQLMode.NO_ZERO_DATE, SQLMode.REAL_AS_FLOAT]
>>> cnx.sql_mode
u'REAL_AS_FLOAT,NO_ZERO_DATE'
```

Returns a string.

#### 21.6.7.2.41. Property `MySQLConnection.time_zone`

This property is used to set the time zone session variable for the current connection and retrieve it.

```
>>> cnx.time_zone = '+00:00'
>>> cur.execute('SELECT NOW()') ; cur.fetchone()
(datetime.datetime(2012, 6, 15, 11, 24, 36),)
>>> cnx.time_zone = '-09:00'
>>> cur.execute('SELECT NOW()') ; cur.fetchone()
(datetime.datetime(2012, 6, 15, 2, 24, 44),)
>>> cnx.time_zone
u'-09:00'
```

Returns a string.

#### 21.6.7.2.42. Property `MySQLConnection.unix_socket`

This read-only property returns the UNIX socket user for connecting with the MySQL server.

Returns a string.

#### 21.6.7.2.43. Property `MySQLConnection.user`

This read-only property returns the username used for connecting with the MySQL server.

Returns a string.

### 21.6.7.3. Class `cursor.MySQLCursor`

The `MySQLCursor` class is used to instantiate object which can execute operation such as SQL queries. They interact with the MySQL server using a `MySQLConnection` object.

#### 21.6.7.3.1. Constructor `cursor.MySQLCursor`

The constructor initializes the instance with the optional `connection`, which should be an instance of `MySQLConnection`.

In most cases, the `MySQLConnection` method `cursor()` is used to instantiate a `MySQLCursor` object.

#### 21.6.7.3.2. Method `MySQLCursor.callproc(procname, args=())`

This method calls a stored procedure with the given name. The `args` sequence of parameters must contain one entry for each argument that the routine expects. The result is returned as modified copy of the input sequence. Input parameters are left untouched, output and input/output parameters replaced with possibly new values.

Result set provided by the stored procedure are automatically fetched and stored as `MySQLBufferedCursor` instances. See `stored_results()` for more information.

The following example shows how to execute a stored procedure which takes two parameters, multiplies the values and returns the product:

```
# Definition of the multiply stored procedure:
# CREATE PROCEDURE multiply(IN pFac1 INT, IN pFac2 INT, OUT pProd INT)
# BEGIN
#   SET pProd := pFac1 * pFac2;
# END

>>> args = (5, 5, 0) # 0 is to hold value of the OUT parameter pProd
>>> cursor.callproc('multiply', args)
('5', '5', 25L)
```

### 21.6.7.3.3. Method `MySQLCursor.close()`

This method will close the MySQL cursor, resetting all results and removing the connection.

Use `close()` every time you are done using the cursor.

### 21.6.7.3.4. Method `MySQLCursor.execute(operation, params=None, multi=False)`

This method prepare the given database `operation` (query or command). The parameters found in the tuple or dictionary `params` will be bound to the variables in the operation. Variables are specified using `%s` markers or named markers `%(name)s`.

For example, insert information about a new employee and selecting again the data of this person:

```

insert = (
    "INSERT INTO employees (emp_no, first_name, last_name, hire_date) "
    "VALUES (%s, %s, %s, %s)"
    data = (2, 'Jane', 'Doe', datetime.date(2012, 3, 23))
    cursor.execute(insert, data)

select = "SELECT * FROM employees WHERE emp_no = %(emp_no)s"
cursor.execute(select, { 'emp_no': 2 })

```

Note that the data is converted from Python object to something MySQL understand. In the above example, the `datetime.date()` instance is converted to '2012-03-23' in the above example.

When `multi` is set to `True`, `execute()` will be able to execute multiple statements. It will return an iterator which makes it possible to go through all results for each statement. Note that using parameters is not working well in this case, and it's usually a good idea to execute each statement on its own.

In the following example we select and insert data in one operation and display the result:

```

operation = 'SELECT 1; INSERT INTO t1 VALUES (); SELECT 2'
for result in cursor.execute(operation):
    if result.with_rows:
        print("Statement '{}' has following rows:".format(
            result.statement))
        print(result.fetchall())
    else:
        print("Affected row(s) by query '{}' was {}".format(
            result.statement, result.rowcount))

```

If the connection was configured to fetch warnings, warnings generated by the operation will be available through the method `MySQLCursor.fetchwarnings()`.

Returns an iterator when `multi` is `True`.

### 21.6.7.3.5. Method `MySQLCursor.executemany(operation, seq_params)`

This method prepares a database operation (query or command) and then execute it against all parameter sequences or mappings found in the sequence `seq_of_params`.

The `executemany()` is simply iterating through the sequence of parameters calling the `execute()` method. Inserting data, however, is optimized by batching them using the multiple rows syntax.

In the following example we are inserting 3 records:

```

data = [
    ('Jane', date(2005, 2, 12)),
    ('Joe', date(2006, 5, 23)),
    ('John', date(2010, 10, 3)),
]
stmt = "INSERT INTO employees (first_name, hire_date) VALUES (%s, %s)"
cursor.executemany(stmt, data)

```

In the above example, the INSERT statement sent to MySQL would be as follows: `INSERT INTO employees (first_name, hire_date) VALUES ('Jane', '2005-02-12'), ('Joe', '2006-05-23'), ('John', '2010-10-03')`.

Note that it is not possible to execute multiple statements using the `executemany()` method. Doing so will raise an `InternalError` exception.

#### 21.6.7.3.6. Method `MySQLCursor.fetchall()`

The method fetches all or remaining rows of a query result set, returning a list of tuples. An empty list is returned when no rows are (anymore) available.

The following examples shows how to retrieve the first 2 rows of a result set, and then retrieve the remaining rows:

```
>>> cursor.execute("SELECT * FROM employees ORDER BY emp_no")
>>> head_rows = cursor.fetchmany(size=2)
>>> remaining_rows = cursor.fetchall()
```

Note that you have to fetch all rows before being able to execute new queries using the same connection.

Returns a list of tuples or empty list when no rows available.

#### 21.6.7.3.7. Method `MySQLCursor.fetchmany(size=1)`

This method fetches the next set of rows of a query results, returning a list of tuples. An empty list is returned when no more rows are available.

The number of rows returned can be specified using the `size` argument, which defaults to one. Fewer rows might be returned, when there are not more rows available than specified by the argument.

Note that you have to fetch all rows before being able to execute new queries using the same connection.

Returns a list of tuples or empty list when no rows available.

#### 21.6.7.3.8. Method `MySQLCursor.fetchone()`

This method retrieves the next row of a query result set, returning a single sequence, or `None` when no more data is available. The returned tuple consists of data returned by the MySQL server converted to Python objects.

The `fetchone()` method is used by `fetchmany()` and `fetchall()`. It is also used when using the `MySQLCursor` instance as an iterator.

The following examples show how to iterate through the result of a query using `fetchone()`:

```
# Using a while-loop
cursor.execute("SELECT * FROM employees")
row = cursor.fetchone()
while row is not None:
    print(row)
    row = cursor.fetchone()

# Using the cursor as iterator
cursor.execute("SELECT * FROM employees")
for row in cursor:
    print(row)
```

Note that you have to fetch all rows before being able to execute new queries using the same connection.

Returns a tuple or `None`.

### 21.6.7.3.9. Method `MySQLCursor.fetchwarnings()`

This method returns a list of tuples containing warnings generated by previously executed statement. Use the connection's `get_warnings` property to toggle whether warnings has to be fetched.

The following example shows a SELECT statement which generated a warning:

```
>>> cnx.get_warnings = True
>>> cursor.execute('SELECT "a"+1')
>>> cursor.fetchall()
[(1.0,)]
>>> cursor.fetchwarnings()
[(u'Warning', 1292, u"Truncated incorrect DOUBLE value: 'a'")]
```

It is also possible to raise errors when warnings are found. See the `MySQLConnection` property `raise_on_warnings`.

Returns a list of tuples.

### 21.6.7.3.10. Method `MySQLCursor.stored_results()`

This method returns an list iterator object which can be used to go through result sets provided by stored procedures after calling them using the `callproc()` method.

In the following example we execute a stored procedure which will provide two result sets. We use `stored_results()` to retrieve them:

```
>>> cursor.callproc('spl')
()
>>> for result in cursor.stored_results():
...     print result.fetchall()
...
[(1,)]
[(2,)]
```

Note that the result sets stay available until you executed another operation or call another stored procedure.

Returns a listiterator.

### 21.6.7.3.11. Property `MySQLCursor.column_names`

This read-only property returns the column names of a result set as sequence of (unicode) strings.

The following example shows how you can create a dictionary out of a tuple containing data with keys using `column_names`:

```
cursor.execute("SELECT last_name, first_name, hire_date "
              "FROM employees WHERE emp_no = %s", (123,))
row = dict(zip(cursor.column_names, cursor.fetchone())
print("{last_name}, {first_name}: {hire_date}".format(row))
```

Returns a tuple.

### 21.6.7.3.12. Property `MySQLCursor.statement`

This read-only property returns the last executed statement. In case multiple statements where executed, it will show the actual statement.

The `statement` property might be useful for debugging and showing what was send to the MySQL server.

Returns a string.

### 21.6.7.3.13. Property `MySQLCursor.with_rows`

This read-only property will return True when the result of the executed operation provides rows.

The `with_rows` property is useful when executing multiple statements and you need to fetch rows. In the following example we only report the affected rows by the `UPDATE` statement:

```
import mysql.connector
cnx = mysql.connector.connect(user='scott', database='test')
cursor = cnx.cursor()
operation = 'SELECT 1; UPDATE t1 SET c1 = 2; SELECT 2'
for result in cursor.execute(operation, multi=True):
    if result.with_rows:
        result.fetchall()
    else:
        print("Updated row(s): {}".format(result.rowcount))
```

### 21.6.7.4. Class `cursor.MySQLCursorBuffered`

This class is inheriting from `cursor.MySQLCursor` and if needed automatically retrieves rows after an operation has been executed.

`MySQLCursorBuffered` can be useful in situations where two queries, with small result sets, need to be combined or computed with each other.

You can either use the `buffered` argument when using the connection's `cursor()` method, or you can use the `buffered connection option` to make all created cursors by default buffering.

```
import mysql.connector

cnx = mysql.connector.connect()

# Only this particular cursor will be buffering results
cursor.cursor(buffered=True)

# All cursors by default buffering
cnx = mysql.connector.connect(buffered=True)
```

See [Section 21.6.5.1, "Tutorial: Raise employee's salary using a buffering cursor"](#) for a practical use case.

### 21.6.7.5. Class `constants.ClientFlag`

This class provides constants defining MySQL client flags which can be used upon connection to configure the session. The `ClientFlag` class is available when importing `mysql.connector`.

```
>>> import mysql.connector
>>> mysql.connector.constants.ClientFlag.FOUND_ROWS
2
```

See [Section 21.6.7.2.30, "Method `MySQLConnection.set\_client\_flags\(flags\)`"](#) and the [connection argument `client\_flag`](#).

Note that the `ClientFlag` class can not be instantiated.

### 21.6.7.6. Class `constants.FieldType`

This class provides all supported MySQL field or data types. They can be useful when dealing with raw data or defining your own converters. The field type is stored with every cursor in the description for each column.

The following example shows how you can print the name of the data types for each of the columns in the result set.

```

from __future__ import print_function
import mysql.connector
from mysql.connector import FieldType

cnx = mysql.connector.connect(user='scott', database='test')
cursor = cnx.cursor()

cursor.execute(
    "SELECT DATE(NOW()) AS `c1`, TIME(NOW()) AS `c2`, "
    "NOW() AS `c3`, 'a string' AS `c4`, 42 AS `c5`")
rows = cursor.fetchall()

for desc in cursor.description:
    colname = desc[0]
    coltype = desc[1]
    print("Column {} has type {}".format(
        colname, FieldType.get_info(coltype)))

cursor.close()
cnx.close()

```

Note that the `FieldType` class can not be instantiated.

#### 21.6.7.7. Class constants `.SQLMode`

This class provides all known MySQL [Server SQL Modes](#). It is mostly used when setting the SQL modes at connection time using the connection's property `sql_mode`. See [Section 21.6.7.2.40](#), "[Property `MySQLConnection.sql\_mode`](#)".

Note that the `SQLMode` class can not be instantiated.

#### 21.6.7.8. Class constants `.CharacterSet`

This class provides all known MySQL characters sets and their default collations. See [Section 21.6.7.2.29](#), "[Method `MySQLConnection.set\_charset\_collation\(charset=None, collation=None\)`](#)" for examples.

Note that the `CharacterSet` class can not be instantiated.

#### 21.6.7.9. Class constants `.RefreshOption`

- `RefreshOption.GRANT`  
Refresh the grant tables, like `FLUSH PRIVILEGES`.
- `RefreshOption.LOG`  
Flush the logs, like `FLUSH LOGS`.
- `RefreshOption.TABLES`  
Flush the table cache, like `FLUSH TABLES`.
- `RefreshOption.HOSTS`  
Flush the host cache, like `FLUSH HOSTS`.
- `RefreshOption.STATUS`  
Reset status variables, like `FLUSH STATUS`.
- `RefreshOption.THREADS`  
Flush the thread cache.

- `RefreshOption.SLAVE`

On a slave replication server, reset the master server information and restart the slave, like `RESET SLAVE`.

- `RefreshOption.MASTER`

On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like `RESET MASTER`.

## 21.6.8. Connector/Python FAQ

Frequently asked questions.

## 21.7. libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change a threaded application to use the embedded library, you normally only have to add calls to the following functions.

**Table 21.32. MySQL Embedded Server Library Functions**

Function	When to Call
<code>mysql_library_init()</code>	Call it before any other MySQL function is called, preferably early in the <code>main()</code> function.
<code>mysql_library_end()</code>	Call it before your program exits.
<code>mysql_thread_init()</code>	Call it in each thread you create that accesses MySQL.
<code>mysql_thread_end()</code>	Call it before calling <code>pthread_exit()</code> .

Then, link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, always compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 5.1 headers, do not compile your application against MySQL 5.5 headers, or vice versa.

Because the `mysql_library_xxx()` functions are also included in `libmysqlclient.a`, you can change between the embedded and the client/server version by just linking your application with the right library. See [Section 21.8.6.40](#), “`mysql_library_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, define the `HAVE_EMBEDDED_PRIVILEGE_CONTROL` [137] compiler flag when you invoke `CMake` to configure your MySQL distribution. See [Section 2.9.4](#), “MySQL Source-Configuration Options”.

### 21.7.1. Compiling Programs with `libmysqld`

In precompiled binary MySQL distributions that include `libmysqld`, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a `libmysqld` library if you build MySQL from source yourself, you should configure MySQL with the `-DWITH_EMBEDDED_SERVER=1` [136] option. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```
gcc mysql_test.c -o mysql_test \  
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. The `mysql_config` command is contained in backticks, not single quotation marks.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

## 21.7.2. Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- [InnoDB](#) is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
- The Event Scheduler is not available. Because of this, the `event_scheduler` [480] system variable is disabled.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

## 21.7.3. Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` [219] option as one of the elements of the second argument of the `mysql_library_init()`

function. See [Section 21.8.6.40](#), “`mysql_library_init()`”, for more information on the `mysql_library_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See [Section 4.2.3.3](#), “Using Option Files”.

## 21.7.4. Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

### Example 1

`test1_libmysqld.c`

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
    { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server",
    "libmysqld_client", NULL };

int main(void)
{
    mysql_library_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
    mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);

    mysql_real_connect(mysql, NULL,NULL,NULL, "database1", 0,NULL,0);

    mysql_query(mysql, "SELECT column1, column2 FROM table1");

    results = mysql_store_result(mysql);

    while((record = mysql_fetch_row(results))) {
        printf("%s - %s \n", record[0], record[1]);
    }

    mysql_free_result(results);
    mysql_close(mysql);
    mysql_library_end();

    return 0;
}
```

Here is the command line for compiling the above program:

```
gcc test1_libmysqld.c -o test1_libmysqld \
    `usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

**Example 2**

To try the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

`test2_libmysqld.c`

```

/*
 * A simple example client, using the embedded MySQL server library
 */

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
    "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
    MYSQL *one, *two;

    /* mysql_library_init() must be called before any other mysql
     * functions.
     *
     * You can use mysql_library_init(0, NULL, NULL), and it
     * initializes the server using groups = {
     *     "server", "embedded", NULL
     * }.
     *
     * In your $HOME/.my.cnf file, you probably want to put:
     *
     * [test2_libmysqld_SERVER]
     * language = /path/to/source/of/mysql/sql/share/english
     *
     * You could, of course, modify argc and argv before passing
     * them to this function. Or you could create new ones in any
     * way you like. But all of the arguments in argv (except for
     * argv[0], which is the program name) should be valid options
     * for the MySQL server.
     *
     * If you link this client against the normal mysqlclient
     * library, this function is just a stub that does nothing.
     */
    mysql_library_init(argc, argv, (char **)server_groups);

    one = db_connect("test");
    two = db_connect(NULL);

    db_do_query(one, "SHOW TABLE STATUS");
    db_do_query(two, "SHOW DATABASES");

    mysql_close(two);
    mysql_close(one);

    /* This must be called after all other mysql functions */
    mysql_library_end();

    exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)

```

```

{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc('\n', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");
    /*
     * Notice that the client and server use separate group names.
     * This is critical, because the server does not accept the
     * client's options, and vice versa.
     */
    mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
    if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
        die(db, "mysql_real_connect failed: %s", mysql_error(db));

    return db;
}

void
db_disconnect(MYSQL *db)
{
    mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
    if (mysql_query(db, query) != 0)
        goto err;

    if (mysql_field_count(db) > 0)
    {
        MYSQL_RES *res;
        MYSQL_ROW row, end_row;
        int num_fields;

        if (!(res = mysql_store_result(db)))
            goto err;
        num_fields = mysql_num_fields(res);
        while ((row = mysql_fetch_row(res)))
        {
            (void)fputs(">> ", stdout);
            for (end_row = row + num_fields; row < end_row; ++row)
                (void)printf("%s\t", row ? (char*)*row : "NULL");
            (void)fputc('\n', stdout);
        }
        (void)fputc('\n', stdout);
        mysql_free_result(res);
    }
    else
        (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

    return;

err:
    die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}

```

### GNUMakefile

```
# This assumes the MySQL software is installed in /usr/local/mysql
```

```

inc      := /usr/local/mysql/include/mysql
lib      := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc     := $(HOME)/mysql-5.6/include
#lib     := $(HOME)/mysql-5.6/libmysqld

CC       := gcc
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS   := -g -W -Wall
LDFLAGS  := -static
# You can change -lmysqld to -mysqlclient to use the
# client/server library
LDLIBS   = -L$(lib) -lmysqld -lm -ldl -lcrypt

ifneq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
# FreeBSD
LDFLAGS += -pthread
else
# Assume Linux
LDLIBS += -lpthread
endif

# This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %c,%o,$(sources))
targets := $(basename $(sources))

all: $(targets)

clean:
    rm -f $(targets) $(objects) *.core

```

## 21.8. MySQL C API

The C API provides low-level access to the MySQL client/server protocol and enables C programs to access database contents. The C API code is distributed with MySQL and implemented in the `libmysqlclient` library. See [Section 21.8.1, “MySQL C API Implementations”](#).

Most other client APIs use the `libmysqlclient` library to communicate with the MySQL server. (Exceptions are except Connector/J and Connector/Net.) This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs because they are referenced from the library. For a list of these variables, see [Section 4.1, “Overview of MySQL Programs”](#).

For instructions on building client programs using the C API, see [Section 21.8.3.1, “Building C API Client Programs”](#). For programming with threads, see [Section 21.8.3.2, “Writing C API Threaded Client Programs”](#). To create a standalone application which includes the “server” and “client” in the same program (and does not communicate with an external MySQL server), see [Section 21.7, “libmysqld, the Embedded MySQL Server Library”](#).

### Note

If, after an upgrade, you experience problems with compiled client programs, such as [Commands out of sync](#) or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the `mysql.h` file and `libmysqlclient.a` library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.15` to `libmysqlclient.so.16`).

Clients have a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (16MB by default). Because buffer sizes

are increased only as demand warrants, simply increasing the maximum limit does not in itself cause more resources to be used. This size check is mostly a precaution against erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each session's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` [502] parameter at server startup. See [Section 8.11.2, "Tuning Server Parameters"](#).

The MySQL server shrinks each communication buffer to `net_buffer_length` [515] bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

## 21.8.1. MySQL C API Implementations

The MySQL C API is a C-based API that client applications written in C can use to communicate with MySQL Server. Client programs refer to C API header files at compile time and link to a C API library file at link time. The library comes in two versions, depending on how the application is intended to communicate with the server:

- `libmysqlclient`: The client version of the library, used for applications that communicate over a network connection as a client of a standalone server process.
- `libmysqld`: The embedded server version of the library, used for applications intended to include an embedded MySQL server within the application itself. The application communicates with its own private server instance.

Both libraries have the same interface. In terms of C API calls, an application communicates with a standalone server the same way it communicates with an embedded server. A given client can be built to communicate with a standalone or embedded server, depending on whether it is linked against `libmysqlclient` or `libmysqld` at build time.

There are two ways to obtain the C API header and library files required to build C API client programs:

- Install a MySQL Server distribution. Server distributions include both `libmysqlclient` and `libmysqld`.
- Install a MySQL Connector/C distribution. Connector/C distributions include only `libmysqlclient`. They do not include `libmysqld`.

For both MySQL Server and MySQL Connector/C, you can install a binary distribution that contains the C API files pre-built, or you can use a source distribution and build the C API files yourself.

Normally, you install either a MySQL Server distribution or a MySQL Connector/C distribution, but not both. It is possible that installing both can cause problems.

The names of the library files to use when linking C API client applications depend on the library type and platform for which a distribution is built:

- On Unix (and Unix-like) systems, the static library is `libmysqlclient.a`. The dynamic library is `libmysqlclient.so` on most Unix systems and `libmysqlclient.dylib` on Mac OS X.

For distributions that include embedded server libraries, the corresponding library names begin with `libmysqld` rather than `libmysqlclient`.

- On Windows, the static library is `mysqlclient.lib` and the dynamic library is `libmysql.dll`. Windows distributions also include `libmysql.lib`, a static import library needed for using the dynamic library.

For distributions that include embedded server libraries, the corresponding library names are `mysqlserver.lib`, `libmysqld.dll`, and `libmysqld.lib`.

Windows distributions also include a set of debug libraries. These have the same names as the nondebug libraries, but are located in the `lib/debug` library. You must use the debug libraries when compiling clients built using the debug C runtime.

On Unix, you may also see libraries that include `_r` in the names. Before MySQL 5.5, these were built as thread-safe (re-entrant) libraries separately from the non-`_r` libraries. As of 5.5, both libraries are the same and the `_r` names are symbolic links to the corresponding non-`_r` names. There is no need to use the `_r` libraries. For example, if you use `mysql_config` to obtain linker flags, you can use `mysql_config --libs` in all cases, even for threaded clients. There is no need to use `mysql_config --libs_r`.

## 21.8.2. Example C API Client Programs

Many of the clients in MySQL source distributions are written in C, such as `mysql`, `mysqladmin`, and `mysqlshow`. If you are looking for examples that demonstrate how to use the C API, take a look at these clients: Obtain a source distribution and look in its `client` directory. See [Section 2.1.3, “How to Get MySQL”](#).

## 21.8.3. Building and Running C API Client Programs

The following sections provide information on building client programs that use the C API. Topics include compiling and linking clients, writing threaded clients, and troubleshooting runtime problems.

### 21.8.3.1. Building C API Client Programs

This section provides guidelines for compiling C programs that use the MySQL C API.

#### Compiling MySQL Clients on Unix

You may need to specify an `-I` option when you compile client programs that use MySQL header files, so that the compiler can find them. For example, if the header files are installed in `/usr/local/mysql/include`, use this option in the compile command:

```
-I/usr/local/mysql/include
```

MySQL clients must be linked using the `-lmysqlclient` option in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use these options in the link command:

```
-L/usr/local/mysql/lib -lmysqlclient
```

The path names may differ on your system. Adjust the `-I` and `-L` options as necessary.

To make it simpler to compile MySQL programs on Unix, use the `mysql_config` script. See [Section 4.7.2, “mysql\\_config — Display Options for Compiling Clients”](#).

`mysql_config` displays the options needed for compiling or linking:

```
shell> mysql_config --cflags
shell> mysql_config --libs
```

You can run those commands to get the proper options and add them manually to compilation or link commands. Alternatively, include the output from `mysql_config` directly within command lines using backticks:

```
shell> gcc -c `mysql_config --cflags` progname.c
```

```
shell> gcc -o progname progname.o `mysql_config --libs`
```

## Compiling MySQL Clients on Microsoft Windows

To specify the header and library file locations, use the facilities provided by your development environment.

On Windows, you can link your code with either the dynamic or static client library. The static library is named `mysqlclient.lib` and the dynamic library is named `libmysql.dll`. In addition, the `libmysql.lib` static import library is needed for using the dynamic library.

If you link with the static library, failure can occur unless these conditions are satisfied:

- The client application must be compiled with the same version of Visual Studio used to compile the library.
- The client application should link the C runtime statically by using the `/MT` compiler option.

If the client application is built in in debug mode and uses the static debug C runtime (`/MTd` compiler option), it can link to the `mysqlclient.lib` static library if that library was built using the same option. If the client application uses the dynamic C runtime (`/MD` option, or `/MDd` option in debug mode), it must be linked to the `libmysql.dll` dynamic library. It cannot link to the static client library.

The MSDN page describing the link options can be found here: <http://msdn.microsoft.com/en-us/library/2kzt1wy3.aspx>

## Troubleshooting Problems Linking to the MySQL Client Library

If the linker cannot find the MySQL client library, you might get undefined-reference errors for symbols that start with `mysql_`, such as those shown here:

```
/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
/tmp/ccFKsdPa.o(.text+0x31): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x69): undefined reference to `mysql_error'
/tmp/ccFKsdPa.o(.text+0x9a): undefined reference to `mysql_close'
```

You should be able to solve this problem by adding `-Ldir_path -lmysqlclient` at the end of your link command, where `dir_path` represents the path name of the directory where the client library is located. To determine the correct directory, try this command:

```
shell> mysql_config --libs
```

The output from `mysql_config` might indicate other libraries that should be specified on the link command as well. You can include `mysql_config` output directly in your compile or link command using backticks. For example:

```
shell> gcc -o progname progname.o `mysql_config --libs`
```

If an error occurs at link time that the `floor` symbol is undefined, link to the math library by adding `-lm` to the end of the compile/link line. Similarly, if you get undefined-reference errors for other functions that should exist on your system, such as `connect()`, check the manual page for the function in question to determine which libraries you should add to the link command.

If you get undefined-reference errors such as the following for functions that don't exist on your system, it usually means that your MySQL client library was compiled on a system that is not 100% compatible with yours:

```
mf_format.o(.text+0x201): undefined reference to `__lxstat'
```

In this case, you should download the latest MySQL or MySQL Connector/C source distribution and compile the MySQL client library yourself. See [Section 2.9, "Installing MySQL from Source"](#), and [Section 21.5, "MySQL Connector/C"](#).

### 21.8.3.2. Writing C API Threaded Client Programs

The client library is almost thread-safe. The biggest problem is that the subroutines in `net.c` that read from sockets are not interrupt-safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_library_init()`, `mysql_init()`, or `mysql_connect()`. To use your own `SIGPIPE` handler, first call `mysql_library_init()`, then install your handler.

If “undefined symbol” errors occur when linking against the `libmysqlclient` client library, in most cases this is because you have not included the thread libraries on the link/compile command.

The client library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Multiple threads cannot send a query to the MySQL server at the same time on the same connection. In particular, you must ensure that between calls to `mysql_query()` and `mysql_store_result()` in one thread, no other thread uses the same connection. You must have a mutex lock around your pair of `mysql_query()` and `mysql_store_result()` calls. After `mysql_store_result()` returns, the lock can be released and other threads may query the same connection.

If you use POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- To use `mysql_use_result()`, you must ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.

You need to know the following if you have a thread that did not create the connection to the MySQL database but is calling MySQL functions:

When you call `mysql_init()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things). If you call a MySQL function before the thread has called `mysql_init()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later. To avoid problems, you must do the following:

1. Call `mysql_library_init()` before any other MySQL functions. It is not thread-safe, so call it before threads are created, or protect the call with a mutex.
2. Arrange for `mysql_thread_init()` to be called early in the thread handler before calling any MySQL function. If you call `mysql_init()`, it will call `mysql_thread_init()` for you.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

The preceding notes regarding `mysql_init()` also apply to `mysql_connect()`, which calls `mysql_init()`.

### 21.8.3.3. Running C API Clients

Undefined-reference errors might occur at runtime when you try to execute a MySQL program. If these errors specify symbols that start with `mysql_` or indicate that the `libmysqlclient` library cannot be found, it means that your system cannot find the shared `libmysqlclient.so` library. The solution to this problem is to tell your system to search for shared libraries in the directory where that library is located. Use whichever of the following methods is appropriate for your system:

- Add the path of the directory where `libmysqlclient.so` is located to the `LD_LIBRARY_PATH` or `LD_LIBRARY` environment variable.
- On Mac OS X, add the path of the directory where `libmysqlclient.dylib` is located to the `DYLD_LIBRARY_PATH` environment variable.
- Copy the shared-library files (such as `libmysqlclient.so`) to some directory that is searched by your system, such as `/lib`, and update the shared library information by executing `ldconfig`. Be sure to copy all related files. A shared library might exist under several names, using symlinks to provide the alternate names.

If the application is linked to the embedded server library, runtime error messages will indicate the `libmysqld` rather than `libmysqlclient` library, but the solution to the problem is the same as just described.

## 21.8.4. C API Data Structures

This section describes C API data structures other than those used for prepared statements. For information about the latter, see [Section 21.8.8, "C API Prepared Statement Data Structures"](#).

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions. Do not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains metadata: information about a field, such as the field's name, type, and size. Its members are described in more detail later in this section. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to `1.84e19`.

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n",
       (unsigned long) mysql_num_rows(result));
```

- `my_bool`

A boolean type, for values that are true (nonzero) or false (zero).

The `MYSQL_FIELD` structure contains the members described in the following list. The definitions apply primarily for columns of result sets such as those produced by `SELECT` statements. In MySQL 5.6, `MYSQL_FIELD` structures are also used to provide metadata for `OUT` and `INOUT` parameters returned from stored procedures executed using prepared `CALL` statements. For such parameters, some of the structure members have a meaning different from the meaning for column values.

- `char * name`

The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias. For a procedure parameter, the parameter name.

- `char * org_name`

The name of the field, as a null-terminated string. Aliases are ignored. For expressions, the value is an empty string. For a procedure parameter, the parameter name.

- `char * table`

The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias. For a `UNION`, the value is the empty string. For a procedure parameter, the procedure name.

- `char * org_table`

The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the underlying table. For a `UNION`, the value is the empty string. For a procedure parameter, the procedure name.

- `char * db`

The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string. For a `UNION`, the value is the empty string. For a procedure parameter, the name of the database containing the procedure.

- `char * catalog`

The catalog name. This value is always `"def"`.

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

The width of the field. This corresponds to the display length, in bytes.

The server determines the `length` value before it generates the result set, so this is the minimum length required for a data type capable of holding the largest possible value from the result column, without knowing in advance the actual values that will be produced by the query for the result set.

- `unsigned long max_length`

The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the “widest” value is `-12.345`, `max_length` is 7 (the length of `'-12.345'`).

If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See [Section 21.8.8, “C API Prepared Statement Data Structures”](#).) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()`. (See [Section 21.8.10.3, “mysql\\_stmt\\_attr\\_set\(\)”](#), and [Section 21.8.10.28, “mysql\\_stmt\\_store\\_result\(\)”](#).)

- `unsigned int name_length`

The length of `name`.

- `unsigned int org_name_length`

The length of `org_name`.

- `unsigned int table_length`

The length of `table`.

- `unsigned int org_table_length`

The length of `org_table`.

- `unsigned int db_length`

The length of `db`.

- `unsigned int catalog_length`

The length of `catalog`.

- `unsigned int def_length`

The length of `def`.

- `unsigned int flags`

Bit-flags that describe the field. The `flags` value may have zero or more of the bits set that are shown in the following table.

Flag Value	Flag Description
<code>NOT_NULL_FLAG</code>	Field can't be <code>NULL</code>
<code>PRI_KEY_FLAG</code>	Field is part of a primary key
<code>UNIQUE_KEY_FLAG</code>	Field is part of a unique key
<code>MULTIPLE_KEY_FLAG</code>	Field is part of a nonunique key
<code>UNSIGNED_FLAG</code>	Field has the <code>UNSIGNED</code> attribute
<code>ZEROFILL_FLAG</code>	Field has the <code>ZEROFILL</code> attribute
<code>BINARY_FLAG</code>	Field has the <code>BINARY</code> attribute
<code>AUTO_INCREMENT_FLAG</code>	Field has the <code>AUTO_INCREMENT</code> attribute
<code>ENUM_FLAG</code>	Field is an <code>ENUM</code> (deprecated)
<code>SET_FLAG</code>	Field is a <code>SET</code> (deprecated)
<code>BLOB_FLAG</code>	Field is a <code>BLOB</code> or <code>TEXT</code> (deprecated)

Flag Value	Flag Description
<code>TIMESTAMP_FLAG</code>	Field is a <code>TIMESTAMP</code> (deprecated)
<code>NUM_FLAG</code>	Field is numeric; see additional notes following table
<code>NO_DEFAULT_VALUE_FLAG</code>	Field has no default value; see additional notes following table

Some of these flags indicate data type information and are superseded by or used in conjunction with the `MYSQL_TYPE_xxx` value in the `field->type` member described later:

- To check for `BLOB` or `TIMESTAMP` values, check whether `type` is `MYSQL_TYPE_BLOB` or `MYSQL_TYPE_TIMESTAMP`. (The `BLOB_FLAG` and `TIMESTAMP_FLAG` flags are unneeded.)
- `ENUM` and `SET` values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the `ENUM_FLAG` or `SET_FLAG` flag is set in the `flags` value.

`NUM_FLAG` indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL`, `MYSQL_TYPE_NEWDECIMAL`, `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, `MYSQL_TYPE_FLOAT`, `MYSQL_TYPE_DOUBLE`, `MYSQL_TYPE_NULL`, `MYSQL_TYPE_LONGLONG`, `MYSQL_TYPE_INT24`, and `MYSQL_TYPE_YEAR`.

`NO_DEFAULT_VALUE_FLAG` indicates that a column has no `DEFAULT` clause in its definition. This does not apply to `NULL` columns (because such columns have a default of `NULL`), or to `AUTO_INCREMENT` columns (which have an implied default value).

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

You may use the convenience macros shown in the following table to determine the boolean status of the `flags` value.

Flag Status	Description
<code>IS_NOT_NULL(flags)</code>	True if this field is defined as <code>NOT NULL</code>
<code>IS_PRI_KEY(flags)</code>	True if this field is a primary key
<code>IS_BLOB(flags)</code>	True if this field is a <code>BLOB</code> or <code>TEXT</code> (deprecated; test <code>field-&gt;type</code> instead)

- `unsigned int decimals`

The number of decimals for numeric fields, and (as of MySQL 5.6.4) the fractional seconds precision for temporal fields.

- `unsigned int charsetnr`

An ID number that indicates the character set/collation pair for the field.

To distinguish between binary and nonbinary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

`charsetnr` values are the same as those displayed in the `Id` column of the `SHOW COLLATION` statement or the `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table. You can use those information sources to see which character set and collation specific `charsetnr` values indicate:

```
mysql> SHOW COLLATION WHERE Id = 63;
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
```

```

+-----+-----+-----+-----+-----+
| binary | binary | 63 | Yes | Yes | 1 |
+-----+-----+-----+-----+-----+

mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
-> FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;
+-----+-----+
| COLLATION_NAME | CHARACTER_SET_NAME |
+-----+-----+
| utf8_general_ci | utf8 |
+-----+-----+

```

- enum `enum_field_types type`

The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

Type Value	Type Description
<code>MYSQL_TYPE_TINY</code>	<code>TINYINT</code> field
<code>MYSQL_TYPE_SHORT</code>	<code>SMALLINT</code> field
<code>MYSQL_TYPE_LONG</code>	<code>INTEGER</code> field
<code>MYSQL_TYPE_INT24</code>	<code>MEDIUMINT</code> field
<code>MYSQL_TYPE_LONGLONG</code>	<code>BIGINT</code> field
<code>MYSQL_TYPE_DECIMAL</code>	<code>DECIMAL</code> or <code>NUMERIC</code> field
<code>MYSQL_TYPE_NEWDECIMAL</code>	Precision math <code>DECIMAL</code> or <code>NUMERIC</code>
<code>MYSQL_TYPE_FLOAT</code>	<code>FLOAT</code> field
<code>MYSQL_TYPE_DOUBLE</code>	<code>DOUBLE</code> or <code>REAL</code> field
<code>MYSQL_TYPE_BIT</code>	<code>BIT</code> field
<code>MYSQL_TYPE_TIMESTAMP</code>	<code>TIMESTAMP</code> field
<code>MYSQL_TYPE_DATE</code>	<code>DATE</code> field
<code>MYSQL_TYPE_TIME</code>	<code>TIME</code> field
<code>MYSQL_TYPE_DATETIME</code>	<code>DATETIME</code> field
<code>MYSQL_TYPE_YEAR</code>	<code>YEAR</code> field
<code>MYSQL_TYPE_STRING</code>	<code>CHAR</code> or <code>BINARY</code> field
<code>MYSQL_TYPE_VAR_STRING</code>	<code>VARCHAR</code> or <code>VARBINARY</code> field
<code>MYSQL_TYPE_BLOB</code>	<code>BLOB</code> or <code>TEXT</code> field (use <code>max_length</code> to determine the maximum length)
<code>MYSQL_TYPE_SET</code>	<code>SET</code> field
<code>MYSQL_TYPE_ENUM</code>	<code>ENUM</code> field
<code>MYSQL_TYPE_GEOMETRY</code>	Spatial field
<code>MYSQL_TYPE_NULL</code>	<code>NULL</code> -type field

The `MYSQL_TYPE_TIME2`, `MYSQL_TYPE_DATETIME2`, and `MYSQL_TYPE_TIMESTAMP2` type codes are used only on the server side. Clients see the `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, and `MYSQL_TYPE_TIMESTAMP` codes.

You can use the `IS_NUM( )` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM( )` and it evaluates to `TRUE` if the field is numeric:

```

if (IS_NUM(field->type))
    printf("Field is numeric\n");

```

`ENUM` and `SET` values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the `ENUM_FLAG` or `SET_FLAG` flag is set in the `flags` value.

## 21.8.5. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See [Section 21.8.6, “C API Function Descriptions”](#).

**Table 21.33. C API Function Names and Descriptions**

Function	Description
<code>my_init()</code>	Initialize global variables, and thread handler in thread-safe programs
<code>mysql_affected_rows()</code>	Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> query
<code>mysql_autocommit()</code>	Toggles autocommit mode on/off
<code>mysql_change_user()</code>	Changes user and database on an open connection
<code>mysql_character_set_name()</code>	Return default character set name for current connection
<code>mysql_client_find_plugin()</code>	Return pointer to plugin
<code>mysql_client_register_plugin()</code>	Register a plugin
<code>mysql_close()</code>	Closes a server connection
<code>mysql_commit()</code>	Commits the transaction
<code>mysql_connect()</code>	Connects to a MySQL server (this function is deprecated; use <code>mysql_real_connect()</code> instead)
<code>mysql_create_db()</code>	Creates a database (this function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead)
<code>mysql_data_seek()</code>	Seeks to an arbitrary row number in a query result set
<code>mysql_debug()</code>	Does a <code>DEBUG_PUSH</code> with the given string
<code>mysql_drop_db()</code>	Drops a database (this function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead)
<code>mysql_dump_debug_info()</code>	Makes the server write debug information to the log
<code>mysql_eof()</code>	Determines whether the last row of a result set has been read (this function is deprecated; <code>mysql_errno()</code> or <code>mysql_error()</code> may be used instead)
<code>mysql_errno()</code>	Returns the error number for the most recently invoked MySQL function
<code>mysql_error()</code>	Returns the error message for the most recently invoked MySQL function
<code>mysql_escape_string()</code>	Escapes special characters in a string for use in an SQL statement
<code>mysql_fetch_field()</code>	Returns the type of the next table field
<code>mysql_fetch_field_direct()</code>	Returns the type of a table field, given a field number
<code>mysql_fetch_fields()</code>	Returns an array of all field structures
<code>mysql_fetch_lengths()</code>	Returns the lengths of all columns in the current row
<code>mysql_fetch_row()</code>	Fetches the next row from the result set
<code>mysql_field_count()</code>	Returns the number of result columns for the most recent statement
<code>mysql_field_seek()</code>	Puts the column cursor on a specified column
<code>mysql_field_tell()</code>	Returns the position of the field cursor used for the last <code>mysql_fetch_field()</code>

Function	Description
<code>mysql_free_result()</code>	Frees memory used by a result set
<code>mysql_get_character_set_name()</code>	Returns information about default character set
<code>mysql_get_client_info()</code>	Returns client version information as a string
<code>mysql_get_client_version()</code>	Returns client version information as an integer
<code>mysql_get_host_info()</code>	Returns a string describing the connection
<code>mysql_get_proto_info()</code>	Returns the protocol version used by the connection
<code>mysql_get_server_info()</code>	Returns the server version number
<code>mysql_get_server_version()</code>	Returns version number of server as an integer
<code>mysql_get_ssl_cipher()</code>	Return current SSL cipher
<code>mysql_hex_string()</code>	Encode string in hexadecimal format
<code>mysql_info()</code>	Returns information about the most recently executed query
<code>mysql_init()</code>	Gets or initializes a <code>MYSQL</code> structure
<code>mysql_insert_id()</code>	Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query
<code>mysql_kill()</code>	Kills a given thread
<code>mysql_library_end()</code>	Finalize the MySQL C API library
<code>mysql_library_init()</code>	Initialize the MySQL C API library
<code>mysql_list_dbs()</code>	Returns database names matching a simple regular expression
<code>mysql_list_fields()</code>	Returns field names matching a simple regular expression
<code>mysql_list_processes()</code>	Returns a list of the current server threads
<code>mysql_list_tables()</code>	Returns table names matching a simple regular expression
<code>mysql_load_plugin()</code>	Load a plugin
<code>mysql_load_plugin_v()</code>	Load a plugin
<code>mysql_more_results()</code>	Checks whether any more results exist
<code>mysql_next_result()</code>	Returns/initiates the next result in multiple-result executions
<code>mysql_num_fields()</code>	Returns the number of columns in a result set
<code>mysql_num_rows()</code>	Returns the number of rows in a result set
<code>mysql_options()</code>	Sets connect options for <code>mysql_real_connect()</code>
<code>mysql_options4()</code>	Sets connect options for <code>mysql_real_connect()</code>
<code>mysql_ping()</code>	Checks whether the connection to the server is working, reconnecting as necessary
<code>mysql_plugin_options()</code>	Set a plugin option
<code>mysql_query()</code>	Executes an SQL query specified as a null-terminated string
<code>mysql_real_connect()</code>	Connects to a MySQL server
<code>mysql_real_escape_string()</code>	Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection
<code>mysql_real_query()</code>	Executes an SQL query specified as a counted string
<code>mysql_refresh()</code>	Flush or reset tables and caches
<code>mysql_reload()</code>	Tells the server to reload the grant tables
<code>mysql_rollback()</code>	Rolls back the transaction
<code>mysql_row_seek()</code>	Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code>

Function	Description
<code>mysql_row_tell()</code>	Returns the row cursor position
<code>mysql_select_db()</code>	Selects a database
<code>mysql_server_end()</code>	Finalize the MySQL C API library
<code>mysql_server_init()</code>	Initialize the MySQL C API library
<code>mysql_set_character_set()</code>	Set default character set for current connection
<code>mysql_set_local_infile_defaults()</code>	Set the <code>LOAD DATA LOCAL INFILE</code> handler callbacks to their default values
<code>mysql_set_local_infile_handler()</code>	Install application-specific <code>LOAD DATA LOCAL INFILE</code> handler callbacks
<code>mysql_set_server_option()</code>	Sets an option for the connection (like <code>multi-statements</code> )
<code>mysql_sqlstate()</code>	Returns the SQLSTATE error code for the last error
<code>mysql_shutdown()</code>	Shuts down the database server
<code>mysql_ssl_set()</code>	Prepare to establish SSL connection to server
<code>mysql_stat()</code>	Returns the server status as a string
<code>mysql_store_result()</code>	Retrieves a complete result set to the client
<code>mysql_thread_end()</code>	Finalize thread handler
<code>mysql_thread_id()</code>	Returns the current thread ID
<code>mysql_thread_init()</code>	Initialize thread handler
<code>mysql_thread_safe()</code>	Returns 1 if the clients are compiled as thread-safe
<code>mysql_use_result()</code>	Initiates a row-by-row result set retrieval
<code>mysql_warning_count()</code>	Returns the warning count for the previous SQL statement

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. This function exists in both the `libmysqlclient` C client library and the `libmysqld` embedded server library, so it is used whether you build a regular client program by linking with the `-libmysqlclient` flag, or an embedded server application by linking with the `-libmysqld` flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the host name, user name, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. Treat these statements the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Choose the approach that is most appropriate for each client application. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you *must* retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is nonzero, the statement should have returned rows,

but didn't. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` enable you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, enabling you to determine when an error occurred and what it was.

## 21.8.6. C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or nonzero to indicate an error. Note that “nonzero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                /* correct */
    ... error ...

if (result < 0)           /* incorrect */
    ... error ...

if (result == -1)        /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

### 21.8.6.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

#### Description

`mysql_affected_rows()` may be called immediately after executing a statement with `mysql_query()` or `mysql_real_query()`. It returns the number of rows changed, deleted, or inserted by the last statement if it was an `UPDATE`, `DELETE`, or `INSERT`. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value is 1 if the row is inserted as a new row and 2 if an existing row is updated.

Following a `CALL` statement for a stored procedure, `mysql_affected_rows()` returns the value that it would return for the last statement executed within the procedure, or 0 if that statement would return

-1. Within the procedure, you can use `ROW_COUNT()` [1272] at the SQL level to obtain the affected-rows value for individual statements.

In MySQL 5.6, `mysql_affected_rows()` returns a meaningful value for a wider range of statements. For details, see the description for `ROW_COUNT()` [1272] in [Section 12.14, “Information Functions”](#).

## Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`.

Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

## Errors

None.

## Example

```
char *stmt = "UPDATE products SET cost=cost*1.25
             WHERE group=10";
mysql_query(&mysql, stmt);
printf("%ld products updated",
       (long) mysql_affected_rows(&mysql));
```

### 21.8.6.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

## Description

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

## Return Values

Zero if successful. Nonzero if an error occurred.

## Errors

None.

### 21.8.6.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char
                          *password, const char *db)
```

## Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case, the user and database are not changed.

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command resets the state as if one had done a new connect. (See [Section 21.8.15, “Controlling Automatic Reconnection Behavior”](#).) It always performs a `ROLLBACK` of any active transactions, closes

and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared statements are released and [HANDLER](#) variables are closed. Locks acquired with [GET\\_LOCK\(\)](#) [1275] are released. These effects occur even if the user didn't change.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

The same that you can get from [mysql\\_real\\_connect\(\)](#).

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#) [3719]

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#) [3718]

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#) [3719]

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#) [3718]

An unknown error occurred.

- [ER\\_UNKNOWN\\_COM\\_ERROR](#) [3663]

The MySQL server doesn't implement this command (probably an old server).

- [ER\\_ACCESS\\_DENIED\\_ERROR](#) [3663]

The user or password was wrong.

- [ER\\_BAD\\_DB\\_ERROR](#) [3664]

The database didn't exist.

- [ER\\_DBACCESS\\_DENIED\\_ERROR](#) [3663]

The user did not have access rights to the database.

- [ER\\_WRONG\\_DB\\_NAME](#) [3667]

The database name was too long.

## Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n",
            mysql_error(&mysql));
}
```

### 21.8.6.4. [mysql\\_character\\_set\\_name\(\)](#)

```
const char *mysql_character_set_name(MYSQL *mysql)
```

## Description

Returns the default character set name for the current connection.

**Return Values**

The default character set name

**Errors**

None.

**21.8.6.5. `mysql_close()`**

```
void mysql_close(MYSQL *mysql)
```

**Description**

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

**Return Values**

None.

**Errors**

None.

**21.8.6.6. `mysql_commit()`**

```
my_bool mysql_commit(MYSQL *mysql)
```

**Description**

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` [470] system variable. In particular, if the value of `completion_type` [470] is `RELEASE` (or 2), the server performs a release after terminating a transaction and closes the client connection. Call `mysql_close()` from the client program to close the connection from the client side.

**Return Values**

Zero if successful. Nonzero if an error occurred.

**Errors**

None.

**21.8.6.7. `mysql_connect()`**

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

**Description**

This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call

`mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

### Return Values

Same as for `mysql_real_connect()`.

### Errors

Same as for `mysql_real_connect()`.

### 21.8.6.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

### Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

### Return Values

Zero if the database was created successfully. Nonzero if an error occurred.

### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST \[3719\]](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)  
An unknown error occurred.

### Example

```
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}
```

### 21.8.6.9. `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

### Description

Seeks to an arbitrary row in a query result set. The `offset` value is a row number. Specify a value in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

**Return Values**

None.

**Errors**

None.

**21.8.6.10. `mysql_debug()`**

```
void mysql_debug(const char *debug)
```

**Description**

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See [MySQL Internals: Porting to Other Systems](#).

**Return Values**

None.

**Errors**

None.

**Example**

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:0,/tmp/client.trace");
```

**21.8.6.11. `mysql_drop_db()`**

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

**Description**

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

**Return Values**

Zero if the database was dropped successfully. Nonzero if an error occurred.

**Errors**

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST \[3719\]](#)  
The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### Example

```
if(mysql_drop_db(&mysql, "my_database"))
    fprintf(stderr, "Failed to drop the database: Error: %s\n",
            mysql_error(&mysql));
```

### 21.8.6.12. [mysql\\_dump\\_debug\\_info\(\)](#)

```
int mysql_dump_debug_info(MYSQL *mysql)
```

#### Description

Instructs the server to write some debug information to the log. For this to work, the connected user must have the [SUPER \[756\]](#) privilege.

#### Return Values

Zero if the command was successful. Nonzero if an error occurred.

#### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.6.13. [mysql\\_eof\(\)](#)

```
my_bool mysql_eof(MYSQL_RES *result)
```

#### Description

This function is deprecated. [mysql\\_errno\(\)](#) or [mysql\\_error\(\)](#) may be used instead.

[mysql\\_eof\(\)](#) determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to [mysql\\_store\\_result\(\)](#), the client receives the entire set in one operation. In this case, a `NULL` return from [mysql\\_fetch\\_row\(\)](#) always means the end of the result set has been reached and it is unnecessary to call [mysql\\_eof\(\)](#). When used with [mysql\\_store\\_result\(\)](#), [mysql\\_eof\(\)](#) always returns true.

On the other hand, if you use [mysql\\_use\\_result\(\)](#) to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call [mysql\\_fetch\\_row\(\)](#) repeatedly. Because an error may occur on the connection during this process, a `NULL` return value from [mysql\\_fetch\\_row\(\)](#) does not necessarily mean the end of the result set was reached normally. In this case, you can use [mysql\\_eof\(\)](#) to determine what happened. [mysql\\_eof\(\)](#) returns a nonzero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

## Return Values

Zero if no error occurred. Nonzero if the end of the result set has been reached.

## Errors

None.

## Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

### 21.8.6.14. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

## Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix C, Errors, Error Codes, and Common Problems](#).

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

## Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

## Errors

None.

### 21.8.6.15. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

## Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, the following two tests are equivalent:

```
if(*mysql_error(&mysql))
{
    // an error occurred
}

if(mysql_error(&mysql)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages. See [Section 10.2, "Setting the Error Message Language"](#).

## Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

## Errors

None.

### 21.8.6.16. `mysql_escape_string()`

Use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current character set.

### 21.8.6.17. `mysql_fetch_field()`

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

## Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

## Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

## Errors

None.

## Example

```
MYSQL_FIELD *field;

while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

### 21.8.6.18. `mysql_fetch_field_direct()`

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int
fieldnr)
```

## Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. Use this function to retrieve the definition for an arbitrary column. Specify a value for `fieldnr` in the range from 0 to `mysql_num_fields(result)-1`.

## Return Values

The `MYSQL_FIELD` structure for the specified column.

## Errors

None.

## Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

### 21.8.6.19. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

## Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

## Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

## Errors

None.

## Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
    printf("Field %u is %s\n", i, fields[i].name);
}
```

### 21.8.6.20. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

## Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing `NULL` values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

## Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). `NULL` if an error occurred.

## Errors

`mysql_fetch_lengths()` is valid only for the current row of the result set. It returns `NULL` if you call it before calling `mysql_fetch_row()` or after retrieving all rows in the result.

## Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n",
            i, lengths[i]);
    }
}
```

```
}
}
```

### 21.8.6.21. `mysql_fetch_row()`

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

#### Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. `NULL` values in the row are indicated by `NULL` pointers.

The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

#### Return Values

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

#### Errors

Note that error is not reset between calls to `mysql_fetch_row()`

- `CR_SERVER_LOST` [3719]

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR` [3718]

An unknown error occurred.

#### Example

```
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
    unsigned long *lengths;
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("[%.*s] ", (int) lengths[i],
            row[i] ? row[i] : "NULL");
    }
    printf("\n");
}
```

### 21.8.6.22. `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

#### Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 21.8.14.1, “Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success”](#).

## Return Values

An unsigned integer representing the number of columns in a result set.

## Errors

None.

## Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

### 21.8.6.23. `mysql_field_seek()`

```
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET
offset)
```

## Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

**Return Values**

The previous value of the field cursor.

**Errors**

None.

**21.8.6.24. `mysql_field_tell()`**

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

**Description**

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

**Return Values**

The current offset of the field cursor.

**Errors**

None.

**21.8.6.25. `mysql_free_result()`**

```
void mysql_free_result(MYSQL_RES *result)
```

**Description**

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

**Return Values**

None.

**Errors**

None.

**21.8.6.26. `mysql_get_character_set_info()`**

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

**Description**

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

**Example**

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set+collation number: %d\n", cs.number);
    printf("character set name: %s\n", cs.name);
}
```

```
printf("collation name: %s\n", cs.csname);
printf("comment: %s\n", cs.comment);
printf("directory: %s\n", cs.dir);
printf("multi byte character min. length: %d\n", cs.mbminlen);
printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

### 21.8.6.27. `mysql_get_client_info()`

```
const char *mysql_get_client_info(void)
```

#### Description

Returns a string that represents the client library version.

#### Return Values

A character string that represents the MySQL client library version.

#### Errors

None.

### 21.8.6.28. `mysql_get_client_version()`

```
unsigned long mysql_get_client_version(void)
```

#### Description

Returns an integer that represents the client library version. The value has the format `XYZZ` where `X` is the major version, `YY` is the release level, and `ZZ` is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

#### Return Values

An integer that represents the MySQL client library version.

#### Errors

None.

### 21.8.6.29. `mysql_get_host_info()`

```
const char *mysql_get_host_info(MYSQL *mysql)
```

#### Description

Returns a string describing the type of connection in use, including the server host name.

#### Return Values

A character string representing the server host name and the connection type.

#### Errors

None.

### 21.8.6.30. `mysql_get_proto_info()`

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

#### Description

Returns the protocol version used by current connection.

**Return Values**

An unsigned integer representing the protocol version used by the current connection.

**Errors**

None.

**21.8.6.31. `mysql_get_server_info()`**

```
const char *mysql_get_server_info(MYSQL *mysql)
```

**Description**

Returns a string that represents the server version number.

**Return Values**

A character string that represents the server version number.

**Errors**

None.

**21.8.6.32. `mysql_get_server_version()`**

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

**Description**

Returns the version number of the server as an integer.

**Return Values**

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 5.1.5 is returned as 50105.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

**Errors**

None.

**21.8.6.33. `mysql_get_ssl_cipher()`**

```
const char *mysql_get_ssl_cipher(MYSQL *mysql)
```

**Description**

`mysql_get_ssl_cipher()` returns the SSL cipher used for the given connection to the server. `mysql` is the connection handler returned from `mysql_init()`.

**Return Values**

A string naming the SSL cipher used for the connection, or `NULL` if no cipher is being used.

**21.8.6.34. `mysql_hex_string()`**

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)
```

## Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 9.1.1, "String Literals"](#).

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0xvalue` or `X'value'` format. However, the return value does not include the `0x` or `X'...`. The caller must supply whichever of those is desired.

## Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"0x");
end += mysql_hex_string(end,"What is this",12);
end = strmov(end,"0x");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
*end++ = '\0';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

## Return Values

The length of the value placed into `to`, not including the terminating null character.

## Errors

None.

### 21.8.6.35. `mysql_info()`

```
const char *mysql_info(MYSQL *mysql)
```

## Description

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

- `INSERT INTO ... SELECT ...`

String format: `Records: 100 Duplicates: 0 Warnings: 0`

- `INSERT INTO ... VALUES (...),(...),(...)...`

String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `LOAD DATA INFILE ...`

String format: `Records: 1 Deleted: 0 Skipped: 0 Warnings: 0`

- `ALTER TABLE`

String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `UPDATE`

String format: `Rows matched: 40 Changed: 40 Warnings: 0`

Note that `mysql_info()` returns a non-NULL value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

## Return Values

A character string representing additional information about the most recently executed statement. `NULL` if no information is available for the statement.

## Errors

None.

### 21.8.6.36. `mysql_init()`

```
MYSQL *mysql_init(MYSQL *mysql)
```

## Description

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

## Return Values

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

## Errors

In case of insufficient memory, `NULL` is returned.

### 21.8.6.37. `mysql_insert_id()`

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

## Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field, or have used `INSERT` or `UPDATE` to set a column value with `LAST_INSERT_ID(expr)` [1269].

The return value of `mysql_insert_id()` is always zero unless explicitly updated under one of the following conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit nonspecial value.
- In the case of a multiple-row `INSERT` statement, `mysql_insert_id()` returns the first automatically generated `AUTO_INCREMENT` value that was successfully inserted.

If no rows are successfully inserted, `mysql_insert_id()` returns 0.

- If an `INSERT ... SELECT` statement is executed, and no automatically generated value is successfully inserted, `mysql_insert_id()` returns the ID of the last inserted row.
- If an `INSERT ... SELECT` statement uses `LAST_INSERT_ID(expr)` [1269], `mysql_insert_id()` returns `expr`.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(expr)` [1269] into any column or by updating any column to `LAST_INSERT_ID(expr)` [1269].
- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

The return value of `mysql_insert_id()` can be simplified to the following sequence:

1. If there is an `AUTO_INCREMENT` column, and an automatically generated value was successfully inserted, return the first such value.
2. If `LAST_INSERT_ID(expr)` [1269] occurred in the statement, return `expr`, even if there was an `AUTO_INCREMENT` column in the affected table.
3. The return value varies depending on the statement used. When called after an `INSERT` statement:
  - If there is an `AUTO_INCREMENT` column in the table, and there were some explicit values for this column that were successfully inserted into the table, return the last of the explicit values.

When called after an `INSERT ... ON DUPLICATE KEY UPDATE` statement:

- If there is an `AUTO_INCREMENT` column in the table and there were some explicit successfully inserted values or some updated values, return the last of the inserted or updated values.

`mysql_insert_id()` returns 0 if the previous statement does not use an `AUTO_INCREMENT` value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

The `LAST_INSERT_ID()` [1269] SQL function will contain the value of the first automatically generated value that was successfully inserted. `LAST_INSERT_ID()` [1269] is not reset between statements because the value of that function is maintained in the server. Another difference from `mysql_insert_id()` is that `LAST_INSERT_ID()` [1269] is not updated if you set an `AUTO_INCREMENT` column to a specific nonspecial value. See [Section 12.14, "Information Functions"](#).

`mysql_insert_id()` returns 0 following a `CALL` statement for a stored procedure that generates an `AUTO_INCREMENT` value because in this case `mysql_insert_id()` applies to `CALL` and not the statement within the procedure. Within the procedure, you can use `LAST_INSERT_ID()` [1269] at the SQL level to obtain the `AUTO_INCREMENT` value.

The reason for the differences between `LAST_INSERT_ID()` [1269] and `mysql_insert_id()` is that `LAST_INSERT_ID()` [1269] is made easy to use in scripts while `mysql_insert_id()` tries to provide more exact information about what happens to the `AUTO_INCREMENT` column.

## Return Values

Described in the preceding discussion.

## Errors

None.

### 21.8.6.38. `mysql_kill()`

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

#### Description

Asks the server to kill the thread specified by `pid`.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `KILL` statement instead.

`mysql_kill()` cannot handle values larger than 32 bits, but as of MySQL 5.6.9 to guard against killing the wrong thread returns an error in these cases:

- If given an ID larger than 32 bits, `mysql_kill()` returns a `CR_INVALID_CONN_HANDLE` [3721] error.
- After the server's internal thread ID counter reaches a value larger than 32 bits, it returns an `ER_DATA_OUT_OF_RANGE` [3705] error for any `mysql_kill()` invocation and `mysql_kill()` fails.

#### Return Values

Zero for success. Nonzero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC` [3719]  
Commands were executed in an improper order.
- `CR_INVALID_CONN_HANDLE` [3721]  
The `pid` was larger than 32 bits.
- `CR_SERVER_GONE_ERROR` [3718]  
The MySQL server has gone away.
- `CR_SERVER_LOST` [3719]  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR` [3718]  
An unknown error occurred.
- `ER_DATA_OUT_OF_RANGE` [3705]  
The server's internal thread ID counter has reached a value larger than 32 bits, at which point it rejects all `mysql_kill()` invocations.

### 21.8.6.39. `mysql_library_end()`

```
void mysql_library_end(void)
```

#### Description

This function finalizes the MySQL library. Call it when you are done using the library (for example, after disconnecting from the server). The action taken by the call depends on whether your application is linked to the MySQL client library or the MySQL embedded server library. For a client program linked against the `libmysqlclient` library by using the `-lmysqlclient` flag, `mysql_library_end()` performs some memory management to clean up. For an embedded server application linked against

the `libmysqld` library by using the `-lmysqld` flag, `mysql_library_end()` shuts down the embedded server and then cleans up.

For usage information, see [Section 21.8.5, “C API Function Overview”](#), and [Section 21.8.6.40, “mysql\\_library\\_init\(\)”](#).

#### 21.8.6.40. `mysql_library_init()`

```
int mysql_library_init(int argc, char **argv, char **groups)
```

##### Description

Call this function to initialize the MySQL library before you call any other MySQL function, whether your application is a regular client program or uses the embedded server. If the application uses the embedded server, this call starts the server and initializes any subsystems (`mysys`, `InnoDB`, and so forth) that the server uses.

After your application is done using the MySQL library, call `mysql_library_end()` to clean up. See [Section 21.8.6.39, “mysql\\_library\\_end\(\)”](#).

The choice of whether the application operates as a regular client or uses the embedded server depends on whether you use the `libmysqlclient` or `libmysqld` library at link time to produce the final executable. For additional information, see [Section 21.8.5, “C API Function Overview”](#).

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. Do this prior to any other client library call.

The `argc` and `argv` arguments are analogous to the arguments to `main()`, and enable passing of options to the embedded server. For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. This is the usual case for applications intended for use only as regular (nonembedded) clients, and the call typically is written as `mysql_library_init(0, NULL, NULL)`.

```
#include <mysql.h>
#include <stdlib.h>

int main(void) {
    if (mysql_library_init(0, NULL, NULL)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }

    /* Use any MySQL API functions here */

    mysql_library_end();

    return EXIT_SUCCESS;
}
```

When arguments are to be passed (`argc` is greater than 0), the first element of `argv` is ignored (it typically contains the program name). `mysql_library_init()` makes a copy of the arguments so it is safe to destroy `argv` or `groups` after the call.

For embedded applications, if you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The `groups` argument is an array of strings that indicate the groups in option files from which to read options. See [Section 4.2.3.3, “Using Option Files”](#). Make the final entry in the array `NULL`. For convenience, if the `groups` argument itself is `NULL`, the `[server]` and `[embedded]` groups are used by default.

```

#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
    "this_program",          /* this string is not used */
    "--datadir=",
    "--key_buffer_size=32M"
};
static char *server_groups[] = {
    "embedded",
    "server",
    "this_program_SERVER",
    (char *)NULL
};

int main(void) {
    if (mysql_library_init(sizeof(server_args) / sizeof(char *),
        server_args, server_groups)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }

    /* Use any MySQL API functions here */

    mysql_library_end();

    return EXIT_SUCCESS;
}

```

## Return Values

Zero if successful. Nonzero if an error occurred.

### 21.8.6.41. `mysql_list_dbs()`

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

## Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW DATABASES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

## Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_OUT\\_OF\\_MEMORY \[3718\]](#)  
Out of memory.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST \[3719\]](#)  
The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

#### 21.8.6.42. `mysql_list_fields()`

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

##### Description

Returns a result set consisting of field names in the given table that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild]`.

It is preferable to use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

##### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

##### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

#### 21.8.6.43. `mysql_list_processes()`

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

##### Description

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

##### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

##### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

#### 21.8.6.44. `mysql_list_tables()`

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

##### Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW TABLES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

##### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

##### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

#### 21.8.6.45. `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

##### Description

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.

`mysql_more_results()` true if more results exist from the currently executed statement, in which case the application must call `mysql_next_result()` to fetch the results.

##### Return Values

`TRUE` (1) if more results exist. `FALSE` (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See [Section 21.8.16, “C API Support for Multiple Statement Execution”](#), and [Section 21.8.6.46, “mysql\\_next\\_result\(\)”](#).

## Errors

None.

### 21.8.6.46. `mysql_next_result()`

```
int mysql_next_result(MYSQL *mysql)
```

## Description

This function is used when you execute multiple statements specified as a single statement string, or when you use `CALL` statements to execute stored procedures, which can return multiple result sets.

`mysql_next_result()` reads the next statement result and returns a status to indicate whether more results exist. If `mysql_next_result()` returns an error, there are no more results.

Before each call to `mysql_next_result()`, you must call `mysql_free_result()` for the current statement if it is a statement that returned a result set (rather than just a result status).

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next statement. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If your program uses `CALL` statements to execute stored procedures, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because `CALL` can return multiple results, process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). In MySQL 5.6, `CLIENT_MULTI_RESULTS` is enabled by default.

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_next_result()` to advance to the next result.

For an example that shows how to use `mysql_next_result()`, see [Section 21.8.16, “C API Support for Multiple Statement Execution”](#).

## Return Values

Return Value	Description
0	Successful and there are more results
-1	Successful and there are no more results
>0	An error occurred

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order. For example, if you didn't call `mysql_use_result()` for a previous result set.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.6.47. `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

#### Description

Returns the number of columns in a result set.

Note that you can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 21.8.14.1, "Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success"](#).

#### Return Values

An unsigned integer representing the number of columns in a result set.

#### Errors

None.

#### Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
    }
}
```

```
}  
}
```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` returns 0. This happens only if something went wrong.

#### 21.8.6.48. `mysql_num_rows()`

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

##### Description

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

`mysql_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_affected_rows()`.

##### Return Values

The number of rows in the result set.

##### Errors

None.

#### 21.8.6.49. `mysql_options()`

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const void *arg)
```

##### Description

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

Call `mysql_options()` after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, specify a pointer to the value of the integer as the `arg` argument.

The following list describes the possible options, their effect, and how `arg` is used for each option. Several of the options apply only when the application is linked against the `libmysqld` embedded server library and are unused for applications linked against the `libmysqlclient` client library. For option descriptions that indicate `arg` is unused, its value is irrelevant; it is conventional to pass 0.

- `MYSQL_DEFAULT_AUTH` (argument type: `char *`)

The name of the authentication plugin to use.

- `MYSQL_ENABLE_CLEARTEXT_PLUGIN` (argument type: `my_bool *`)

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.6.7.

- `MYSQL_INIT_COMMAND` (argument type: `char *`)

SQL statement to execute when connecting to the MySQL server. Automatically re-executed if reconnection occurs.

- `MYSQL_OPT_BIND` (argument: `char *`)

The network interface from which to connect to the server. This is used when the client host has multiple network interfaces. The argument is a host name or IP address (specified as a string). This option was added in MySQL 5.6.1.

- `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` (argument type: `my_bool *`)

Indicate whether the client can handle expired passwords. For more information, see [Section 6.3.6, “Password Expiration and Sandbox Mode”](#). This option was added in MySQL 5.6.10.

- `MYSQL_OPT_COMPRESS` (argument: not used)

Use the compressed client/server protocol.

- `MYSQL_OPT_CONNECT_ATTR_DELETE` (argument types: `char *`)

Given a key name, this option deletes a key/value pair from the current set of connection attributes to be passed to the server at connect time. The argument is a pointer to a null-terminated string naming the key. Comparison of the key name with existing keys is case sensitive.

See also the description for the `MYSQL_OPT_CONNECT_ATTR_RESET` option, as well as the description for the `MYSQL_OPT_CONNECT_ATTR_ADD` option in the description of the `mysql_options4()` function. That function description also includes a usage example. These options were added in MySQL 5.6.6.

Connection attributes are exposed through the `session_connect_attrs` and `session_account_connect_attrs` Performance Schema tables. See [Section 20.9.7, “Performance Schema Connection Attribute Tables”](#).

- `MYSQL_OPT_CONNECT_ATTR_RESET` (argument not used)

This option resets (clears) the current set of connection attributes to be passed to the server at connect time.

See also the description for the `MYSQL_OPT_CONNECT_ATTR_DELETE` option, as well as the description for the `MYSQL_OPT_CONNECT_ATTR_ADD` option in the description of the `mysql_options4()` function. That function description also includes a usage example. These options were added in MySQL 5.6.6.

Connection attributes are exposed through the `session_connect_attrs` and `session_account_connect_attrs` Performance Schema tables. See [Section 20.9.7, “Performance Schema Connection Attribute Tables”](#).

- `MYSQL_OPT_CONNECT_TIMEOUT` (argument type: `unsigned int *`)

Connect timeout in seconds.

- `MYSQL_OPT_GUESS_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this enables the library to guess whether to use the embedded server or a remote server. “Guess” means that if the host name is set and is not `localhost`, it uses a remote server. This behavior is the default. `MYSQL_OPT_USE_EMBEDDED_CONNECTION` and `MYSQL_OPT_USE_REMOTE_CONNECTION` can be used to override it. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_LOCAL_INFILE` (argument type: optional pointer to `unsigned int`)

If no pointer is given or if pointer points to an `unsigned int` that has a nonzero value, the `LOAD LOCAL INFILE` statement is enabled.

- `MYSQL_OPT_NAMED_PIPE` (argument: not used)

Use named pipes to connect to a MySQL server on Windows, if the server permits named-pipe connections.

- `MYSQL_OPT_PROTOCOL` (argument type: `unsigned int *`)

Type of protocol to use. Specify one of the enum values of `mysql_protocol_type` defined in `mysql.h`.

- `MYSQL_OPT_READ_TIMEOUT` (argument type: `unsigned int *`)

The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP `Close_Wait_Timeout` value of 10 minutes.

Implementation of this timeout uses mechanisms that may not be available on all platforms. On such a platform, a client that issues a read call might under certain circumstances wait without timing out. For example, a client might not time out if the server is not responding because it is waiting for a “disk full” condition to clear.

- `MYSQL_OPT_RECONNECT` (argument type: `my_bool *`)

Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect is off by default; this option provides a way to set reconnection behavior explicitly.

- `MYSQL_OPT_SSL_CA` (argument type: `char *`)

The path to a file that contains a list of trusted SSL CAs. This option was added in MySQL 5.6.3.

- `MYSQL_OPT_SSL_CAPATH` (argument type: `char *`)

The path to a directory that contains trusted SSL CA certificates in PEM format. This option was added in MySQL 5.6.3.

- `MYSQL_OPT_SSL_CERT` (argument type: `char *`)

The name of the SSL certificate file to use for establishing a secure connection. This option was added in MySQL 5.6.3.

- `MYSQL_OPT_SSL_CIPHER` (argument type: `char *`)

A list of permissible ciphers to use for SSL encryption. This option was added in MySQL 5.6.3.

- `MYSQL_OPT_SSL_CRL` (argument type: `char *`)

The path to a file containing certificate revocation lists in PEM format. This option was added in MySQL 5.6.3.

- `MYSQL_OPT_SSL_CRLPATH` (argument type: `char *`)

The path to a directory that contains files containing certificate revocation lists in PEM format. This option was added in MySQL 5.6.3.

- `MYSQL_OPT_SSL_KEY` (argument type: `char *`)

The name of the SSL key file to use for establishing a secure connection. This option was added in MySQL 5.6.3.

- `MYSQL_OPT_SSL_VERIFY_SERVER_CERT` (argument type: `my_bool *`)

Enable or disable verification of the server's Common Name value in its certificate against the host name used when connecting to the server. The connection is rejected if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default.

- `MYSQL_OPT_USE_EMBEDDED_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this forces the use of the embedded server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_USE_REMOTE_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this forces the use of a remote server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_USE_RESULT` (argument: not used)

This option is unused.

- `MYSQL_OPT_WRITE_TIMEOUT` (argument type: `unsigned int *`)

The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are `net_retry_count` [515] retries if necessary, so the total effective timeout value is `net_retry_count` [515] times the option value.

- `MYSQL_PLUGIN_DIR` (argument type: `char *`)

The directory in which to look for client plugins.

- `MYSQL_READ_DEFAULT_FILE` (argument type: `char *`)

Read options from the named option file instead of from `my.cnf`.

- `MYSQL_READ_DEFAULT_GROUP` (argument type: `char *`)

Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.

- `MYSQL_REPORT_DATA_TRUNCATION` (argument type: `my_bool *`)

Enable or disable reporting of data truncation errors for prepared statements using the `error` member of `MYSQL_BIND` structures. (Default: enabled.)

- `MYSQL_SECURE_AUTH` (argument type: `my_bool *`)

Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later. As of MySQL 5.6.7, this option is enabled by default.

- `MYSQL_SERVER_PUBLIC_KEY` (argument type: `char *`)

The path name to a file containing the server RSA public key. The file must be in PEM format. The public key is used for RSA encryption of the client password for connections to the server made using accounts that authenticate with the `sha256_password` plugin. This option is ignored for client accounts that do not authenticate with that plugin. It is also ignored if password encryption is not needed, as is the case when the client connects to the server using an SSL connection.

The server sends the public key to the client as needed, so it is not necessary to use this option for RSA password encryption to occur. It is more efficient to do so because then the server need not send the key.

For additional discussion regarding use of the `sha256_password` plugin, including how to get the RSA public key, see [Section 6.3.7.2, “The SHA-256 Authentication Plugin”](#).

This option was added in MySQL 5.6.6.

- `MYSQL_SET_CHARSET_DIR` (argument type: `char *`)

The path name to the directory that contains character set definition files.

- `MYSQL_SET_CHARSET_NAME` (argument type: `char *`)

The name of the character set to use as the default character set. The argument can be `MYSQL_AUTODETECT_CHARSET_NAME` to cause the character set to be autodetected based on the operating system setting (see [Section 10.1.4, “Connection Character Sets and Collations”](#)).

- `MYSQL_SET_CLIENT_IP` (argument type: `char *`)

For an application linked against the `libmysqld` embedded server library (when `libmysqld` is compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_SHARED_MEMORY_BASE_NAME` (argument type: `char *`)

The name of the shared-memory object for communication to the server on Windows, if the server supports shared-memory connections. Specify the same value as the `--shared-memory-base-name` [\[439\]](#) option used for the `mysqld` server you want to connect to.

The `client` group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options.

Option	Description
<code>character-sets-dir=path</code>	The directory where character sets are installed.
<code>compress</code>	Use the compressed client/server protocol.
<code>connect-timeout=seconds</code>	Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.
<code>database=db_name</code>	Connect to this database if no database was specified in the connect command.
<code>debug</code>	Debug options.
<code>default-character-set=charset_name</code>	The default character set to use.
<code>disable-local-infile</code>	Disable use of <code>LOAD DATA LOCAL</code> .
<code>enable-cleartext-plugin</code>	Enable the <code>mysql_clear_password</code> cleartext authentication plugin. Added in MySQL 5.6.7.
<code>host=host_name</code>	Default host name.
<code>init-command=stmt</code>	Statement to execute when connecting to MySQL server. Automatically re-executed if reconnection occurs.
<code>interactive-timeout=seconds</code>	Same as specifying <code>CLIENT_INTERACTIVE</code> to <code>mysql_real_connect()</code> . See <a href="#">Section 21.8.6.53, “mysql_real_connect()”</a> .
<code>local-infile[={0 1}]</code>	If no argument or nonzero argument, enable use of <code>LOAD DATA LOCAL</code> ; otherwise disable.

Option	Description
<code>max_allowed_packet=bytes</code>	Maximum size of packet that client can read from server.
<code>multi-queries, multi-results</code>	Enable multiple result sets from multiple-statement executions or stored procedures.
<code>multi-statements</code>	Enable the client to send multiple statements in a single string (separated by ";").
<code>password=password</code>	Default password.
<code>pipe</code>	Use named pipes to connect to a MySQL server on Windows.
<code>port=port_num</code>	Default port number.
<code>protocol={TCP   SOCKET   PIPE   MEMORY}</code>	The protocol to use when connecting to the server.
<code>return-found-rows</code>	Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code> .
<code>shared-memory-base-name=name</code>	Shared-memory name to use to connect to server.
<code>socket=path</code>	Default socket file.
<code>ssl-ca=file_name</code>	Certificate Authority file.
<code>ssl-capath=path</code>	Certificate Authority directory.
<code>ssl-cert=file_name</code>	Certificate file.
<code>ssl-cipher=cipher_list</code>	Permissible SSL ciphers.
<code>ssl-key=file_name</code>	Key file.
<code>timeout=seconds</code>	Like <code>connect-timeout</code> .
<code>user</code>	Default user.

`timeout` has been replaced by `connect-timeout`, but `timeout` is still supported in MySQL 5.6 for backward compatibility.

For more information about option files, see [Section 4.2.3.3, "Using Option Files"](#).

## Return Values

Zero for success. Nonzero if you specify an unknown option.

## Example

The following `mysql_options()` calls request the use of compression in the client/server protocol, cause options to be read from the `[odbc]` group of option files, and disable transaction autocommit mode:

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_OPT_COMPRESS, 0);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "odbc");
mysql_options(&mysql, MYSQL_INIT_COMMAND, "SET autocommit=0");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

This code requests that the client use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

### 21.8.6.50. `mysql_options4()`

```
int mysql_options4(MYSQL *mysql, enum mysql_option option, const void *arg1,
const void *arg2)
```

## Description

`mysql_options4()` is similar to `mysql_options()` but has an extra fourth argument so that two values can be passed for the option specified in the second argument. This function was added in MySQL 5.6.6.

The following list describes the permitted options, their effect, and how `arg1` and `arg2` are used.

- `MYSQL_OPT_CONNECT_ATTR_ADD` (argument types: `char *`, `char *`)

This option adds a key/value pair to the current set of connection attributes to be passed to the server at connect time. Both arguments are pointers to null-terminated strings. The first and second strings indicate the key and value, respectively. If the key already exists in the current set of connection attributes, the new value replaces the existing one. Comparison of the key name with existing keys is case sensitive.

Key names that begin with an underscore (`_`) are reserved for internal use and should not be used by application programs.

See also the descriptions for the `MYSQL_OPT_CONNECT_ATTR_RESET`, `MYSQL_OPT_CONNECT_ATTR_DELETE` options in the description of the `mysql_options()` function.

Connection attributes are exposed through the `session_connect_attrs` and `session_account_connect_attrs` Performance Schema tables. See [Section 20.9.7, "Performance Schema Connection Attribute Tables"](#).

## Return Values

Zero for success. Nonzero if you specify an unknown option.

## Example

This example demonstrates the calls that specify connection attributes:

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_RESET, 0);
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key1", "value1");
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key2", "value2");
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key3", "value3");
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_DELETE, "key1");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
mysql_options(&mysql,MYSQL_OPT_CONNECT_ATTR_RESET, 0);
```

### 21.8.6.51. `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

## Description

Checks whether the connection to the server is working. If the connection has gone down and auto-reconnect is enabled an attempt to reconnect is made. If the connection is down and auto-reconnect is disabled, `mysql_ping()` returns an error.

Auto-reconnect is disabled by default. To enable it, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option. For details, see [Section 21.8.6.49](#), “`mysql_options()`”.

`mysql_ping()` can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

If `mysql_ping()` does cause a reconnect, there is no explicit indication of it. To determine whether a reconnect occurs, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier has changed.

If reconnect occurs, some characteristics of the connection will have been reset. For details about these characteristics, see [Section 21.8.15](#), “[Controlling Automatic Reconnection Behavior](#)”.

## Return Values

Zero if the connection to the server is active. Nonzero if an error occurred. A nonzero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)  
An unknown error occurred.

### 21.8.6.52. `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *stmt_str)
```

## Description

Executes the SQL statement pointed to by the null-terminated string `stmt_str`. Normally, the string must consist of a single SQL statement without a terminating semicolon (“;”) or `\g`. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 21.8.16](#), “[C API Support for Multiple Statement Execution](#)”.

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()` interprets as the end of the statement string.)

If you want to know whether the statement returns a result set, you can use `mysql_field_count()` to check for this. See [Section 21.8.6.22](#), “[mysql\\_field\\_count\(\)](#)”.

## Return Values

Zero if the statement was successful. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- `CR_SERVER_LOST` [3719]

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR` [3718]

An unknown error occurred.

### 21.8.6.53. `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char
*user, const char *passwd, const char *db, unsigned int port, const char
*unix_socket, unsigned long client_flag)
```

#### Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handle structure.

The parameters are specified as follows:

- For the first parameter, specify the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()`, call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See [Section 21.8.6.49](#), “`mysql_options()`”.
- The value of `host` may be either a host name or an IP address. If `host` is `NULL` or the string “localhost”, a connection to the local host is assumed. For Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled. Otherwise, TCP/IP is used. For Unix, the client connects using a Unix socket file. For local connections, you can also influence the type of connection to use with the `MYSQL_OPT_PROTOCOL` or `MYSQL_OPT_NAMED_PIPE` options to `mysql_options()`. The type of connection must be supported by the server. For a `host` value of “.” on Windows, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.
- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string “”, the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current user name must be specified explicitly. See the Connector/ODBC section of [Chapter 21](#), *Connectors and APIs*.
- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This enables the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

#### Note

Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- The `user` and `passwd` parameters use whatever character set has been configured for the `MYSQL` object. By default, this is `latin1`, but can be changed by calling `mysql_options(mysql, MYSQL_SET_CHARSET_NAME, "charset_name")` prior to connecting.
- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.

- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe to use. Note that the `host` parameter determines the type of the connection.
- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features.

Flag Name	Flag Description
<code>CAN_HANDLE_EXPIRED_PASSWORDS</code>	The client can handle expired passwords. For more information, see <a href="#">Section 6.3.6, “Password Expiration and Sandbox Mode”</a> . This option was added in MySQL 5.6.10.
<code>CLIENT_COMPRESS</code>	Use compression protocol.
<code>CLIENT_FOUND_ROWS</code>	Return the number of found (matched) rows, not the number of changed rows.
<code>CLIENT_IGNORE_SIGPIPE</code>	Prevents the client library from installing a <code>SIGPIPE</code> signal handler. This can be used to avoid conflicts with a handler that the application has already installed.
<code>CLIENT_IGNORE_SPACE</code>	Permit spaces after function names. Makes all functions names reserved words.
<code>CLIENT_INTERACTIVE</code>	Permit <code>interactive_timeout</code> [490] seconds (instead of <code>wait_timeout</code> [563] seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> [563] variable is set to the value of the session <code>interactive_timeout</code> [490] variable.
<code>CLIENT_LOCAL_FILES</code>	Enable <code>LOAD DATA LOCAL</code> handling.
<code>CLIENT_MULTI_RESULTS</code>	Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This flag is automatically enabled if <code>CLIENT_MULTI_STATEMENTS</code> is enabled. See the note following this table for more information about this flag.
<code>CLIENT_MULTI_STATEMENTS</code>	Tell the server that the client may send multiple statements in a single string (separated by “;”). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag.
<code>CLIENT_NO_SCHEMA</code>	Do not permit the <code>db_name.tbl_name.col_name</code> syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.
<code>CLIENT_ODBC</code>	Unused.
<code>CLIENT_SSL</code>	Use SSL (encrypted protocol). Do not set this option within an application program; it is set internally in the client library. Instead, use <code>mysql_ssl_set()</code> before calling <code>mysql_real_connect()</code> .
<code>CLIENT_REMEMBER_OPTIONS</code>	Remember options specified by calls to <code>mysql_options()</code> . Without this option, if <code>mysql_real_connect()</code> fails, you must repeat the <code>mysql_options()</code> calls before trying to connect again. With this option, the <code>mysql_options()</code> calls need not be repeated.

If your program uses `CALL` statements to execute stored procedures, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because `CALL`

can return multiple results, process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). In MySQL 5.6, `CLIENT_MULTI_RESULTS` is enabled by default.

If you enable `CLIENT_MULTI_STATEMENTS` or `CLIENT_MULTI_RESULTS`, process the result for every call to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 21.8.16, “C API Support for Multiple Statement Execution”](#).

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the `mysql_real_connect()` call. To do this, call `mysql_options()` with the `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP` option before calling `mysql_real_connect()`. Then, in the `mysql_real_connect()` call, specify the “no-value” value for each parameter to be read from an option file:

- For `host`, specify a value of `NULL` or the empty string (`" "`).
- For `user`, specify a value of `NULL` or the empty string.
- For `passwd`, specify a value of `NULL`. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For `db`, specify a value of `NULL` or the empty string.
- For `port`, specify a value of 0.
- For `unix_socket`, specify a value of `NULL`.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

## Return Values

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

## Errors

- `CR_CONN_HOST_ERROR` [3718]  
Failed to connect to the MySQL server.
- `CR_CONNECTION_ERROR` [3718]  
Failed to connect to the local MySQL server.
- `CR_IPSOCK_ERROR` [3718]  
Failed to create an IP socket.
- `CR_OUT_OF_MEMORY` [3718]  
Out of memory.
- `CR_SOCKET_CREATE_ERROR` [3718]  
Failed to create a Unix socket.

- [CR\\_UNKNOWN\\_HOST \[3718\]](#)

Failed to find the IP address for the host name.

- [CR\\_VERSION\\_ERROR \[3718\]](#)

A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version.

- [CR\\_NAMEDPIPEOPEN\\_ERROR \[3719\]](#)

Failed to create a named pipe on Windows.

- [CR\\_NAMEDPIPEWAIT\\_ERROR \[3719\]](#)

Failed to wait for a named pipe on Windows.

- [CR\\_NAMEDPIPESETSTATE\\_ERROR \[3719\]](#)

Failed to get a pipe handler on Windows.

- [CR\\_SERVER\\_LOST \[3719\]](#)

If [connect\\_timeout \[472\]](#) > 0 and it took longer than [connect\\_timeout \[472\]](#) seconds to connect to the server or if the server died while executing the `init-command`.

- [CR\\_ALREADY\\_CONNECTED \[3721\]](#)

The `MYSQL` connection handle is already connected.

## Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "your_prog_name");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some nonstandard way.

Note that upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

### 21.8.6.54. `mysql_real_escape_string()`

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to, const char
*from, unsigned long length)
```

Note that `mysql` must be a valid, open connection. This is needed because the escaping depends on the character set in use by the server.

## Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 9.1.1, "String Literals"](#).

The string in `from` is encoded to an escaped SQL string, taking into account the current character set of the connection. The result is placed in `to` and a terminating null byte is appended. Characters encoded are “\”, “,”, “'”, `NUL` (ASCII 0), “\n”, “\r”, and Control+Z. Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. `mysql_real_escape_string()` quotes the other characters to make them easier to read in log files. For comparison, see the quoting rules for literal strings and the `QUOTE()` [1183] SQL function in [Section 9.1.1, “String Literals”](#), and [Section 12.5, “String Functions”](#).

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and you need room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

If you need to change the character set of the connection, use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.

## Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
*end++ = '\';
end += mysql_real_escape_string(&mysql, end,"What is this",12);
*end++ = '\';
*end++ = ',';
*end++ = '\';
end += mysql_real_escape_string(&mysql, end,"binary data: \0\r\n",16);
*end++ = '\';
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

## Return Values

The length of the value placed into `to`, not including the terminating null character.

## Errors

None.

### 21.8.6.55. `mysql_real_query()`

```
int mysql_real_query(MYSQL *mysql, const char *stmt_str, unsigned long
length)
```

## Description

Executes the SQL statement pointed to by `stmt_str`, a string `length` bytes long. Normally, the string must consist of a single SQL statement without a terminating semicolon (“;”) or `\g`. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 21.8.16, “C API Support for Multiple Statement Execution”](#).

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()`

interprets as the end of the statement string.) In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the statement string.

If you want to know whether the statement returns a result set, you can use `mysql_field_count()` to check for this. See [Section 21.8.6.22](#), “`mysql_field_count()`”.

## Return Values

Zero if the statement was successful. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST \[3719\]](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)  
An unknown error occurred.

### 21.8.6.56. `mysql_refresh()`

```
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

## Description

This function flushes tables or caches, or resets replication server information. The connected user must have the [RELOAD \[755\]](#) privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- [REFRESH\\_GRANT](#)  
Refresh the grant tables, like `FLUSH PRIVILEGES`.
- [REFRESH\\_LOG](#)  
Flush the logs, like `FLUSH LOGS`.
- [REFRESH\\_TABLES](#)  
Flush the table cache, like `FLUSH TABLES`.
- [REFRESH\\_HOSTS](#)  
Flush the host cache, like `FLUSH HOSTS`.
- [REFRESH\\_STATUS](#)  
Reset status variables, like `FLUSH STATUS`.
- [REFRESH\\_THREADS](#)  
Flush the thread cache.

- [REFRESH\\_SLAVE](#)

On a slave replication server, reset the master server information and restart the slave, like [RESET SLAVE](#).

- [REFRESH\\_MASTER](#)

On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like [RESET MASTER](#).

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.6.57. [mysql\\_reload\(\)](#)

```
int mysql_reload(MYSQL *mysql)
```

## Description

Asks the MySQL server to reload the grant tables. The connected user must have the [RELOAD \[755\]](#) privilege.

This function is deprecated. It is preferable to use [mysql\\_query\(\)](#) to issue an SQL [FLUSH PRIVILEGES](#) statement instead.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.6.58. `mysql_rollback()`

```
my_bool mysql_rollback(MYSQL *mysql)
```

#### Description

Rolls back the current transaction.

The action of this function is subject to the value of the `completion_type` [470] system variable. In particular, if the value of `completion_type` [470] is `RELEASE` (or 2), the server performs a release after terminating a transaction and closes the client connection. Call `mysql_close()` from the client program to close the connection from the client side.

#### Return Values

Zero if successful. Nonzero if an error occurred.

#### Errors

None.

### 21.8.6.59. `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

#### Description

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset, typically a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

#### Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

#### Errors

None.

### 21.8.6.60. `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

#### Description

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

Use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

#### Return Values

The current offset of the row cursor.

## Errors

None.

### 21.8.6.61. `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

#### Description

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

#### Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST \[3719\]](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)  
An unknown error occurred.

### 21.8.6.62. `mysql_set_character_set()`

```
int mysql_set_character_set(MYSQL *mysql, const char *csname)
```

#### Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`

#### Return Values

Zero for success. Nonzero if an error occurred.

## Example

```
MYSQL mysql;

mysql_init(&mysql);
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

```

}

if (!mysql_set_character_set(&mysql, "utf8"))
{
    printf("New client character set: %s\n",
        mysql_character_set_name(&mysql));
}

```

### 21.8.6.63. `mysql_set_local_infile_default()`

```
void mysql_set_local_infile_default(MYSQL *mysql);
```

#### Description

Sets the `LOAD LOCAL DATA INFILE` handler callback functions to the defaults used internally by the C client library. The library calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.

#### Return Values

None.

#### Errors

None.

### 21.8.6.64. `mysql_set_local_infile_handler()`

```
void mysql_set_local_infile_handler(MYSQL *mysql, int (*local_infile_init)
(void **, const char *, void *), int (*local_infile_read)(void *, char *,
unsigned int), void (*local_infile_end)(void *), int (*local_infile_error)
(void *, char*, unsigned int), void *userdata);
```

#### Description

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL INFILE` statements. It enables application programs to exert control over local (client-side) data file reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```
int
local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the data file, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value that is passed to `mysql_set_local_infile_handler()`.

Make the initialization function return zero for success, nonzero for an error.

```
int
local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data is stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```
void
local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. Within this function, deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```
int
local_infile_error(void *ptr,
                  char *error_msg,
                  unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message is written, and `error_msg_len` is the length of the buffer. Write the message as a null-terminated string, at most `error_msg_len-1` bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you can then issue a `LOAD DATA LOCAL INFILE` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The file name specified in `LOAD DATA LOCAL INFILE` will be passed as the second parameter to the `local_infile_init()` callback.

## Return Values

None.

## Errors

None.

### 21.8.6.65. `mysql_set_server_option()`

```
int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option option)
```

## Description

Enables or disables an option for the connection. `option` can have one of the following values.

Option	Description
<code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code>	Enable multiple-statement support
<code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code>	Disable multiple-statement support

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 21.8.16, “C API Support for Multiple Statement Execution”](#).

Enabling multiple-statement support with `MYSQL_OPTION_MULTI_STATEMENTS_ON` does not have quite the same effect as enabling it by passing the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`: `CLIENT_MULTI_STATEMENTS` also enables `CLIENT_MULTI_RESULTS`. If you are using the `CALL SQL` statement in your programs, multiple-result support must be enabled; this means that `MYSQL_OPTION_MULTI_STATEMENTS_ON` by itself is insufficient to permit the use of `CALL`.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [ER\\_UNKNOWN\\_COM\\_ERROR \[3663\]](#)

The server didn't support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server didn't support the option one tried to set.

### 21.8.6.66. `mysql_shutdown()`

```
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level
shutdown_level)
```

## Description

Asks the database server to shut down. The connected user must have the [SHUTDOWN \[756\]](#) privilege. MySQL 5.6 servers support only one type of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Additional shutdown levels are planned to make it possible to choose the desired level. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in [Section 5.1.12, "The Shutdown Process"](#).

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.6.67. `mysql_sqlstate()`

```
const char *mysql_sqlstate(MYSQL *mysql)
```

## Description

Returns a null-terminated string containing the SQLSTATE error code for the most recently executed SQL statement. The error code consists of five characters. '00000' means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix C, Errors, Error Codes, and Common Problems](#).

SQLSTATE values returned by `mysql_sqlstate()` differ from MySQL-specific error numbers returned by `mysql_errno()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value 'HY000' (general error) is used for unmapped error numbers.

If you call `mysql_sqlstate()` after `mysql_real_connect()` fails, `mysql_sqlstate()` might not return a useful value. For example, this happens if a host is blocked by the server and the connection is closed without any SQLSTATE value being sent to the client.

## Return Values

A null-terminated character string containing the SQLSTATE error code.

## See Also

See [Section 21.8.6.14, "mysql\\_errno\(\)"](#), [Section 21.8.6.15, "mysql\\_error\(\)"](#), and [Section 21.8.10.27, "mysql\\_stmt\\_sqlstate\(\)"](#).

### 21.8.6.68. `mysql_ssl_set()`

```
my_bool mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert, const
char *ca, const char *capath, const char *cipher)
```

## Description

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless SSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the path name to the key file.
- `cert` is the path name to the certificate file.
- `ca` is the path name to the certificate authority file.
- `capath` is the path name to a directory that contains trusted SSL CA certificates in PEM format.
- `cipher` is a list of permissible ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`.

## Return Values

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

### 21.8.6.69. `mysql_stat()`

```
const char *mysql_stat(MYSQL *mysql)
```

#### Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

#### Return Values

A character string describing the server status. `NULL` if an error occurred.

#### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST \[3719\]](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)  
An unknown error occurred.

### 21.8.6.70. `mysql_store_result()`

```
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

#### Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

You don't have to call `mysql_store_result()` or `mysql_use_result()` for other statements, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect whether the statement has a result set by checking whether `mysql_store_result()` returns a nonzero value (more about this later).

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 21.8.16, "C API Support for Multiple Statement Execution"](#).

If you want to know whether a statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 21.8.6.22, "mysql\\_field\\_count\(\)"](#).

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the statement didn't return a result set (for example, if it was an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking whether `mysql_error()` returns a nonempty string, `mysql_errno()` returns nonzero, or `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

After you have called `mysql_store_result()` and gotten back a result that isn't a null pointer, you can call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

See [Section 21.8.14.1, “Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success”](#).

## Return Values

A `MYSQL_RES` result structure with the results. `NULL` (0) if an error occurred.

## Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_OUT\\_OF\\_MEMORY \[3718\]](#)

Out of memory.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.6.71. `mysql_thread_id()`

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

## Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

### Note

This function does not work correctly if thread IDs become larger than 32 bits, which can occur on some systems. To avoid problems with `mysql_thread_id()`, do not use it. To get the connection ID, execute a `SELECT CONNECTION_ID()` query and retrieve the result.

## Return Values

The thread ID of the current connection.

## Errors

None.

### 21.8.6.72. `mysql_use_result()`

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

## Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` [502] bytes.

On the other hand, you shouldn't use `mysql_use_result()` if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

## Return Values

A `MYSQL_RES` result structure. `NULL` if an error occurred.

## Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC` [3719]  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY` [3718]  
Out of memory.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.6.73. `mysql_warning_count()`

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

#### Description

Returns the number of errors, warnings, and notes generated during execution of the previous SQL statement.

#### Return Values

The warning count.

#### Errors

None.

## 21.8.7. C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and nonprepared statements and choose whichever yields best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

For a list of SQL statements that can be used as prepared statements, see [Section 13.5, “SQL Syntax for Prepared Statements”](#).

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 8.9.4, “Caching of Prepared Statements and Stored Programs”](#).

## 21.8.8. C API Prepared Statement Data Structures

Prepared statements use several data structures:

- To obtain a statement handle, pass a `MYSQL` connection handler to `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT` data structure. This structure is used for further operations with

the statement. To specify the statement to prepare, pass the `MYSQL_STMT` pointer and the statement string to `mysql_stmt_prepare()`.

- To provide input parameters for a prepared statement, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_param()`. To receive output column values, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_result()`.
- The `MYSQL_TIME` structure is used to transfer temporal data in both directions.

The following discussion describes the prepared statement data types in detail. For examples that show how to use them, see [Section 21.8.10.10](#), “`mysql_stmt_execute()`”, and [Section 21.8.10.11](#), “`mysql_stmt_fetch()`”.

- `MYSQL_STMT`

This structure is a handle for a prepared statement. A handle is created by calling `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT`. The handle is used for all subsequent operations with the statement until you close it with `mysql_stmt_close()`, at which point the handle becomes invalid.

The `MYSQL_STMT` structure has no members intended for application use. Applications should not try to copy a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server):

- For input, use `MYSQL_BIND` structures with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`.
- For output, use `MYSQL_BIND` structures with `mysql_stmt_bind_result()` to bind buffers to result set columns, for use in fetching rows with `mysql_stmt_fetch()`.

To use a `MYSQL_BIND` structure, zero its contents to initialize it, then set its members appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The `MYSQL_BIND` structure contains the following members for use by application programs. For several of the members, the manner of use depends on whether the structure is used for input or output.

- `enum enum_field_types buffer_type`

The type of the buffer. This member indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored. For permissible `buffer_type` values, see [Section 21.8.8.1](#), “C API Prepared Statement Type Codes”.

- `void *buffer`

A pointer to the buffer to be used for data transfer. This is the address of a C language variable.

For input, `buffer` is a pointer to the variable in which you store the data value for a statement parameter. When you call `mysql_stmt_execute()`, MySQL use the value stored in the variable

in place of the corresponding parameter marker in the statement (specified with `?` in the statement string).

For output, `buffer` is a pointer to the variable in which to return a result set column value. When you call `mysql_stmt_fetch()`, MySQL stores a column value from the current row of the result set in this variable. You can access the value when the call returns.

To minimize the need for MySQL to perform type conversions between C language values on the client side and SQL values on the server side, use C variables that have types similar to those of the corresponding SQL values:

- For numeric data types, `buffer` should point to a variable of the proper numeric C type. For integer variables (which can be `char` for single-byte values or an integer type for larger values), you should also indicate whether the variable has the `unsigned` attribute by setting the `is_unsigned` member, described later.
- For character (nonbinary) and binary string data types, `buffer` should point to a character buffer.
- For date and time data types, `buffer` should point to a `MYSQL_TIME` structure.

For guidelines about mapping between C types and SQL types and notes about type conversions, see [Section 21.8.8.1, “C API Prepared Statement Type Codes”](#), and [Section 21.8.8.2, “C API Prepared Statement Type Conversions”](#).

- `unsigned long buffer_length`

The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()` to specify input values, or the maximum number of output data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. `length` is used for character or binary C data.

For input parameter data binding, set `*length` to indicate the actual length of the parameter value stored in `*buffer`. This is used by `mysql_stmt_execute()`.

For output value binding, MySQL sets `*length` when you call `mysql_stmt_fetch()`. The `mysql_stmt_fetch()` return value determines how to interpret the length:

- If the return value is 0, `*length` indicates the actual length of the parameter value.
- If the return value is `MYSQL_DATA_TRUNCATED`, `*length` indicates the nontruncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

`length` is ignored for numeric and temporal data types because the `buffer_type` value determines the length of the data value.

If you must determine the length of a returned value before fetching it, see [Section 21.8.10.11, “mysql\\_stmt\\_fetch\(\)”](#), for some strategies.

- `my_bool *is_null`

This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter.

`is_null` is a *pointer* to a boolean scalar, not a boolean scalar, to provide flexibility in how you specify `NULL` values:

- If your data values are always `NULL`, use `MYSQL_TYPE_NULL` as the `buffer_type` value when you bind the column. The other `MYSQL_BIND` members, including `is_null`, do not matter.
- If your data values are always `NOT NULL`, set `is_null = (my_bool*) 0`, and set the other members appropriately for the variable you are binding.
- In all other cases, set the other members appropriately and set `is_null` to the address of a `my_bool` variable. Set that variable's value to true or false appropriately between executions to indicate whether the corresponding data value is `NULL` or `NOT NULL`, respectively.

For output, when you fetch a row, MySQL sets the value pointed to by `is_null` to true or false according to whether the result set column value returned from the statement is or is not `NULL`.

- `my_bool is_unsigned`

This member applies for C variables with data types that can be `unsigned` (`char`, `short int`, `int`, `long long int`). Set `is_unsigned` to true if the variable pointed to by `buffer` is `unsigned` and false otherwise. For example, if you bind a `signed char` variable to `buffer`, specify a type code of `MYSQL_TYPE_TINY` and set `is_unsigned` to false. If you bind an `unsigned char` instead, the type code is the same but `is_unsigned` should be true. (For `char`, it is not defined whether it is signed or unsigned, so it is best to be explicit about signedness by using `signed char` or `unsigned char`.)

`is_unsigned` applies only to the C language variable on the client side. It indicates nothing about the signedness of the corresponding SQL value on the server side. For example, if you use an `int` variable to supply a value for a `BIGINT UNSIGNED` column, `is_unsigned` should be false because `int` is a signed type. If you use an `unsigned int` variable to supply a value for a `BIGINT` column, `is_unsigned` should be true because `unsigned int` is an unsigned type. MySQL performs the proper conversion between signed and unsigned values in both directions, although a warning occurs if truncation results.

- `my_bool *error`

For output, set this member to point to a `my_bool` variable to have truncation information for the parameter stored there after a row fetching operation. When truncation reporting is enabled, `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `*error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

- `MYSQL_TIME`

This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. Set the `buffer` member to point to a `MYSQL_TIME` structure, and set the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types (`MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATE`, `MYSQL_TYPE_DATETIME`, `MYSQL_TYPE_TIMESTAMP`).

The `MYSQL_TIME` structure contains the members listed in the following table.

Member	Description
<code>unsigned int year</code>	The year
<code>unsigned int month</code>	The month of the year
<code>unsigned int day</code>	The day of the month

Member	Description
<code>unsigned int hour</code>	The hour of the day
<code>unsigned int minute</code>	The minute of the hour
<code>unsigned int second</code>	The second of the minute
<code>my_bool neg</code>	A boolean flag indicating whether the time is negative
<code>unsigned long second_part</code>	The fractional part of the second in microseconds (unused before MySQL 5.6.4)

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used. The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See [Section 21.8.18, “C API Prepared Statement Handling of Date and Time Values”](#).

### 21.8.8.1. C API Prepared Statement Type Codes

The `buffer_type` member of `MYSQL_BIND` structures indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for input values sent to the server. The table shows the C variable types that you can use, the corresponding type codes, and the SQL data types for which the supplied value can be used without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

Input Variable C Type	<code>buffer_type</code> Value	SQL Type of Destination Value
<code>signed char</code>	<code>MYSQL_TYPE_TINY</code>	<code>TINYINT</code>
<code>short int</code>	<code>MYSQL_TYPE_SHORT</code>	<code>SMALLINT</code>
<code>int</code>	<code>MYSQL_TYPE_LONG</code>	<code>INT</code>
<code>long long int</code>	<code>MYSQL_TYPE_LONGLONG</code>	<code>BIGINT</code>
<code>float</code>	<code>MYSQL_TYPE_FLOAT</code>	<code>FLOAT</code>
<code>double</code>	<code>MYSQL_TYPE_DOUBLE</code>	<code>DOUBLE</code>
<code>MYSQL_TIME</code>	<code>MYSQL_TYPE_TIME</code>	<code>TIME</code>
<code>MYSQL_TIME</code>	<code>MYSQL_TYPE_DATE</code>	<code>DATE</code>
<code>MYSQL_TIME</code>	<code>MYSQL_TYPE_DATETIME</code>	<code>DATETIME</code>
<code>MYSQL_TIME</code>	<code>MYSQL_TYPE_TIMESTAMP</code>	<code>TIMESTAMP</code>
<code>char[ ]</code>	<code>MYSQL_TYPE_STRING</code>	<code>TEXT</code> , <code>CHAR</code> , <code>VARCHAR</code>
<code>char[ ]</code>	<code>MYSQL_TYPE_BLOB</code>	<code>BLOB</code> , <code>BINARY</code> , <code>VARBINARY</code>
	<code>MYSQL_TYPE_NULL</code>	<code>NULL</code>

Use `MYSQL_TYPE_NULL` as indicated in the description for the `is_null` member in [Section 21.8.8, “C API Prepared Statement Data Structures”](#).

For input string data, use `MYSQL_TYPE_STRING` or `MYSQL_TYPE_BLOB` depending on whether the value is a character (nonbinary) or binary string:

- `MYSQL_TYPE_STRING` indicates character input string data. The value is assumed to be in the character set indicated by the `character_set_client` [467] system variable. If the server stores the value into a column with a different character set, it converts the value to that character set.

- `MYSQL_TYPE_BLOB` indicates binary input string data. The value is treated as having the `binary` character set. That is, it is treated as a byte string and no conversion occurs.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for output values received from the server. The table shows the SQL types of received values, the corresponding type codes that such values have in result set metadata, and the recommended C language data types to bind to the `MYSQL_BIND` structure to receive the SQL values without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

SQL Type of Received Value	<code>buffer_type</code> Value	Output Variable C Type
TINYINT	<code>MYSQL_TYPE_TINY</code>	signed char
SMALLINT	<code>MYSQL_TYPE_SHORT</code>	short int
MEDIUMINT	<code>MYSQL_TYPE_INT24</code>	int
INT	<code>MYSQL_TYPE_LONG</code>	int
BIGINT	<code>MYSQL_TYPE_LONGLONG</code>	long long int
FLOAT	<code>MYSQL_TYPE_FLOAT</code>	float
DOUBLE	<code>MYSQL_TYPE_DOUBLE</code>	double
DECIMAL	<code>MYSQL_TYPE_NEWDECIMAL</code>	char[ ]
YEAR	<code>MYSQL_TYPE_SHORT</code>	short int
TIME	<code>MYSQL_TYPE_TIME</code>	<code>MYSQL_TIME</code>
DATE	<code>MYSQL_TYPE_DATE</code>	<code>MYSQL_TIME</code>
DATETIME	<code>MYSQL_TYPE_DATETIME</code>	<code>MYSQL_TIME</code>
TIMESTAMP	<code>MYSQL_TYPE_TIMESTAMP</code>	<code>MYSQL_TIME</code>
CHAR, BINARY	<code>MYSQL_TYPE_STRING</code>	char[ ]
VARCHAR, VARBINARY	<code>MYSQL_TYPE_VAR_STRING</code>	char[ ]
TINYBLOB, TINYTEXT	<code>MYSQL_TYPE_TINY_BLOB</code>	char[ ]
BLOB, TEXT	<code>MYSQL_TYPE_BLOB</code>	char[ ]
MEDIUMBLOB, MEDIUMTEXT	<code>MYSQL_TYPE_MEDIUM_BLOB</code>	char[ ]
LOBLOB, LONGTEXT	<code>MYSQL_TYPE_LONG_BLOB</code>	char[ ]
BIT	<code>MYSQL_TYPE_BIT</code>	char[ ]

### 21.8.8.2. C API Prepared Statement Type Conversions

Prepared statements transmit data between the client and server using C language variables on the client side that correspond to SQL values on the server side. If there is a mismatch between the C variable type on the client side and the corresponding SQL value type on the server side, MySQL performs implicit type conversions in both directions.

MySQL knows the type code for the SQL value on the server side. The `buffer_type` value in the `MYSQL_BIND` structure indicates the type code of the C variable that holds the value on the client side. The two codes together tell MySQL what conversion must be performed, if any. Here are some examples:

- If you use `MYSQL_TYPE_LONG` with an `int` variable to pass an integer value to the server that is to be stored into a `FLOAT` column, MySQL converts the value to floating-point format before storing it.
- If you fetch an SQL `MEDIUMINT` column value, but specify a `buffer_type` value of `MYSQL_TYPE_LONGLONG` and use a C variable of type `long long int` as the destination buffer,

MySQL converts the `MEDIUMINT` value (which requires less than 8 bytes) for storage into the `long long int` (an 8-byte variable).

- If you fetch a numeric column with a value of 255 into a `char[4]` character array and specify a `buffer_type` value of `MYSQL_TYPE_STRING`, the resulting value in the array is a 4-byte string `'255\0'`.
- MySQL returns `DECIMAL` values as the string representation of the original server-side value, which is why the corresponding C type is `char[]`. For example, `12.345` is returned to the client as `'12.345'`. If you specify `MYSQL_TYPE_NEWDECIMAL` and bind a string buffer to the `MYSQL_BIND` structure, `mysql_stmt_fetch()` stores the value in the buffer as a string without conversion. If instead you specify a numeric variable and type code, `mysql_stmt_fetch()` converts the string-format `DECIMAL` value to numeric form.
- For the `MYSQL_TYPE_BIT` type code, `BIT` values are returned into a string buffer, which is why the corresponding C type is `char[]`. The value represents a bit string that requires interpretation on the client side. To return the value as a type that is easier to deal with, you can cause the value to be cast to integer using either of the following types of expressions:

```
SELECT bit_col + 0 FROM t
SELECT CAST(bit_col AS UNSIGNED) FROM t
```

To retrieve the value, bind an integer variable large enough to hold the value and specify the appropriate corresponding integer type code.

Before binding variables to the `MYSQL_BIND` structures that are to be used for fetching column values, you can check the type codes for each column of the result set. This might be desirable if you want to determine which variable types would be best to use to avoid type conversions. To get the type codes, call `mysql_stmt_result_metadata()` after executing the prepared statement with `mysql_stmt_execute()`. The metadata provides access to the type codes for the result set as described in [Section 21.8.10.23](#), “`mysql_stmt_result_metadata()`”, and [Section 21.8.4](#), “C API Data Structures”.

To determine whether output string values in a result set returned from the server contain binary or nonbinary data, check whether the `charsetnr` value of the result set metadata is 63 (see [Section 21.8.4](#), “C API Data Structures”). If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

If you cause the `max_length` member of the `MYSQL_FIELD` column metadata structures to be set (by calling `mysql_stmt_attr_set()`), be aware that the `max_length` values for the result set indicate the lengths of the longest string representation of the result values, not the lengths of the binary representation. That is, `max_length` does not necessarily correspond to the size of the buffers needed to fetch the values with the binary protocol used for prepared statements. Choose the size of the buffers according to the types of the variables into which you fetch the values. For example, a `TINYINT` column containing the value -128 might have a `max_length` value of 4. But the binary representation of any `TINYINT` value requires only 1 byte for storage, so you can supply a `signed char` variable in which to store the value and set `is_unsigned` to indicate that values are signed.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 8.9.4](#), “Caching of Prepared Statements and Stored Programs”.

## 21.8.9. C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See [Section 21.8.10](#), “C API Prepared Statement Function Descriptions”.

Function	Description
<code>mysql_stmt_affected_rows()</code>	Returns the number of rows changed, deleted, or inserted by prepared <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> statement
<code>mysql_stmt_attr_get()</code>	Gets value of an attribute for a prepared statement
<code>mysql_stmt_attr_set()</code>	Sets an attribute for a prepared statement
<code>mysql_stmt_bind_param()</code>	Associates application data buffers with the parameter markers in a prepared SQL statement
<code>mysql_stmt_bind_result()</code>	Associates application data buffers with columns in a result set
<code>mysql_stmt_close()</code>	Frees memory used by a prepared statement
<code>mysql_stmt_data_seek()</code>	Seeks to an arbitrary row number in a statement result set
<code>mysql_stmt_errno()</code>	Returns the error number for the last statement execution
<code>mysql_stmt_error()</code>	Returns the error message for the last statement execution
<code>mysql_stmt_execute()</code>	Executes a prepared statement
<code>mysql_stmt_fetch()</code>	Fetches the next row of data from a result set and returns data for all bound columns
<code>mysql_stmt_fetch_column()</code>	Fetch data for one column of the current row of a result set
<code>mysql_stmt_field_count()</code>	Returns the number of result columns for the most recent statement
<code>mysql_stmt_free_result()</code>	Free the resources allocated to a statement handle
<code>mysql_stmt_init()</code>	Allocates memory for a <code>MYSQL_STMT</code> structure and initializes it
<code>mysql_stmt_insert_id()</code>	Returns the ID generated for an <code>AUTO_INCREMENT</code> column by a prepared statement
<code>mysql_stmt_next_result()</code>	Returns/initiates the next result in a multiple-result execution
<code>mysql_stmt_num_rows()</code>	Returns the row count from a buffered statement result set
<code>mysql_stmt_param_count()</code>	Returns the number of parameters in a prepared statement
<code>mysql_stmt_param_metadata()</code>	(Return parameter metadata in the form of a result set) Currently, this function does nothing
<code>mysql_stmt_prepare()</code>	Prepares an SQL statement string for execution
<code>mysql_stmt_reset()</code>	Resets the statement buffers in the server
<code>mysql_stmt_result_metadata()</code>	Returns prepared statement metadata in the form of a result set
<code>mysql_stmt_row_seek()</code>	Seeks to a row offset in a statement result set, using value returned from <code>mysql_stmt_row_tell()</code>
<code>mysql_stmt_row_tell()</code>	Returns the statement row cursor position
<code>mysql_stmt_send_long_data()</code>	Sends long data in chunks to server
<code>mysql_stmt_sqlstate()</code>	Returns the <code>SQLSTATE</code> error code for the last statement execution
<code>mysql_stmt_store_result()</code>	Retrieves a complete result set to the client

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare()` to prepare the statement string, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

You can send text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See [Section 21.8.10.26](#), “`mysql_stmt_send_long_data()`”.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

When statement execution has been completed, close the statement handle using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

## Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.
2. If the statement will produce a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.
3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.
4. Call `mysql_stmt_execute()` to execute the statement.
5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.
6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.
7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and the number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the current row of the result set and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error number, error message, and SQLSTATE code using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

## Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string `"SELECT ?"`.
2. Call `mysql_stmt_bind_param()` to bind the value `3` to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare [1] SELECT ?
Execute [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. `N` is a positive integer. If there are multiple prepared statements active simultaneously for the client, `N` may be greater than 1. Each `Execute` lines shows a prepared statement after substitution of data values for `?` parameters.

## 21.8.10. C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

### 21.8.10.1. `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

#### Description

`mysql_stmt_affected_rows()` may be called immediately after executing a statement with `mysql_stmt_execute()`. It is like `mysql_affected_rows()` but for prepared statements. For a description of what the affected-rows value returned by this function means, See [Section 21.8.6.1](#), “`mysql_affected_rows()`”.

#### Errors

None.

#### Example

See the Example in [Section 21.8.10.10](#), “`mysql_stmt_execute()`”.

### 21.8.10.2. `mysql_stmt_attr_get()`

```
my_bool mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, void *arg)
```

#### Description

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, `arg` should point to the value of the integer.

See [Section 21.8.10.3](#), “`mysql_stmt_attr_set()`”, for a list of options and option types.

## Return Values

Zero if successful. Nonzero if `option` is unknown.

## Errors

None.

### 21.8.10.3. `mysql_stmt_attr_set()`

```
my_bool mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, const void *arg)
```

## Description

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set. The `arg` argument is the value for the option. `arg` should point to a variable that is set to the desired attribute value. The variable type is as indicated in the following table.

The following table shows the possible `option` values.

Option	Argument Type	Function
<code>STMT_ATTR_UPDATE_MAX_LENGTH</code>	<code>my_bool *</code>	If set to 1, causes <code>mysql_stmt_store_result()</code> to update the metadata <code>MYSQL_FIELD-&gt;max_length</code> value.
<code>STMT_ATTR_CURSOR_TYPE</code>	<code>unsigned long *</code>	Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. <code>*arg</code> can be <code>CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>CURSOR_TYPE_READ_ONLY</code> .
<code>STMT_ATTR_PREFETCH_ROWS</code>	<code>unsigned long *</code>	Number of rows to fetch from server at a time when using a cursor. <code>*arg</code> can be in the range from 1 to the maximum value of <code>unsigned long</code> . The default is 1.

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

## Return Values

Zero if successful. Nonzero if `option` is unknown.

## Errors

None.

## Example

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
                        (void*) &prefetch_rows);
/* ... check return value ... */
```

### 21.8.10.4. `mysql_stmt_bind_param()`

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

## Description

`mysql_stmt_bind_param()` is used to bind input data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each `?` parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

Section 21.8.8, “C API Prepared Statement Data Structures”, describes the members of each `MYSQL_BIND` element and how they should be set to provide input values.

## Return Values

Zero if the bind operation was successful. Nonzero if an error occurred.

## Errors

- `CR_UNSUPPORTED_PARAM_TYPE` [3720]

The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.

- `CR_OUT_OF_MEMORY` [3718]

Out of memory.

- `CR_UNKNOWN_ERROR` [3718]

An unknown error occurred.

## Example

See the Example in Section 21.8.10.10, “`mysql_stmt_execute()`”.

### 21.8.10.5. `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

## Description

`mysql_stmt_bind_result()` is used to associate (that is, bind) output columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol doesn't return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol places data into the newly bound buffers when the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and length of the output buffer into which the value should be stored. [Section 21.8.8, "C API Prepared Statement Data Structures"](#), describes the members of each `MYSQL_BIND` element and how they should be set to receive output values.

## Return Values

Zero if the bind operation was successful. Nonzero if an error occurred.

## Errors

- [CR\\_UNSUPPORTED\\_PARAM\\_TYPE \[3720\]](#)  
The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.
- [CR\\_OUT\\_OF\\_MEMORY \[3718\]](#)  
Out of memory.
- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)  
An unknown error occurred.

## Example

See the Example in [Section 21.8.10.11, "mysql\\_stmt\\_fetch\(\)"](#).

### 21.8.10.6. `mysql_stmt_close()`

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

## Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

## Return Values

Zero if the statement was freed successfully. Nonzero if an error occurred.

## Errors

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

## Example

See the Example in [Section 21.8.10.10](#), “`mysql_stmt_execute()`”.

### 21.8.10.7. `mysql_stmt_data_seek()`

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

## Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

## Return Values

None.

## Errors

None.

### 21.8.10.8. `mysql_stmt_errno()`

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

## Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysql_error.h`. Errors also are listed at [Appendix C, Errors, Error Codes, and Common Problems](#).

## Return Values

An error code value. Zero if no error occurred.

## Errors

None.

### 21.8.10.9. `mysql_stmt_error()`

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

## Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (“”) is returned if no error occurred. This means the following two tests are equivalent:

```
if (*mysql_stmt_errno(stmt))
{
    // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages.

## Return Values

A character string that describes the error. An empty string if no error occurred.

## Errors

None.

### 21.8.10.10. `mysql_stmt_execute()`

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

## Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

Statement processing following `mysql_stmt_execute()` depends on the type of statement:

- For an `UPDATE`, `DELETE`, or `INSERT`, the number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`.
- For a statement such as `SELECT` that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to [Section 21.8.10.11, “mysql\\_stmt\\_fetch\(\)”](#).

Do not following invocation of `mysql_stmt_execute()` with a call to `mysql_store_result()` or `mysql_use_result()`. Those functions are not intended for processing results from prepared statements.

For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 8.9.4, “Caching of Prepared Statements and Stored Programs”](#).

## Return Values

Zero if execution was successful. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_OUT\\_OF\\_MEMORY \[3718\]](#)

Out of memory.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

## Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle. For an example that shows how to retrieve data, see [Section 21.8.10.11](#), “`mysql_stmt_fetch()`”.

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(coll INT,\
                                col2 VARCHAR(40),\
                                col3 SMALLINT,\
                                col4 TIMESTAMP)"

#define INSERT_SAMPLE "INSERT INTO \
    test_table(coll,col2,col3) \
    VALUES(?,?,?)"

MYSQL_STMT *stmt;
MYSQL_BIND bind[3];
my_ulonglong affected_rows;
int param_count;
short small_data;
int int_data;
char str_data[STRING_SIZE];
unsigned long str_length;
my_bool is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
{
    fprintf(stderr, " DROP TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
{
    fprintf(stderr, " CREATE TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
/* sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_SAMPLE, strlen(INSERT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), INSERT failed\n");
```

```

fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
exit(0);
}
fprintf(stdout, " prepare, INSERT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in INSERT: %d\n", param_count);

if (param_count != 3) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
    exit(0);
}

/* Bind the data for all 3 parameters */

memset(bind, 0, sizeof(bind));

/* INTEGER PARAM */
/* This is a number type, so there is no need
   to specify buffer_length */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;
bind[0].is_null= 0;
bind[0].length= 0;

/* STRING PARAM */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= 0;
bind[1].length= &str_length;

/* SMALLINT PARAM */

bind[2].buffer= (char *)&small_data;
bind[2].is_null= &is_null;
bind[2].length= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, " mysql_stmt_bind_param() failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Specify the data values for the first row */
int_data= 10; /* integer */
strncpy(str_data, "MySQL", STRING_SIZE); /* string */
str_length= strlen(str_data);

/* INSERT SMALLINT data as NULL */
is_null= 1;

/* Execute the INSERT statement - 1*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute(), 1 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");

```

```

    exit(0);
}

/* Specify data values for second row,
   then re-execute the statement */
int_data= 1000;
strncpy(str_data, "
        The most popular Open Source database",
        STRING_SIZE);
str_length= strlen(str_data);
small_data= 1000;          /* smallint */
is_null= 0;              /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

### Note

For complete examples on the use of prepared statement functions, refer to the file `tests/mysql_client_test.c`. This file can be obtained from a MySQL source distribution or from the Bazaar source repository.

#### 21.8.10.11. `mysql_stmt_fetch()`

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

#### Description

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists; that is, after a call to `mysql_stmt_execute()` for a statement such as `SELECT` that produces a result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer. All columns must be bound by the application before it calls `mysql_stmt_fetch()`.

By default, result sets are fetched unbuffered a row at a time from the server. To buffer the entire result set on the client, call `mysql_stmt_store_result()` after binding the data buffers and before calling `mysql_stmt_fetch()`.

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains `TRUE` (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal

type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

Type	Length
<code>MYSQL_TYPE_TINY</code>	1
<code>MYSQL_TYPE_SHORT</code>	2
<code>MYSQL_TYPE_LONG</code>	4
<code>MYSQL_TYPE_LONGLONG</code>	8
<code>MYSQL_TYPE_FLOAT</code>	4
<code>MYSQL_TYPE_DOUBLE</code>	8
<code>MYSQL_TYPE_TIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATE</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATETIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_STRING</code>	<code>data_length</code>
<code>MYSQL_TYPE_BLOB</code>	<code>data_length</code>

In some cases you might want to determine the length of a column value before fetching it with `mysql_stmt_fetch()`. For example, the value might be a long string or `BLOB` value for which you want to know how much space must be allocated. To accomplish this, you can use these strategies:

- Before invoking `mysql_stmt_fetch()` to retrieve individual rows, pass `STMT_ATTR_UPDATE_MAX_LENGTH` to `mysql_stmt_attr_set()`, then invoke `mysql_stmt_store_result()` to buffer the entire result on the client side. Setting the `STMT_ATTR_UPDATE_MAX_LENGTH` attribute causes the maximal length of column values to be indicated by the `max_length` member of the result set metadata returned by `mysql_stmt_result_metadata()`.
- Invoke `mysql_stmt_fetch()` with a zero-length buffer for the column in question and a pointer in which the real length can be stored. Then use the real length with `mysql_stmt_fetch_column()`.

```
real_length= 0;

bind[0].buffer= 0;
bind[0].buffer_length= 0;
bind[0].length= &real_length
mysql_stmt_bind_result(stmt, bind);

mysql_stmt_fetch(stmt);
if (real_length > 0)
{
    data= malloc(real_length);
    bind[0].buffer= data;
    bind[0].buffer_length= real_length;
    mysql_stmt_fetch_column(stmt, bind, 0, 0);
}
```

## Return Values

Return Value	Description
0	Successful, the data has been fetched to application data buffers.
1	Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code> .
<code>MYSQL_NO_DATA</code>	No more rows/data exists
<code>MYSQL_DATA_TRUNCATED</code>	Data truncation occurred

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. To determine which column values were truncated when this value is returned, check the `error` members of the

`MYSQL_BIND` structures used for fetching values. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC` [3719]  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY` [3718]  
Out of memory.
- `CR_SERVER_GONE_ERROR` [3718]  
The MySQL server has gone away.
- `CR_SERVER_LOST` [3719]  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR` [3718]  
An unknown error occurred.
- `CR_UNSUPPORTED_PARAM_TYPE` [3720]  
The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.
- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

## Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`. (This example expects to retrieve the two rows inserted by the example shown in [Section 21.8.10.10](#), “`mysql_stmt_execute()`”.) The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 \
                      FROM test_table"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[4];
MYSQL_RES       *prepare_meta_result;
MYSQL_TIME      ts;
unsigned long   length[4];
int             param_count, column_count, row_count;
short          small_data;
int            int_data;
char           str_data[STRING_SIZE];
my_bool       is_null[4];
my_bool       error[4];

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, SELECT_SAMPLE, strlen(SELECT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), SELECT failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
```

```
}
fprintf(stdout, " prepare, SELECT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in SELECT: %d\n", param_count);

if (param_count != 0) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
    exit(0);
}

/* Fetch result set meta information */
prepare_meta_result = mysql_stmt_result_metadata(stmt);
if (!prepare_meta_result)
{
    fprintf(stderr,
            " mysql_stmt_result_metadata(), \
            returned no meta information\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get total columns in the query */
column_count= mysql_num_fields(prepare_meta_result);
fprintf(stdout,
        " total columns in SELECT statement: %d\n",
        column_count);

if (column_count != 4) /* validate column count */
{
    fprintf(stderr, " invalid column count returned by MySQL\n");
    exit(0);
}

/* Execute the SELECT query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute(), failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Bind the result buffers for all 4 columns before fetching them */

memset(bind, 0, sizeof(bind));

/* INTEGER COLUMN */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;
bind[0].is_null= &is_null[0];
bind[0].length= &length[0];
bind[0].error= &error[0];

/* STRING COLUMN */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= &is_null[1];
bind[1].length= &length[1];
bind[1].error= &error[1];

            ts.year, ts.month, ts.day,
            ts.hour, ts.minute, ts.second,
            length[3]);
    fprintf(stdout, "\n");
}

/* Validate rows fetched */
fprintf(stdout, " total rows fetched: %d\n", row_count);
if (row_count != 2)
{
    fprintf(stderr, " MySQL failed to return all rows\n");
    exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);
```

```
/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
```

### 21.8.10.12. `mysql_stmt_fetch_column()`

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int
column, unsigned long offset)
```

#### Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

#### Return Values

Zero if the value was fetched successfully. Nonzero if an error occurred.

#### Errors

- [CR\\_INVALID\\_PARAMETER\\_NO \[3720\]](#)  
Invalid column number.
- [CR\\_NO\\_DATA \[3721\]](#)  
The end of the result set has already been reached.

### 21.8.10.13. `mysql_stmt_field_count()`

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

#### Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

#### Return Values

An unsigned integer representing the number of columns in a result set.

#### Errors

None.

### 21.8.10.14. `mysql_stmt_free_result()`

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

#### Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, `mysql_stmt_free_result()` closes it.

## Return Values

Zero if the result set was freed successfully. Nonzero if an error occurred.

## Errors

### 21.8.10.15. `mysql_stmt_init()`

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

## Description

Create a `MYSQL_STMT` handle. The handle should be freed with `mysql_stmt_close(MYSQL_STMT *)`.

See also [Section 21.8.8, “C API Prepared Statement Data Structures”](#), for more information.

## Return Values

A pointer to a `MYSQL_STMT` structure in case of success. `NULL` if out of memory.

## Errors

- `CR_OUT_OF_MEMORY` [3718]

Out of memory.

### 21.8.10.16. `mysql_stmt_insert_id()`

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

## Description

Returns the value generated for an `AUTO_INCREMENT` column by the prepared `INSERT` or `UPDATE` statement. Use this function after you have executed a prepared `INSERT` statement on a table which contains an `AUTO_INCREMENT` field.

See [Section 21.8.6.37, “`mysql\_insert\_id\(\)`”](#), for more information.

## Return Values

Value for `AUTO_INCREMENT` column which was automatically generated or explicitly set during execution of prepared statement, or value generated by `LAST_INSERT_ID(expr)` [1269] function. Return value is undefined if statement does not set `AUTO_INCREMENT` value.

## Errors

None.

### 21.8.10.17. `mysql_stmt_next_result()`

```
int mysql_stmt_next_result(MYSQL_STMT *mysql)
```

## Description

This function is used when you use prepared `CALL` statements to execute stored procedures, which can return multiple result sets. Use a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. If a procedure has `OUT` or `INOUT` parameters, their values will be returned as a single-row result set following any other result sets. The values will appear in the order in which they are declared in the procedure parameter list.

`mysql_stmt_next_result()` returns a status to indicate whether more results exist. If `mysql_stmt_next_result()` returns an error, there are no more results.

Before each call to `mysql_stmt_next_result()`, you must call `mysql_stmt_free_result()` for the current result if it produced a result set (rather than just a result status).

After calling `mysql_stmt_next_result()` the state of the connection is as if you had called `mysql_stmt_execute()`. This means that you can call `mysql_stmt_bind_result()`, `mysql_stmt_affected_rows()`, and so forth.

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_stmt_next_result()` to advance to the next result.

For an example that shows how to use `mysql_stmt_next_result()`, see [Section 21.8.19, “C API Support for Prepared CALL Statements”](#).

## Return Values

Return Value	Description
0	Successful and there are more results
-1	Successful and there are no more results
>0	An error occurred

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.10.18. `mysql_stmt_num_rows()`

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

## Description

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether you used `mysql_stmt_store_result()` to buffer the entire result set in the statement handle. If you use `mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately. Otherwise, the row count is unavailable unless you count the rows as you fetch them.

`mysql_stmt_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_stmt_affected_rows()`.

**Return Values**

The number of rows in the result set.

**Errors**

None.

**21.8.10.19. `mysql_stmt_param_count()`**

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

**Description**

Returns the number of parameter markers present in the prepared statement.

**Return Values**

An unsigned long integer representing the number of parameters in a statement.

**Errors**

None.

**Example**

See the Example in [Section 21.8.10.10](#), "`mysql_stmt_execute()`".

**21.8.10.20. `mysql_stmt_param_metadata()`**

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

This function currently does nothing.

**Description****Return Values****Errors****21.8.10.21. `mysql_stmt_prepare()`**

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *stmt_str, unsigned long length)
```

**Description**

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `stmt_str` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon ("`;`") or `\g` to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (`?`) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are permitted in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not permitted for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine

the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 8.9.4, “Caching of Prepared Statements and Stored Programs”](#).

## Return Values

Zero if the statement was prepared successfully. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_OUT\\_OF\\_MEMORY \[3718\]](#)

Out of memory.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns nonzero), the error message can be obtained by calling `mysql_stmt_error()`.

## Example

See the Example in [Section 21.8.10.10, “mysql\\_stmt\\_execute\(\)”](#).

### 21.8.10.22. `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

## Description

Resets a prepared statement on client and server to state after prepare. It resets the statement on the server, data sent using `mysql_stmt_send_long_data()`, unbuffered result sets and current errors. It does not clear bindings or stored result sets. Stored result sets will be cleared when executing the prepared statement (or closing it).

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

## Return Values

Zero if the statement was reset successfully. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST \[3719\]](#)

The connection to the server was lost during the query

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### 21.8.10.23. `mysql_stmt_result_metadata()`

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

#### Description

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`
- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

#### Return Values

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

#### Errors

- [CR\\_OUT\\_OF\\_MEMORY \[3718\]](#)

Out of memory.

- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)

An unknown error occurred.

### Example

See the Example in [Section 21.8.10.11](#), “`mysql_stmt_fetch()`”.

#### 21.8.10.24. `mysql_stmt_row_seek()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt, MYSQL_ROW_OFFSET
offset)
```

### Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

### Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

### Errors

None.

#### 21.8.10.25. `mysql_stmt_row_tell()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

### Description

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

### Return Values

The current offset of the row cursor.

### Errors

None.

#### 21.8.10.26. `mysql_stmt_send_long_data()`

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int
parameter_number, const char *data, unsigned long length)
```

### Description

Enables an application to send parameter data to the server in pieces (or “chunks”). Call this function after `mysql_stmt_bind_param()` and before `mysql_stmt_execute()`. It can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the `TEXT` or `BLOB` data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

#### Note

The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See [Section 21.8.10.22](#), “`mysql_stmt_reset()`”.

As of MySQL 5.6.3, the `max_allowed_packet` [502] system variable controls the maximum size of parameter values that can be sent with `mysql_stmt_send_long_data()`.

## Return Values

Zero if the data is sent successfully to server. Nonzero if an error occurred.

## Errors

- [CR\\_INVALID\\_BUFFER\\_USE \[3720\]](#)  
The parameter does not have a string or binary type.
- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_OUT\\_OF\\_MEMORY \[3718\]](#)  
Out of memory.
- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)  
An unknown error occurred.

## Example

The following example demonstrates how to send the data for a `TEXT` column in chunks. It inserts the data value `'MySQL - The most popular Open Source database'` into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO \  
                    test_long_data(text_column) VALUES(?)"  
  
MYSQL_BIND bind[1];  
long        length;  
  
stmt = mysql_stmt_init(mysql);  
if (!stmt)  
{  
    fprintf(stderr, "mysql_stmt_init(), out of memory\n");  
    exit(0);  
}  
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY))  
{  
    fprintf(stderr, "\nmysql_stmt_prepare(), INSERT failed");  
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
```

```

    exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, "\n param bind failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply data in chunks to server */
if (mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,
    " - The most popular Open Source database",40))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n mysql_stmt_execute failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

```

### 21.8.10.27. `mysql_stmt_sqlstate()`

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix C, Errors, Error Codes, and Common Problems](#).

Note that not all MySQL errors are yet mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.

#### Return Values

A null-terminated character string containing the SQLSTATE error code.

### 21.8.10.28. `mysql_stmt_store_result()`

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

#### Description

Result sets are produced by calling `mysql_stmt_execute()` to executed prepared statements for SQL statements such as `SELECT`, `SHOW`, `DESCRIBE`, and `EXPLAIN`. By default,

result sets for successfully executed prepared statements are not buffered on the client and `mysql_stmt_fetch()` fetches them one at a time from the server. To cause the complete result set to be buffered on the client, call `mysql_stmt_store_result()` after binding data buffers with `mysql_stmt_bind_result()` and before calling `mysql_stmt_fetch()` to fetch rows. (For an example, see [Section 21.8.10.11](#), “`mysql_stmt_fetch()`”.)

`mysql_stmt_store_result()` is optional for result set processing, unless you will call `mysql_stmt_data_seek()`, `mysql_stmt_row_seek()`, or `mysql_stmt_row_tell()`. Those functions require a seekable result set.

It is unnecessary to call `mysql_stmt_store_result()` after executing an SQL statement that does not produce a result set, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to [Section 21.8.10.23](#), “`mysql_stmt_result_metadata()`”.

#### Note

MySQL doesn't by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications don't need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See [Section 21.8.10.3](#), “`mysql_stmt_attr_set()`”.

## Return Values

Zero if the results are buffered successfully. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC \[3719\]](#)  
Commands were executed in an improper order.
- [CR\\_OUT\\_OF\\_MEMORY \[3718\]](#)  
Out of memory.
- [CR\\_SERVER\\_GONE\\_ERROR \[3718\]](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST \[3719\]](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR \[3718\]](#)  
An unknown error occurred.

## 21.8.11. C API Threaded Function Descriptions

To create a threaded client, use the functions described in the following sections. See also [Section 21.8.3.2](#), “[Writing C API Threaded Client Programs](#)”.

### 21.8.11.1. `my_init()`

```
void my_init(void)
```

## Description

`my_init()` initializes some global variables that MySQL needs. It also calls `mysql_thread_init()` for this thread.

It is necessary for `my_init()` to be called early in the initialization phase of a program's use of the MySQL library. However, `my_init()` is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you ensure that your program invokes one of those functions before any other MySQL calls, there is no need to invoke `my_init()` explicitly.

To access the prototype for `my_init()`, your program should include these header files:

```
#include <my_global.h>
#include <my_sys.h>
```

## Return Values

None.

### 21.8.11.2. `mysql_thread_end()`

```
void mysql_thread_end(void)
```

## Description

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

`mysql_thread_end()` is not invoked automatically by the client library. It must be called explicitly to avoid a memory leak.

## Return Values

None.

### 21.8.11.3. `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

## Description

This function must be called early within each created thread to initialize thread-specific variables. However, you may not necessarily need to invoke it explicitly: `mysql_thread_init()` is automatically called by `my_init()`, which itself is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you invoke any of those functions, `mysql_thread_init()` will be called for you.

## Return Values

Zero if successful. Nonzero if an error occurred.

### 21.8.11.4. `mysql_thread_safe()`

```
unsigned int mysql_thread_safe(void)
```

## Description

This function indicates whether the client library is compiled as thread-safe.

## Return Values

1 if the client library is thread-safe, 0 otherwise.

## 21.8.12. C API Embedded Server Function Descriptions

MySQL applications can be written to use an embedded server. See [Section 21.7, “libmysqld, the Embedded MySQL Server Library”](#). To write such an application, you must link it against the `libmysqld` library by using the `-lmysqld` flag rather than linking it against the `libmysqlclient` client library by using the `-libmysqlclient` flag. However, the calls to initialize and finalize the library are the same whether you write a client application or one that uses the embedded server: Call `mysql_library_init()` to initialize the library and `mysql_library_end()` when you are done with it. See [Section 21.8.5, “C API Function Overview”](#).

### 21.8.12.1. `mysql_server_init()`

```
int mysql_server_init(int argc, char **argv, char **groups)
```

#### Description

This function initializes the MySQL library, which must be done before you call any other MySQL function. However, `mysql_server_init()` is deprecated and you should call `mysql_library_init()` instead. See [Section 21.8.6.40, “mysql\\_library\\_init\(\)”](#).

#### Return Values

Zero if successful. Nonzero if an error occurred.

### 21.8.12.2. `mysql_server_end()`

```
void mysql_server_end(void)
```

#### Description

This function finalizes the MySQL library, which should be done when you are done using the library. However, `mysql_server_end()` is deprecated and `mysql_library_end()` should be used instead. See [Section 21.8.6.39, “mysql\\_library\\_end\(\)”](#).

#### Return Values

None.

## 21.8.13. C API Client Plugin Functions

This section describes functions used for the client-side plugin API. They enable management of client plugins. For a description of the `st_mysql_client_plugin` structure used by these functions, see [Section 22.2.4.2.3, “Client Plugin Descriptors”](#).

It is unlikely that a client program needs to call the functions in this section. For example, a client that supports the use of authentication plugins normally causes a plugin to be loaded by calling `mysql_options()` to set the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options:

```
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";

/* ... process command-line options ... */

mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept `--plugin-dir` and `--default-auth` options that enable users to override the default values.

### 21.8.13.1. `mysql_client_find_plugin()`

```
struct st_mysql_client_plugin *mysql_client_find_plugin(MYSQL *mysql, const
char *name, int type)
```

#### Description

Returns a pointer to a loaded plugin, loading the plugin first if necessary. An error occurs if the type is invalid or the plugin cannot be found or loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `name`: The plugin name.
- `type`: The plugin type.

#### Return Values

A pointer to the plugin for success. `NULL` if an error occurred.

#### Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 21.8.6.15](#), “`mysql_error()`”, and [Section 21.8.6.14](#), “`mysql_errno()`”.

#### Example

```
MYSQL mysql;
struct st_mysql_client_plugin *p;

if ((p = mysql_client_find_plugin(&mysql, "myplugin",
                                MYSQL_CLIENT_AUTHENTICATION_PLUGIN, 0)))
{
    printf("Plugin version: %d.%d.%d\n", p->version[0], p->version[1], p->version[2]);
}
```

### 21.8.13.2. `mysql_client_register_plugin()`

```
struct st_mysql_client_plugin *mysql_client_register_plugin(MYSQL *mysql,
struct st_mysql_client_plugin *plugin)
```

#### Description

Adds a plugin structure to the list of loaded plugins. An error occurs if the plugin is already loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `plugin`: A pointer to the plugin structure.

#### Return Values

A pointer to the plugin for success. `NULL` if an error occurred.

## Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 21.8.6.15](#), “`mysql_error()`”, and [Section 21.8.6.14](#), “`mysql_errno()`”.

### 21.8.13.3. `mysql_load_plugin()`

```
struct st_mysql_client_plugin *mysql_load_plugin(MYSQL *mysql, const char
*name, int type, int argc, ...)
```

## Description

Loads a MySQL client plugin, specified by name and type. An error occurs if the type is invalid or the plugin cannot be loaded.

It is not possible to load multiple plugins of the same type. An error occurs if you try to load a plugin of a type already loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `name`: The name of the plugin to load.
- `type`: The type of plugin to load, or `-1` to disable type checking. If type is not `-1`, only plugins matching the type are considered for loading.
- `argc`: The number of following arguments (0 if there are none). Interpretation of any following arguments depends on the plugin type.

Another way to cause plugins to be loaded is to set the `LIBMYSQL_PLUGINS` environment variable to a semicolon-separated list of plugin names. For example:

```
shell> export LIBMYSQL_PLUGINS="myplugin1;myplugin2"
```

Plugins named by `LIBMYSQL_PLUGINS` are loaded when the client program calls `mysql_library_init()`. No error is reported if problems occur loading these plugins.

As of MySQL 5.6.10, the `LIBMYSQL_PLUGIN_DIR` environment variable can be set to the path name of the directory in which to look for client plugins. This variable is used in two ways:

- During client plugin preloading, the value of the `--plugin-dir` option is not available, so client plugin loading fails unless the plugins are located in the hardwired default directory. If the plugins are located elsewhere, `LIBMYSQL_PLUGIN_DIR` environment variable can be set to the proper directory to enable plugin preloading to succeed.
- For explicit client plugin loading, the `mysql_load_plugin()` and `mysql_load_plugin_v()` C API functions use the `LIBMYSQL_PLUGIN_DIR` value if it exists and the `--plugin-dir` option was not given. If `--plugin-dir` is given, `mysql_load_plugin()` and `mysql_load_plugin_v()` ignore `LIBMYSQL_PLUGIN_DIR`.

## Return Values

A pointer to the plugin if it was loaded successfully. `NULL` if an error occurred.

## Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 21.8.6.15](#), “`mysql_error()`”, and [Section 21.8.6.14](#), “`mysql_errno()`”.

## Example

```
MYSQL mysql;

if(!mysql_load_plugin(&mysql, "myplugin",
                     MYSQL_CLIENT_AUTHENTICATION_PLUGIN, 0))
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
    exit(-1);
}
```

## See Also

See also [Section 21.8.13.3](#), “`mysql_load_plugin()`”, [Section 21.8.6.15](#), “`mysql_error()`”, [Section 21.8.6.14](#), “`mysql_errno()`”.

### 21.8.13.4. `mysql_load_plugin_v()`

```
struct st_mysql_client_plugin *mysql_load_plugin_v(MYSQL *mysql, const char
*name, int type, int argc, va_list args)
```

## Description

This function is equivalent to `mysql_load_plugin()`, but it accepts a `va_list` instead of a variable list of parameters.

## See Also

See also [Section 21.8.13.3](#), “`mysql_load_plugin()`”.

### 21.8.13.5. `mysql_plugin_options()`

```
int mysql_plugin_options(struct st_mysql_client_plugin *plugin, const char
*option, const void *value)
```

## Description

Passes an option type and value to a plugin. This function can be called multiple times to set several options. If the plugin does not have an option handler, an error occurs.

Specify the parameters as follows:

- `plugin`: A pointer to the plugin structure.
- `option`: The option to be set.
- `value`: A pointer to the option value.

## Return Values

Zero for success, 1 if an error occurred. If the plugin has an option handler, that handler should also return zero for success and 1 if an error occurred.

## 21.8.14. Common Questions and Problems When Using the C API

### 21.8.14.1. Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return `NULL` following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).

- The data could not be read (an error occurred on the connection).
- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a nonempty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a nonzero value, the statement should have produced a nonempty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

### 21.8.14.2. What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an `INSERT`, `UPDATE`, or `DELETE`.

For a fast re-create, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.
- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See [Section 21.8.6.37](#), “`mysql_insert_id()`”.
- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

### 21.8.14.3. How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
    used_id = mysql_insert_id(&mysql);
}
```

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

When inserting multiple values, the last automatically incremented value is returned.

For `LAST_INSERT_ID()` [1269], the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a nonmagic value (that is, a value that is not `NULL` and not `0`). Using `LAST_INSERT_ID()` [1269] and `AUTO_INCREMENT` columns simultaneously from multiple clients is perfectly valid. Each client will receive the last inserted ID for the last statement *that* client executed.

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
  VALUES(NULL,'text');           # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
  VALUES(LAST_INSERT_ID(),'text'); # use ID in second table
```

Note that `mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` [1269] returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()` [1269].

For more information on obtaining the last ID in an `AUTO_INCREMENT` column:

- For information on `LAST_INSERT_ID()` [1269], which can be used within an SQL statement, see [Section 12.14, “Information Functions”](#).
- For information on `mysql_insert_id()`, the function you use from within the C API, see [Section 21.8.6.37, “mysql\\_insert\\_id\(\)”](#).
- For information on obtaining the auto-incremented value when using Connector/J, see [Section 21.3.6.4, “Retrieving AUTO\\_INCREMENT Column Values through JDBC”](#).
- For information on obtaining the auto-incremented value when using Connector/ODBC, see [Section 21.1.7.1.1, “Obtaining Auto-Increment Values”](#).

## 21.8.15. Controlling Automatic Reconnection Behavior

The MySQL client library can perform an automatic reconnection to the server if it finds that the connection is down when you attempt to send a statement to the server to be executed. In this case, the library tries once to reconnect to the server and send the statement again.

In MySQL 5.6, auto-reconnect is disabled by default.

If it is important for your application to know that the connection has been dropped (so that it can exit or take action to adjust for the loss of state information), be sure that auto-reconnect is disabled. To ensure this, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option:

```
my_bool reconnect = 0;
mysql_options(&mysql, MYSQL_OPT_RECONNECT, &reconnect);
```

If the connection has gone down, the effect of `mysql_ping()` depends on the auto-reconnect state. If auto-reconnect is enabled, `mysql_ping()` performs a reconnect. Otherwise, it returns an error.

Some client programs might provide the capability of controlling automatic reconnection. For example, `mysql` reconnects by default, but the `--skip-reconnect` [252] option can be used to suppress this behavior.

If an automatic reconnection does occur (for example, as a result of calling `mysql_ping()`), there is no explicit indication of it. To check for reconnection, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier has changed.

Automatic reconnection can be convenient because you need not implement your own reconnect code, but if a reconnection does occur, several aspects of the connection state are reset on the server side and your application will not know about it. The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.

- All `TEMPORARY` tables are closed (and dropped).
- Session variables are reinitialized to the values of the corresponding variables. This also affects variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- `HANDLER` variables are closed.
- The value of `LAST_INSERT_ID()` [1269] is reset to 0.
- Locks acquired with `GET_LOCK()` [1275] are released.
- The association of the client with the Performance Schema `threads` table row that determines connection thread instrumentation is lost. If the client reconnects after a disconnect, the session will be associated with a new row in the `threads` table and the thread monitoring state may be different. See [Section 20.9.9.3, “The threads Table”](#).

If the connection drops, it is possible that the session associated with the connection on the server side will still be running if the server has not yet detected that the client is no longer connected. In this case, any locks held by the original connection still belong to that session, so you may want to kill it by calling `mysql_kill()`.

## 21.8.16. C API Support for Multiple Statement Execution

By default, `mysql_query()` and `mysql_real_query()` interpret their statement string argument as a single statement to be executed, and you process the result according to whether the statement produces a result set (a set of rows, as for `SELECT`) or an affected-rows count (as for `INSERT`, `UPDATE`, and so forth).

MySQL 5.6 also supports the execution of a string containing multiple statements separated by semicolon (“;”) characters. This capability is enabled by special options that are specified either when you connect to the server with `mysql_real_connect()` or after connecting by calling `mysql_set_server_option()`.

Executing a multiple-statement string can produce multiple result sets or row-count indicators. Processing these results involves a different approach than for the single-statement case: After handling the result from the first statement, it is necessary to check whether more results exist and process them in turn if so. To support multiple-result processing, the C API includes the `mysql_more_results()` and `mysql_next_result()` functions. These functions are used at the end of a loop that iterates as long as more results are available. *Failure to process the result this way may result in a dropped connection to the server.*

Multiple-result processing also is required if you execute `CALL` statements for stored procedures. Results from a stored procedure have these characteristics:

- Statements within the procedure may produce result sets (for example, if it executes `SELECT` statements). These result sets are returned in the order that they are produced as the procedure executes.

In general, the caller cannot know how many result sets a procedure will return. Procedure execution may depend on loops or conditional statements that cause the execution path to differ from one call to the next. Therefore, you must be prepared to retrieve multiple results.

- The final result from the procedure is a status result that includes no result set. The status indicates whether the procedure succeeded or an error occurred.

The multiple statement and result capabilities can be used only with `mysql_query()` or `mysql_real_query()`. They cannot be used with the prepared statement interface. Prepared

statement handles are defined to work only with strings that contain a single statement. See [Section 21.8.7, “C API Prepared Statements”](#).

To enable multiple-statement execution and result processing, the following options may be used:

- The `mysql_real_connect()` function has a `flags` argument for which two option values are relevant:
  - `CLIENT_MULTI_RESULTS` enables the client program to process multiple results. This option *must* be enabled if you execute `CALL` statements for stored procedures that produce result sets. Otherwise, such procedures result in an error `Error 1312 (0A000): PROCEDURE proc_name can't return a result set in the given context`. In MySQL 5.6, `CLIENT_MULTI_RESULTS` is enabled by default.
  - `CLIENT_MULTI_STATEMENTS` enables `mysql_query()` and `mysql_real_query()` to execute statement strings containing multiple statements separated by semicolons. This option also enables `CLIENT_MULTI_RESULTS` implicitly, so a `flags` argument of `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()` is equivalent to an argument of `CLIENT_MULTI_STATEMENTS | CLIENT_MULTI_RESULTS`. That is, `CLIENT_MULTI_STATEMENTS` is sufficient to enable multiple-statement execution and all multiple-result processing.
- After the connection to the server has been established, you can use the `mysql_set_server_option()` function to enable or disable multiple-statement execution by passing it an argument of `MYSQL_OPTION_MULTI_STATEMENTS_ON` or `MYSQL_OPTION_MULTI_STATEMENTS_OFF`. Enabling multiple-statement execution with this function also enables processing of “simple” results for a multiple-statement string where each statement produces a single result, but is *not* sufficient to permit processing of stored procedures that produce result sets.

The following procedure outlines a suggested strategy for handling multiple statements:

1. Pass `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()`, to fully enable multiple-statement execution and multiple-result processing.
2. After calling `mysql_query()` or `mysql_real_query()` and verifying that it succeeds, enter a loop within which you process statement results.
3. For each iteration of the loop, handle the current statement result, retrieving either a result set or an affected-rows count. If an error occurs, exit the loop.
4. At the end of the loop, call `mysql_next_result()` to check whether another result exists and initiate retrieval for it if so. If no more results are available, exit the loop.

One possible implementation of the preceding strategy is shown following. The final part of the loop can be reduced to a simple test of whether `mysql_next_result()` returns nonzero. The code as written distinguishes between no more results and an error, which enables a message to be printed for the latter occurrence.

```

/* connect to server with the CLIENT_MULTI_STATEMENTS option */
if (mysql_real_connect (mysql, host_name, user_name, password,
    db_name, port_num, socket_name, CLIENT_MULTI_STATEMENTS) == NULL)
{
    printf("mysql_real_connect() failed\n");
    mysql_close(mysql);
    exit(1);
}

/* execute multiple statements */
status = mysql_query(mysql,
    "DROP TABLE IF EXISTS test_table;\
    CREATE TABLE test_table(id INT);\
    INSERT INTO test_table VALUES(10);\
    UPDATE test_table SET id=20 WHERE id=10;\

```

```

        SELECT * FROM test_table;\
        DROP TABLE test_table");
if (status)
{
    printf("Could not execute statement(s)");
    mysql_close(mysql);
    exit(0);
}

/* process each statement result */
do {
    /* did current statement return data? */
    result = mysql_store_result(mysql);
    if (result)
    {
        /* yes; process rows and free the result set */
        process_result_set(mysql, result);
        mysql_free_result(result);
    }
    else /* no result set or error */
    {
        if (mysql_field_count(mysql) == 0)
        {
            printf("%lld rows affected\n",
                mysql_affected_rows(mysql));
        }
        else /* some error occurred */
        {
            printf("Could not retrieve result set\n");
            break;
        }
    }
}
/* more results? -1 = no, >0 = error, 0 = yes (keep looping) */
if ((status = mysql_next_result(mysql)) > 0)
    printf("Could not execute statement\n");
} while (status == 0);

mysql_close(mysql);

```

## 21.8.17. C API Prepared Statement Problems

Here follows a list of the currently known problems with prepared statements:

- [TIME](#), [TIMESTAMP](#), and [DATETIME](#) do not support parts of seconds (for example, from [DATE\\_FORMAT\(\)](#) [1215]).
- When converting an integer to string, [ZEROFILL](#) is honored with prepared statements in some cases where the MySQL server doesn't print the leading zeros. (For example, with [MIN\(number-with-zerofill\)](#) [1284]).
- When converting a floating-point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.
- Prepared statements use the query cache under the conditions described in [Section 8.9.3.1, "How the Query Cache Operates"](#).
- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by ";" characters).
- The capabilities of prepared [CALL](#) statements are described in [Section 21.8.19, "C API Support for Prepared CALL Statements"](#).

## 21.8.18. C API Prepared Statement Handling of Date and Time Values

The binary (prepared statement) protocol enables you to send and receive date and time values ([DATE](#), [TIME](#), [DATETIME](#), and [TIMESTAMP](#)), using the [MYSQL\\_TIME](#) structure. The members of this structure are described in [Section 21.8.8, "C API Prepared Statement Data Structures"](#).

To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the `MYSQL_BIND` structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you're sending. For `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.
2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.
3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value to be passed.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_stmt_bind_result()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handle.

```

MYSQL_TIME  ts;
MYSQL_BIND  bind[3];
MYSQL_STMT  *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field, \
              timestamp_field) VALUES(?,?,?);");

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, "mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(mysql, query, strlen(query)))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
...
bind[1]= bind[2]= bind[0];
...

mysql_stmt_bind_param(stmt, bind);

/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;

mysql_stmt_execute(stmt);

```

## 21.8.19. C API Support for Prepared `CALL` Statements

This section describes prepared-statement support in the C API for stored procedures executed using `CALL` statements:

In MySQL 5.6, stored procedures executed using prepared `CALL` statements can be used in the following ways:

- A stored procedure can produce any number of result sets. The number of columns and the data types of the columns need not be the same for all result sets.
- The final values of `OUT` and `INOUT` parameters are available to the calling application after the procedure returns. These parameters are returned as an extra single-row result set following any result sets produced by the procedure itself. The row contains the values of the `OUT` and `INOUT` parameters in the order in which they are declared in the procedure parameter list.

The following discussion shows how to use these capabilities through the C API for prepared statements. To use prepared `CALL` statements through the `PREPARE` and `EXECUTE` statements, see [Section 13.2.1, “CALL Syntax”](#).

If an application might be compiled or executed in a context where a version of MySQL older than 5.5.3 is used, prepared `CALL` capabilities for multiple result sets and `OUT` or `INOUT` parameters might not be available:

- For the client side, the application will not compile unless the libraries are from MySQL 5.5.3 or higher (the API function and symbols introduced in that version will not be present).
- To verify at runtime that the server is recent enough, a client can use this test:

```
if (mysql_get_server_version(mysql) < 50503)
{
    fprintf(stderr,
           "Server does not support required CALL capabilities\n");
    mysql_close(mysql);
    exit (1);
}
```

An application that executes a prepared `CALL` statement should use a loop that fetches a result and then invokes `mysql_stmt_next_result()` to determine whether there are more results. The results consist of any result sets produced by the stored procedure followed by a final status value that indicates whether the procedure terminated successfully.

If the procedure has `OUT` or `INOUT` parameters, the result set preceding the final status value contains their values. To determine whether a result set contains parameter values, test whether the `SERVER_PS_OUT_PARAMS` bit is set in the `server_status` member of the `MYSQL` connection handler:

```
mysql->server_status & SERVER_PS_OUT_PARAMS
```

The following example uses a prepared `CALL` statement to execute a stored procedure that produces multiple result sets and that provides parameter values back to the caller by means of `OUT` and `INOUT` parameters. The procedure takes parameters of all three types (`IN`, `OUT`, `INOUT`), displays their initial values, assigns new values, displays the updated values, and returns. The expected return information from the procedure therefore consists of multiple result sets and a final status:

- One result set from a `SELECT` that displays the initial parameter values: `10`, `NULL`, `30`. (The `OUT` parameter is assigned a value by the caller, but this assignment is expected to be ineffective: `OUT` parameters are seen as `NULL` within a procedure until assigned a value within the procedure.)
- One result set from a `SELECT` that displays the modified parameter values: `100`, `200`, `300`.
- One result set containing the final `OUT` and `INOUT` parameter values: `200`, `300`.

- A final status packet.

The code to execute the procedure:

```

MYSQL_STMT *stmt;
MYSQL_BIND ps_params[3]; /* input parameter buffers */
int         int_data[3]; /* input/output values */
my_bool     is_null[3]; /* output value nullability */
int         status;

/* set up stored procedure */
status = mysql_query(mysql, "DROP PROCEDURE IF EXISTS p1");
test_error(mysql, status);

status = mysql_query(mysql,
    "CREATE PROCEDURE p1("
    "  IN p_in INT, "
    "  OUT p_out INT, "
    "  INOUT p_inout INT) "
    "BEGIN "
    "  SELECT p_in, p_out, p_inout; "
    "  SET p_in = 100, p_out = 200, p_inout = 300; "
    "  SELECT p_in, p_out, p_inout; "
    "END");
test_error(mysql, status);

/* initialize and prepare CALL statement with parameter placeholders */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    printf("Could not initialize statement\n");
    exit(1);
}
status = mysql_stmt_prepare(stmt, "CALL p1(?, ?, ?)", 16);
test_stmt_error(stmt, status);

/* initialize parameters: p_in, p_out, p_inout (all INT) */
memset(ps_params, 0, sizeof (ps_params));

ps_params[0].buffer_type = MYSQL_TYPE_LONG;
ps_params[0].buffer = (char *) &int_data[0];
ps_params[0].length = 0;
ps_params[0].is_null = 0;

ps_params[1].buffer_type = MYSQL_TYPE_LONG;
ps_params[1].buffer = (char *) &int_data[1];
ps_params[1].length = 0;
ps_params[1].is_null = 0;

ps_params[2].buffer_type = MYSQL_TYPE_LONG;
ps_params[2].buffer = (char *) &int_data[2];
ps_params[2].length = 0;
ps_params[2].is_null = 0;

/* bind parameters */
status = mysql_stmt_bind_param(stmt, ps_params);
test_stmt_error(stmt, status);

/* assign values to parameters and execute statement */
int_data[0] = 10; /* p_in */
int_data[1] = 20; /* p_out */
int_data[2] = 30; /* p_inout */

status = mysql_stmt_execute(stmt);
test_stmt_error(stmt, status);

/* process results until there are no more */
do {
    int i;
    int num_fields; /* number of columns in result */
    MYSQL_FIELD *fields; /* for result set metadata */
    MYSQL_BIND *rs_bind; /* for output buffers */

```

```
/* the column count is > 0 if there is a result set */
/* 0 if the result is only the final status packet */
num_fields = mysql_stmt_field_count(stmt);

if (num_fields > 0)
{
    /* there is a result set to fetch */
    printf("Number of columns in result: %d\n", (int) num_fields);

    /* what kind of result set is this? */
    printf("Data: ");
    if(mysql->server_status & SERVER_PS_OUT_PARAMS)
        printf("this result set contains OUT/INOUT parameters\n");
    else
        printf("this result set is produced by the procedure\n");

    MYSQL_RES *rs_metadata = mysql_stmt_result_metadata(stmt);
    test_stmt_error(stmt, rs_metadata == NULL);

    fields = mysql_fetch_fields(rs_metadata);

    rs_bind = (MYSQL_BIND *) malloc(sizeof (MYSQL_BIND) * num_fields);
    if (!rs_bind)
    {
        printf("Cannot allocate output buffers\n");
        exit(1);
    }
    memset(rs_bind, 0, sizeof (MYSQL_BIND) * num_fields);

    /* set up and bind result set output buffers */
    for (i = 0; i < num_fields; ++i)
    {
        rs_bind[i].buffer_type = fields[i].type;
        rs_bind[i].is_null = &is_null[i];

        switch (fields[i].type)
        {
            case MYSQL_TYPE_LONG:
                rs_bind[i].buffer = (char *) &(int_data[i]);
                rs_bind[i].buffer_length = sizeof (int_data);
                break;

            default:
                fprintf(stderr, "ERROR: unexpected type: %d.\n", fields[i].type);
                exit(1);
        }
    }
}

status = mysql_stmt_bind_result(stmt, rs_bind);
test_stmt_error(stmt, status);

/* fetch and display result set rows */
while (1)
{
    status = mysql_stmt_fetch(stmt);

    if (status == 1 || status == MYSQL_NO_DATA)
        break;

    for (i = 0; i < num_fields; ++i)
    {
        switch (rs_bind[i].buffer_type)
        {
            case MYSQL_TYPE_LONG:
                if (*rs_bind[i].is_null)
                    printf(" val[%d] = NULL;", i);
                else
                    printf(" val[%d] = %ld;",
                        i, (long) *((int *) rs_bind[i].buffer));
                break;
        }
    }
}
```

```

        default:
            printf(" unexpected type (%d)\n",
                rs_bind[i].buffer_type);
        }
    }
    printf("\n");
}

mysql_free_result(rs_metadata); /* free metadata */
free(rs_bind);                /* free output buffers */
}
else
{
    /* no columns = final status packet */
    printf("End of procedure output\n");
}

/* more results? -1 = no, >0 = error, 0 = yes (keep looking) */
status = mysql_stmt_next_result(stmt);
if (status > 0)
    test_stmt_error(stmt, status);
} while (status == 0);

mysql_stmt_close(stmt);

```

Execution of the procedure should produce the following output:

```

Number of columns in result: 3
Data: this result set is produced by the procedure
val[0] = 10; val[1] = NULL; val[2] = 30;
Number of columns in result: 3
Data: this result set is produced by the procedure
val[0] = 100; val[1] = 200; val[2] = 300;
Number of columns in result: 2
Data: this result set contains OUT/INOUT parameters
val[0] = 200; val[1] = 300;
End of procedure output

```

The code uses two utility routines, `test_error()` and `test_stmt_error()`, to check for errors and terminate after printing diagnostic information if an error occurred:

```

static void test_error(MYSQL *mysql, int status)
{
    if (status)
    {
        fprintf(stderr, "Error: %s (errno: %d)\n",
            mysql_error(mysql), mysql_errno(mysql));
        exit(1);
    }
}

static void test_stmt_error(MYSQL_STMT *stmt, int status)
{
    if (status)
    {
        fprintf(stderr, "Error: %s (errno: %d)\n",
            mysql_stmt_error(stmt), mysql_stmt_errno(stmt));
        exit(1);
    }
}

```

## 21.9. MySQL PHP API

PHP is a server-side, HTML-embedded scripting language that may be used to create dynamic Web pages. It is available for most operating systems and Web servers, and can access most common databases, including MySQL. PHP may be run as a separate program or compiled as a module for use with a Web server.

PHP provides three different MySQL API extensions:

- [Section 21.9.3, “MySQL Improved Extension \(`Mysqli`\)”](#): Stands for “MySQL, Improved”; this extension is available as of PHP 5.0.0. It is intended for use with MySQL 4.1.1 and later. This extension fully supports the authentication protocol used in MySQL 5.0, as well as the Prepared Statements and Multiple Statements APIs. In addition, this extension provides an advanced, object-oriented programming interface.
- [Section 21.9.4, “MySQL Functions \(`PDO\_MYSQL`\) \(`MySQL \(PDO\)`\)”](#): Not its own API, but instead it's a MySQL driver for the PHP database abstraction layer PDO (PHP Data Objects). The PDO MySQL driver sits in the layer below PDO itself, and provides MySQL-specific functionality. This extension is available as of PHP 5.1.0.
- [Section 21.9.2, “Original MySQL API \(`Mysql`\)”](#): Available for PHP versions 4 and 5, this extension is intended for use with MySQL versions prior to MySQL 4.1. This extension does not support the improved authentication protocol used in MySQL 4.1, nor does it support prepared statements or multiple statements. To use this extension with MySQL 4.1, you will likely configure the MySQL server to set the `old_passwords` [517] system variable to 1 (see [Section C.5.2.4, “Client does not support authentication protocol”](#)).

This extension is deprecated as of PHP 5.5.0, and its use is highly discouraged. All users are encouraged to migrate to either `mysqli` or `PDO_MYSQL`. For further information, see [Section 21.9.1.3, “Choosing an API”](#).

The PHP distribution and documentation are available from the [PHP Web site](#).

## 21.9.1. Overview of the MySQL PHP drivers

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

### 21.9.1.1. Introduction

There are three PHP APIs for accessing the MySQL database. This guide explains the [terminology](#) used to describe each API, information about [choosing which API](#) to use, and also information to help choose which MySQL [library to use](#) with the API.

### 21.9.1.2. Terminology overview

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

This section provides an introduction to the options available to you when developing a PHP application that needs to interact with a MySQL database.

*What is an API?*

An Application Programming Interface, or API, defines the classes, methods, functions and variables that your application will need to call in order to carry out its desired task. In the case of PHP applications that need to communicate with databases the necessary APIs are usually exposed via PHP extensions.

APIs can be procedural or object-oriented. With a procedural API you call functions to carry out tasks, with the object-oriented API you instantiate classes and then call methods on the resulting objects. Of the two the latter is usually the preferred interface, as it is more modern and leads to better organized code.

When writing PHP applications that need to connect to the MySQL server there are several API options available. This document discusses what is available and how to select the best solution for your application.

### *What is a Connector?*

In the MySQL documentation, the term *connector* refers to a piece of software that allows your application to connect to the MySQL database server. MySQL provides connectors for a variety of languages, including PHP.

If your PHP application needs to communicate with a database server you will need to write PHP code to perform such activities as connecting to the database server, querying the database and other database-related functions. Software is required to provide the API that your PHP application will use, and also handle the communication between your application and the database server, possibly using other intermediate libraries where necessary. This software is known generically as a connector, as it allows your application to *connect* to a database server.

### *What is a Driver?*

A driver is a piece of software designed to communicate with a specific type of database server. The driver may also call a library, such as the MySQL Client Library or the MySQL Native Driver. These libraries implement the low-level protocol used to communicate with the MySQL database server.

By way of an example, the [PHP Data Objects \(PDO\) \[2985\]](#) database abstraction layer may use one of several database-specific drivers. One of the drivers it has available is the PDO MySQL driver, which allows it to interface with the MySQL server.

Sometimes people use the terms connector and driver interchangeably, this can be confusing. In the MySQL-related documentation the term “driver” is reserved for software that provides the database-specific part of a connector package.

### *What is an Extension?*

In the PHP documentation you will come across another term - *extension*. The PHP code consists of a core, with optional extensions to the core functionality. PHP's MySQL-related extensions, such as the [mysqli](#) extension, and the [mysql](#) extension, are implemented using the PHP extension framework.

An extension typically exposes an API to the PHP programmer, to allow its facilities to be used programmatically. However, some extensions which use the PHP extension framework do not expose an API to the PHP programmer.

The PDO MySQL driver extension, for example, does not expose an API to the PHP programmer, but provides an interface to the PDO layer above it.

The terms API and extension should not be taken to mean the same thing, as an extension may not necessarily expose an API to the programmer.

## 21.9.1.3. Choosing an API

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

PHP offers three different APIs to connect to MySQL. Below we show the APIs provided by the `mysql`, `mysqli`, and `PDO` extensions. Each code snippet creates a connection to a MySQL server running on "example.com" using the username "user" and the password "password". And a query is run to greet the user.

### **Example 21.13. Comparing the three MySQL APIs**

```
<?php
// mysqli
$mysqli = new mysqli("example.com", "user", "password", "database");
$result = $mysqli->query("SELECT 'Hello, dear MySQL user!' AS _message FROM DUAL");
$row = $result->fetch_assoc();
echo htmlentities($row['_message']);
```

```
// PDO
$pdo = new PDO('mysql:host=example.com;dbname=database', 'user', 'password');
$stmt = $pdo->query("SELECT 'Hello, dear MySQL user!' AS _message FROM DUAL");
$row = $stmt->fetch(PDO::FETCH_ASSOC);
echo htmlentities($row['_message']);

// mysql
$c = mysql_connect("example.com", "user", "password");
mysql_select_db("database");
$result = mysql_query("SELECT 'Hello, dear MySQL user!' AS _message FROM DUAL");
$row = mysql_fetch_assoc($result);
echo htmlentities($row['_message']);
?>
```

### Recommended API

It is recommended to use either the [mysqli](#) or [PDO\\_MySQL](#) extensions. It is not recommended to use the old [mysql](#) extension for new development, as it has been deprecated as of PHP 5.5.0 and will be removed in the future. A detailed feature comparison matrix is provided below. The overall performance of all three extensions is considered to be about the same. Although the performance of the extension contributes only a fraction of the total run time of a PHP web request. Often, the impact is as low as 0.1%.

### Feature comparison

	<b>ext/mysqli</b>	<b>PDO_MySQL</b>	<b>ext/mysql</b>
PHP version introduced	5.0	5.1	2.0
Included with PHP 5.x	Yes	Yes	Yes
Development status	Active	Active	Maintenance only
Lifecycle	Active	Active	Deprecated
Recommended for new projects	Yes	Yes	No
OOP Interface	Yes	Yes	No
Procedural Interface	Yes	No	Yes
API supports non-blocking, asynchronous queries with mysqlnd	Yes	No	No
Persistent Connections	Yes	Yes	Yes
API supports Charsets	Yes	Yes	Yes
API supports server-side Prepared Statements	Yes	Yes	No
API supports client-side Prepared Statements	No	Yes	No
API supports Stored Procedures	Yes	Yes	No
API supports Multiple Statements	Yes	Most	No
API supports Transactions	Yes	Yes	No
Transactions can be controlled with SQL	Yes	Yes	Yes
Supports all MySQL 5.1+ functionality	Yes	Most	No

### 21.9.1.4. Choosing a library

Copyright 1997-2012 the PHP Documentation Group. [2906]

The `mysqli`, `PDO_MySQL` and `mysql` PHP extensions are lightweight wrappers on top of a C client library. The extensions can either use the `mysqlnd` library or the `libmysqlclient` library. Choosing a library is a compile time decision.

The `mysqlnd` library is part of the PHP distribution since 5.3.0. It offers features like lazy connections and query caching, features that are not available with `libmysqlclient`, so using the built-in `mysqlnd` library is highly recommended. See the [mysqlnd documentation](#) for additional details, and a listing of features and functionality that it offers.

#### Example 21.14. Configure commands for using `mysqlnd` or `libmysqlclient`

```
// Recommended, compiles with mysqlnd
$ ./configure --with-mysqli=mysqlnd --with-pdo-mysql=mysqlnd --with-mysql=mysqlnd

// Not recommended, compiles with libmysqlclient
$ ./configure --with-mysqli=/path/to/mysql_config --with-pdo-mysql=/path/to/mysql_config --with-mysql=
```

#### Library feature comparison

It is recommended to use the `mysqlnd` library instead of the MySQL Client Server library (`libmysqlclient`). Both libraries are supported and constantly being improved.

	MySQL native driver ( <code>mysqlnd</code> )	MySQL client server library ( <code>libmysqlclient</code> )
Part of the PHP distribution	Yes	No
PHP version introduced	5.3.0	N/A
License	PHP License 3.01	Dual-License
Development status	Active	Active
Lifecycle	No end announced	No end announced
PHP 5.4 compile default (for all MySQL extensions)	Yes	No
PHP 5.3 compile default (for all MySQL extensions)	No	Yes
Compression protocol support	Yes (5.3.1+)	Yes
SSL support	Yes (5.3.3+)	Yes
Named pipe support	Yes (5.3.4+)	Yes
Non-blocking, asynchronous queries	Yes	No
Performance statistics	Yes	No
LOAD LOCAL INFILE respects the <a href="#">open_basedir directive</a>	Yes	No
Uses PHP's native memory management system (e.g., follows PHP memory limits)	Yes	No
Return numeric column as double (COM_QUERY)	Yes	No
Return numeric column as string (COM_QUERY)	Yes	Yes

	MySQL native driver ( <a href="#">mysqlnd</a> )	MySQL client server library ( <a href="#">libmysqlclient</a> )
Plugin API	Yes	Limited
Read/Write splitting for MySQL Replication	Yes, with plugin	No
Load Balancing	Yes, with plugin	No
Fail over	Yes, with plugin	No
Lazy connections	Yes, with plugin	No
Query caching	Yes, with plugin	No
Transparent query manipulations (E.g., auto-EXPLAIN or monitoring)	Yes, with plugin	No

### 21.9.1.5. Concepts

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

These concepts are specific to the MySQL drivers for PHP.

#### 21.9.1.5.1. Buffered and Unbuffered queries

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

Queries are using the buffered mode by default. This means that query results are immediately transferred from the MySQL Server to PHP in is then kept in the memory of the PHP process. This allows additional operations like counting the number of rows, and moving (seeking) the current result pointer. It also allows issuing further queries on the same connection while working on the result set. The downside of the buffered mode is that larger result sets might require quite a lot memory. The memory will be kept occupied till all references to the result set are unset or the result set was explicitly freed, which will automatically happen during request end the latest. The terminology "store result" is also used for buffered mode, as the whole result set is stored at once.

#### Note

When using `libmysqlclient` as library PHP's memory limit won't count the memory used for result sets unless the data is fetched into PHP variables. With `mysqlnd` the memory accounted for will include the full result set.

Unbuffered MySQL queries execute the query and then return a resource while the data is still waiting on the MySQL server for being fetched. This uses less memory on the PHP-side, but can increase the load on the server. Unless the full result set was fetched from the server no further queries can be sent over the same connection. Unbuffered queries can also be referred to as "use result".

Following these characteristics buffered queries should be used in cases where you expect only a limited result set or need to know the amount of returned rows before reading all rows. Unbuffered mode should be used when you expect larger results.

Because buffered queries are the default, the examples below will demonstrate how to execute unbuffered queries with each API.

#### Example 21.15. Unbuffered query example: `mysqli`

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");
$result = $mysqli->query("SELECT Name FROM City", MYSQLI_USE_RESULT);

if ($result) {
    while ($row = $result->fetch_assoc()) {
```

```

        echo $row['Name'] . PHP_EOL;
    }
}
$uresult->close();
?>

```

**Example 21.16. Unbuffered query example: pdo\_mysql**

```

<?php
$pdo = new PDO("mysql:host=localhost;dbname=world", 'my_user', 'my_pass');
$pdo->setAttribute(PDO::MYSQL_ATTR_USE_BUFFERED_QUERY, false);

$uresult = $pdo->query("SELECT Name FROM City");
if ($uresult) {
    while ($row = $uresult->fetch(PDO::FETCH_ASSOC)) {
        echo $row['Name'] . PHP_EOL;
    }
}
?>

```

**Example 21.17. Unbuffered query example: mysql**

```

<?php
$conn = mysql_connect("localhost", "my_user", "my_pass");
$db    = mysql_select_db("world");

$uresult = mysql_unbuffered_query("SELECT Name FROM City");
if ($uresult) {
    while ($row = mysql_fetch_assoc($uresult)) {
        echo $row['Name'] . PHP_EOL;
    }
}
?>

```

**21.9.1.5.2. Character sets**

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

Ideally a proper character set will be set at the server level, and doing this is described within the [Character Set Configuration](#) section of the MySQL Server manual. Alternatively, each MySQL API offers a method to set the character set at runtime.

**The character set and character escaping**

The character set should be understood and defined, as it has an affect on every action, and includes security implications. For example, the escaping mechanism (e.g., [mysqli\\_real\\_escape\\_string](#) for mysqli, [mysql\\_real\\_escape\\_string](#) for mysql, and [PDO::quote](#) for PDO\_MySQL) will adhere to this setting. It is important to realize that these functions will not use the character set that is defined with a query, so for example the following will not have an effect on them:

**Example 21.18. Problems with setting the character set with SQL**

```

<?php

$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

// Will not affect $mysqli->real_escape_string();
$mysqli->query("SET NAMES utf8");

```

```
// Will not affect $mysqli->real_escape_string();
$mysqli->query("SET CHARACTER SET utf8");

// But, this will affect $mysqli->real_escape_string();
$mysqli->set_charset('utf8');

?>
```

Below are examples that demonstrate how to properly alter the character set at runtime using each API.

### Example 21.19. Setting the character set example: [mysqli](#)

```
<?php

$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

if (!$mysqli->set_charset('utf8')) {
    printf("Error loading character set utf8: %s\n", $mysqli->error);
} else {
    printf("Current character set: %s\n", $mysqli->character_set_name());
}

print_r( $mysqli->get_charset() );

?>
```

### Example 21.20. Setting the character set example: [pdo\\_mysql](#)

Note: This only works as of PHP 5.3.6.

```
<?php
$pdo = new PDO("mysql:host=localhost;dbname=world;charset=utf8", 'my_user', 'my_pass');
?>
```

### Example 21.21. Setting the character set example: [mysql](#)

```
<?php

$conn = mysql_connect("localhost", "my_user", "my_pass");
$db   = mysql_select_db("world");

if (!mysql_set_charset('utf8', $conn)) {
    echo "Error: Unable to set the character set.\n";
    exit;
}

echo 'Your current character set is: ' . mysql_client_encoding($conn);

?>
```

## 21.9.2. Original MySQL API ([Mysql](#))

Copyright 1997-2012 the PHP Documentation Group. [2906]

This extension is deprecated as of PHP 5.5.0, and is not recommended for writing new code as it will be removed in the future. Instead, either the [mysqli](#) or [PDO\\_MySQL](#) extension should be used. See also the [MySQL API Overview](#) for further help while choosing a MySQL API.

These functions allow you to access MySQL database servers. More information about MySQL can be found at <http://www.mysql.com/>.

Documentation for MySQL can be found at <http://dev.mysql.com/doc/>.

### 21.9.2.1. Installing/Configuring

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### 21.9.2.1.1. Requirements

Copyright 1997-2012 the PHP Documentation Group. [2906]

In order to have these functions available, you must compile PHP with MySQL support.

#### 21.9.2.1.2. Installation

Copyright 1997-2012 the PHP Documentation Group. [2906]

For compiling, simply use the `--with-mysql[=DIR]` configuration option where the optional `[DIR]` points to the MySQL installation directory.

Although this MySQL extension is compatible with MySQL 4.1.0 and greater, it doesn't support the extra functionality that these versions provide. For that, use the [MySQLi](#) extension.

If you would like to install the `mysql` extension along with the `mysqli` extension you have to use the same client library to avoid any conflicts.

##### 21.9.2.1.2.1. Installation on Linux Systems

Copyright 1997-2012 the PHP Documentation Group. [2906]

Note: `[DIR]` is the path to the MySQL client library files (*headers and libraries*), which can be downloaded from MySQL.

**Table 21.34. ext/mysql compile time support matrix**

PHP Version	Default	Configure Options: <a href="#">mysqlnd</a>	Configure Options: <a href="#">libmysqlclient</a>	Changelog
4.x.x	<code>libmysqlclient</code>	Not Available	<code>--without-mysql</code> to disable	MySQL enabled by default, MySQL client libraries are bundled
5.0.x, 5.1.x, 5.2.x	<code>libmysqlclient</code>	Not Available	<code>--with-mysql=[DIR]</code>	MySQL is no longer enabled by default, and the MySQL client libraries are <b>no longer bundled</b>
5.3.x	<code>libmysqlclient</code>	<code>--with-mysql=mysqlnd</code>	<code>--with-mysql=[DIR]</code>	<code>mysqlnd</code> is now available
5.4.x	<code>mysqlnd</code>	<code>--with-mysql</code>	<code>--with-mysql=[DIR]</code>	<code>mysqlnd</code> is now the default

##### 21.9.2.1.2.2. Installation on Windows Systems

Copyright 1997-2012 the PHP Documentation Group. [2906]

## 21.9.2.1.2.2.1. PHP 4

Copyright 1997-2012 the PHP Documentation Group. [2906]

The PHP MySQL extension is compiled into PHP.

## 21.9.2.1.2.2.2. PHP 5.0.x, 5.1.x, 5.2.x

Copyright 1997-2012 the PHP Documentation Group. [2906]

MySQL is no longer enabled by default, so the `php_mysql.dll` DLL must be enabled inside of `php.ini`. Also, PHP needs access to the MySQL client library. A file named `libmysql.dll` is included in the Windows PHP distribution and in order for PHP to talk to MySQL this file needs to be available to the Windows systems `PATH`. See the FAQ titled "How do I add my PHP directory to the `PATH` on Windows" for information on how to do this. Although copying `libmysql.dll` to the Windows system directory also works (because the system directory is by default in the system's `PATH`), it's not recommended.

As with enabling any PHP extension (such as `php_mysql.dll`), the PHP directive `extension_dir` should be set to the directory where the PHP extensions are located. See also the [Manual Windows Installation Instructions](#). An example `extension_dir` value for PHP 5 is `c:\php\ext`

**Note**

If when starting the web server an error similar to the following occurs: "Unable to load dynamic library './php\_mysql.dll'", this is because `php_mysql.dll` and/or `libmysql.dll` cannot be found by the system.

## 21.9.2.1.2.2.3. PHP 5.3.0+

Copyright 1997-2012 the PHP Documentation Group. [2906]

The [MySQL Native Driver](#) is enabled by default. Include `php_mysql.dll`, but `libmysql.dll` is no longer required or used.

## 21.9.2.1.2.3. MySQL Installation Notes

Copyright 1997-2012 the PHP Documentation Group. [2906]

**Warning**

Crashes and startup problems of PHP may be encountered when loading this extension in conjunction with the `recode` extension. See the [recode](#) extension for more information.

**Note**

If you need charsets other than *latin* (default), you have to install external (not bundled) `libmysqlclient` with compiled charset support.

## 21.9.2.1.3. Runtime Configuration

Copyright 1997-2012 the PHP Documentation Group. [2906]

The behaviour of these functions is affected by settings in `php.ini`.

**Table 21.35. MySQL Configuration Options**

Name	Default	Changeable	Changelog
<a href="#">mysql.allow_local_infile</a>	"1"	PHP_INI_SYSTEM	
<a href="#">mysql.allow_persistent</a>	"1"	PHP_INI_SYSTEM	
<a href="#">mysql.max_persistent</a>	"-1"	PHP_INI_SYSTEM	

Name	Default	Changeable	Changelog
<a href="#">mysql.max_links</a>	"-1"	PHP_INI_SYSTEM	
<a href="#">mysql.trace_mode</a>	"0"	PHP_INI_ALL	Available since PHP 4.3.0.
<a href="#">mysql.default_port</a>	NULL	PHP_INI_ALL	
<a href="#">mysql.default_socket</a>	NULL	PHP_INI_ALL	Available since PHP 4.0.1.
<a href="#">mysql.default_host</a>	NULL	PHP_INI_ALL	
<a href="#">mysql.default_user</a>	NULL	PHP_INI_ALL	
<a href="#">mysql.default_password</a>	NULL	PHP_INI_ALL	
<a href="#">mysql.connect_timeout</a>	"60"	PHP_INI_ALL	PHP_INI_SYSTEM in PHP <= 4.3.2. Available since PHP 4.3.0.

For further details and definitions of the PHP\_INI\_\* modes, see the <http://www.php.net/manual/en/configuration.changes.modes>.

Here's a short explanation of the configuration directives.

<a href="#">mysql.allow_local_infile</a> integer	Allow accessing, from PHP's perspective, local files with LOAD DATA statements
<a href="#">mysql.allow_persistent</a> boolean	Whether to allow <a href="#">persistent connections</a> to MySQL.
<a href="#">mysql.max_persistent</a> integer	The maximum number of persistent MySQL connections per process.
<a href="#">mysql.max_links</a> integer	The maximum number of MySQL connections per process, including persistent connections.
<a href="#">mysql.trace_mode</a> boolean	Trace mode. When <a href="#">mysql.trace_mode</a> is enabled, warnings for table/index scans, non free result sets, and SQL-Errors will be displayed. (Introduced in PHP 4.3.0)
<a href="#">mysql.default_port</a> string	The default TCP port number to use when connecting to the database server if no other port is specified. If no default is specified, the port will be obtained from the <code>MYSQL_TCP_PORT</code> environment variable, the <code>mysql-tcp</code> entry in <code>/etc/services</code> or the compile-time <code>MYSQL_PORT</code> constant, in that order. Win32 will only use the <code>MYSQL_PORT</code> constant.
<a href="#">mysql.default_socket</a> string	The default socket name to use when connecting to a local database server if no other socket name is specified.
<a href="#">mysql.default_host</a> string	The default server host to use when connecting to the database server if no other host is specified. Doesn't apply in <a href="#">SQL safe mode</a> .
<a href="#">mysql.default_user</a> string	The default user name to use when connecting to the database server if no other name is specified. Doesn't apply in <a href="#">SQL safe mode</a> .
<a href="#">mysql.default_password</a> string	The default password to use when connecting to the database server if no other password is specified. Doesn't apply in <a href="#">SQL safe mode</a> .
<a href="#">mysql.connect_timeout</a> integer	Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.

#### 21.9.2.1.4. Resource Types

Copyright 1997-2012 the PHP Documentation Group. [2906]

There are two resource types used in the MySQL module. The first one is the link identifier for a database connection, the second a resource which holds the result of a query.

#### 21.9.2.2. Changelog

Copyright 1997-2012 the PHP Documentation Group. [2906]

The following changes have been made to classes/functions/methods of this extension.

##### General Changelog for the `ext/mysql` extension

This changelog references the `ext/mysql` extension.

##### Changes to existing functions

The following list is a compilation of changelog entries from the `ext/mysql` functions.

##### Global `ext/mysql` changes

The following is a list of changes to the entire `ext/mysql` extension.

Version	Description
5.5.0	This extension has been deprecated. Connecting to a MySQL database via <code>mysql_connect</code> , <code>mysql_pconnect</code> or an implicit connection via any other <code>mysql_*</code> function will generate an <code>E_DEPRECATED</code> error.
5.5.0	All of the old deprecated functions and aliases now emit <code>E_DEPRECATED</code> errors. These functions are:  <code>mysql()</code> , <code>mysql_fieldname()</code> , <code>mysql_fieldtable()</code> , <code>mysql_fieldlen()</code> , <code>mysql_fieldtype()</code> , <code>mysql_fieldflags()</code> , <code>mysql_selectdb()</code> , <code>mysql_createdb()</code> , <code>mysql_dropdb()</code> , <code>mysql_freeresult()</code> , <code>mysql_numfields()</code> , <code>mysql_numrows()</code> , <code>mysql_listdbs()</code> , <code>mysql_listtables()</code> , <code>mysql_listfields()</code> , <code>mysql_db_name()</code> , <code>mysql_dbname()</code> , <code>mysql_tablename()</code> , and <code>mysql_table_name()</code> .

#### 21.9.2.3. Predefined Constants

Copyright 1997-2012 the PHP Documentation Group. [2906]

The constants below are defined by this extension, and will only be available when the extension has either been compiled into PHP or dynamically loaded at runtime.

Since PHP 4.3.0 it is possible to specify additional client flags for the `mysql_connect` and `mysql_pconnect` functions. The following constants are defined:

**Table 21.36. MySQL client constants**

Constant	Description
<code>MYSQL_CLIENT_COMPRESS</code>	Use compression protocol
<code>MYSQL_CLIENT_IGNORE_SPACE</code>	Allow space after function names

Constant	Description
<code>MYSQL_CLIENT_INTERACTIVE</code>	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> ) of inactivity before closing the connection.
<code>MYSQL_CLIENT_SSL</code>	Use SSL encryption. This flag is only available with version 4.x of the MySQL client library or newer. Version 3.23.x is bundled both with PHP 4 and Windows binaries of PHP 5.

The function `mysql_fetch_array` uses a constant for the different types of result arrays. The following constants are defined:

**Table 21.37. MySQL fetch constants**

Constant	Description
<code>MYSQL_ASSOC</code>	Columns are returned into the array having the fieldname as the array index.
<code>MYSQL_BOTH</code>	Columns are returned into the array having both a numerical index and the fieldname as the array index.
<code>MYSQL_NUM</code>	Columns are returned into the array having a numerical index to the fields. This index starts with 0, the first field in the result.

## 21.9.2.4. Examples

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

### 21.9.2.4.1. MySQL extension overview example

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

This simple example shows how to connect, execute a query, print resulting rows and disconnect from a MySQL database.

#### Example 21.22. MySQL extension overview example

```
<?php
// Connecting, selecting database
$link = mysql_connect('mysql_host', 'mysql_user', 'mysql_password')
    or die('Could not connect: ' . mysql_error());
echo 'Connected successfully';
mysql_select_db('my_database') or die('Could not select database');

// Performing SQL query
$query = 'SELECT * FROM my_table';
$result = mysql_query($query) or die('Query failed: ' . mysql_error());

// Printing results in HTML
echo "<table>\n";
while ($line = mysql_fetch_array($result, MYSQL_ASSOC)) {
    echo "\t<tr>\n";
    foreach ($line as $col_value) {
        echo "\t\t<td>$col_value</td>\n";
    }
    echo "\t</tr>\n";
}
echo "</table>\n";

// Free resultset
mysql_free_result($result);
```

```
// Closing connection
mysql_close($link);
?>
```

## 21.9.2.5. MySQL Functions

Copyright 1997-2012 the PHP Documentation Group. [2906]

### Note

Most MySQL functions accept *link\_identifier* as the last optional parameter. If it is not provided, last opened connection is used. If it doesn't exist, connection is tried to establish with default parameters defined in `php.ini`. If it is not successful, functions return `FALSE`.

### 21.9.2.5.1. `mysql_affected_rows`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_affected_rows`

Get number of affected rows in previous MySQL operation

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_affected_rows
PDOStatement::rowCount
```

### Description

```
int mysql_affected_rows(
    resource link_identifier
    = =NULL);
```

Get the number of affected rows by the last INSERT, UPDATE, REPLACE or DELETE query associated with *link\_identifier*.

### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns the number of affected rows on success, and -1 if the last query failed.

If the last query was a DELETE query with no WHERE clause, all of the records will have been deleted from the table but this function will return zero with MySQL versions prior to 4.1.2.

When using UPDATE, MySQL will not update columns where the new value is the same as the old value. This creates the possibility that `mysql_affected_rows` may not actually equal the number of rows matched, only the number of rows that were literally affected by the query.

The REPLACE statement first deletes the record with the same primary key and then inserts the new record. This function returns the number of deleted records plus the number of inserted records.

In the case of "INSERT ... ON DUPLICATE KEY UPDATE" queries, the return value will be [1](#) if an insert was performed, or [2](#) for an update of an existing row.

## Examples

### Example 21.23. [mysql\\_affected\\_rows](#) example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
mysql_select_db('mydb');

/* this should return the correct numbers of deleted records */
mysql_query('DELETE FROM mytable WHERE id < 10');
printf("Records deleted: %d\n", mysql_affected_rows());

/* with a where clause that is never true, it should return 0 */
mysql_query('DELETE FROM mytable WHERE 0');
printf("Records deleted: %d\n", mysql_affected_rows());
?>
```

The above example will output something similar to:

```
Records deleted: 10
Records deleted: 0
```

### Example 21.24. [mysql\\_affected\\_rows](#) example using transactions

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
mysql_select_db('mydb');

/* Update records */
mysql_query("UPDATE mytable SET used=1 WHERE id < 10");
printf ("Updated records: %d\n", mysql_affected_rows());
mysql_query("COMMIT");
?>
```

The above example will output something similar to:

```
Updated Records: 10
```

## Notes

### Transactions

If you are using transactions, you need to call [mysql\\_affected\\_rows](#) after your INSERT, UPDATE, or DELETE query, not after the COMMIT.

**SELECT Statements**

To retrieve the number of rows returned by a SELECT, it is possible to use `mysql_num_rows`.

**Cascaded Foreign Keys**

`mysql_affected_rows` does not count rows affected implicitly through the use of ON DELETE CASCADE and/or ON UPDATE CASCADE in foreign key constraints.

**See Also**

`mysql_num_rows`  
`mysql_info`

**21.9.2.5.2. `mysql_client_encoding`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_client_encoding`

Returns the name of the character set

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_character_set_name`

**Description**

```
string mysql_client_encoding(
    resource link_identifier
    = =NULL);
```

Retrieves the `character_set` variable from MySQL.

**Parameters**

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

**Return Values**

Returns the default character set name for the current connection.

**Examples****Example 21.25. `mysql_client_encoding` example**

```
<?php
$link    = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$charset = mysql_client_encoding($link);

echo "The current character set is: $charset\n";
```

```
?>
```

The above example will output something similar to:

```
The current character set is: latin1
```

### See Also

[mysql\\_set\\_charset](#)  
[mysql\\_real\\_escape\\_string](#)

### 21.9.2.5.3. *mysql\_close*

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_close](#)

Close MySQL connection

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_close](#)  
 PDO: Assign the value of `NULL` to the PDO object

### Description

```
bool mysql_close(
    resource link_identifier
    = =NULL);
```

*mysql\_close* closes the non-persistent connection to the MySQL server that's associated with the specified link identifier. If *link\_identifier* isn't specified, the last opened link is used.

Using *mysql\_close* isn't usually necessary, as non-persistent open links are automatically closed at the end of the script's execution. See also [freeing resources](#).

### Parameters

*link\_identifier* The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no connection is found or established, an [E\\_WARNING](#) level error is generated.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 21.26. *mysql\_close* example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
```

```
die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);
?>
```

The above example will output:

```
Connected successfully
```

## Notes

### Note

`mysql_close` will not close persistent links created by `mysql_pconnect`.

## See Also

[mysql\\_connect](#)  
[mysql\\_free\\_result](#)

### 21.9.2.5.4. [mysql\\_connect](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_connect](#)

Open a connection to a MySQL Server

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_connect](#)  
[PDO::\\_\\_construct](#)

## Description

```
resource mysql_connect(
    string server
        = =ini_get("mysql.default_host"),
    string username
        = =ini_get("mysql.default_user"),
    string password
        = =ini_get("mysql.default_password"),
    bool new_link
        = =false,
    int client_flags
        = =0);
```

Opens or reuses a connection to a MySQL server.

## Parameters

*server*

The MySQL server. It can also include a port number. e.g. "hostname:port" or a path to a local socket e.g. ":/path/to/socket" for the localhost.

If the PHP directive `mysql.default_host` is undefined (default), then the default value is 'localhost:3306'. In [SQL safe mode](#), this parameter is ignored and value 'localhost:3306' is always used.

*username*

The username. Default value is defined by `mysql.default_user`. In [SQL safe mode](#), this parameter is ignored and the name of the user that owns the server process is used.

*password*

The password. Default value is defined by `mysql.default_password`. In [SQL safe mode](#), this parameter is ignored and empty password is used.

*new\_link*

If a second call is made to `mysql_connect` with the same arguments, no new link will be established, but instead, the link identifier of the already opened link will be returned. The *new\_link* parameter modifies this behavior and makes `mysql_connect` always open a new link, even if `mysql_connect` was called before with the same parameters. In [SQL safe mode](#), this parameter is ignored.

*client\_flags*

The *client\_flags* parameter can be a combination of the following constants: 128 (enable `LOAD DATA LOCAL` handling), `MYSQL_CLIENT_SSL`, `MYSQL_CLIENT_COMPRESS`, `MYSQL_CLIENT_IGNORE_SPACE` or `MYSQL_CLIENT_INTERACTIVE`. Read the section about [Table 21.36, “MySQL client constants”](#) for further information. In [SQL safe mode](#), this parameter is ignored.

## Return Values

Returns a MySQL link identifier on success or `FALSE` on failure.

## Changelog

Version	Description
5.5.0	This function will generate an <code>E_DEPRECATED</code> error.
4.3.0	Added the <i>client_flags</i> parameter.
4.2.0	Added the <i>new_link</i> parameter.

## Examples

### Example 21.27. `mysql_connect` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);
?>
```

### Example 21.28. `mysql_connect` example using `hostname:port` syntax

```
<?php
// we connect to example.com and port 3307
$link = mysql_connect('example.com:3307', 'mysql_user', 'mysql_password');
```

```

if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);

// we connect to localhost at port 3307
$link = mysql_connect('127.0.0.1:3307', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);
?>

```

### Example 21.29. `mysql_connect` example using `"/path/to/socket"` syntax

```

<?php
// we connect to localhost and socket e.g. /tmp/mysql.sock

// variant 1: omit localhost
$link = mysql_connect('/:tmp/mysql', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);

// variant 2: with localhost
$link = mysql_connect('localhost:/tmp/mysql.sock', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);
?>

```

### Notes

#### Note

Whenever you specify "localhost" or "localhost:port" as server, the MySQL client library will override this and try to connect to a local socket (named pipe on Windows). If you want to use TCP/IP, use "127.0.0.1" instead of "localhost". If the MySQL client library tries to connect to the wrong local socket, you should set the correct path as `mysql.default_host string` in your PHP configuration and leave the server field blank.

#### Note

The link to the server will be closed as soon as the execution of the script ends, unless it's closed earlier by explicitly calling `mysql_close`.

#### Note

You can suppress the error message on failure by prepending a `@` to the function name.

#### Note

Error "Can't create TCP/IP socket (10106)" usually means that the `variables_order` configure directive doesn't contain character `E`. On Windows, if

the environment is not copied the `SYSTEMROOT` environment variable won't be available and PHP will have problems loading Winsock.

### See Also

`mysql_pconnect`  
`mysql_close`

#### 21.9.2.5.5. `mysql_create_db`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_create_db`

Create a MySQL database

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_query`  
`PDO::query`

### Description

```
bool mysql_create_db(
    string database_name,
    resource link_identifier
    = =NULL);
```

`mysql_create_db` attempts to create a new database on the server associated with the specified link identifier.

### Parameters

*database\_name*

The name of the database being created.

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 21.30. `mysql_create_db` alternative example

The function `mysql_create_db` is deprecated. It is preferable to use `mysql_query` to issue an `sql CREATE DATABASE` statement instead.

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
```

```
$sql = 'CREATE DATABASE my_db';
if (mysql_query($sql, $link)) {
    echo "Database my_db created successfully\n";
} else {
    echo 'Error creating database: ' . mysql_error() . "\n";
}
?>
```

The above example will output something similar to:

```
Database my_db created successfully
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used:  
[mysql\\_createdb](#)

### Note

This function will not be available if the MySQL extension was built against a MySQL 4.x client library.

## See Also

[mysql\\_query](#)  
[mysql\\_select\\_db](#)

### 21.9.2.5.6. [mysql\\_data\\_seek](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_data\\_seek](#)

Move internal result pointer

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_data\\_seek](#)  
[PDO::FETCH\\_ORI\\_ABS](#)

## Description

```
bool mysql_data_seek(
    resource result,
    int row_number);
```

[mysql\\_data\\_seek](#) moves the internal row pointer of the MySQL result associated with the specified result identifier to point to the specified row number. The next call to a MySQL fetch function, such as [mysql\\_fetch\\_assoc](#), would return that row.

*row\_number* starts at 0. The *row\_number* should be a value in the range from 0 to [mysql\\_num\\_rows](#) - 1. However if the result set is empty ([mysql\\_num\\_rows](#) == 0), a seek to 0 will fail with a [E\\_WARNING](#) and [mysql\\_data\\_seek](#) will return [FALSE](#).

## Parameters

- result* The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).
- row\_number* The desired row number of the new result pointer.

## Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

## Examples

### Example 21.31. [mysql\\_data\\_seek](#) example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
$db_selected = mysql_select_db('sample_db');
if (!$db_selected) {
    die('Could not select database: ' . mysql_error());
}
$query = 'SELECT last_name, first_name FROM friends';
$result = mysql_query($query);
if (!$result) {
    die('Query failed: ' . mysql_error());
}
/* fetch rows in reverse order */
for ($i = mysql_num_rows($result) - 1; $i >= 0; $i--) {
    if (!mysql_data_seek($result, $i)) {
        echo "Cannot seek to row $i: " . mysql_error() . "\n";
        continue;
    }

    if (!$row = mysql_fetch_assoc($result)) {
        continue;
    }

    echo $row['last_name'] . ' ' . $row['first_name'] . "<br />\n";
}

mysql_free_result($result);
?>
```

## Notes

### Note

The function [mysql\\_data\\_seek](#) can be used in conjunction only with [mysql\\_query](#), not with [mysql\\_unbuffered\\_query](#).

## See Also

[mysql\\_query](#)  
[mysql\\_num\\_rows](#)  
[mysql\\_fetch\\_row](#)  
[mysql\\_fetch\\_assoc](#)  
[mysql\\_fetch\\_array](#)  
[mysql\\_fetch\\_object](#)

### 21.9.2.5.7. [mysql\\_db\\_name](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_db\\_name](#)

Retrieves database name from the call to [mysql\\_list\\_dbs](#)

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

Query: `SELECT DATABASE()`

### Description

```
string mysql_db_name(
    resource result,
    int row,
    mixed field
    = =NULL);
```

Retrieve the database name from a call to [mysql\\_list\\_dbs](#).

### Parameters

<i>result</i>	The result pointer from a call to <a href="#">mysql_list_dbs</a> .
<i>row</i>	The index into the result set.
<i>field</i>	The field name.

### Return Values

Returns the database name on success, and `FALSE` on failure. If `FALSE` is returned, use [mysql\\_error](#) to determine the nature of the error.

### Changelog

Version	Description
5.5.0	The <a href="#">mysql_list_dbs</a> function is deprecated, and emits an <code>E_DEPRECATED</code> level error.

### Examples

#### Example 21.32. [mysql\\_db\\_name](#) example

```
<?php
error_reporting(E_ALL);

$link = mysql_connect('dbhost', 'username', 'password');
$db_list = mysql_list_dbs($link);

$i = 0;
$cnt = mysql_num_rows($db_list);
while ($i < $cnt) {
    echo mysql_db_name($db_list, $i) . "\n";
    $i++;
}
?>
```

### Notes

**Note**

For backward compatibility, the following deprecated alias may be used:  
`mysql_dbname`

**See Also**

`mysql_list_dbs`  
`mysql_tablename`

**21.9.2.5.8. `mysql_db_query`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_db_query`

Selects a database and executes a query on it

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_select_db` then the query  
`PDO::__construct`

**Description**

```
resource mysql_db_query(
    string database,
    string query,
    resource link_identifier
    = =NULL);
```

`mysql_db_query` selects a database, and executes a query on it.

**Warning**

This function has been *DEPRECATED* as of PHP 5.3.0. Relying on this feature is highly discouraged.

**Parameters**

<code>database</code>	The name of the database that will be selected.
<code>query</code>	The MySQL query. Data inside the query should be <a href="#">properly escaped</a> .
<code>link_identifier</code>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If no connection is found or established, an <code>E_WARNING</code> level error is generated.

**Return Values**

Returns a positive MySQL result resource to the query result, or `FALSE` on error. The function also returns `TRUE` / `FALSE` for `INSERT/UPDATE/DELETE` queries to indicate success/failure.

**Changelog**

Version	Description
5.3.0	This function now throws an E_DEPRECATED notice.
4.0.6	This function is deprecated, do not use this function. Use <a href="#">mysql_select_db</a> and <a href="#">mysql_query</a> instead.

## Examples

### Example 21.33. [mysql\\_db\\_query](#) alternative example

```
<?php

if (!$link = mysql_connect('mysql_host', 'mysql_user', 'mysql_password')) {
    echo 'Could not connect to mysql';
    exit;
}

if (!mysql_select_db('mysql_dbname', $link)) {
    echo 'Could not select database';
    exit;
}

$sql      = 'SELECT foo FROM bar WHERE id = 42';
$result   = mysql_query($sql, $link);

if (!$result) {
    echo "DB Error, could not query the database\n";
    echo 'MySQL Error: ' . mysql_error();
    exit;
}

while ($row = mysql_fetch_assoc($result)) {
    echo $row['foo'];
}

mysql_free_result($result);

?>
```

## Notes

### Note

Be aware that this function does *NOT* switch back to the database you were connected to before. In other words, you can't use this function to *temporarily* run a sql query on another database, you would have to manually switch back. Users are strongly encouraged to use the [database.table](#) syntax in their sql queries or [mysql\\_select\\_db](#) instead of this function.

## See Also

[mysql\\_select\\_db](#)

### 21.9.2.5.9. [mysql\\_drop\\_db](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_drop\\_db](#)

Drop (delete) a MySQL database

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

Execute a `DROP DATABASE` query

**Description**

```
bool mysql_drop_db(
    string database_name,
    resource link_identifier
    = =NULL);
```

`mysql_drop_db` attempts to drop (remove) an entire database from the server associated with the specified link identifier. This function is deprecated, it is preferable to use `mysql_query` to issue an `sql DROP DATABASE` statement instead.

**Parameters**

*database\_name*

The name of the database that will be deleted.

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples****Example 21.34. `mysql_drop_db` alternative example**

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}

$sql = 'DROP DATABASE my_db';
if (mysql_query($sql, $link)) {
    echo "Database my_db was successfully dropped\n";
} else {
    echo 'Error dropping database: ' . mysql_error() . "\n";
}
?>
```

**Notes****Warning**

This function will not be available if the MySQL extension was built against a MySQL 4.x client library.

**Note**

For backward compatibility, the following deprecated alias may be used:  
`mysql_dropdb`

**See Also**[mysql\\_query](#)**21.9.2.5.10. [mysql\\_errno](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_errno](#)

Returns the numerical value of the error message from previous MySQL operation

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_errno](#)  
[PDO::errorCode](#)

**Description**

```
int mysql_errno(
    resource link_identifier
    = =NULL);
```

Returns the error number from the last MySQL function.

Errors coming back from the MySQL database backend no longer issue warnings. Instead, use [mysql\\_errno](#) to retrieve the error code. Note that this function only returns the error code from the most recently executed MySQL function (not including [mysql\\_error](#) and [mysql\\_errno](#)), so if you want to use it, make sure you check the value before calling another MySQL function.

**Parameters***link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If no connection is found or established, an [E\\_WARNING](#) level error is generated.

**Return Values**

Returns the error number from the last MySQL function, or 0 (zero) if no error occurred.

**Examples****Example 21.35. [mysql\\_errno](#) example**

```
<?php
$link = mysql_connect("localhost", "mysql_user", "mysql_password");

if (!mysql_select_db("nonexistentdb", $link)) {
    echo mysql_errno($link) . ": " . mysql_error($link) . "\n";
}

mysql_select_db("kossu", $link);
if (!mysql_query("SELECT * FROM nonexistenttable", $link)) {
    echo mysql_errno($link) . ": " . mysql_error($link) . "\n";
}
?>
```

The above example will output something similar to:

```
1049: Unknown database 'nonexistentdb'
1146: Table 'kossu.nonexistenttable' doesn't exist
```

### See Also

[mysql\\_error](#)  
[MySQL error codes](#)

#### 21.9.2.5.11. [mysql\\_error](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_error](#)

Returns the text of the error message from previous MySQL operation

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_error
PDO::errorInfo
```

### Description

```
string mysql_error(
    resource link_identifier
    = =NULL);
```

Returns the error text from the last MySQL function. Errors coming back from the MySQL database backend no longer issue warnings. Instead, use [mysql\\_error](#) to retrieve the error text. Note that this function only returns the error text from the most recently executed MySQL function (not including [mysql\\_error](#) and [mysql\\_errno](#)), so if you want to use it, make sure you check the value before calling another MySQL function.

### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If no connection is found or established, an [E\\_WARNING](#) level error is generated.

### Return Values

Returns the error text from the last MySQL function, or '' (empty string) if no error occurred.

### Examples

#### Example 21.36. [mysql\\_error](#) example

```
<?php
$link = mysql_connect("localhost", "mysql_user", "mysql_password");
```

```
mysql_select_db("nonexistentdb", $link);
echo mysql_errno($link) . ": " . mysql_error($link) . "\n";

mysql_select_db("kossu", $link);
mysql_query("SELECT * FROM nonexistenttable", $link);
echo mysql_errno($link) . ": " . mysql_error($link) . "\n";
?>
```

The above example will output something similar to:

```
1049: Unknown database 'nonexistentdb'
1146: Table 'kossu.nonexistenttable' doesn't exist
```

### See Also

[mysql\\_errno](#)  
[MySQL error codes](#)

#### 21.9.2.5.12. [mysql\\_escape\\_string](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_escape\\_string](#)

Escapes a string for use in a `mysql_query`

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_escape_string
PDO::quote
```

### Description

```
string mysql_escape_string(
    string unescaped_string);
```

This function will escape the *unescaped\_string*, so that it is safe to place it in a `mysql_query`. This function is deprecated.

This function is identical to [mysql\\_real\\_escape\\_string](#) except that [mysql\\_real\\_escape\\_string](#) takes a connection handler and escapes the string according to the current character set. [mysql\\_escape\\_string](#) does not take a connection argument and does not respect the current charset setting.

#### Warning

This function has been *DEPRECATED* as of PHP 5.3.0. Relying on this feature is highly discouraged.

### Parameters

*unescaped\_string*                      The string that is to be escaped.

### Return Values

Returns the escaped string.

### Changelog

Version	Description
5.3.0	This function now throws an E_DEPRECATED notice.
4.3.0	This function became deprecated, do not use this function. Instead, use <a href="#">mysql_real_escape_string</a> .

### Examples

#### Example 21.37. [mysql\\_escape\\_string](#) example

```
<?php
$item = "Zak's Laptop";
$escaped_item = mysql_escape_string($item);
printf("Escaped string: %s\n", $escaped_item);
?>
```

The above example will output:

```
Escaped string: Zak\'s Laptop
```

### Notes

#### Note

[mysql\\_escape\\_string](#) does not escape `%` and `_`.

### See Also

[mysql\\_real\\_escape\\_string](#)

The [magic\\_quotes\\_gpc](#) directive.

#### 21.9.2.5.13. [mysql\\_fetch\\_array](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_fetch\\_array](#)

Fetch a result row as an associative array, a numeric array, or both

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_fetch\\_array](#)

`PDOStatement::fetch`

### Description

```
array mysql_fetch_array(
    resource result,
    int result_type
    = =MYSQL_BOTH);
```

Returns an array that corresponds to the fetched row and moves the internal data pointer ahead.

### Parameters

*result*                      The result resource that is being evaluated. This result comes from a call to `mysql_query`.

*result\_type*                The type of array that is to be fetched. It's a constant and can take the following values: `MYSQL_ASSOC` , `MYSQL_NUM` , and `MYSQL_BOTH` .

### Return Values

Returns an array of strings that corresponds to the fetched row, or `FALSE` if there are no more rows. The type of returned array depends on how *result\_type* is defined. By using `MYSQL_BOTH` (default), you'll get an array with both associative and number indices. Using `MYSQL_ASSOC` , you only get associative indices (as `mysql_fetch_assoc` works), using `MYSQL_NUM` , you only get number indices (as `mysql_fetch_row` works).

If two or more columns of the result have the same field names, the last column will take precedence. To access the other column(s) of the same name, you must use the numeric index of the column or make an alias for the column. For aliased columns, you cannot access the contents with the original column name.

### Examples

#### Example 21.38. Query with aliased duplicate field names

```
SELECT table1.field AS foo, table2.field AS bar FROM table1, table2
```

#### Example 21.39. `mysql_fetch_array` with `MYSQL_NUM`

```
<?php
mysql_connect("localhost", "mysql_user", "mysql_password") or
    die("Could not connect: " . mysql_error());
mysql_select_db("mydb");

$result = mysql_query("SELECT id, name FROM mytable");

while ($row = mysql_fetch_array($result, MYSQL_NUM)) {
    printf("ID: %s Name: %s", $row[0], $row[1]);
}

mysql_free_result($result);
?>
```

#### Example 21.40. `mysql_fetch_array` with `MYSQL_ASSOC`

```
<?php
mysql_connect("localhost", "mysql_user", "mysql_password") or
    die("Could not connect: " . mysql_error());
mysql_select_db("mydb");

$result = mysql_query("SELECT id, name FROM mytable");
```

```
while ($row = mysql_fetch_array($result, MYSQL_ASSOC)) {
    printf("ID: %s Name: %s", $row["id"], $row["name"]);
}

mysql_free_result($result);
?>
```

**Example 21.41. `mysql_fetch_array` with `MYSQL_BOTH`**

```
<?php
mysql_connect("localhost", "mysql_user", "mysql_password") or
    die("Could not connect: " . mysql_error());
mysql_select_db("mydb");

$result = mysql_query("SELECT id, name FROM mytable");

while ($row = mysql_fetch_array($result, MYSQL_BOTH)) {
    printf("ID: %s Name: %s", $row[0], $row["name"]);
}

mysql_free_result($result);
?>
```

**Notes****Performance**

An important thing to note is that using `mysql_fetch_array` is *not significantly* slower than using `mysql_fetch_row`, while it provides a significant added value.

**Note**

Field names returned by this function are *case-sensitive*.

**Note**

This function sets NULL fields to the PHP `NULL` value.

**See Also**

[mysql\\_fetch\\_row](#)  
[mysql\\_fetch\\_assoc](#)  
[mysql\\_data\\_seek](#)  
[mysql\\_query](#)

**21.9.2.5.14. `mysql_fetch_assoc`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_fetch\\_assoc](#)

Fetch a result row as an associative array

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_fetch_assoc  
PDOStatement::fetch(PDO::FETCH_ASSOC)
```

## Description

```
array mysqli_fetch_assoc(  
    resource result);
```

Returns an associative array that corresponds to the fetched row and moves the internal data pointer ahead. `mysqli_fetch_assoc` is equivalent to calling `mysqli_fetch_array` with `MYSQLI_ASSOC` for the optional second parameter. It only returns an associative array.

## Parameters

*result* The result resource that is being evaluated. This result comes from a call to `mysqli_query`.

## Return Values

Returns an associative array of strings that corresponds to the fetched row, or `FALSE` if there are no more rows.

If two or more columns of the result have the same field names, the last column will take precedence. To access the other column(s) of the same name, you either need to access the result with numeric indices by using `mysqli_fetch_row` or add alias names. See the example at the `mysqli_fetch_array` description about aliases.

## Examples

### Example 21.42. An expanded `mysqli_fetch_assoc` example

```
<?php  
  
$conn = mysqli_connect("localhost", "mysql_user", "mysql_password");  
  
if (!$conn) {  
    echo "Unable to connect to DB: " . mysqli_error();  
    exit;  
}  
  
if (!mysqli_select_db("mydbname")) {  
    echo "Unable to select mydbname: " . mysqli_error();  
    exit;  
}  
  
$sql = "SELECT id as userid, fullname, userstatus  
        FROM   sometable  
        WHERE  userstatus = 1";  
  
$result = mysqli_query($sql);  
  
if (!$result) {  
    echo "Could not successfully run query ($sql) from DB: " . mysqli_error();  
    exit;  
}  
  
if (mysqli_num_rows($result) == 0) {  
    echo "No rows found, nothing to print so am exiting";  
    exit;  
}  
  
// While a row of data exists, put that row in $row as an associative array  
// Note: If you're expecting just one row, no need to use a loop  
// Note: If you put extract($row); inside the following loop, you'll  
//       then create $userid, $fullname, and $userstatus
```

```
while ($row = mysql_fetch_assoc($result)) {
    echo $row["userid"];
    echo $row["fullname"];
    echo $row["userstatus"];
}

mysql_free_result($result);

?>
```

## Notes

### Performance

An important thing to note is that using `mysql_fetch_assoc` is *not significantly* slower than using `mysql_fetch_row`, while it provides a significant added value.

### Note

Field names returned by this function are *case-sensitive*.

### Note

This function sets NULL fields to the PHP [NULL](#) value.

## See Also

### 21.9.2.5.15. [mysql\\_fetch\\_field](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_fetch\\_field](#)

Get column information from a result and return as an object

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_fetch\\_field](#)  
`PDOStatement::getColumnMeta`

## Description

```
object mysql_fetch_field(
    resource result,
    int field_offset
    = 0);
```

Returns an object containing field information. This function can be used to obtain information about fields in the provided query result.

## Parameters

- result* The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).
- field\_offset* The numerical field offset. If the field offset is not specified, the next field that was not yet retrieved by this function is retrieved. The [field\\_offset](#) starts at 0.

## Return Values

Returns an object containing field information. The properties of the object are:

- name - column name
- table - name of the table the column belongs to, which is the alias name if one is defined
- max\_length - maximum length of the column
- not\_null - 1 if the column cannot be [NULL](#)
- primary\_key - 1 if the column is a primary key
- unique\_key - 1 if the column is a unique key
- multiple\_key - 1 if the column is a non-unique key
- numeric - 1 if the column is numeric
- blob - 1 if the column is a BLOB
- type - the type of the column
- unsigned - 1 if the column is unsigned
- zerofill - 1 if the column is zero-filled

## Examples

### Example 21.43. [mysql\\_fetch\\_field](#) example

```
<?php
$conn = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$conn) {
    die('Could not connect: ' . mysql_error());
}
mysql_select_db('database');
$result = mysql_query('select * from table');
if (!$result) {
    die('Query failed: ' . mysql_error());
}
/* get column metadata */
$i = 0;
while ($i < mysql_num_fields($result)) {
    echo "Information for column $i:<br />\n";
    $meta = mysql_fetch_field($result, $i);
    if (!$meta) {
        echo "No information available<br />\n";
    }
    echo "<pre>
blob:          $meta->blob
max_length:    $meta->max_length
multiple_key:  $meta->multiple_key
name:          $meta->name
not_null:      $meta->not_null
numeric:       $meta->numeric
```

```

primary_key: $meta->primary_key
table:       $meta->table
type:       $meta->type
unique_key: $meta->unique_key
unsigned:   $meta->unsigned
zerofill:   $meta->zerofill
</pre>";
    $i++;
}
mysql_free_result($result);
?>

```

## Notes

### Note

Field names returned by this function are *case-sensitive*.

### Note

If field or tablename are aliased in the SQL query the aliased name will be returned. The original name can be retrieved for instance by using [mysqli\\_result::fetch\\_field](#).

## See Also

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_fetch\\_lengths](#)

Get the length of each output in a result

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_fetch\\_lengths](#)  
[PDOStatement::getColumnMeta](#)

## Description

```

array mysql_fetch_lengths(
    resource result);

```

Returns an array that corresponds to the lengths of each field in the last row fetched by MySQL.

[mysql\\_fetch\\_lengths](#) stores the lengths of each result column in the last row returned by [mysql\\_fetch\\_row](#), [mysql\\_fetch\\_assoc](#), [mysql\\_fetch\\_array](#), and [mysql\\_fetch\\_object](#) in an array, starting at offset 0.

## Parameters

*result*

The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).

## Return Values

An array of lengths on success or `FALSE` on failure.

## Examples

### Example 21.44. A `mysql_fetch_lengths` example

```
<?php
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}
$row      = mysql_fetch_assoc($result);
$lengths = mysql_fetch_lengths($result);

print_r($row);
print_r($lengths);
?>
```

The above example will output something similar to:

```
Array
(
    [id] => 42
    [email] => user@example.com
)
Array
(
    [0] => 2
    [1] => 16
)
```

Fetch a result row as an object

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_fetch_object`  
`PDOStatement::fetch(PDO::FETCH_OBJ)`

## Description

```
object mysql_fetch_object(
```

```
resource result,
string class_name,
array params);
```

Returns an object with properties that correspond to the fetched row and moves the internal data pointer ahead.

### Parameters

<i>result</i>	The result resource that is being evaluated. This result comes from a call to <code>mysql_query</code> .
<i>class_name</i>	The name of the class to instantiate, set the properties of and return. If not specified, a <code>stdClass</code> object is returned.
<i>params</i>	An optional array of parameters to pass to the constructor for <i>class_name</i> objects.

### Return Values

Returns an object with string properties that correspond to the fetched row, or `FALSE` if there are no more rows.

### Changelog

Version	Description
5.0.0	Added the ability to return as a different object.

### Examples

#### Example 21.45. `mysql_fetch_object` example

```
<?php
mysql_connect("hostname", "user", "password");
mysql_select_db("mydb");
$result = mysql_query("select * from mytable");
while ($row = mysql_fetch_object($result)) {
    echo $row->user_id;
    echo $row->fullname;
}
mysql_free_result($result);
?>
```

#### Example 21.46. `mysql_fetch_object` example

```
<?php
class foo {
    public $name;
}

mysql_connect("hostname", "user", "password");
mysql_select_db("mydb");

$result = mysql_query("select name from mytable limit 1");
$obj = mysql_fetch_object($result, 'foo');
var_dump($obj);
?>
```

### Notes

**Performance**

Speed-wise, the function is identical to `mysql_fetch_array`, and almost as quick as `mysql_fetch_row` (the difference is insignificant).

**Note**

`mysql_fetch_object` is similar to `mysql_fetch_array`, with one difference - an object is returned, instead of an array. Indirectly, that means that you can only access the data by the field names, and not by their offsets (numbers are illegal property names).

**Note**

Field names returned by this function are *case-sensitive*.

**Note**

This function sets NULL fields to the PHP `NULL` value.

**See Also**

`mysql_fetch_array`  
`mysql_fetch_assoc`  
`mysql_fetch_row`  
`mysql_data_seek`  
`mysql_query`

**21.9.2.5.18. `mysql_fetch_row`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_fetch_row`

Get a result row as an enumerated array

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_fetch_row  
PDOStatement::fetch(PDO::FETCH_NUM)
```

**Description**

```
array mysql_fetch_row(  
    resource result);
```

Returns a numerical array that corresponds to the fetched row and moves the internal data pointer ahead.

**Parameters**

*result*

The result resource that is being evaluated. This result comes from a call to `mysql_query`.

**Return Values**

Returns an numerical array of strings that corresponds to the fetched row, or `FALSE` if there are no more rows.

`mysql_fetch_row` fetches one row of data from the result associated with the specified result identifier. The row is returned as an array. Each result column is stored in an array offset, starting at offset 0.

## Examples

### Example 21.47. Fetching one row with `mysql_fetch_row`

```
<?php
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}
$row = mysql_fetch_row($result);

echo $row[0]; // 42
echo $row[1]; // the email value
?>
```

## Notes

### Note

This function sets NULL fields to the PHP `NULL` value.

## See Also

`mysql_fetch_array`  
`mysql_fetch_assoc`  
`mysql_fetch_object`  
`mysql_data_seek`  
`mysql_fetch_lengths`  
`mysql_result`

### 21.9.2.5.19. `mysql_field_flags`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_field_flags`

Get the flags associated with the specified field in a result

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_fetch_fields` [flags]  
`PDOStatement::getColumnMeta` [flags]

## Description

```
string mysql_field_flags(
    resource result,
```

```
int field_offset);
```

`mysql_field_flags` returns the field flags of the specified field. The flags are reported as a single word per flag separated by a single space, so that you can split the returned value using `explode`.

### Parameters

*result*

The result resource that is being evaluated. This result comes from a call to `mysql_query`.

*field\_offset*

The numerical field offset. The *field\_offset* starts at 0. If *field\_offset* does not exist, an error of level `E_WARNING` is also issued.

### Return Values

Returns a string of flags associated with the result or `FALSE` on failure.

The following flags are reported, if your version of MySQL is current enough to support them: `"not_null"`, `"primary_key"`, `"unique_key"`, `"multiple_key"`, `"blob"`, `"unsigned"`, `"zerofill"`, `"binary"`, `"enum"`, `"auto_increment"` and `"timestamp"`.

### Examples

#### Example 21.48. A `mysql_field_flags` example

```
<?php
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}
$flags = mysql_field_flags($result, 0);

echo $flags;
print_r(explode(' ', $flags));
?>
```

The above example will output something similar to:

```
not_null primary_key auto_increment
Array
(
    [0] => not_null
    [1] => primary_key
    [2] => auto_increment
)
```

### Notes

#### Note

For backward compatibility, the following deprecated alias may be used: `mysql_fieldflags`

### See Also

`mysql_field_type`  
`mysql_field_len`

### 21.9.2.5.20. `mysql_field_len`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_field_len`

Returns the length of the specified field

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_fetch_field_direct [length]  
PDOStatement::getColumnMeta [len]
```

#### Description

```
int mysql_field_len(  
    resource result,  
    int field_offset);
```

`mysql_field_len` returns the length of the specified field.

#### Parameters

*result*

The result resource that is being evaluated. This result comes from a call to `mysql_query`.

*field\_offset*

The numerical field offset. The *field\_offset* starts at 0. If *field\_offset* does not exist, an error of level `E_WARNING` is also issued.

#### Return Values

The length of the specified field index on success or `FALSE` on failure.

#### Examples

##### Example 21.49. `mysql_field_len` example

```
<?php  
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");  
if (!$result) {  
    echo 'Could not run query: ' . mysql_error();  
    exit;  
}  
  
// Will get the length of the id field as specified in the database  
// schema.  
$length = mysql_field_len($result, 0);  
echo $length;  
?>
```

#### Notes

#### Note

For backward compatibility, the following deprecated alias may be used:  
`mysql_fieldlen`

**See Also**

[mysql\\_fetch\\_lengths](#)  
[strlen](#)

**21.9.2.5.21. [mysql\\_field\\_name](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_field\\_name](#)

Get the name of the specified field in a result

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_fetch\\_field\\_direct](#) [*name*] or [*orgname*]  
[PDOStatement::getColumnMeta](#) [*name*]

**Description**

```
string mysql_field_name(
    resource result,
    int field_offset);
```

[mysql\\_field\\_name](#) returns the name of the specified field index.

**Parameters**

*result*

The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).

*field\_offset*

The numerical field offset. The *field\_offset* starts at 0. If *field\_offset* does not exist, an error of level [E\\_WARNING](#) is also issued.

**Return Values**

The name of the specified field index on success or [FALSE](#) on failure.

**Examples****Example 21.50. [mysql\\_field\\_name](#) example**

```
<?php
/* The users table consists of three fields:
 *   user_id
 *   username
 *   password.
 */
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect to MySQL server: ' . mysql_error());
}
$dbname = 'mydb';
$db_selected = mysql_select_db($dbname, $link);
if (!$db_selected) {
    die("Could not set $dbname: " . mysql_error());
}
```

```
$res = mysql_query('select * from users', $link);

echo mysql_field_name($res, 0) . "\n";
echo mysql_field_name($res, 2);
?>
```

The above example will output:

```
user_id
password
```

## Notes

### Note

Field names returned by this function are *case-sensitive*.

### Note

### 21.9.2.5.22. [mysql\\_field\\_seek](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_field\\_seek](#)

Set result pointer to a specified field offset

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_field\\_seek](#)  
[PDOStatement::fetch](#) using optional parameters

## Description

```
bool mysql_field_seek(
    resource result,
    int field_offset);
```

Seeks to the specified field offset. If the next call to [mysql\\_fetch\\_field](#) doesn't include a field offset, the field offset specified in [mysql\\_field\\_seek](#) will be returned.

## Parameters

*result*

The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).

`field_offset`

The numerical field offset. The `field_offset` starts at 0. If `field_offset` does not exist, an error of level `E_WARNING` is also issued.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**See Also**`mysql_fetch_field`**21.9.2.5.23. `mysql_field_table`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_field_table`

Get name of the table the specified field is in

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_fetch_field_direct` [`table`] or [`orgtable`]  
`PDOStatement::getColumnMeta` [`table`]

**Description**

```
string mysql_field_table(
    resource result,
    int field_offset);
```

Returns the name of the table that the specified field is in.

**Parameters**`result`

The result resource that is being evaluated. This result comes from a call to `mysql_query`.

`field_offset`

The numerical field offset. The `field_offset` starts at 0. If `field_offset` does not exist, an error of level `E_WARNING` is also issued.

**Return Values**

The name of the table on success.

**Examples****Example 21.51. A `mysql_field_table` example**

```
<?php
$query = "SELECT account.*, country.* FROM account, country WHERE country.name = 'Portugal' AND account.co
// get the result from the DB
$result = mysql_query($query);
// Lists the table name and then the field name
```

```
for ($i = 0; $i < mysql_num_fields($result); ++$i) {
    $table = mysql_field_table($result, $i);
    $field = mysql_field_name($result, $i);

    echo "$table: $field\n";
}
?>
```

## Notes

[mysql\\_list\\_tables](#)

### 21.9.2.5.24. [mysql\\_field\\_type](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_field\\_type](#)

Get the type of the specified field in a result

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_fetch\\_field\\_direct](#) [type]  
[PDOStatement::getColumnMeta](#) [driver:decl\_type] or [pdo\_type]

## Description

```
string mysql_field_type(
    resource result,
    int field_offset);
```

[mysql\\_field\\_type](#) is similar to the [mysql\\_field\\_name](#) function. The arguments are identical, but the field type is returned instead.

## Parameters

*result*

The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).

*field\_offset*

The numerical field offset. The *field\_offset* starts at 0. If *field\_offset* does not exist, an error of level [E\\_WARNING](#) is also issued.

## Return Values

The returned field type will be one of "int", "real", "string", "blob", and others as detailed in the [MySQL documentation](#).

## Examples

**Example 21.52. `mysql_field_type` example**

```
<?php
mysql_connect("localhost", "mysql_username", "mysql_password");
mysql_select_db("mysql");
$result = mysql_query("SELECT * FROM func");
$fields = mysql_num_fields($result);
$rows   = mysql_num_rows($result);
$table  = mysql_field_table($result, 0);
echo "Your '" . $table . "' table has " . $fields . " fields and " . $rows . " record(s)\n";
echo "The table has the following fields:\n";
for ($i=0; $i < $fields; $i++) {
    $type = mysql_field_type($result, $i);
    $name = mysql_field_name($result, $i);
    $len  = mysql_field_len($result, $i);
    $flags = mysql_field_flags($result, $i);
    echo $type . " " . $name . " " . $len . " " . $flags . "\n";
}
mysql_free_result($result);
mysql_close();
?>
```

The above example will output something similar to:

```
Your 'func' table has 4 fields and 1 record(s)
The table has the following fields:
string name 64 not_null primary_key binary
int ret 1 not_null
string dl 128 not_null
string type 9 not_null enum
```

**Notes****Note**

For backward compatibility, the following deprecated alias may be used:  
[mysql\\_fieldtype](#)

**See Also**

[mysql\\_field\\_name](#)  
[mysql\\_field\\_len](#)

**21.9.2.5.25. `mysql_free_result`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_free\\_result](#)

Free result memory

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_free\\_result](#)

Assign the value of `NULL` to the PDO object, or  
[PDOStatement::closeCursor](#)

## Description

```
bool mysql_free_result(  
    resource result);
```

`mysql_free_result` will free all memory associated with the result identifier `result`.

`mysql_free_result` only needs to be called if you are concerned about how much memory is being used for queries that return large result sets. All associated result memory is automatically freed at the end of the script's execution.

## Parameters

`result` The result resource that is being evaluated. This result comes from a call to `mysql_query`.

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

If a non-resource is used for the `result`, an error of level `E_WARNING` will be emitted. It's worth noting that `mysql_query` only returns a resource for `SELECT`, `SHOW`, `EXPLAIN`, and `DESCRIBE` queries.

## Examples

### Example 21.53. A `mysql_free_result` example

```
<?php  
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");  
if (!$result) {  
    echo 'Could not run query: ' . mysql_error();  
    exit;  
}  
/* Use the result, assuming we're done with it afterwards */  
$row = mysql_fetch_assoc($result);  
  
/* Now we free up the result and continue on with our script */  
mysql_free_result($result);  
  
echo $row['id'];  
echo $row['email'];  
?>
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used:  
`mysql_freeresult`

### 21.9.2.5.26. `mysql_get_client_info`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_get\\_client\\_info](#)

## Get MySQL client info

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_get_client_info  
PDO::getAttribute(PDO::ATTR_CLIENT_VERSION)
```

**Description**

```
string mysql_get_client_info();
```

`mysql_get_client_info` returns a string that represents the client library version.

**Return Values**

The MySQL client version.

**Examples****Example 21.54. `mysql_get_client_info` example**

```
<?php  
printf("MySQL client info: %s\n", mysql_get_client_info());  
?>
```

The above example will output something similar to:

```
MySQL client info: 3.23.39
```

**See Also**

```
mysql_get_host_info  
mysql_get_proto_info  
mysql_get_server_info
```

**21.9.2.5.27. `mysql_get_host_info`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_get\\_host\\_info](#)

## Get MySQL host info

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_get_host_info  
PDO::getAttribute(PDO::ATTR_CONNECTION_STATUS)
```

## Description

```
string mysql_get_host_info(  
    resource link_identifier  
    = =NULL);
```

Describes the type of connection in use for the connection, including the server host name.

## Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If no connection is found or established, an [E\\_WARNING](#) level error is generated.

## Return Values

Returns a string describing the type of MySQL connection in use for the connection or [FALSE](#) on failure.

## Examples

### Example 21.55. [mysql\\_get\\_host\\_info](#) example

```
<?php  
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');  
if (!$link) {  
    die('Could not connect: ' . mysql_error());  
}  
printf("MySQL host info: %s\n", mysql_get_host_info());  
?>
```

The above example will output something similar to:

```
MySQL host info: Localhost via UNIX socket
```

## See Also

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_get\\_proto\\_info](#)

Get MySQL protocol info

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_get\\_proto\\_info](#)

## Description

```
int mysql_get_proto_info(
    resource link_identifier
    = =NULL);
```

Retrieves the MySQL protocol.

## Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If no connection is found or established, an [E\\_WARNING](#) level error is generated.

## Return Values

Returns the MySQL protocol on success or [FALSE](#) on failure.

## Examples

### Example 21.56. [mysql\\_get\\_proto\\_info](#) example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
printf("MySQL protocol version: %s\n", mysql_get_proto_info());
?>
```

The above example will output something similar to:

```
MySQL protocol version: 10
```

## See Also

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_get\\_server\\_info](#)

Get MySQL server info

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_get\\_server\\_info](#)

```
mysql::getAttribute(PDO::ATTR_SERVER_VERSION)
```

## Description

```
string mysql_get_server_info(
    resource link_identifier
    = =NULL);
```

Retrieves the MySQL server version.

## Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

## Return Values

Returns the MySQL server version on success or `FALSE` on failure.

## Examples

### Example 21.57. `mysql_get_server_info` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
printf("MySQL server version: %s\n", mysql_get_server_info());
?>
```

The above example will output something similar to:

```
MySQL server version: 4.0.1-alpha
```

### 21.9.2.5.30. `mysql_info`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_info`

Get information about the most recent query

## Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

**mysql\_info****Description**

```
string mysql_info(
    resource link_identifier
    = =NULL);
```

Returns detailed information about the last query.

**Parameters**

`link_identifier`

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

**Return Values**

Returns information about the statement on success, or `FALSE` on failure. See the example below for which statements provide information, and what the returned value may look like. Statements that are not listed will return `FALSE`.

**Examples****Example 21.58. Relevant MySQL Statements**

Statements that return string values. The numbers are only for illustrating purpose; their values will correspond to the query.

```
INSERT INTO ... SELECT ...
String format: Records: 23 Duplicates: 0 Warnings: 0
INSERT INTO ... VALUES (...),(...),(...)...
String format: Records: 37 Duplicates: 0 Warnings: 0
LOAD DATA INFILE ...
String format: Records: 42 Deleted: 0 Skipped: 0 Warnings: 0
ALTER TABLE
String format: Records: 60 Duplicates: 0 Warnings: 0
UPDATE
String format: Rows matched: 65 Changed: 65 Warnings: 0
```

**Notes****Note**

`mysql_info` returns a non-`FALSE` value for the `INSERT ... VALUES` statement only if multiple value lists are specified in the statement.

`mysql_insert_id`  
`mysql_stat`

**21.9.2.5.31. mysql\_insert\_id**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_insert_id`

Get the ID generated in the last query

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_insert_id
PDO::lastInsertId
```

### Description

```
int mysql_insert_id(
    resource link_identifier
    = =NULL);
```

Retrieves the ID generated for an AUTO\_INCREMENT column by the previous query (usually INSERT).

### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If no connection is found or established, an [E\\_WARNING](#) level error is generated.

### Return Values

The ID generated for an AUTO\_INCREMENT column by the previous query on success, `0` if the previous query does not generate an AUTO\_INCREMENT value, or `FALSE` if no MySQL connection was established.

### Examples

#### Example 21.59. [mysql\\_insert\\_id](#) example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
mysql_select_db('mydb');

mysql_query("INSERT INTO mytable (product) values ('kossu')");
printf("Last inserted record has id %d\n", mysql_insert_id());
?>
```

### Notes

### Caution

[mysql\\_insert\\_id](#) will convert the return type of the native MySQL C API function [mysql\\_insert\\_id\(\)](#) to a type of `long` (named `int` in PHP). If your AUTO\_INCREMENT column has a column type of BIGINT (64 bits) the conversion may result in an incorrect value. Instead, use the internal MySQL SQL function `LAST_INSERT_ID()` in a SQL query. For more information about PHP's maximum integer values, please see the [integer](#) documentation.

**Note**

Because `mysql_insert_id` acts on the last performed query, be sure to call `mysql_insert_id` immediately after the query that generates the value.

**Note**

The value of the MySQL SQL function `LAST_INSERT_ID()` always contains the most recently generated `AUTO_INCREMENT` value, and is not reset between queries.

**See Also**

`mysql_query`  
`mysql_info`

**21.9.2.5.32. `mysql_list_dbs`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_list_dbs`

List databases available on a MySQL server

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

SQL Query: `SHOW DATABASES`

**Description**

```
resource mysql_list_dbs(
    resource link_identifier
    = =NULL);
```

Returns a result pointer containing the databases available from the current `mysql` daemon.

**Warning**

This function has been *DEPRECATED* as of PHP 5.4.0. Relying on this function is highly discouraged.

**Parameters**

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

**Return Values**

Returns a result pointer resource on success, or `FALSE` on failure. Use the `mysql_tablename` function to traverse this result pointer, or any function for result tables, such as `mysql_fetch_array`.

**Examples**

**Example 21.60. `mysql_list_dbs` example**

```
<?php
// Usage without mysql_list_dbs()
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$res = mysql_query("SHOW DATABASES");

while ($row = mysql_fetch_assoc($res)) {
    echo $row['Database'] . "\n";
}

// Deprecated as of PHP 5.4.0
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$db_list = mysql_list_dbs($link);

while ($row = mysql_fetch_object($db_list)) {
    echo $row->Database . "\n";
}
?>
```

The above example will output something similar to:

```
database1
database2
database3
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used:

`mysql_listdbs`

## See Also

[mysql\\_db\\_name](#)

### 21.9.2.5.33. [mysql\\_list\\_fields](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_list\\_fields](#)

List MySQL table fields

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

SQL Query: `SHOW COLUMNS FROM sometable`

## Description

```
resource mysql_list_fields(
    string database_name,
    string table_name,
    resource link_identifier
    = =NULL);
```

Retrieves information about the given table name.

This function is deprecated. It is preferable to use `mysql_query` to issue an SQL `SHOW COLUMNS FROM table [LIKE 'name']` statement instead.

### Parameters

<i>database_name</i>	The name of the database that's being queried.
<i>table_name</i>	The name of the table that's being queried.
<i>link_identifier</i>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If no connection is found or established, an <code>E_WARNING</code> level error is generated.

### Return Values

A result pointer resource on success, or `FALSE` on failure.

The returned result can be used with `mysql_field_flags`, `mysql_field_len`, `mysql_field_name` and `mysql_field_type`.

### Examples

#### Example 21.61. Alternate to deprecated `mysql_list_fields`

```
<?php
$result = mysql_query("SHOW COLUMNS FROM sometable");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}
if (mysql_num_rows($result) > 0) {
    while ($row = mysql_fetch_assoc($result)) {
        print_r($row);
    }
}
?>
```

The above example will output something similar to:

```
Array
(
    [Field] => id
    [Type] => int(7)
    [Null] =>
    [Key] => PRI
    [Default] =>
    [Extra] => auto_increment
)
Array
(
    [Field] => email
    [Type] => varchar(100)
    [Null] =>
    [Key] =>
    [Default] =>
    [Extra] =>
)
```

### Notes

**Note**

For backward compatibility, the following deprecated alias may be used:  
`mysql_listfields`

**See Also**

`mysql_field_flags`  
`mysql_info`

**21.9.2.5.34. `mysql_list_processes`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_list_processes`

List MySQL processes

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_thread_id`

**Description**

```
resource mysql_list_processes(
    resource link_identifier
    = =NULL);
```

Retrieves the current MySQL server threads.

**Parameters**

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

**Return Values**

A result pointer resource on success or `FALSE` on failure.

**Examples****Example 21.62. `mysql_list_processes` example**

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');

$result = mysql_list_processes($link);
while ($row = mysql_fetch_assoc($result)){
    printf("%s %s %s %s %s\n", $row["Id"], $row["Host"], $row["db"],
        $row["Command"], $row["Time"]);
}
mysql_free_result($result);
?>
```

The above example will output something similar to:

```
1 localhost test Processlist 0
4 localhost mysql sleep 5
```

#### 21.9.2.5.35. [mysql\\_list\\_tables](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_list\\_tables](#)

List tables in a MySQL database

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

SQL Query: `SHOW TABLES FROM sometable`

### Description

```
resource mysql_list_tables(
    string database,
    resource link_identifier
    = =NULL);
```

Retrieves a list of table names from a MySQL database.

This function is deprecated. It is preferable to use [mysql\\_query](#) to issue an SQL `SHOW TABLES [FROM db_name] [LIKE 'pattern']` statement instead.

### Parameters

<i>database</i>	The name of the database
<i>link_identifier</i>	The MySQL connection. If the link identifier is not specified, the last link opened by <a href="#">mysql_connect</a> is assumed. If no such link is found, it will try to create one as if <a href="#">mysql_connect</a> was called with no arguments. If no connection is found or established, an <a href="#">E_WARNING</a> level error is generated.

### Return Values

A result pointer resource on success or `FALSE` on failure.

Use the [mysql\\_tablename](#) function to traverse this result pointer, or any function for result tables, such as [mysql\\_fetch\\_array](#).

### Changelog

Version	Description
4.3.7	This function became deprecated.

## Examples

### Example 21.63. [mysql\\_list\\_tables](#) alternative example

```
<?php
$dbname = 'mysql_dbname';

if (!mysql_connect('mysql_host', 'mysql_user', 'mysql_password')) {
    echo 'Could not connect to mysql';
    exit;
}

$sql = "SHOW TABLES FROM $dbname";
$result = mysql_query($sql);

if (!$result) {
    echo "DB Error, could not list tables\n";
    echo 'MySQL Error: ' . mysql_error();
    exit;
}

while ($row = mysql_fetch_row($result)) {
    echo "Table: {$row[0]}\n";
}

mysql_free_result($result);
?>
```

## Notes

### 21.9.2.5.36. [mysql\\_num\\_fields](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_num\\_fields](#)

Get number of fields in result

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_field\\_count](#)  
[PDOStatement::columnCount](#)

## Description

```
int mysql_num_fields(
    resource result);
```

Retrieves the number of fields from a query.

## Parameters

`result` The result resource that is being evaluated. This result comes from a call to `mysql_query`.

## Return Values

Returns the number of fields in the result set resource on success or `FALSE` on failure.

## Examples

### Example 21.64. A `mysql_num_fields` example

```
<?php
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}

/* returns 2 because id,email == two fields */
echo mysql_num_fields($result);
?>
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used:  
`mysql_numfields`

## See Also

`mysql_select_db`  
`mysql_query`  
`mysql_fetch_field`  
`mysql_num_rows`

### 21.9.2.5.37. `mysql_num_rows`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_num_rows`

Get number of rows in result

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the `MySQLi` or `PDO_MySQL` extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_stmt_num_rows`  
`PDOStatement::rowCount`

## Description

```
int mysql_num_rows(
    resource result);
```

Retrieves the number of rows from a result set. This command is only valid for statements like `SELECT` or `SHOW` that return an actual result set. To retrieve the number of rows affected by a `INSERT`, `UPDATE`, `REPLACE` or `DELETE` query, use [mysql\\_affected\\_rows](#).

### Parameters

*result* The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).

### Return Values

The number of rows in a result set on success or `FALSE` on failure.

### Examples

#### Example 21.65. [mysql\\_num\\_rows](#) example

```
<?php
$link = mysql_connect("localhost", "mysql_user", "mysql_password");
mysql_select_db("database", $link);

$result = mysql_query("SELECT * FROM table1", $link);
$num_rows = mysql_num_rows($result);

echo "$num_rows Rows\n";

?>
```

### Notes

#### Note

If you use [mysql\\_unbuffered\\_query](#), [mysql\\_num\\_rows](#) will not return the correct value until all the rows in the result set have been retrieved.

#### Note

For backward compatibility, the following deprecated alias may be used:  
[mysql\\_numrows](#)

### See Also

[mysql\\_select\\_db](#)  
[mysql\\_query](#)

#### 21.9.2.5.38. [mysql\\_pconnect](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_pconnect](#)

Open a persistent connection to a MySQL server

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See

also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_connect` with `p`: host prefix  
`PDO::__construct` with `PDO::ATTR_PERSISTENT` as a driver option

## Description

```
resource mysql_pconnect(
    string server
        = =ini_get("mysql.default_host"),
    string username
        = =ini_get("mysql.default_user"),
    string password
        = =ini_get("mysql.default_password"),
    int client_flags
        = =0);
```

Establishes a persistent connection to a MySQL server.

`mysql_pconnect` acts very much like `mysql_connect` with two major differences.

First, when connecting, the function would first try to find a (persistent) link that's already open with the same host, username and password. If one is found, an identifier for it will be returned instead of opening a new connection.

Second, the connection to the SQL server will not be closed when the execution of the script ends. Instead, the link will remain open for future use (`mysql_close` will not close links established by `mysql_pconnect`).

This type of link is therefore called 'persistent'.

## Parameters

<i>server</i>	The MySQL server. It can also include a port number. e.g. "hostname:port" or a path to a local socket e.g. ":/path/to/socket" for the localhost.  If the PHP directive <code>mysql.default_host</code> is undefined (default), then the default value is 'localhost:3306'
<i>username</i>	The username. Default value is the name of the user that owns the server process.
<i>password</i>	The password. Default value is an empty password.
<i>client_flags</i>	The <code>client_flags</code> parameter can be a combination of the following constants: 128 (enable <code>LOAD DATA LOCAL</code> handling), <code>MYSQL_CLIENT_SSL</code> , <code>MYSQL_CLIENT_COMPRESS</code> , <code>MYSQL_CLIENT_IGNORE_SPACE</code> or <code>MYSQL_CLIENT_INTERACTIVE</code> .

## Return Values

Returns a MySQL persistent link identifier on success, or `FALSE` on failure.

## Changelog

Version	Description
5.5.0	This function will generate an <code>E_DEPRECATED</code> error.
4.3.0	Added the <code>client_flags</code> parameter.

## Notes

### Note

Note, that these kind of links only work if you are using a module version of PHP. See the [Persistent Database Connections](#) section for more information.

### Warning

Using persistent connections can require a bit of tuning of your Apache and MySQL configurations to ensure that you do not exceed the number of connections allowed by MySQL.

### Note

You can suppress the error message on failure by prepending a `@` to the function name.

## See Also

[mysql\\_connect](#)  
[Persistent Database Connections](#)

### 21.9.2.5.39. [mysql\\_ping](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_ping](#)

Ping a server connection or reconnect if there is no connection

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_ping](#)

## Description

```
bool mysql_ping(  
    resource link_identifier  
    = =NULL);
```

Checks whether or not the connection to the server is working. If it has gone down, an automatic reconnection is attempted. This function can be used by scripts that remain idle for a long while, to check whether or not the server has closed the connection and reconnect if necessary.

### Note

Automatic reconnection is disabled by default in versions of MySQL  $\geq$  5.0.3.

## Parameters

[link\\_identifier](#)

The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If no connection is found or established, an [E\\_WARNING](#) level error is generated.

## Return Values

Returns [TRUE](#) if the connection to the server MySQL server is working, otherwise [FALSE](#) .

## Examples

### Example 21.66. A [mysql\\_ping](#) example

```

<?php
set_time_limit(0);

$conn = mysql_connect('localhost', 'mysqluser', 'mypass');
$db   = mysql_select_db('mydb');

/* Assuming this query will take a long time */
$result = mysql_query($sql);
if (!$result) {
    echo 'Query #1 failed, exiting.';
    exit;
}

/* Make sure the connection is still alive, if not, try to reconnect */
if (!mysql_ping($conn)) {
    echo 'Lost connection, exiting after query #1';
    exit;
}
mysql_free_result($result);

/* So the connection is still alive, let's run another query */
$result2 = mysql_query($sql2);
?>

```

## See Also

[mysql\\_thread\\_id](#)  
[mysql\\_list\\_processes](#)

### 21.9.2.5.40. [mysql\\_query](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_query](#)

Send a MySQL query

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_query](#)  
[PDO::query](#)

## Description

```

resource mysql_query(
    string query,
    resource link_identifier
    = =NULL);

```

[mysql\\_query](#) sends a unique query (multiple queries are not supported) to the currently active database on the server that's associated with the specified [link\\_identifier](#).

## Parameters

<code>query</code>	An SQL query  The query string should not end with a semicolon. Data inside the query should be <a href="#">properly escaped</a> .
<code>link_identifier</code>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If no connection is found or established, an <code>E_WARNING</code> level error is generated.

## Return Values

For SELECT, SHOW, DESCRIBE, EXPLAIN and other statements returning resultset, `mysql_query` returns a resource on success, or `FALSE` on error.

For other type of SQL statements, INSERT, UPDATE, DELETE, DROP, etc, `mysql_query` returns `TRUE` on success or `FALSE` on error.

The returned result resource should be passed to `mysql_fetch_array`, and other functions for dealing with result tables, to access the returned data.

Use `mysql_num_rows` to find out how many rows were returned for a SELECT statement or `mysql_affected_rows` to find out how many rows were affected by a DELETE, INSERT, REPLACE, or UPDATE statement.

`mysql_query` will also fail and return `FALSE` if the user does not have permission to access the table(s) referenced by the query.

## Examples

### Example 21.67. Invalid Query

The following query is syntactically invalid, so `mysql_query` fails and returns `FALSE`.

```
<?php
$result = mysql_query('SELECT * WHERE 1=1');
if (!$result) {
    die('Invalid query: ' . mysql_error());
}
?>
```

### Example 21.68. Valid Query

The following query is valid, so `mysql_query` returns a resource.

```
<?php
// This could be supplied by a user, for example
$firstname = 'fred';
$lastname = 'fox';

// Formulate Query
// This is the best way to perform an SQL query
// For more examples, see mysql_real_escape_string()
$query = sprintf("SELECT firstname, lastname, address, age FROM friends
    WHERE firstname='%s' AND lastname='%s'",
    mysql_real_escape_string($firstname),
    mysql_real_escape_string($lastname));
```

```
// Perform Query
$result = mysql_query($query);

// Check result
// This shows the actual query sent to MySQL, and the error. Useful for debugging.
if (!$result) {
    $message = 'Invalid query: ' . mysql_error() . "\n";
    $message .= 'Whole query: ' . $query;
    die($message);
}

// Use result
// Attempting to print $result won't allow access to information in the resource
// One of the mysql result functions must be used
// See also mysql_result(), mysql_fetch_array(), mysql_fetch_row(), etc.
while ($row = mysql_fetch_assoc($result)) {
    echo $row['firstname'];
    echo $row['lastname'];
    echo $row['address'];
    echo $row['age'];
}

// Free the resources associated with the result set
// This is done automatically at the end of the script
mysql_free_result($result);
?>
```

#### 21.9.2.5.41. [mysql\\_real\\_escape\\_string](#)

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

- [mysql\\_real\\_escape\\_string](#)

Escapes special characters in a string for use in an SQL statement

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_real\\_escape\\_string](#)  
[PDO::quote](#)

#### Description

```
string mysql_real_escape_string(
    string unescaped_string,
    resource link_identifier
    = =NULL);
```

Escapes special characters in the *unescaped\_string*, taking into account the current character set of the connection so that it is safe to place it in a *mysql\_query*. If binary data is to be inserted, this function must be used.

`mysql_real_escape_string` calls MySQL's library function `mysql_real_escape_string`, which prepends backslashes to the following characters: `\x00`, `\n`, `\r`, `\`, `'`, `"` and `\x1a`.

This function must always (with few exceptions) be used to make data safe before sending a query to MySQL.

#### Security: the default character set

The character set must be set either at the server level, or with the API function `mysql_set_charset` for it to affect `mysql_real_escape_string`. See the concepts section on [character sets](#) for more information.

#### Parameters

*unescaped\_string*

The string that is to be escaped.

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

#### Return Values

Returns the escaped string, or `FALSE` on error.

#### Examples

##### Example 21.69. Simple `mysql_real_escape_string` example

```
<?php
// Connect
$link = mysql_connect('mysql_host', 'mysql_user', 'mysql_password')
    OR die(mysql_error());

// Query
$query = sprintf("SELECT * FROM users WHERE user='%s' AND password='%s'",
    mysql_real_escape_string($user),
    mysql_real_escape_string($password));
?>
```

##### Example 21.70. An example SQL Injection Attack

```
<?php
// We didn't check $_POST['password'], it could be anything the user wanted! For example:
$_POST['username'] = 'aidan';
$_POST['password'] = "' OR ''='";

// Query database to check if there are any matching users
$query = "SELECT * FROM users WHERE user='{$_POST['username']}' AND password='{$_POST['password']}'";
mysql_query($query);

// This means the query sent to MySQL would be:
echo $query;
?>
```

The query sent to MySQL:

```
SELECT * FROM users WHERE user='aidan' AND password='' OR ''=''
```

This would allow anyone to log in without a valid password.

## Notes

### Note

A MySQL connection is required before using `mysql_real_escape_string` otherwise an error of level `E_WARNING` is generated, and `FALSE` is returned. If `link_identifier` isn't defined, the last MySQL connection is used.

### Note

If `magic_quotes_gpc` is enabled, first apply `stripslashes` to the data. Using this function on data which has already been escaped will escape the data twice.

### Note

If this function is not used to escape data, the query is vulnerable to [SQL Injection Attacks](#).

### Note

`mysql_real_escape_string` does not escape `%` and `_`. These are wildcards in MySQL if combined with `LIKE`, `GRANT`, or `REVOKE`.

## See Also

`mysql_set_charset`

The `magic_quotes_runtime` directive

### 21.9.2.5.42. `mysql_result`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_result`

Get result data

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_data_seek` in conjunction with `mysqli_field_seek` and `mysqli_fetch_field`  
`PDOStatement::fetchColumn`

## Description

```
string mysql_result(
    resource result,
    int row,
    mixed field
    = =0);
```

Retrieves the contents of one cell from a MySQL result set.

When working on large result sets, you should consider using one of the functions that fetch an entire row (specified below). As these functions return the contents of multiple cells in one function call, they're MUCH quicker than [mysql\\_result](#). Also, note that specifying a numeric offset for the field argument is much quicker than specifying a fieldname or tablename.fieldname argument.

### Parameters

<i>result</i>	The result resource that is being evaluated. This result comes from a call to <a href="#">mysql_query</a> .
<i>row</i>	The row number from the result that's being retrieved. Row numbers start at 0.
<i>field</i>	The name or offset of the field being retrieved.  It can be the field's offset, the field's name, or the field's table dot field name (tablename.fieldname). If the column name has been aliased ('select foo as bar from...'), use the alias instead of the column name. If undefined, the first field is retrieved.

### Return Values

The contents of one cell from a MySQL result set on success, or [FALSE](#) on failure.

### Examples

#### Example 21.71. [mysql\\_result](#) example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
if (!mysql_select_db('database_name')) {
    die('Could not select database: ' . mysql_error());
}
$result = mysql_query('SELECT name FROM work.employee');
if (!$result) {
    die('Could not query:' . mysql_error());
}
echo mysql_result($result, 2); // outputs third employee's name

mysql_close($link);
?>
```

### Notes

#### Note

Calls to [mysql\\_result](#) should not be mixed with calls to other functions that deal with the result set.

### See Also

[mysql\\_fetch\\_row](#)  
[mysql\\_fetch\\_array](#)  
[mysql\\_fetch\\_assoc](#)  
[mysql\\_fetch\\_object](#)

#### 21.9.2.5.43. [mysql\\_select\\_db](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_select_db`

Select a MySQL database

### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_select_db`  
 PDO: `::__construct` (part of dsn)

### Description

```
bool mysql_select_db(
    string database_name,
    resource link_identifier
    = =NULL);
```

Sets the current active database on the server that's associated with the specified link identifier. Every subsequent call to `mysql_query` will be made on the active database.

### Parameters

*database\_name*

The name of the database that is to be selected.

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an [E\\_WARNING](#) level error is generated.

### Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

### Examples

#### Example 21.72. `mysql_select_db` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Not connected : ' . mysql_error());
}

// make foo the current db
$db_selected = mysql_select_db('foo', $link);
if (!$db_selected) {
    die ('Can\'t use foo : ' . mysql_error());
}
?>
```

### Notes

### Note

For backward compatibility, the following deprecated alias may be used:  
`mysql_selectdb`

**See Also**

[mysql\\_pconnect](#)  
[mysql\\_query](#)

**21.9.2.5.44. [mysql\\_set\\_charset](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_set\\_charset](#)

Sets the client character set

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

[mysqli\\_character\\_set\\_name](#)

PDO: Add `charset` to the connection string, such as `charset=utf8`

**Description**

```
bool mysql_set_charset(
    string charset,
    resource link_identifier
    = =NULL);
```

Sets the default character set for the current connection.

**Parameters**

*charset*

A valid character set name.

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Notes****Note**

This function requires MySQL 5.0.7 or later.

**Note**

This is the preferred way to change the charset. Using [mysql\\_query](#) to set it (such as `SET NAMES utf8`) is not recommended. See the [MySQL character set concepts](#) section for more information.

**See Also**

[mysql\\_client\\_encoding](#)  
[Setting character sets in MySQL](#)

---

## List of character sets that MySQL supports

### 21.9.2.5.45. `mysql_stat`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysql_stat`

Get current system status

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

```
mysqli_stat  
PDO::getAttribute(PDO::ATTR_SERVER_INFO)
```

#### Description

```
string mysql_stat(  
    resource link_identifier  
    = =NULL);
```

`mysql_stat` returns the current server status.

#### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

#### Return Values

Returns a string with the status for uptime, threads, queries, open tables, flush tables and queries per second. For a complete list of other status variables, you have to use the `SHOW STATUS SQL` command. If *link\_identifier* is invalid, `NULL` is returned.

#### Examples

##### Example 21.73. `mysql_stat` example

```
<?php  
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');  
$status = explode(' ', mysql_stat($link));  
print_r($status);  
?>
```

The above example will output something similar to:

```
Array  
(  
    [0] => Uptime: 5380  
    [1] => Threads: 2  
    [2] => Questions: 1321299  
    [3] => Slow queries: 0  
    [4] => Opens: 26  
    [5] => Flush tables: 1
```

```
[6] => Open tables: 17
[7] => Queries per second avg: 245.595
)
```

#### Example 21.74. Alternative `mysql_stat` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$result = mysql_query('SHOW STATUS', $link);
while ($row = mysql_fetch_assoc($result)) {
    echo $row['Variable_name'] . ' = ' . $row['Value'] . "\n";
}
?>
```

The above example will output something similar to:

```
back_log = 50
basedir = /usr/local/
bdb_cache_size = 8388600
bdb_log_buffer_size = 32768
bdb_home = /var/db/mysql/
bdb_max_lock = 10000
bdb_logdir =
bdb_shared_data = OFF
bdb_tmpdir = /var/tmp/
...
```

#### See Also

#### 21.9.2.5.46. `mysql_tablename`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_tablename](#)

Get table name of field

#### Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

SQL Query: `SHOW TABLES`

#### Description

```
string mysql_tablename(
    resource result,
    int i);
```

Retrieves the table name from a *result*.

This function is deprecated. It is preferable to use `mysql_query` to issue an SQL `SHOW TABLES [FROM db_name] [LIKE 'pattern']` statement instead.

**Parameters**

<i>result</i>	A result pointer resource that's returned from <a href="#">mysql_list_tables</a> .
<i>i</i>	The integer index (row/table number)

**Return Values**

The name of the table on success or `FALSE` on failure.

Use the [mysql\\_tablename](#) function to traverse this result pointer, or any function for result tables, such as [mysql\\_fetch\\_array](#).

**Changelog**

Version	Description
5.5.0	The <a href="#">mysql_tablename</a> function is deprecated, and emits an <code>E_DEPRECATED</code> level error.

**Examples****Example 21.75. [mysql\\_tablename](#) example**

```
<?php
mysql_connect("localhost", "mysql_user", "mysql_password");
$result = mysql_list_tables("mydb");
$num_rows = mysql_num_rows($result);
for ($i = 0; $i < $num_rows; $i++) {
    echo "Table: ", mysql_tablename($result, $i), "\n";
}

mysql_free_result($result);
?>
```

**Notes****Note**

The [mysql\\_num\\_rows](#) function may be used to determine the number of tables in the result pointer.

**See Also**

[mysql\\_list\\_tables](#)  
[mysql\\_field\\_table](#)  
[mysql\\_db\\_name](#)

**21.9.2.5.47. [mysql\\_thread\\_id](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_thread\\_id](#)

Return the current thread ID

**Warning**

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See

also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

`mysqli_thread_id`

## Description

```
int mysql_thread_id(  
    resource link_identifier  
    = =NULL);
```

Retrieves the current thread ID. If the connection is lost, and a reconnect with `mysql_ping` is executed, the thread ID will change. This means only retrieve the thread ID when needed.

## Parameters

`link_identifier` The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

## Return Values

The thread ID on success or `FALSE` on failure.

## Examples

### Example 21.76. `mysql_thread_id` example

```
<?php  
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');  
$thread_id = mysql_thread_id($link);  
if ($thread_id){  
    printf("current thread id is %d\n", $thread_id);  
}  
?>
```

The above example will output something similar to:

```
current thread id is 73
```

## See Also

[mysql\\_ping](#)

### 21.9.2.5.48. `mysql_unbuffered_query`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysql\\_unbuffered\\_query](#)

Send an SQL query to MySQL without fetching and buffering the result rows.

## Warning

This extension is deprecated as of PHP 5.5.0, and will be removed in the future. Instead, the [MySQLi](#) or [PDO\\_MySQL](#) extension should be used. See

also [MySQL: choosing an API](#) guide and [related FAQ](#) for more information. Alternatives to this function include:

See: [Buffered and Unbuffered queries](#)

## Description

```
resource mysqli_unbuffered_query(  
    string query,  
    resource link_identifier  
    = =NULL);
```

`mysqli_unbuffered_query` sends the SQL query *query* to MySQL without automatically fetching and buffering the result rows as `mysqli_query` does. This saves a considerable amount of memory with SQL queries that produce large result sets, and you can start working on the result set immediately after the first row has been retrieved as you don't have to wait until the complete SQL query has been performed. To use `mysqli_unbuffered_query` while multiple database connections are open, you must specify the optional parameter *link\_identifier* to identify which connection you want to use.

## Parameters

*query*

The SQL query to execute.

Data inside the query should be [properly escaped](#).

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysqli_connect` is assumed. If no such link is found, it will try to create one as if `mysqli_connect` was called with no arguments. If no connection is found or established, an `E_WARNING` level error is generated.

## Return Values

For SELECT, SHOW, DESCRIBE or EXPLAIN statements, `mysqli_unbuffered_query` returns a resource on success, or `FALSE` on error.

For other type of SQL statements, UPDATE, DELETE, DROP, etc, `mysqli_unbuffered_query` returns `TRUE` on success or `FALSE` on error.

## Notes

### Note

The benefits of `mysqli_unbuffered_query` come at a cost: you cannot use `mysqli_num_rows` and `mysqli_data_seek` on a result set returned from `mysqli_unbuffered_query`, until all rows are fetched. You also have to fetch all result rows from an unbuffered SQL query before you can send a new SQL query to MySQL, using the same *link\_identifier*.

## 21.9.3. MySQL Improved Extension (*Mysqli*)

Copyright 1997-2012 the PHP Documentation Group. [2906]

The `mysqli` extension allows you to access the functionality provided by MySQL 4.1 and above. More information about the MySQL Database server can be found at <http://www.mysql.com/>

An overview of software available for using MySQL from PHP can be found at [Section 21.9.3.2, "Overview"](#)

Documentation for MySQL can be found at <http://dev.mysql.com/doc/>.

Parts of this documentation included from MySQL manual with permissions of Oracle Corporation.

### 21.9.3.1. Examples

Copyright 1997-2012 the PHP Documentation Group. [2906]

All examples in the `mysqli` documentation use the world database. The world database can be found at <http://downloads.mysql.com/docs/world.sql.gz>

### 21.9.3.2. Overview

Copyright 1997-2012 the PHP Documentation Group. [2906]

This section provides an introduction to the options available to you when developing a PHP application that needs to interact with a MySQL database.

*What is an API?*

An Application Programming Interface, or API, defines the classes, methods, functions and variables that your application will need to call in order to carry out its desired task. In the case of PHP applications that need to communicate with databases the necessary APIs are usually exposed via PHP extensions.

APIs can be procedural or object-oriented. With a procedural API you call functions to carry out tasks, with the object-oriented API you instantiate classes and then call methods on the resulting objects. Of the two the latter is usually the preferred interface, as it is more modern and leads to better organized code.

When writing PHP applications that need to connect to the MySQL server there are several API options available. This document discusses what is available and how to select the best solution for your application.

*What is a Connector?*

In the MySQL documentation, the term *connector* refers to a piece of software that allows your application to connect to the MySQL database server. MySQL provides connectors for a variety of languages, including PHP.

If your PHP application needs to communicate with a database server you will need to write PHP code to perform such activities as connecting to the database server, querying the database and other database-related functions. Software is required to provide the API that your PHP application will use, and also handle the communication between your application and the database server, possibly using other intermediate libraries where necessary. This software is known generically as a connector, as it allows your application to *connect* to a database server.

*What is a Driver?*

A driver is a piece of software designed to communicate with a specific type of database server. The driver may also call a library, such as the MySQL Client Library or the MySQL Native Driver. These libraries implement the low-level protocol used to communicate with the MySQL database server.

By way of an example, the [PHP Data Objects \(PDO\) \[2985\]](#) database abstraction layer may use one of several database-specific drivers. One of the drivers it has available is the PDO MYSQL driver, which allows it to interface with the MySQL server.

Sometimes people use the terms connector and driver interchangeably, this can be confusing. In the MySQL-related documentation the term “driver” is reserved for software that provides the database-specific part of a connector package.

### *What is an Extension?*

In the PHP documentation you will come across another term - *extension*. The PHP code consists of a core, with optional extensions to the core functionality. PHP's MySQL-related extensions, such as the [mysqli](#) extension, and the [mysql](#) extension, are implemented using the PHP extension framework.

An extension typically exposes an API to the PHP programmer, to allow its facilities to be used programmatically. However, some extensions which use the PHP extension framework do not expose an API to the PHP programmer.

The PDO MySQL driver extension, for example, does not expose an API to the PHP programmer, but provides an interface to the PDO layer above it.

The terms API and extension should not be taken to mean the same thing, as an extension may not necessarily expose an API to the programmer.

### *What are the main PHP API offerings for using MySQL?*

There are three main API options when considering connecting to a MySQL database server:

- PHP's MySQL Extension
- PHP's [mysqli](#) Extension
- PHP Data Objects (PDO)

Each has its own advantages and disadvantages. The following discussion aims to give a brief introduction to the key aspects of each API.

### *What is PHP's MySQL Extension?*

This is the original extension designed to allow you to develop PHP applications that interact with a MySQL database. The [mysql](#) extension provides a procedural interface and is intended for use only with MySQL versions older than 4.1.3. This extension can be used with versions of MySQL 4.1.3 or newer, but not all of the latest MySQL server features will be available.

#### **Note**

If you are using MySQL versions 4.1.3 or later it is *strongly* recommended that you use the [mysqli](#) extension instead.

The [mysql](#) extension source code is located in the PHP extension directory `ext/mysql`.

For further information on the [mysql](#) extension, see [Section 21.9.2, "Original MySQL API \(MySQL\)"](#).

### *What is PHP's [mysqli](#) Extension?*

The [mysqli](#) extension, or as it is sometimes known, the MySQL *improved* extension, was developed to take advantage of new features found in MySQL systems versions 4.1.3 and newer. The [mysqli](#) extension is included with PHP versions 5 and later.

The [mysqli](#) extension has a number of benefits, the key enhancements over the [mysql](#) extension being:

- Object-oriented interface
- Support for Prepared Statements
- Support for Multiple Statements
- Support for Transactions

- Enhanced debugging capabilities
- Embedded server support

**Note**

If you are using MySQL versions 4.1.3 or later it is *strongly* recommended that you use this extension.

As well as the object-oriented interface the extension also provides a procedural interface.

The `mysqli` extension is built using the PHP extension framework, its source code is located in the directory `ext/mysqli`.

For further information on the `mysqli` extension, see [Section 21.9.3, “MySQL Improved Extension \(Mysqli\)”](#).

*What is PDO?*

PHP Data Objects, or PDO, is a database abstraction layer specifically for PHP applications. PDO provides a consistent API for your PHP application regardless of the type of database server your application will connect to. In theory, if you are using the PDO API, you could switch the database server you used, from say Firebird to MySQL, and only need to make minor changes to your PHP code.

Other examples of database abstraction layers include JDBC for Java applications and DBI for Perl.

While PDO has its advantages, such as a clean, simple, portable API, its main disadvantage is that it doesn't allow you to use all of the advanced features that are available in the latest versions of MySQL server. For example, PDO does not allow you to use MySQL's support for Multiple Statements.

PDO is implemented using the PHP extension framework, its source code is located in the directory `ext/pdo`.

For further information on PDO, see the <http://www.php.net/book.pdo>.

*What is the PDO MYSQL driver?*

The PDO MYSQL driver is not an API as such, at least from the PHP programmer's perspective. In fact the PDO MYSQL driver sits in the layer below PDO itself and provides MySQL-specific functionality. The programmer still calls the PDO API, but PDO uses the PDO MYSQL driver to carry out communication with the MySQL server.

The PDO MYSQL driver is one of several available PDO drivers. Other PDO drivers available include those for the Firebird and PostgreSQL database servers.

The PDO MYSQL driver is implemented using the PHP extension framework. Its source code is located in the directory `ext/pdo_mysql`. It does not expose an API to the PHP programmer.

For further information on the PDO MYSQL driver, see [Section 21.9.4, “MySQL Functions \(PDO\\_MYSQL\) \(MySQL \(PDO\)\)”](#).

*What is PHP's MySQL Native Driver?*

In order to communicate with the MySQL database server the `mysql` extension, `mysqli` and the PDO MYSQL driver each use a low-level library that implements the required protocol. In the past, the only available library was the MySQL Client Library, otherwise known as `libmysqlclient`.

However, the interface presented by `libmysqlclient` was not optimized for communication with PHP applications, as `libmysqlclient` was originally designed with C applications in mind. For this reason the MySQL Native Driver, `mysqlnd`, was developed as an alternative to `libmysqlclient` for PHP applications.

The `mysql` extension, the `mysqli` extension and the PDO MySQL driver can each be individually configured to use either `libmysqlclient` or `mysqlnd`. As `mysqlnd` is designed specifically to be utilised in the PHP system it has numerous memory and speed enhancements over `libmysqlclient`. You are strongly encouraged to take advantage of these improvements.

**Note**

The MySQL Native Driver can only be used with MySQL server versions 4.1.3 and later.

The MySQL Native Driver is implemented using the PHP extension framework. The source code is located in `ext/mysqlnd`. It does not expose an API to the PHP programmer.

*Comparison of Features*

The following table compares the functionality of the three main methods of connecting to MySQL from PHP:

**Table 21.38. Comparison of MySQL API options for PHP**

	PHP's <code>mysqli</code> Extension	PDO (Using PDO MySQL Driver and MySQL Native Driver)	PHP's MySQL Extension
PHP version introduced	5.0	5.0	Prior to 3.0
Included with PHP 5.x	yes	yes	Yes
MySQL development status	Active development	Active development as of PHP 5.3	Maintenance only
Recommended by MySQL for new projects	Yes - preferred option	Yes	No
API supports Charsets	Yes	Yes	No
API supports server-side Prepared Statements	Yes	Yes	No
API supports client-side Prepared Statements	No	Yes	No
API supports Stored Procedures	Yes	Yes	No
API supports Multiple Statements	Yes	Most	No
Supports all MySQL 4.1+ functionality	Yes	Most	No

**21.9.3.3. Quick start guide**

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

This quick start guide will help with choosing and gaining familiarity with the PHP MySQL API.

This quick start gives an overview on the `mysqli` extension. Code examples are provided for all major aspects of the API. Database concepts are explained to the degree needed for presenting concepts specific to MySQL.

Required: A familiarity with the PHP programming language, the SQL language, and basic knowledge of the MySQL server.

**21.9.3.3.1. Dual procedural and object-oriented interface**

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The `mysqli` extension features a dual interface. It supports the procedural and object-oriented programming paradigm.

Users migrating from the old `mysql` extension may prefer the procedural interface. The procedural interface is similar to that of the old `mysql` extension. In many cases, the function names differ only by prefix. Some `mysqli` functions take a connection handle as their first argument, whereas matching functions in the old `mysql` interface take it as an optional last argument.

#### Example 21.77. Easy migration from the old `mysql` extension

```
<?php
$mysqli = mysqli_connect("example.com", "user", "password", "database");
$res = mysqli_query($mysqli, "SELECT 'Please, do not use ' AS _msg FROM DUAL");
$row = mysqli_fetch_assoc($res);
echo $row['_msg'];

$mysql = mysql_connect("localhost", "root", "");
mysql_select_db("test");
$res = mysql_query("SELECT 'the mysql extension for new developments.' AS _msg FROM DUAL", $mysql);
$row = mysql_fetch_assoc($res);
echo $row['_msg'];
?>
```

The above example will output:

```
Please, do not use the mysql extension for new developments.
```

#### *The object-oriented interface*

In addition to the classical procedural interface, users can choose to use the object-oriented interface. The documentation is organized using the object-oriented interface. The object-oriented interface shows functions grouped by their purpose, making it easier to get started. The reference section gives examples for both syntax variants.

There are no significant performance differences between the two interfaces. Users can base their choice on personal preference.

#### Example 21.78. Object-oriented and procedural interface

```
<?php
$mysqli = mysqli_connect("example.com", "user", "password", "database");
if (mysqli_connect_errno($mysqli)) {
    echo "Failed to connect to MySQL: " . mysqli_connect_error();
}

$res = mysqli_query($mysqli, "SELECT 'A world full of ' AS _msg FROM DUAL");
$row = mysqli_fetch_assoc($res);
echo $row['_msg'];

$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: " . $mysqli->connect_error;
}

$res = $mysqli->query("SELECT 'choices to please everybody.' AS _msg FROM DUAL");
$row = $res->fetch_assoc();
echo $row['_msg'];
?>
```

The above example will output:

A world full of choices to please everybody.

The object oriented interface is used for the quickstart because the reference section is organized that way.

### *Mixing styles*

It is possible to switch between styles at any time. Mixing both styles is not recommended for code clarity and coding style reasons.

### **Example 21.79. Bad coding style**

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: " . $mysqli->connect_error;
}

$res = mysqli_query($mysqli, "SELECT 'Possible but bad style.' AS _msg FROM DUAL");
if (!$res) {
    echo "Failed to run query: (" . $mysqli->errno . ") " . $mysqli->error;
}

if ($row = $res->fetch_assoc()) {
    echo $row['_msg'];
}
?>
```

The above example will output:

Possible but bad style.

[The MySQLi Extension Function Summary](#)

### **21.9.3.3.2. Connections**

Copyright 1997-2012 the PHP Documentation Group. [2906]

The MySQL server supports the use of different transport layers for connections. Connections use TCP/IP, Unix domain sockets or Windows named pipes.

The hostname `localhost` has a special meaning. It is bound to the use of Unix domain sockets. It is not possible to open a TCP/IP connection using the hostname `localhost` you must use `127.0.0.1` instead.

### **Example 21.80. Special meaning of localhost**

```
<?php
$mysqli = new mysqli("localhost", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}
echo $mysqli->host_info . "\n";

$mysqli = new mysqli("127.0.0.1", "user", "password", "database", 3306);
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

echo $mysqli->host_info . "\n";
?>
```

The above example will output:

```
Localhost via UNIX socket
127.0.0.1 via TCP/IP
```

### *Connection parameter defaults*

Depending on the connection function used, assorted parameters can be omitted. If a parameter is not provided, then the extension attempts to use the default values that are set in the PHP configuration file.

### **Example 21.81. Setting defaults**

```
mysqli.default_host=192.168.2.27
mysqli.default_user=root
mysqli.default_pw=""
mysqli.default_port=3306
mysqli.default_socket=/tmp/mysql.sock
```

The resulting parameter values are then passed to the client library that is used by the extension. If the client library detects empty or unset parameters, then it may default to the library built-in values.

### *Built-in connection library defaults*

If the host value is unset or empty, then the client library will default to a Unix socket connection on [localhost](#). If socket is unset or empty, and a Unix socket connection is requested, then a connection to the default socket on [/tmp/mysql.sock](#) is attempted.

On Windows systems, the host name `.` is interpreted by the client library as an attempt to open a Windows named pipe based connection. In this case the socket parameter is interpreted as the pipe name. If not given or empty, then the socket (pipe name) defaults to `\\.pipe\MySQL`.

If neither a Unix domain socket based not a Windows named pipe based connection is to be established and the port parameter value is unset, the library will default to port [3306](#).

The [mysqldb](#) library and the MySQL Client Library (libmysqlclient) implement the same logic for determining defaults.

### *Connection options*

Connection options are available to, for example, set init commands which are executed upon connect, or for requesting use of a certain charset. Connection options must be set before a network connection is established.

For setting a connection option, the connect operation has to be performed in three steps: creating a connection handle with [mysqli\\_init](#), setting the requested options using [mysqli\\_options](#), and establishing the network connection with [mysqli\\_real\\_connect](#).

### *Connection pooling*

The [mysqli](#) extension supports persistent database connections, which are a special kind of pooled connections. By default, every database connection opened by a script is either explicitly closed by the user during runtime or released automatically at the end of the script. A persistent connection is not. Instead it is put into a pool for later reuse, if a connection to the same server using the same username, password, socket, port and default database is opened. Reuse saves connection overhead.

Every PHP process is using its own [mysqli](#) connection pool. Depending on the web server deployment model, a PHP process may serve one or multiple requests. Therefore, a pooled connection may be used by one or more scripts subsequently.

### *Persistent connection*

If a unused persistent connection for a given combination of host, username, password, socket, port and default database can not be found in the connection pool, then [mysqli](#) opens a new connection. The use of persistent connections can be enabled and disabled using the PHP directive [mysqli.allow\\_persistent](#). The total number of connections opened by a script can be limited with [mysqli.max\\_links](#). The maximum number of persistent connections per PHP process can be restricted with [mysqli.max\\_persistent](#). Please note, that the web server may spawn many PHP processes.

A common complain about persistent connections is that their state is not reset before reuse. For example, open and unfinished transactions are not automatically rolled back. But also, authorization changes which happened in the time between putting the connection into the pool and reusing it are not reflected. This may be seen as an unwanted side-effect. On the contrary, the name [persistent](#) may be understood as a promise that the state is persisted.

The [mysqli](#) extension supports both interpretations of a persistent connection: state persisted, and state reset before reuse. The default is reset. Before a persistent connection is reused, the [mysqli](#) extension implicitly calls [mysqli\\_change\\_user](#) to reset the state. The persistent connection appears to the user as if it was just opened. No artifacts from previous usages are visible.

The [mysqli\\_change\\_user](#) function is an expensive operation. For best performance, users may want to recompile the extension with the compile flag [MYSQLI\\_NO\\_CHANGE\\_USER\\_ON\\_PCONNECT](#) being set.

It is left to the user to choose between safe behavior and best performance. Both are valid optimization goals. For ease of use, the safe behavior has been made the default at the expense of maximum performance.

## 21.9.3.3.3. Executing statements

Copyright 1997-2012 the PHP Documentation Group. [2906]

Statements can be executed with the [mysqli\\_query](#), [mysqli\\_real\\_query](#) and [mysqli\\_multi\\_query](#) functions. The [mysqli\\_query](#) function is the most common, and combines

the executing statement with a buffered fetch of its result set, if any, in one call. Calling `mysqli_query` is identical to calling `mysqli_real_query` followed by `mysqli_store_result`.

### Example 21.82. Connecting to MySQL

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT)") ||
    !$mysqli->query("INSERT INTO test(id) VALUES (1)")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}
?>
```

#### *Buffered result sets*

After statement execution results can be retrieved at once to be buffered by the client or by read row by row. Client-side result set buffering allows the server to free resources associated with the statement results as early as possible. Generally speaking, clients are slow consuming result sets. Therefore, it is recommended to use buffered result sets. `mysqli_query` combines statement execution and result set buffering.

PHP applications can navigate freely through buffered results. Navigation is fast because the result sets are held in client memory. Please, keep in mind that it is often easier to scale by client than it is to scale the server.

### Example 21.83. Navigation through buffered results

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT)") ||
    !$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

$res = $mysqli->query("SELECT id FROM test ORDER BY id ASC");

echo "Reverse order...\n";
for ($row_no = $res->num_rows - 1; $row_no >= 0; $row_no--) {
    $res->data_seek($row_no);
    $row = $res->fetch_assoc();
    echo " id = " . $row['id'] . "\n";
}

echo "Result set order...\n";
$res->data_seek(0);
while ($row = $res->fetch_assoc()) {
    echo " id = " . $row['id'] . "\n";
}
?>
```

The above example will output:

```
Reverse order...
id = 3
id = 2
id = 1
Result set order...
id = 1
id = 2
id = 3
```

### *Unbuffered result sets*

If client memory is a short resource and freeing server resources as early as possible to keep server load low is not needed, unbuffered results can be used. Scrolling through unbuffered results is not possible before all rows have been read.

### **Example 21.84. Navigation through unbuffered results**

```
<?php
$mysqli->real_query("SELECT id FROM test ORDER BY id ASC");
$res = $mysqli->use_result();

echo "Result set order...\n";
while ($row = $res->fetch_assoc()) {
    echo " id = " . $row['id'] . "\n";
}
?>
```

### *Result set values data types*

The `mysqli_query`, `mysqli_real_query` and `mysqli_multi_query` functions are used to execute non-prepared statements. At the level of the MySQL Client Server Protocol, the command `COM_QUERY` and the text protocol are used for statement execution. With the text protocol, the MySQL server converts all data of a result sets into strings before sending. This conversion is done regardless of the SQL result set column data type. The mysql client libraries receive all column values as strings. No further client-side casting is done to convert columns back to their native types. Instead, all values are provided as PHP strings.

### **Example 21.85. Text protocol returns strings by default**

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT, label CHAR(1))") ||
    !$mysqli->query("INSERT INTO test(id, label) VALUES (1, 'a')")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

$res = $mysqli->query("SELECT id, label FROM test WHERE id = 1");
$row = $res->fetch_assoc();

printf("id = %s (%s)\n", $row['id'], gettype($row['id']));
printf("label = %s (%s)\n", $row['label'], gettype($row['label']));
?>
```

The above example will output:

```
id = 1 (string)
label = a (string)
```

It is possible to convert integer and float columns back to PHP numbers by setting the [MYSQLI\\_OPT\\_INT\\_AND\\_FLOAT\\_NATIVE](#) connection option, if using the `mysqlnd` library. If set, the `mysqlnd` library will check the result set meta data column types and convert numeric SQL columns to PHP numbers, if the PHP data type value range allows for it. This way, for example, SQL INT columns are returned as integers.

#### Example 21.86. Native data types with `mysqlnd` and connection option

```
<?php
$mysqli = mysqli_init();
$mysqli->options(MYSQLI_OPT_INT_AND_FLOAT_NATIVE, 1);
$mysqli->real_connect("example.com", "user", "password", "database");

if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT, label CHAR(1))") ||
    !$mysqli->query("INSERT INTO test(id, label) VALUES (1, 'a')")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

$res = $mysqli->query("SELECT id, label FROM test WHERE id = 1");
$row = $res->fetch_assoc();

printf("id = %s (%s)\n", $row['id'], gettype($row['id']));
printf("label = %s (%s)\n", $row['label'], gettype($row['label']));
?>
```

The above example will output:

```
id = 1 (integer)
label = a (string)
```

### 21.9.3.3.4. Prepared Statements

Copyright 1997-2012 the PHP Documentation Group. [2906]

The MySQL database supports prepared statements. A prepared statement or a parameterized statement is used to execute the same statement repeatedly with high efficiency.

*Basic workflow*

The prepared statement execution consists of two stages: prepare and execute. At the prepare stage a statement template is sent to the database server. The server performs a syntax check and initializes server internal resources for later use.

The MySQL server supports using anonymous, positional placeholder with `?`.

#### Example 21.87. First stage: prepare

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

/* Non-prepared statement */
if (!$mysqli->query("DROP TABLE IF EXISTS test") || !$mysqli->query("CREATE TABLE test(id INT)")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

/* Prepared statement, stage 1: prepare */
if (!$stmt = $mysqli->prepare("INSERT INTO test(id) VALUES (?)")) {
    echo "Prepare failed: (" . $mysqli->errno . ") " . $mysqli->error;
}
?>
```

Prepare is followed by execute. During execute the client binds parameter values and sends them to the server. The server creates a statement from the statement template and the bound values to execute it using the previously created internal resources.

#### Example 21.88. Second stage: bind and execute

```
<?php
/* Prepared statement, stage 2: bind and execute */
$id = 1;
if (!$stmt->bind_param("i", $id)) {
    echo "Binding parameters failed: (" . $stmt->errno . ") " . $stmt->error;
}

if (!$stmt->execute()) {
    echo "Execute failed: (" . $stmt->errno . ") " . $stmt->error;
}
?>
```

#### *Repeated execution*

A prepared statement can be executed repeatedly. Upon every execution the current value of the bound variable is evaluated and sent to the server. The statement is not parsed again. The statement template is not transferred to the server again.

#### Example 21.89. INSERT prepared once, executed multiple times

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

/* Non-prepared statement */
if (!$mysqli->query("DROP TABLE IF EXISTS test") || !$mysqli->query("CREATE TABLE test(id INT)")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

/* Prepared statement, stage 1: prepare */
```

```
if (!($stmt = $mysqli->prepare("INSERT INTO test(id) VALUES (?)")) {
    echo "Prepare failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

/* Prepared statement, stage 2: bind and execute */
$id = 1;
if (!$stmt->bind_param("i", $id)) {
    echo "Binding parameters failed: (" . $stmt->errno . ") " . $stmt->error;
}

if (!$stmt->execute()) {
    echo "Execute failed: (" . $stmt->errno . ") " . $stmt->error;
}

/* Prepared statement: repeated execution, only data transferred from client to server */
for ($id = 2; $id < 5; $id++) {
    if (!$stmt->execute()) {
        echo "Execute failed: (" . $stmt->errno . ") " . $stmt->error;
    }
}

/* explicit close recommended */
$stmt->close();

/* Non-prepared statement */
$res = $mysqli->query("SELECT id FROM test");
var_dump($res->fetch_all());
?>
```

The above example will output:

```
array(4) {
  [0]=>
  array(1) {
    [0]=>
    string(1) "1"
  }
  [1]=>
  array(1) {
    [0]=>
    string(1) "2"
  }
  [2]=>
  array(1) {
    [0]=>
    string(1) "3"
  }
  [3]=>
  array(1) {
    [0]=>
    string(1) "4"
  }
}
```

Every prepared statement occupies server resources. Statements should be closed explicitly immediately after use. If not done explicitly, the statement will be closed when the statement handle is freed by PHP.

Using a prepared statement is not always the most efficient way of executing a statement. A prepared statement executed only once causes more client-server round-trips than a non-prepared statement. This is why the [SELECT](#) is not run as a prepared statement above.

Also, consider the use of the MySQL multi-INSERT SQL syntax for INSERTs. For the example, multi-INSERT requires less round-trips between the server and client than the prepared statement shown above.

**Example 21.90. Less round trips using multi-INSERT SQL**

```
<?php
if (!$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3), (4)")) {
    echo "Multi-INSERT failed: (" . $mysqli->errno . ") " . $mysqli->error;
}
?>
```

*Result set values data types*

The MySQL Client Server Protocol defines a different data transfer protocol for prepared statements and non-prepared statements. Prepared statements are using the so called binary protocol. The MySQL server sends result set data "as is" in binary format. Results are not serialized into strings before sending. The client libraries do not receive strings only. Instead, they will receive binary data and try to convert the values into appropriate PHP data types. For example, results from an SQL [INT](#) column will be provided as PHP integer variables.

**Example 21.91. Native datatypes**

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT, label CHAR(1))") ||
    !$mysqli->query("INSERT INTO test(id, label) VALUES (1, 'a')")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

$stmt = $mysqli->prepare("SELECT id, label FROM test WHERE id = 1");
$stmt->execute();
$res = $stmt->get_result();
$row = $res->fetch_assoc();

printf("id = %s (%s)\n", $row['id'], gettype($row['id']));
printf("label = %s (%s)\n", $row['label'], gettype($row['label']));
?>
```

The above example will output:

```
id = 1 (integer)
label = a (string)
```

This behavior differs from non-prepared statements. By default, non-prepared statements return all results as strings. This default can be changed using a connection option. If the connection option is used, there are no differences.

*Fetching results using bound variables*

Results from prepared statements can either be retrieved by binding output variables, or by requesting a [mysqli\\_result](#) object.

Output variables must be bound after statement execution. One variable must be bound for every column of the statements result set.

**Example 21.92. Output variable binding**

```

<?php
mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT, label CHAR(1))") ||
    !$mysqli->query("INSERT INTO test(id, label) VALUES (1, 'a')")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$stmt = $mysqli->prepare("SELECT id, label FROM test")) {
    echo "Prepare failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$stmt->execute()) {
    echo "Execute failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

$out_id = NULL;
$out_label = NULL;
if (!$stmt->bind_result($out_id, $out_label)) {
    echo "Binding output parameters failed: (" . $stmt->errno . ") " . $stmt->error;
}

while ($stmt->fetch()) {
    printf("id = %s (%s), label = %s (%s)\n", $out_id, gettype($out_id), $out_label, gettype($out_label));
}
?>

```

The above example will output:

```
id = 1 (integer), label = a (string)
```

Prepared statements return unbuffered result sets by default. The results of the statement are not implicitly fetched and transferred from the server to the client for client-side buffering. The result set takes server resources until all results have been fetched by the client. Thus it is recommended to consume results timely. If a client fails to fetch all results or the client closes the statement before having fetched all data, the data has to be fetched implicitly by `mysqli`.

It is also possible to buffer the results of a prepared statement using `mysqli_stmt_store_result`.

#### *Fetching results using `mysqli_result` interface*

Instead of using bound results, results can also be retrieved through the `mysqli_result` interface. `mysqli_stmt_get_result` returns a buffered result set.

#### **Example 21.93. Using `mysqli_result` to fetch results**

```

<?php
mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT, label CHAR(1))") ||
    !$mysqli->query("INSERT INTO test(id, label) VALUES (1, 'a')")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$stmt = $mysqli->prepare("SELECT id, label FROM test ORDER BY id ASC")) {

```

```

    echo "Prepare failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$stmt->execute()) {
    echo "Execute failed: (" . $stmt->errno . ") " . $stmt->error;
}

if (!$res = $stmt->get_result()) {
    echo "Getting result set failed: (" . $stmt->errno . ") " . $stmt->error;
}

var_dump($res->fetch_all());
?>

```

The above example will output:

```

array(1) {
  [0]=>
  array(2) {
    [0]=>
    int(1)
    [1]=>
    string(1) "a"
  }
}

```

Using the [mysqli\\_result](#) interface offers the additional benefit of flexible client-side result set navigation.

#### Example 21.94. Buffered result set for flexible read out

```

<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT, label CHAR(1))") ||
    !$mysqli->query("INSERT INTO test(id, label) VALUES (1, 'a'), (2, 'b'), (3, 'c')")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$stmt = $mysqli->prepare("SELECT id, label FROM test")) {
    echo "Prepare failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$stmt->execute()) {
    echo "Execute failed: (" . $stmt->errno . ") " . $stmt->error;
}

if (!$res = $stmt->get_result()) {
    echo "Getting result set failed: (" . $stmt->errno . ") " . $stmt->error;
}

for ($row_no = ($res->num_rows - 1); $row_no >= 0; $row_no--) {
    $res->data_seek($row_no);
    var_dump($res->fetch_assoc());
}
$res->close();
?>

```

The above example will output:

```

array(2) {
  ["id"]=>
  int(3)
  ["label"]=>
  string(1) "c"
}
array(2) {
  ["id"]=>
  int(2)
  ["label"]=>
  string(1) "b"
}
array(2) {
  ["id"]=>
  int(1)
  ["label"]=>
  string(1) "a"
}

```

### *Escaping and SQL injection*

Bound variables will be escaped automatically by the server. The server inserts their escaped values at the appropriate places into the statement template before execution. A hint must be provided to the server for the type of bound variable, to create an appropriate conversion. See the [mysqli\\_stmt\\_bind\\_param](#) function for more information.

The automatic escaping of values within the server is sometimes considered a security feature to prevent SQL injection. The same degree of security can be achieved with non-prepared statements, if input values are escaped correctly.

### *Client-side prepared statement emulation*

The API does not include emulation for client-side prepared statement emulation.

### *Quick prepared - non-prepared statement comparison*

The table below compares server-side prepared and non-prepared statements.

**Table 21.39. Comparison of prepared and non-prepared statements**

	<b>Prepared Statement</b>	<b>Non-prepared statement</b>
Client-server round trips, SELECT, single execution	2	1
Statement string transferred from client to server	1	1
Client-server round trips, SELECT, repeated (n) execution	1 + n	n
Statement string transferred from client to server	1 template, n times bound parameter, if any	n times together with parameter, if any
Input parameter binding API	Yes, automatic input escaping	No, manual input escaping
Output variable binding API	Yes	No
Supports use of mysqli_result API	Yes, use <a href="#">mysqli_stmt_get_result</a>	Yes
Buffered result sets	Yes, use <a href="#">mysqli_stmt_get_result</a> or binding with <a href="#">mysqli_stmt_store_result</a>	Yes, default of <a href="#">mysqli_query</a>

	Prepared Statement	Non-prepared statement
Unbuffered result sets	Yes, use output binding API	Yes, use <code>mysqli_real_query</code> with <code>mysqli_use_result</code>
MySQL Client Server protocol data transfer flavor	Binary protocol	Text protocol
Result set values SQL data types	Preserved when fetching	Converted to string or preserved when fetching
Supports all SQL statements	Recent MySQL versions support most but not all	Yes

### 21.9.3.3.5. Stored Procedures

Copyright 1997-2012 the PHP Documentation Group. [2906]

The MySQL database supports stored procedures. A stored procedure is a subroutine stored in the database catalog. Applications can call and execute the stored procedure. The `CALL` SQL statement is used to execute a stored procedure.

#### Parameter

Stored procedures can have `IN`, `INOUT` and `OUT` parameters, depending on the MySQL version. The `mysqli` interface has no special notion for the different kinds of parameters.

#### IN parameter

Input parameters are provided with the `CALL` statement. Please, make sure values are escaped correctly.

#### Example 21.95. Calling a stored procedure

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") || !$mysqli->query("CREATE TABLE test(id INT)")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$mysqli->query("DROP PROCEDURE IF EXISTS p") ||
    !$mysqli->query("CREATE PROCEDURE p(IN id_val INT) BEGIN INSERT INTO test(id) VALUES(id_val); END;")) {
    echo "Stored procedure creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$mysqli->query("CALL p(1)")) {
    echo "CALL failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$res = $mysqli->query("SELECT id FROM test")) {
    echo "SELECT failed: (" . $mysqli->errno . ") " . $mysqli->error;
}
```

```

}

var_dump($res->fetch_assoc());
?>

```

The above example will output:

```

array(1) {
  ["id"]=>
  string(1) "1"
}

```

### *INOUT/OUT parameter*

The values of *INOUT/OUT* parameters are accessed using session variables.

### **Example 21.96. Using session variables**

```

<?php
mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP PROCEDURE IF EXISTS p") ||
    !$mysqli->query('CREATE PROCEDURE p(OUT msg VARCHAR(50)) BEGIN SELECT "Hi!" INTO msg; END;')) {
    echo "Stored procedure creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$mysqli->query("SET @msg = ''") || !$mysqli->query("CALL p(@msg)")) {
    echo "CALL failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$res = $mysqli->query("SELECT @msg as _p_out")) {
    echo "Fetch failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

$row = $res->fetch_assoc();
echo $row['_p_out'];
?>

```

The above example will output:

```

Hi!

```

Application and framework developers may be able to provide a more convenient API using a mix of session variables and databased catalog inspection. However, please note the possible performance impact of a custom solution based on catalog inspection.

### *Handling result sets*

Stored procedures can return result sets. Result sets returned from a stored procedure cannot be fetched correctly using `mysqli_query`. The `mysqli_query` function combines statement execution and fetching the first result set into a buffered result set, if any. However, there are additional stored procedure result sets hidden from the user which cause `mysqli_query` to fail returning the user expected result sets.

Result sets returned from a stored procedure are fetched using `mysqli_real_query` or `mysqli_multi_query`. Both functions allow fetching any number of result sets returned by a statement, such as `CALL`. Failing to fetch all result sets returned by a stored procedure causes an error.

### Example 21.97. Fetching results from stored procedures

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT)") ||
    !$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$mysqli->query("DROP PROCEDURE IF EXISTS p") ||
    !$mysqli->query('CREATE PROCEDURE p() READS SQL DATA BEGIN SELECT id FROM test; SELECT id + 1 FROM test')) {
    echo "Stored procedure creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$mysqli->multi_query("CALL p()")) {
    echo "CALL failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

do {
    if ($res = $mysqli->store_result()) {
        printf("---\n");
        var_dump($res->fetch_all());
        $res->free();
    } else {
        if ($mysqli->errno) {
            echo "Store failed: (" . $mysqli->errno . ") " . $mysqli->error;
        }
    }
} while ($mysqli->more_results() && $mysqli->next_result());
?>
```

The above example will output:

```
---
array(3) {
  [0]=>
  array(1) {
    [0]=>
    string(1) "1"
  }
  [1]=>
  array(1) {
    [0]=>
    string(1) "2"
  }
  [2]=>
  array(1) {
    [0]=>
    string(1) "3"
  }
}
---
array(3) {
  [0]=>
  array(1) {
    [0]=>
    string(1) "2"
  }
}
```

```

}
[1]=>
array(1) {
  [0]=>
    string(1) "3"
}
[2]=>
array(1) {
  [0]=>
    string(1) "4"
}
}

```

### *Use of prepared statements*

No special handling is required when using the prepared statement interface for fetching results from the same stored procedure as above. The prepared statement and non-prepared statement interfaces are similar. Please note, that not every MySQL server version may support preparing the [CALL SQL](#) statement.

### **Example 21.98. Stored Procedures and Prepared Statements**

```

<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT)") ||
    !$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$mysqli->query("DROP PROCEDURE IF EXISTS p") ||
    !$mysqli->query('CREATE PROCEDURE p() READS SQL DATA BEGIN SELECT id FROM test; SELECT id + 1 FROM test;')) {
    echo "Stored procedure creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!(($stmt = $mysqli->prepare("CALL p()"))) {
    echo "Prepare failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$stmt->execute()) {
    echo "Execute failed: (" . $stmt->errno . ") " . $stmt->error;
}

do {
    if ($res = $stmt->get_result()) {
        printf("---\n");
        var_dump(mysqli_fetch_all($res));
        mysqli_free_result($res);
    } else {
        if ($stmt->errno) {
            echo "Store failed: (" . $stmt->errno . ") " . $stmt->error;
        }
    }
} while ($stmt->more_results() && $stmt->next_result());
?>

```

Of course, use of the bind API for fetching is supported as well.

### **Example 21.99. Stored Procedures and Prepared Statements using bind API**

```

<?php
if (!$stmt = $mysqli->prepare("CALL p())) {
    echo "Prepare failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

if (!$stmt->execute()) {
    echo "Execute failed: (" . $stmt->errno . ") " . $stmt->error;
}

do {

    $id_out = NULL;
    if (!$stmt->bind_result($id_out)) {
        echo "Bind failed: (" . $stmt->errno . ") " . $stmt->error;
    }

    while ($stmt->fetch()) {
        echo "id = $id_out\n";
    }
} while ($stmt->more_results() && $stmt->next_result());
?>

```

### 21.9.3.3.6. Multiple Statements

Copyright 1997-2012 the PHP Documentation Group. [2906]

MySQL optionally allows having multiple statements in one statement string. Sending multiple statements at once reduces client-server round trips but requires special handling.

Multiple statements or multi queries must be executed with [mysqli\\_multi\\_query](#). The individual statements of the statement string are separated by semicolon. Then, all result sets returned by the executed statements must be fetched.

The MySQL server allows having statements that do return result sets and statements that do not return result sets in one multiple statement.

#### Example 21.100. Multiple Statements

```

<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

if (!$mysqli->query("DROP TABLE IF EXISTS test") || !$mysqli->query("CREATE TABLE test(id INT)")) {
    echo "Table creation failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

$sql = "SELECT COUNT(*) AS _num FROM test; ";
$sql.= "INSERT INTO test(id) VALUES (1); ";
$sql.= "SELECT COUNT(*) AS _num FROM test; ";

if (!$mysqli->multi_query($sql)) {
    echo "Multi query failed: (" . $mysqli->errno . ") " . $mysqli->error;
}

do {
    if ($res = $mysqli->store_result()) {
        var_dump($res->fetch_all(MYSQLI_ASSOC));
    }
}

```

```
        $res->free();
    }
} while ($mysqli->more_results() && $mysqli->next_result());
?>
```

The above example will output:

```
array(1) {
  [0]=>
  array(1) {
    ["_num"]=>
    string(1) "0"
  }
}
array(1) {
  [0]=>
  array(1) {
    ["_num"]=>
    string(1) "1"
  }
}
```

### *Security considerations*

The API functions [mysqli\\_query](#) and [mysqli\\_real\\_query](#) do not set a connection flag necessary for activating multi queries in the server. An extra API call is used for multiple statements to reduce the likeliness of accidental SQL injection attacks. An attacker may try to add statements such as `;` [DROP DATABASE mysql](#) or `;` [SELECT SLEEP\(999\)](#). If the attacker succeeds in adding SQL to the statement string but [mysqli\\_multi\\_query](#) is not used, the server will not execute the second, injected and malicious SQL statement.

### **Example 21.101. SQL Injection**

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
$res    = $mysqli->query("SELECT 1; DROP TABLE mysql.user");
if (!$res) {
    echo "Error executing query: (" . $mysqli->errno . ") " . $mysqli->error;
}
?>
```

The above example will output:

```
Error executing query: (1064) You have an error in your SQL syntax;
check the manual that corresponds to your MySQL server version for the right syntax
to use near 'DROP TABLE mysql.user' at line 1
```

### *Prepared statements*

Use of the multiple statement with prepared statements is not supported.

### 21.9.3.3.7. API support for transactions

Copyright 1997-2012 the PHP Documentation Group. [2906]

The MySQL server supports transactions depending on the storage engine used. Since MySQL 5.5, the default storage engine is InnoDB. InnoDB has full ACID transaction support.

Transactions can either be controlled using SQL or API calls. It is recommended to use API calls for enabling and disabling the auto commit mode and for committing and rolling back transactions.

#### Example 21.102. Setting auto commit mode with SQL and through the API

```
<?php
mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

/* Recommended: using API to control transactional settings */
mysqli->autocommit(false);

/* Won't be monitored and recognized by the replication and the load balancing plugin */
if (!$mysqli->query('SET AUTOCOMMIT = 0')) {
    echo "Query failed: (" . $mysqli->errno . ") " . $mysqli->error;
}
?>
```

Optional feature packages, such as the replication and load balancing plugin, can easily monitor API calls. The replication plugin offers transaction aware load balancing, if transactions are controlled with API calls. Transaction aware load balancing is not available if SQL statements are used for setting auto commit mode, committing or rolling back a transaction.

#### Example 21.103. Commit and rollback

```
<?php
mysqli = new mysqli("example.com", "user", "password", "database");
mysqli->autocommit(false);

mysqli->query("INSERT INTO test(id) VALUES (1)");
mysqli->rollback();

mysqli->query("INSERT INTO test(id) VALUES (2)");
mysqli->commit();
?>
```

Please note, that the MySQL server cannot roll back all statements. Some statements cause an implicit commit.

### 21.9.3.3.8. Metadata

Copyright 1997-2012 the PHP Documentation Group. [2906]

A MySQL result set contains metadata. The metadata describes the columns found in the result set. All metadata sent by MySQL is accessible through the [mysqli](#) interface. The extension performs no or

negligible changes to the information it receives. Differences between MySQL server versions are not aligned.

Meta data is access through the [mysqli\\_result](#) interface.

#### Example 21.104. Accessing result set meta data

```
<?php
$mysqli = new mysqli("example.com", "user", "password", "database");
if ($mysqli->connect_errno) {
    echo "Failed to connect to MySQL: (" . $mysqli->connect_errno . ") " . $mysqli->connect_error;
}

$res = $mysqli->query("SELECT 1 AS _one, 'Hello' AS _two FROM DUAL");
var_dump($res->fetch_fields());
?>
```

The above example will output:

```
array(2) {
  [0]=>
  object(stdClass)#3 (13) {
    ["name"]=>
    string(4) "_one"
    ["orgname"]=>
    string(0) ""
    ["table"]=>
    string(0) ""
    ["orgtable"]=>
    string(0) ""
    ["def"]=>
    string(0) ""
    ["db"]=>
    string(0) ""
    ["catalog"]=>
    string(3) "def"
    ["max_length"]=>
    int(1)
    ["length"]=>
    int(1)
    ["charsetnr"]=>
    int(63)
    ["flags"]=>
    int(32897)
    ["type"]=>
    int(8)
    ["decimals"]=>
    int(0)
  }
  [1]=>
  object(stdClass)#4 (13) {
    ["name"]=>
    string(4) "_two"
    ["orgname"]=>
    string(0) ""
    ["table"]=>
    string(0) ""
    ["orgtable"]=>
    string(0) ""
    ["def"]=>
    string(0) ""
    ["db"]=>
    string(0) ""
    ["catalog"]=>
    string(3) "def"
    ["max_length"]=>
    int(5)
  }
}
```

```
[ "length" ]=>
int(5)
[ "charsetnr" ]=>
int(8)
[ "flags" ]=>
int(1)
[ "type" ]=>
int(253)
[ "decimals" ]=>
int(31)
}
}
```

### Prepared statements

Meta data of result sets created using prepared statements are accessed the same way. A suitable `mysqli_result` handle is returned by `mysqli_stmt_result_metadata`.

### Example 21.105. Prepared statements metadata

```
<?php
$stmt = $mysqli->prepare("SELECT 1 AS _one, 'Hello' AS _two FROM DUAL");
$stmt->execute();
$res = $stmt->result_metadata();
var_dump($res->fetch_fields());
?>
```

## 21.9.3.4. Installing/Configuring

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

### 21.9.3.4.1. Requirements

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

In order to have these functions available, you must compile PHP with support for the `mysqli` extension.

#### Note

The `mysqli` extension is designed to work with MySQL version 4.1.13 or newer, or 5.0.7 or newer. For previous versions, please see the [MySQL](#) extension documentation.

### 21.9.3.4.2. Installation

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The `mysqli` extension was introduced with PHP version 5.0.0. The MySQL Native Driver was included in PHP version 5.3.0.

#### 21.9.3.4.2.1. Installation on Linux

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The common Unix distributions include binary versions of PHP that can be installed. Although these binary versions are typically built with support for MySQL extensions enabled, the extension libraries

themselves may need to be installed using an additional package. Check the package manager that comes with your chosen distribution for availability.

Unless your Unix distribution comes with a binary package of PHP with the [mysqli](#) extension available, you will need to build PHP from source code. Building PHP from source allows you to specify the MySQL extensions you want to use, as well as your choice of client library for each extension.

The MySQL Native Driver is the recommended option, as it results in improved performance and gives access to features not available when using the MySQL Client Library. Refer to [What is PHP's MySQL Native Driver? \[2985\]](#) for a brief overview of the advantages of MySQL Native Driver.

The `/path/to/mysqli_config` represents the location of the `mysqli_config` program that comes with MySQL Server.

**Table 21.40. mysqli compile time support matrix**

PHP Version	Default	Configure Options: <a href="#">mysqli</a>	Configure Options: <a href="#">libmysqlclient</a>	Changelog
5.0.x, 5.1.x, 5.2.x	libmysqlclient	Not Available	<code>--with-mysqli=/path/to/mysqli_config</code>	
5.3.x	libmysqlclient	<code>--with-mysqli=mysqli</code>	<code>--with-mysqli=/path/to/mysqli_config</code>	mysqli is now supported
5.4.x	mysqli	<code>--with-mysqli</code>	<code>--with-mysqli=/path/to/mysqli_config</code>	mysqli is now the default

Note that it is possible to freely mix MySQL extensions and client libraries. For example, it is possible to enable the MySQL extension to use the MySQL Client Library (`libmysqlclient`), while configuring the [mysqli](#) extension to use the MySQL Native Driver. However, all permutations of extension and client library are possible.

The following example builds the MySQL extension to use the MySQL Client Library, and the [mysqli](#) and PDO MySQL extensions to use the MySQL Native Driver:

```
./configure --with-mysql=/usr/bin/mysqli_config \
--with-mysqli=mysqli \
--with-pdo-mysql=mysqli \
[other options]
```

#### 21.9.3.4.2.2. Installation on Windows Systems

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

On Windows, PHP is most commonly installed using the binary installer.

##### 21.9.3.4.2.2.1. PHP 5.0, 5.1, 5.2

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

Once PHP has been installed, some configuration is required to enable [mysqli](#) and specify the client library you want it to use.

The [mysqli](#) extension is not enabled by default, so the `php_mysqli.dll` DLL must be enabled inside of `php.ini`. In order to do this you need to find the `php.ini` file (typically located

in `c:\php`), and make sure you remove the comment (semi-colon) from the start of the line `extension=php_mysqli.dll`, in the section marked `[PHP_MYSQLI]`.

Also, if you want to use the MySQL Client Library with `mysqli`, you need to make sure PHP can access the client library file. The MySQL Client Library is included as a file named `libmysql.dll` in the Windows PHP distribution. This file needs to be available in the Windows system's `PATH` environment variable, so that it can be successfully loaded. See the FAQ titled "[How do I add my PHP directory to the PATH on Windows](#)" for information on how to do this. Copying `libmysql.dll` to the Windows system directory (typically `c:\Windows\system`) also works, as the system directory is by default in the system's `PATH`. However, this practice is strongly discouraged.

As with enabling any PHP extension (such as `php_mysqli.dll`), the PHP directive `extension_dir` should be set to the directory where the PHP extensions are located. See also the [Manual Windows Installation Instructions](#). An example `extension_dir` value for PHP 5 is `c:\php\ext`.

#### Note

If when starting the web server an error similar to the following occurs: "Unable to load dynamic library './php\_mysqli.dll'", this is because `php_mysqli.dll` and/or `libmysql.dll` cannot be found by the system.

#### 21.9.3.4.2.2. PHP 5.3.0+

Copyright 1997-2012 the PHP Documentation Group. [2906]

On Windows, for PHP versions 5.3 and newer, the `mysqli` extension is enabled and uses the MySQL Native Driver by default. This means you don't need to worry about configuring access to `libmysql.dll`.

#### 21.9.3.4.3. Runtime Configuration

Copyright 1997-2012 the PHP Documentation Group. [2906]

The behaviour of these functions is affected by settings in `php.ini`.

**Table 21.41. MySQLi Configuration Options**

Name	Default	Changeable	Changelog
<code>mysqli.allow_local_infile</code>	"1"	PHP_INI_SYSTEM	Available since PHP 5.2.4.
<code>mysqli.allow_persistent</code>	"1"	PHP_INI_SYSTEM	Available since PHP 5.3.0.
<code>mysqli.max_persistent</code>	"-1"	PHP_INI_SYSTEM	Available since PHP 5.3.0.
<code>mysqli.max_links</code>	"-1"	PHP_INI_SYSTEM	Available since PHP 5.0.0.
<code>mysqli.default_port</code>	"3306"	PHP_INI_ALL	Available since PHP 5.0.0.
<code>mysqli.default_socket</code>	NULL	PHP_INI_ALL	Available since PHP 5.0.0.
<code>mysqli.default_host</code>	NULL	PHP_INI_ALL	Available since PHP 5.0.0.
<code>mysqli.default_user</code>	NULL	PHP_INI_ALL	Available since PHP 5.0.0.
<code>mysqli.default_pw</code>	NULL	PHP_INI_ALL	Available since PHP 5.0.0.

Name	Default	Changeable	Changelog
<a href="#">mysqli.reconnect</a>	"0"	PHP_INI_SYSTEM	Available since PHP 4.3.5.
<a href="#">mysqli.cache_size</a>	"2000"	PHP_INI_SYSTEM	Available since PHP 5.3.0.

For further details and definitions of the preceding `PHP_INI_*` constants, see the chapter on [configuration changes](#).

Here's a short explanation of the configuration directives.

<a href="#">mysqli.allow_local_infile</a> integer	Allow accessing, from PHP's perspective, local files with LOAD DATA statements
<a href="#">mysqli.allow_persistent</a> integer	Enable the ability to create persistent connections using <a href="#">mysqli_connect</a> .
<a href="#">mysqli.max_persistent</a> integer	Maximum of persistent connections that can be made. Set to 0 for unlimited.
<a href="#">mysqli.max_links</a> integer	The maximum number of MySQL connections per process.
<a href="#">mysqli.default_port</a> integer	The default TCP port number to use when connecting to the database server if no other port is specified. If no default is specified, the port will be obtained from the <code>MYSQL_TCP_PORT</code> environment variable, the <code>mysql-tcp</code> entry in <code>/etc/services</code> or the compile-time <code>MYSQL_PORT</code> constant, in that order. Win32 will only use the <code>MYSQL_PORT</code> constant.
<a href="#">mysqli.default_socket</a> string	The default socket name to use when connecting to a local database server if no other socket name is specified.
<a href="#">mysqli.default_host</a> string	The default server host to use when connecting to the database server if no other host is specified. Doesn't apply in <a href="#">safe mode</a> .
<a href="#">mysqli.default_user</a> string	The default user name to use when connecting to the database server if no other name is specified. Doesn't apply in <a href="#">safe mode</a> .
<a href="#">mysqli.default_pw</a> string	The default password to use when connecting to the database server if no other password is specified. Doesn't apply in <a href="#">safe mode</a> .
<a href="#">mysqli.reconnect</a> integer	Automatically reconnect if the connection was lost.
<a href="#">mysqli.cache_size</a> integer	Available only with <a href="#">mysqli</a> .

Users cannot set `MYSQL_OPT_READ_TIMEOUT` through an API call or runtime configuration setting. Note that if it were possible there would be differences between how `libmysqlclient` and streams would interpret the value of `MYSQL_OPT_READ_TIMEOUT`.

#### 21.9.3.4.4. Resource Types

Copyright 1997-2012 the PHP Documentation Group. [2906]

This extension has no resource types defined.

#### 21.9.3.5. The `mysqli` Extension and Persistent Connections

Copyright 1997-2012 the PHP Documentation Group. [2906]

Persistent connection support was introduced in PHP 5.3 for the `mysqli` extension. Support was already present in PDO MySQL and `ext/mysql`. The idea behind persistent connections is that a connection between a client process and a database can be reused by a client process, rather than

being created and destroyed multiple times. This reduces the overhead of creating fresh connections every time one is required, as unused connections are cached and ready to be reused.

Unlike the `mysql` extension, `mysqli` does not provide a separate function for opening persistent connections. To open a persistent connection you must prepend `p:` to the hostname when connecting.

The problem with persistent connections is that they can be left in unpredictable states by clients. For example, a table lock might be activated before a client terminates unexpectedly. A new client process reusing this persistent connection will get the connection “as is”. Any cleanup would need to be done by the new client process before it could make good use of the persistent connection, increasing the burden on the programmer.

The persistent connection of the `mysqli` extension however provides built-in cleanup handling code. The cleanup carried out by `mysqli` includes:

- Rollback active transactions
- Close and drop temporary tables
- Unlock tables
- Reset session variables
- Close prepared statements (always happens with PHP)
- Close handler
- Release locks acquired with `GET_LOCK`

This ensures that persistent connections are in a clean state on return from the connection pool, before the client process uses them.

The `mysqli` extension does this cleanup by automatically calling the C-API function `mysql_change_user()`.

The automatic cleanup feature has advantages and disadvantages though. The advantage is that the programmer no longer needs to worry about adding cleanup code, as it is called automatically. However, the disadvantage is that the code could *potentially* be a little slower, as the code to perform the cleanup needs to run each time a connection is returned from the connection pool.

It is possible to switch off the automatic cleanup code, by compiling PHP with `MYSQLI_NO_CHANGE_USER_ON_PCONNECT` defined.

**Note**

The `mysqli` extension supports persistent connections when using either MySQL Native Driver or MySQL Client Library.

### 21.9.3.6. Predefined Constants

Copyright 1997-2012 the PHP Documentation Group. [2906]

The constants below are defined by this extension, and will only be available when the extension has either been compiled into PHP or dynamically loaded at runtime.

`MYSQLI_READ_DEFAULT_GROUP` Read options from the named group from `my.cnf` or the file specified with `MYSQLI_READ_DEFAULT_FILE`

`MYSQLI_READ_DEFAULT_FILE` Read options from the named option file instead of from `my.cnf`

`MYSQLI_OPT_CONNECT_TIMEOUT` Connect timeout in seconds

`MYSQLI_OPT_LOCAL_INFILE` Enables command `LOAD LOCAL INFILE`

<code>MYSQLI_INIT_COMMAND</code>	Command to execute when connecting to MySQL server. Will automatically be re-executed when reconnecting.
<code>MYSQLI_CLIENT_SSL</code>	Use SSL (encrypted protocol). This option should not be set by application programs; it is set internally in the MySQL client library
<code>MYSQLI_CLIENT_COMPRESS</code>	Use compression protocol
<code>MYSQLI_CLIENT_INTERACTIVE</code>	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> variable will be set to the value of the session <code>interactive_timeout</code> variable.
<code>MYSQLI_CLIENT_IGNORE_SPACE</code>	Allow spaces after function names. Makes all functions names reserved words.
<code>MYSQLI_CLIENT_NO_SCHEMA</code>	Don't allow the <code>db_name.tbl_name.col_name</code> syntax.
<code>MYSQLI_CLIENT_MULTI_QUERY</code>	Allows multiple semicolon-delimited queries in a single <code>mysqli_query</code> call.
<code>MYSQLI_STORE_RESULT</code>	For using buffered resultsets
<code>MYSQLI_USE_RESULT</code>	For using unbuffered resultsets
<code>MYSQLI_ASSOC</code>	Columns are returned into the array having the fieldname as the array index.
<code>MYSQLI_NUM</code>	Columns are returned into the array having an enumerated index.
<code>MYSQLI_BOTH</code>	Columns are returned into the array having both a numerical index and the fieldname as the associative index.
<code>MYSQLI_NOT_NULL_FLAG</code>	Indicates that a field is defined as <code>NOT NULL</code>
<code>MYSQLI_PRI_KEY_FLAG</code>	Field is part of a primary index
<code>MYSQLI_UNIQUE_KEY_FLAG</code>	Field is part of a unique index.
<code>MYSQLI_MULTIPLE_KEY_FLAG</code>	Field is part of an index.
<code>MYSQLI_BLOB_FLAG</code>	Field is defined as <code>BLOB</code>
<code>MYSQLI_UNSIGNED_FLAG</code>	Field is defined as <code>UNSIGNED</code>
<code>MYSQLI_ZEROFILL_FLAG</code>	Field is defined as <code>ZEROFILL</code>
<code>MYSQLI_AUTO_INCREMENT_FLAG</code>	Field is defined as <code>AUTO_INCREMENT</code>
<code>MYSQLI_TIMESTAMP_FLAG</code>	Field is defined as <code>TIMESTAMP</code>
<code>MYSQLI_SET_FLAG</code>	Field is defined as <code>SET</code>
<code>MYSQLI_NUM_FLAG</code>	Field is defined as <code>NUMERIC</code>
<code>MYSQLI_PART_KEY_FLAG</code>	Field is part of an multi-index
<code>MYSQLI_GROUP_FLAG</code>	Field is part of <code>GROUP BY</code>
<code>MYSQLI_TYPE_DECIMAL</code>	Field is defined as <code>DECIMAL</code>
<code>MYSQLI_TYPE_NEWDECIMAL</code>	Precision math <code>DECIMAL</code> or <code>NUMERIC</code> field (MySQL 5.0.3 and up)
<code>MYSQLI_TYPE_BIT</code>	Field is defined as <code>BIT</code> (MySQL 5.0.3 and up)

<code>MYSQLI_TYPE_TINY</code>	Field is defined as <code>TINYINT</code>
<code>MYSQLI_TYPE_SHORT</code>	Field is defined as <code>SMALLINT</code>
<code>MYSQLI_TYPE_LONG</code>	Field is defined as <code>INT</code>
<code>MYSQLI_TYPE_FLOAT</code>	Field is defined as <code>FLOAT</code>
<code>MYSQLI_TYPE_DOUBLE</code>	Field is defined as <code>DOUBLE</code>
<code>MYSQLI_TYPE_NULL</code>	Field is defined as <code>DEFAULT NULL</code>
<code>MYSQLI_TYPE_TIMESTAMP</code>	Field is defined as <code>TIMESTAMP</code>
<code>MYSQLI_TYPE_LONGLONG</code>	Field is defined as <code>BIGINT</code>
<code>MYSQLI_TYPE_INT24</code>	Field is defined as <code>MEDIUMINT</code>
<code>MYSQLI_TYPE_DATE</code>	Field is defined as <code>DATE</code>
<code>MYSQLI_TYPE_TIME</code>	Field is defined as <code>TIME</code>
<code>MYSQLI_TYPE_DATETIME</code>	Field is defined as <code>DATETIME</code>
<code>MYSQLI_TYPE_YEAR</code>	Field is defined as <code>YEAR</code>
<code>MYSQLI_TYPE_NEWDATE</code>	Field is defined as <code>DATE</code>
<code>MYSQLI_TYPE_INTERVAL</code>	Field is defined as <code>INTERVAL</code>
<code>MYSQLI_TYPE_ENUM</code>	Field is defined as <code>ENUM</code>
<code>MYSQLI_TYPE_SET</code>	Field is defined as <code>SET</code>
<code>MYSQLI_TYPE_TINY_BLOB</code>	Field is defined as <code>TINYBLOB</code>
<code>MYSQLI_TYPE_MEDIUM_BLOB</code>	Field is defined as <code>MEDIUMBLOB</code>
<code>MYSQLI_TYPE_LONG_BLOB</code>	Field is defined as <code>LOB</code>
<code>MYSQLI_TYPE_BLOB</code>	Field is defined as <code>BLOB</code>
<code>MYSQLI_TYPE_VAR_STRING</code>	Field is defined as <code>VARCHAR</code>
<code>MYSQLI_TYPE_STRING</code>	Field is defined as <code>CHAR</code> or <code>BINARY</code>
<code>MYSQLI_TYPE_CHAR</code>	Field is defined as <code>TINYINT</code> . For <code>CHAR</code> , see <code>MYSQLI_TYPE_STRING</code>
<code>MYSQLI_TYPE_GEOMETRY</code>	Field is defined as <code>GEOMETRY</code>
<code>MYSQLI_NEED_DATA</code>	More data available for bind variable
<code>MYSQLI_NO_DATA</code>	No more data available for bind variable
<code>MYSQLI_DATA_TRUNCATED</code>	Data truncation occurred. Available since PHP 5.1.0 and MySQL 5.0.5.
<code>MYSQLI_ENUM_FLAG</code>	Field is defined as <code>ENUM</code> . Available since PHP 5.3.0.
<code>MYSQLI_CURSOR_TYPE_FOR_UPDATE</code>	
<code>MYSQLI_CURSOR_TYPE_NO_CURSOR</code>	
<code>MYSQLI_CURSOR_TYPE_READ_ONLY</code>	

---

<code>MYSQLI_CURSOR_TYPE_SCROLLABLE</code>	
<code>MYSQLI_STMT_ATTR_CURSOR_TYPE</code>	
<code>MYSQLI_STMT_ATTR_PREFETCH_ROWS</code>	
<code>MYSQLI_STMT_ATTR_UPDATE_MAX_LENGTH</code>	
<code>MYSQLI_SET_CHARSET_NAME</code>	
<code>MYSQLI_REPORT_INDEX</code>	Report if no index or bad index was used in a query.
<code>MYSQLI_REPORT_ERROR</code>	Report errors from <code>mysqli</code> function calls.
<code>MYSQLI_REPORT_STRICT</code>	Throw a <code>mysqli_sql_exception</code> for errors instead of warnings.
<code>MYSQLI_REPORT_ALL</code>	Set all options on (report all).
<code>MYSQLI_REPORT_OFF</code>	Turns reporting off.
<code>MYSQLI_DEBUG_TRACE_ENABLED</code>	Is set to 1 if <code>mysqli_debug</code> functionality is enabled.
<code>MYSQLI_SERVER_QUERY_NO_GOOD_INDEX_USED</code>	
<code>MYSQLI_SERVER_QUERY_NO_INDEX_USED</code>	
<code>MYSQLI_REFRESH_GRANT</code>	Refreshes the grant tables.
<code>MYSQLI_REFRESH_LOG</code>	Flushes the logs, like executing the <code>FLUSH LOGS</code> SQL statement.
<code>MYSQLI_REFRESH_TABLES</code>	Flushes the table cache, like executing the <code>FLUSH TABLES</code> SQL statement.
<code>MYSQLI_REFRESH_HOSTS</code>	Flushes the host cache, like executing the <code>FLUSH HOSTS</code> SQL statement.
<code>MYSQLI_REFRESH_STATUS</code>	Reset the status variables, like executing the <code>FLUSH STATUS</code> SQL statement.
<code>MYSQLI_REFRESH_THREADS</code>	Flushes the thread cache.
<code>MYSQLI_REFRESH_SLAVE</code>	On a slave replication server: resets the master server information, and restarts the slave. Like executing the <code>RESET SLAVE</code> SQL statement.
<code>MYSQLI_REFRESH_MASTER</code>	On a master replication server: removes the binary log files listed in the binary log index, and truncates the index file. Like executing the <code>RESET MASTER</code> SQL statement.

### 21.9.3.7. Notes

Copyright 1997-2012 the PHP Documentation Group. [2906]

Some implementation notes:

1. Support was added for `MYSQL_TYPE_GEOMETRY` to the `MySQLi` extension in PHP 5.3.
2. Note there are different internal implementations within `libmysqlclient` and `mysqlnd` for handling columns of type `MYSQL_TYPE_GEOMETRY`. Generally speaking, `mysqlnd` will allocate significantly less memory. For example, if there is a `POINT` column in a result set, `libmysqlclient` may pre-allocate up to 4GB of RAM although less than 50 bytes are needed for holding a `POINT` column in memory. Memory allocation is much lower, less than 50 bytes, if using `mysqlnd`.

**21.9.3.8. The MySQLi Extension Function Summary**

Copyright 1997-2012 the PHP Documentation Group. [2906]

**Table 21.42. Summary of `mysqli` methods**

<b>mysqli Class</b>			
<b>OOP Interface</b>	<b>Procedural Interface</b>	<b>Alias (Do not use)</b>	<b>Description</b>
<i>Properties</i>			
<a href="#">\$mysqli::affected_rows</a>	<code>mysqli_affected_rows</code>	N/A	Gets the number of affected rows in a previous MySQL operation
<a href="#">\$mysqli::client_info</a>	<code>mysqli_get_client_info</code>	N/A	Returns the MySQL client version as a string
<a href="#">\$mysqli::client_version</a>	<code>mysqli_get_client_version</code>	N/A	Returns MySQL client version info as an integer
<a href="#">\$mysqli::connect_errno</a>	<code>mysqli_connect_errno</code>	N/A	Returns the error code from last connect call
<a href="#">\$mysqli::connect_error</a>	<code>mysqli_connect_error</code>	N/A	Returns a string description of the last connect error
<a href="#">\$mysqli::errno</a>	<code>mysqli_errno</code>	N/A	Returns the error code for the most recent function call
<a href="#">\$mysqli::error</a>	<code>mysqli_error</code>	N/A	Returns a string description of the last error
<a href="#">\$mysqli::field_count</a>	<code>mysqli_field_count</code>	N/A	Returns the number of columns for the most recent query
<a href="#">\$mysqli::host_info</a>	<code>mysqli_get_host_info</code>	N/A	Returns a string representing the type of connection used
<a href="#">\$mysqli::protocol_version</a>	<code>mysqli_get_proto_info</code>	N/A	Returns the version of the MySQL protocol used
<a href="#">\$mysqli::server_info</a>	<code>mysqli_get_server_info</code>	N/A	Returns the version of the MySQL server
<a href="#">\$mysqli::server_version</a>	<code>mysqli_get_server_version</code>	N/A	Returns the version of the MySQL server as an integer
<a href="#">\$mysqli::info</a>	<code>mysqli_info</code>	N/A	Retrieves information about the most recently executed query
<a href="#">\$mysqli::insert_id</a>	<code>mysqli_insert_id</code>	N/A	Returns the auto generated id used in the last query
<a href="#">\$mysqli::sqlstate</a>	<code>mysqli_sqlstate</code>	N/A	Returns the SQLSTATE error from previous MySQL operation

<b>mysqli Class</b>			
<b>OOP Interface</b>	<b>Procedural Interface</b>	<b>Alias (Do not use)</b>	<b>Description</b>
<a href="#">\$mysqli::warning_count</a>	<code>mysqli_warning_count</code>	N/A	Returns the number of warnings from the last query for the given link
<i>Methods</i>			
<code>mysqli::autocommit</code>	<code>mysqli_autocommit</code>	N/A	Turns on or off auto-committing database modifications
<code>mysqli::change_user</code>	<code>mysqli_change_user</code>	N/A	Changes the user of the specified database connection
<code>mysqli::character_set_name</code> <a href="#">mysqli::client_encoding</a>	<code>mysqli_character_set_name</code>	<code>mysqli_client_encoding</code>	Returns the default character set for the database connection
<code>mysqli::close</code>	<code>mysqli_close</code>	N/A	Closes a previously opened database connection
<code>mysqli::commit</code>	<code>mysqli_commit</code>	N/A	Commits the current transaction
<code>mysqli::__construct</code>	<code>mysqli_connect</code>	N/A	Open a new connection to the MySQL server [Note: static (i.e. class) method]
<code>mysqli::debug</code>	<code>mysqli_debug</code>	N/A	Performs debugging operations
<code>mysqli::dump_debug_info</code>	<code>mysqli_dump_debug_info</code>	N/A	Dump debugging information into the log
<code>mysqli::get_charset</code>	<code>mysqli_get_charset</code>	N/A	Returns a character set object
<code>mysqli::get_connection_stats</code>	<code>mysqli_get_connection_stats</code>	N/A	Returns client connection statistics. Available only with <a href="#">mysqliInD</a> .
<code>mysqli::get_client_info</code>	<code>mysqli_get_client_info</code>	N/A	Returns the MySQL client version as a string
<code>mysqli::get_client_statistics</code>	<code>mysqli_get_client_statistics</code>	N/A	Returns client per-process statistics. Available only with <a href="#">mysqliInD</a> .
<code>mysqli::get_cache_statistics</code>	<code>mysqli_get_cache_statistics</code>	N/A	Returns client Zval cache statistics. Available only with <a href="#">mysqliInD</a> .
<code>mysqli::get_server_info</code>	<code>mysqli_get_server_info</code>	N/A	NOT DOCUMENTED
<code>mysqli::get_warnings</code>	<code>mysqli_get_warnings</code>	N/A	NOT DOCUMENTED
<code>mysqli::init</code>	<code>mysqli_init</code>	N/A	Initializes MySQLi and returns a resource for use with <code>mysqli_real_connect</code> .

<b>mysqli Class</b>			
<b>OOP Interface</b>	<b>Procedural Interface</b>	<b>Alias (Do not use)</b>	<b>Description</b>
			[Not called on an object, as it returns a \$mysqli object.]
<code>mysqli::kill</code>	<code>mysqli_kill</code>	N/A	Asks the server to kill a MySQL thread
<code>mysqli::more_results</code>	<code>mysqli_more_results</code>	N/A	Check if there are any more query results from a multi query
<code>mysqli::multi_query</code>	<code>mysqli_multi_query</code>	N/A	Performs a query on the database
<code>mysqli::next_result</code>	<code>mysqli_next_result</code>	N/A	Prepare next result from multi_query
<code>mysqli::options</code>	<code>mysqli_options</code>	<code>mysqli_set_opt</code>	Set options
<code>mysqli::ping</code>	<code>mysqli_ping</code>	N/A	Pings a server connection, or tries to reconnect if the connection has gone down
<code>mysqli::prepare</code>	<code>mysqli_prepare</code>	N/A	Prepare an SQL statement for execution
<code>mysqli::query</code>	<code>mysqli_query</code>	N/A	Performs a query on the database
<code>mysqli::real_connect</code>	<code>mysqli_real_connect</code>	N/A	Opens a connection to a mysql server
<code>mysqli::real_escape_string</code> <code>mysqli::escape_string</code>	<code>mysqli_real_escape_string</code> <code>mysqli_escape_string</code>	<code>mysqli_escape_string</code>	Escapes special characters in a string for use in an SQL statement, taking into account the current charset of the connection
<code>mysqli::real_query</code>	<code>mysqli_real_query</code>	N/A	Execute an SQL query
<code>mysqli::refresh</code>	<code>mysqli_refresh</code>	N/A	Flushes tables or caches, or resets the replication server information
<code>mysqli::rollback</code>	<code>mysqli_rollback</code>	N/A	Rolls back current transaction
<code>mysqli::select_db</code>	<code>mysqli_select_db</code>	N/A	Selects the default database for database queries
<code>mysqli::set_charset</code>	<code>mysqli_set_charset</code>	N/A	Sets the default client character set
<code>mysqli::set_local_infile_handler_default</code>	<code>mysqli_set_local_infile_handler_default</code>	N/A	Unsets user defined handler for load local infile command

<b>mysqli Class</b>			
<b>OOP Interface</b>	<b>Procedural Interface</b>	<b>Alias (Do not use)</b>	<b>Description</b>
<code>mysqli::set_local_infile_handler</code>	<code>mysqli_set_local_infile_handler</code>	N/A	Set callback function for LOAD DATA LOCAL INFILE command
<code>mysqli::ssl_set</code>	<code>mysqli_ssl_set</code>	N/A	Used for establishing secure connections using SSL
<code>mysqli::stat</code>	<code>mysqli_stat</code>	N/A	Gets the current system status
<code>mysqli::stmt_init</code>	<code>mysqli_stmt_init</code>	N/A	Initializes a statement and returns an object for use with <code>mysqli_stmt_prepare</code>
<code>mysqli::store_result</code>	<code>mysqli_store_result</code>	N/A	Transfers a result set from the last query
<code>mysqli::thread_id</code>	<code>mysqli_thread_id</code>	N/A	Returns the thread ID for the current connection
<code>mysqli::thread_safe</code>	<code>mysqli_thread_safe</code>	N/A	Returns whether thread safety is given or not
<code>mysqli::use_result</code>	<code>mysqli_use_result</code>	N/A	Initiate a result set retrieval

**Table 21.43. Summary of `mysqli_stmt` methods**

<b>MySQL_STMT</b>			
<b>OOP Interface</b>	<b>Procedural Interface</b>	<b>Alias (Do not use)</b>	<b>Description</b>
<i>Properties</i>			
<code>\$mysqli_stmt::affected_rows</code>	<code>mysqli_stmt_affected_rows</code>	N/A	Returns the total number of rows changed, deleted, or inserted by the last executed statement
<code>\$mysqli_stmt::errno</code>	<code>mysqli_stmt_errno</code>	N/A	Returns the error code for the most recent statement call
<code>\$mysqli_stmt::error</code>	<code>mysqli_stmt_error</code>	N/A	Returns a string description for last statement error
<code>\$mysqli_stmt::field_count</code>	<code>mysqli_stmt_field_count</code>	N/A	Returns the number of field in the given statement - not documented
<code>\$mysqli_stmt::insert_id</code>	<code>mysqli_stmt_insert_id</code>	N/A	Get the ID generated from the previous INSERT operation
<code>\$mysqli_stmt::num_rows</code>	<code>mysqli_stmt_num_rows</code>	N/A	Return the number of rows in statements result set

MySQL_STMT			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<code>\$mysqli_stmt::param_count</code>	<code>mysqli_stmt_param_count</code>	<code>mysqli_param_count</code>	Returns the number of parameter for the given statement
<code>\$mysqli_stmt::sqlstate</code>	<code>mysqli_stmt_sqlstate</code>	N/A	Returns SQLSTATE error from previous statement operation
<i>Methods</i>			
<code>mysqli_stmt::attr_get</code>	<code>mysqli_stmt_attr_get</code>	N/A	Used to get the current value of a statement attribute
<code>mysqli_stmt::attr_set</code>	<code>mysqli_stmt_attr_set</code>	N/A	Used to modify the behavior of a prepared statement
<code>mysqli_stmt::bind_param</code>	<code>mysqli_stmt_bind_param</code>	<code>mysqli_bind_param</code>	Binds variables to a prepared statement as parameters
<code>mysqli_stmt::bind_result</code>	<code>mysqli_stmt_bind_result</code>	<code>mysqli_bind_result</code>	Binds variables to a prepared statement for result storage
<code>mysqli_stmt::close</code>	<code>mysqli_stmt_close</code>	N/A	Closes a prepared statement
<code>mysqli_stmt::data_seek</code>	<code>mysqli_stmt_data_seek</code>	N/A	Seeks to an arbitrary row in statement result set
<code>mysqli_stmt::execute</code>	<code>mysqli_stmt_execute</code>	<code>mysqli_execute</code>	Executes a prepared Query
<code>mysqli_stmt::fetch</code>	<code>mysqli_stmt_fetch</code>	<code>mysqli_fetch</code>	Fetch results from a prepared statement into the bound variables
<code>mysqli_stmt::free_result</code>	<code>mysqli_stmt_free_result</code>	N/A	Frees stored result memory for the given statement handle
<code>mysqli_stmt::get_result</code>	<code>mysqli_stmt_get_result</code>	N/A	Gets a result set from a prepared statement. Available only with <a href="#">mysqli</a> .
<code>mysqli_stmt::get_warnings</code>	<code>mysqli_stmt_get_warnings</code>	N/A	NOT DOCUMENTED
<code>\$mysqli_stmt::more_results()</code>	<code>mysqli_stmt_more_results()</code>	N/A	NOT DOCUMENTED Available only with <a href="#">mysqli</a> .
<code>\$mysqli_stmt::next_result()</code>	<code>mysqli_stmt_next_result()</code>	N/A	NOT DOCUMENTED Available only with <a href="#">mysqli</a> .
<code>mysqli_stmt::num_rows</code>	<code>mysqli_stmt_num_rows</code>	N/A	See also property <a href="#">\$mysqli_stmt::num_rows</a>
<code>mysqli_stmt::prepare</code>	<code>mysqli_stmt_prepare</code>	N/A	Prepare an SQL statement for execution

MySQL_STMT			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<code>mysqli_stmt::reset</code>	<code>mysqli_stmt_reset</code>	N/A	Resets a prepared statement
<code>mysqli_stmt::result_metadata</code>	<code>mysqli_stmt_result_metadata</code>	<code>mysqli_stmt_get_metadata</code>	Returns result set metadata from a prepared statement
<code>mysqli_stmt::send_long_data</code>	<code>mysqli_stmt_send_long_data</code>	<code>mysqli_stmt_send_long_data</code>	Send data in blocks
<code>mysqli_stmt::store_result</code>	<code>mysqli_stmt_store_result</code>	N/A	Transfers a result set from a prepared statement

Table 21.44. Summary of `mysqli_result` methods

mysqli_result			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<i>Properties</i>			
<code>\$mysqli_result::current_field</code>	<code>mysqli_field_tell</code>	N/A	Get current field offset of a result pointer
<code>\$mysqli_result::field_count</code>	<code>mysqli_num_fields</code>	N/A	Get the number of fields in a result
<code>\$mysqli_result::lengths</code>	<code>mysqli_fetch_lengths</code>	N/A	Returns the lengths of the columns of the current row in the result set
<code>\$mysqli_result::num_rows</code>	<code>mysqli_num_rows</code>	N/A	Gets the number of rows in a result
<i>Methods</i>			
<code>mysqli_result::data_seek</code>	<code>mysqli_data_seek</code>	N/A	Adjusts the result pointer to an arbitrary row in the result
<code>mysqli_result::fetch</code>	<code>mysqli_fetch_all</code>	N/A	Fetches all result rows and returns the result set as an associative array, a numeric array, or both. Available only with <code>mysqli</code> .
<code>mysqli_result::fetch_array</code>	<code>mysqli_fetch_array</code>	N/A	Fetch a result row as an associative, a numeric array, or both
<code>mysqli_result::fetch_assoc</code>	<code>mysqli_fetch_assoc</code>	N/A	Fetch a result row as an associative array
<code>mysqli_result::fetch_direct_field</code>	<code>mysqli_fetch_direct_field</code>	N/A	Fetch meta-data for a single field
<code>mysqli_result::fetch_field</code>	<code>mysqli_fetch_field</code>	N/A	Returns the next field in the result set
<code>mysqli_result::fetch_fields</code>	<code>mysqli_fetch_fields</code>	N/A	Returns an array of objects representing the fields in a result set

<code>mysqli_result</code>			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<code>mysqli_result::fetch_object</code>	<code>mysqli_fetch_object</code>	N/A	Returns the current row of a result set as an object
<code>mysqli_result::fetch_row</code>	<code>mysqli_fetch_row</code>	N/A	Get a result row as an enumerated array
<code>mysqli_result::field_seek</code>	<code>mysqli_field_seek</code>	N/A	Set result pointer to a specified field offset
<code>mysqli_result::free</code> , <code>mysqli_result::close</code> , <code>mysqli_result::free_result</code>	<code>mysqli_free_result</code>	N/A	Frees the memory associated with a result

**Table 21.45. Summary of `mysqli_driver` methods**

MySQL_Driver			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<i>Properties</i>			
N/A			
<i>Methods</i>			
<code>mysqli_driver::embedded_server_end</code>	<code>mysqli_embedded_server_end</code>	N/A	NOT DOCUMENTED
<code>mysqli_driver::embedded_server_start</code>	<code>mysqli_embedded_server_start</code>	N/A	NOT DOCUMENTED

**Note**

Alias functions are provided for backward compatibility purposes only. Do not use them in new projects.

### 21.9.3.9. The `mysqli` class (`mysqli`)

Copyright 1997-2012 the PHP Documentation Group. [2906]

Represents a connection between PHP and a MySQL database.

```

mysqli {
    mysqli

    Properties

    int
        mysqli->affected_rows ;

    string
        mysqli->client_info ;

    int
        mysqli->client_version ;

    string
        mysqli->connect_errno ;

    string
        mysqli->connect_error ;

    int
        mysqli->errno ;

    array

```

```
mysqli->error_list ;

string
mysqli->error ;

int
mysqli->field_count ;

int
mysqli->client_version ;

string
mysqli->host_info ;

string
mysqli->protocol_version ;

mysqli_stmt mysqli::stmt_init();

mysqli_result mysqli::store_result();

mysqli_result mysqli::use_result();
}
```

### 21.9.3.9.1. `mysqli::$affected_rows`, `mysqli_affected_rows`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$affected_rows`

`mysqli_affected_rows`

Gets the number of affected rows in a previous MySQL operation

#### Description

Object oriented style

```
int
mysqli->affected_rows ;
```

Procedural style

```
int mysqli_affected_rows(
    mysqli link);
```

Returns the number of rows affected by the last `INSERT`, `UPDATE`, `REPLACE` or `DELETE` query.

For `SELECT` statements `mysqli_affected_rows` works like `mysqli_num_rows`.

#### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error.

#### Note

If the number of affected rows is greater than maximal int value, the number of affected rows will be returned as a string.

#### Examples

**Example 21.106. \$mysqli->affected\_rows example**

## Object oriented style

```

<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Insert rows */
$mysqli->query("CREATE TABLE Language SELECT * from CountryLanguage");
printf("Affected rows (INSERT): %d\n", $mysqli->affected_rows);

$mysqli->query("ALTER TABLE Language ADD Status int default 0");

/* update rows */
$mysqli->query("UPDATE Language SET Status=1 WHERE Percentage > 50");
printf("Affected rows (UPDATE): %d\n", $mysqli->affected_rows);

/* delete rows */
$mysqli->query("DELETE FROM Language WHERE Percentage < 50");
printf("Affected rows (DELETE): %d\n", $mysqli->affected_rows);

/* select all rows */
$result = $mysqli->query("SELECT CountryCode FROM Language");
printf("Affected rows (SELECT): %d\n", $mysqli->affected_rows);

$result->close();

/* Delete table Language */
$mysqli->query("DROP TABLE Language");

/* close connection */
$mysqli->close();
?>

```

## Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

if (!$link) {
    printf("Can't connect to localhost. Error: %s\n", mysqli_connect_error());
    exit();
}

/* Insert rows */
mysqli_query($link, "CREATE TABLE Language SELECT * from CountryLanguage");
printf("Affected rows (INSERT): %d\n", mysqli_affected_rows($link));

mysqli_query($link, "ALTER TABLE Language ADD Status int default 0");

/* update rows */
mysqli_query($link, "UPDATE Language SET Status=1 WHERE Percentage > 50");
printf("Affected rows (UPDATE): %d\n", mysqli_affected_rows($link));

/* delete rows */
mysqli_query($link, "DELETE FROM Language WHERE Percentage < 50");
printf("Affected rows (DELETE): %d\n", mysqli_affected_rows($link));

/* select all rows */
$result = mysqli_query($link, "SELECT CountryCode FROM Language");
printf("Affected rows (SELECT): %d\n", mysqli_affected_rows($link));

```

```
mysqli_free_result($result);

/* Delete table Language */
mysqli_query($link, "DROP TABLE Language");

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Affected rows (INSERT): 984
Affected rows (UPDATE): 168
Affected rows (DELETE): 815
Affected rows (SELECT): 169
```

#### 21.9.3.9.2. [mysqli::autocommit](#), [mysqli\\_autocommit](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::autocommit](#)

[mysqli\\_autocommit](#)

Turns on or off auto-committing database modifications

### Description

Object oriented style

```
bool mysqli::autocommit(
    bool mode);
```

Procedural style

```
bool mysqli_autocommit(
    mysqli link,
    bool mode);
```

Turns on or off auto-commit mode on queries for the database connection.

To determine the current state of autocommit use the SQL command `SELECT @@autocommit`.

### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

*mode* Whether to turn on auto-commit or not.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Notes

**Note**

This function doesn't work with non transactional table types (like MyISAM or ISAM).

**Examples****Example 21.107. `mysqli::autocommit` example**

## Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* turn autocommit on */
$mysqli->autocommit(TRUE);

if ($result = $mysqli->query("SELECT @@autocommit")) {
    $row = $result->fetch_row();
    printf("Autocommit is %s\n", $row[0]);
    $result->free();
}

/* close connection */
$mysqli->close();
?>
```

## Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

if (!$link) {
    printf("Can't connect to localhost. Error: %s\n", mysqli_connect_error());
    exit();
}

/* turn autocommit on */
mysqli_autocommit($link, TRUE);

if ($result = mysqli_query($link, "SELECT @@autocommit")) {
    $row = mysqli_fetch_row($result);
    printf("Autocommit is %s\n", $row[0]);
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Autocommit is 1
```

**See Also**

```
mysqli_commit
mysqli_rollback
```

### 21.9.3.9.3. *mysqli::change\_user*, *mysqli\_change\_user*

Copyright 1997-2012 the PHP Documentation Group. [2906]

- *mysqli::change\_user*

```
mysqli_change_user
```

Changes the user of the specified database connection

#### Description

Object oriented style

```
bool mysqli::change_user(
    string user,
    string password,
    string database);
```

Procedural style

```
bool mysqli_change_user(
    mysqli link,
    string user,
    string password,
    string database);
```

Changes the user of the specified database connection and sets the current database.

In order to successfully change users a valid *username* and *password* parameters must be provided and that user must have sufficient permissions to access the desired database. If for any reason authorization fails, the current user authentication will remain.

#### Parameters

<i>link</i>	Procedural style only: A link identifier returned by <i>mysqli_connect</i> or <i>mysqli_init</i>
<i>user</i>	The MySQL user name.
<i>password</i>	The MySQL password.
<i>database</i>	The database to change to.

If desired, the `NULL` value may be passed resulting in only changing the user and not selecting a database. To select a database in this case use the *mysqli\_select\_db* function.

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### Notes

#### Note

Using this command will always cause the current database connection to behave as if was a completely new database connection, regardless of if the operation was completed successfully. This reset includes performing a rollback on any active transactions, closing all temporary tables, and unlocking all locked tables.

## Examples

### Example 21.108. `mysqli::change_user` example

#### Object oriented style

```
<?php
/* connect database test */
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Set Variable a */
$mysqli->query("SET @a:=1");

/* reset all and select a new database */
$mysqli->change_user("my_user", "my_password", "world");

if ($result = $mysqli->query("SELECT DATABASE()")) {
    $row = $result->fetch_row();
    printf("Default database: %s\n", $row[0]);
    $result->close();
}

if ($result = $mysqli->query("SELECT @a")) {
    $row = $result->fetch_row();
    if ($row[0] === NULL) {
        printf("Value of variable a is NULL\n");
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

#### Procedural style

```
<?php
/* connect database test */
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Set Variable a */
mysqli_query($link, "SET @a:=1");

/* reset all and select a new database */
mysqli_change_user($link, "my_user", "my_password", "world");

if ($result = mysqli_query($link, "SELECT DATABASE()")) {
    $row = mysqli_fetch_row($result);
    printf("Default database: %s\n", $row[0]);
    mysqli_free_result($result);
}

if ($result = mysqli_query($link, "SELECT @a")) {
    $row = mysqli_fetch_row($result);
}
```

```
if ($row[0] === NULL) {
    printf("Value of variable a is NULL\n");
}
mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Default database: world
Value of variable a is NULL
```

- [mysqli::character\\_set\\_name](#)  
[mysqli\\_character\\_set\\_name](#)

Returns the default character set for the database connection

### Description

Object oriented style

```
string mysqli::character_set_name();
```

Procedural style

```
string mysqli_character_set_name(
    mysqli link);
```

Returns the current character set for the database connection.

### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

The default character set for the current connection

### Examples

#### Example 21.109. [mysqli::character\\_set\\_name](#) example

Object oriented style

```
<?php
```

```
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Print current character set */
$charset = $mysqli->character_set_name();
printf("Current character set is %s\n", $charset);

$mysqli->close();
?>
```

### Procedural style

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Print current character set */
$charset = mysqli_character_set_name($link);
printf("Current character set is %s\n", $charset);

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Current character set is latin1_swedish_ci
```

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\$client\\_info](#)  
[mysqli\\_get\\_client\\_info](#)

Get MySQL client info

### Description

Object oriented style

```
string
```

```
mysqli->client_info ;
```

### Procedural style

```
string mysqli_get_client_info(  
    mysqli link);
```

Returns a string that represents the MySQL client library version.

### Return Values

A string that represents the MySQL client library version

### Examples

#### Example 21.110. `mysqli_get_client_info`

```
<?php  
  
/* We don't need a connection to determine  
   the version of mysql client library */  
  
printf("Client library version: %s\n", mysqli_get_client_info());  
?>
```

#### 21.9.3.9.6. `mysqli::$client_version`, `mysqli_get_client_version`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$client_version`  
`mysqli_get_client_version`

Returns the MySQL client version as a string

### Description

Object oriented style

```
int  
mysqli->client_version ;
```

### Procedural style

```
int mysqli_get_client_version(  
    mysqli link);
```

Returns client version number as an integer.

### Return Values

A number that represents the MySQL client library version in format: `main_version*10000 + minor_version *100 + sub_version`. For example, 4.1.0 is returned as 40100.

This is useful to quickly determine the version of the client library to know if some capability exists.

### Examples

**Example 21.111. `mysqli_get_client_version`**

```
<?php
/* We don't need a connection to determine
   the version of mysql client library */
printf("Client library version: %d\n", mysqli_get_client_version());
?>
```

[mysqli\\_close](#)

Closes a previously opened database connection

**Description**

Object oriented style

```
bool mysqli::close();
```

Procedural style

```
bool mysqli_close(
    mysqli link);
```

Closes a previously opened database connection.

**Parameters**

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

**Return Values**

Returns [TRUE](#) on success or [FALSE](#) on failure.

**Examples**

See [mysqli\\_connect](#).

- `mysqli::commit`

`mysqli_commit`

Commits the current transaction

## Description

Object oriented style

```
bool mysqli::commit();
```

Procedural style

```
bool mysqli_commit(
    mysqli link);
```

Commits the current transaction for the database connection.

## Parameters

*link*

Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Examples

### Example 21.112. `mysqli::commit` example

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE Language LIKE CountryLanguage");

/* set autocommit to off */
$mysqli->autocommit(FALSE);

/* Insert some values */
$mysqli->query("INSERT INTO Language VALUES ('DEU', 'Bavarian', 'F', 11.2)");
$mysqli->query("INSERT INTO Language VALUES ('DEU', 'Swabian', 'F', 9.4)");

/* commit transaction */
$mysqli->commit();

/* drop table */
$mysqli->query("DROP TABLE Language");

/* close connection */
$mysqli->close();
?>
```

Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* set autocommit to off */
mysqli_autocommit($link, FALSE);

mysqli_query($link, "CREATE TABLE Language LIKE CountryLanguage");

/* Insert some values */
mysqli_query($link, "INSERT INTO Language VALUES ('DEU', 'Bavarian', 'F', 11.2)");
mysqli_query($link, "INSERT INTO Language VALUES ('DEU', 'Swabian', 'F', 9.4)");

/* commit transaction */
mysqli_commit($link);

/* close connection */
mysqli_close($link);
?>
```

#### 21.9.3.9.9. [mysqli::\\$connect\\_errno](#), [mysqli\\_connect\\_errno](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\$connect\\_errno](#)

[mysqli\\_connect\\_errno](#)

Returns the error code from last connect call

### Description

Object oriented style

```
string
mysqli->connect_errno ;
```

Procedural style

```
int mysqli_connect_errno();
```

Returns the last error code number from the last call to [mysqli\\_connect](#).

### Note

Client error message numbers are listed in the MySQL [errmsg.h](#) header file, server error message numbers are listed in [mysqld\\_error.h](#). In the MySQL source distribution you can find a complete list of error messages and error numbers in the file [Docs/mysqld\\_error.txt](#).

### Return Values

An error code value for the last call to [mysqli\\_connect](#), if it failed. zero means no error occurred.

### Examples

**Example 21.113. `$mysqli->connect_errno` example**

Object oriented style

```
<?php
$mysqli = @new mysqli('localhost', 'fake_user', 'my_password', 'my_db');

if ($mysqli->connect_errno) {
    die('Connect Error: ' . $mysqli->connect_errno);
}
?>
```

Procedural style

```
<?php
$link = @mysqli_connect('localhost', 'fake_user', 'my_password', 'my_db');

if (!$link) {
    die('Connect Error: ' . mysqli_connect_errno());
}
?>
```

The above examples will output:

```
Connect Error: 1045
```

**See Also**

[mysqli\\_connect](#)  
[mysqli\\_connect\\_error](#)  
[mysqli\\_errno](#)  
[mysqli\\_error](#)  
[mysqli\\_sqlstate](#)

**21.9.3.9.10. `mysqli::$connect_error`, `mysqli_connect_error`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$connect_error`

`mysqli_connect_error`

Returns a string description of the last connect error

**Description**

Object oriented style

```
string
mysqli->connect_error ;
```

Procedural style

```
string mysqli_connect_error();
```

Returns the last error message string from the last call to `mysqli_connect`.

**Return Values**

A string that describes the error. [NULL](#) is returned if no error occurred.

## Examples

### Example 21.114. `$mysqli->connect_error` example

Object oriented style

```
<?php
$mysqli = @new mysqli('localhost', 'fake_user', 'my_password', 'my_db');

// Works as of PHP 5.2.9 and 5.3.0.
if ($mysqli->connect_error) {
    die('Connect Error: ' . $mysqli->connect_error);
}
?>
```

Procedural style

```
<?php
$link = @mysqli_connect('localhost', 'fake_user', 'my_password', 'my_db');

if (!$link) {
    die('Connect Error: ' . mysqli_connect_error());
}
?>
```

The above examples will output:

```
Connect Error: Access denied for user 'fake_user'@'localhost' (using password: YES)
```

## Notes

### Warning

The `mysqli->connect_error` property only works properly as of PHP versions 5.2.9 and 5.3.0. Use the [mysqli\\_connect\\_error](#) function if compatibility with earlier PHP versions is required.

## See Also

### 21.9.3.9.11. [mysqli::\\_\\_construct](#), [mysqli\\_connect](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\_\\_construct](#)

[mysqli\\_connect](#)

Open a new connection to the MySQL server

## Description

## Object oriented style

```
mysqli::__construct(
    string host
        = =ini_get("mysqli.default_host"),
    string username
        = =ini_get("mysqli.default_user"),
    string passwd
        = =ini_get("mysqli.default_pw"),
    string dbname
        = "",
    int port
        = =ini_get("mysqli.default_port"),
    string socket
        = =ini_get("mysqli.default_socket"));
```

## Procedural style

```
mysqli mysqli_connect(
    string host
        = =ini_get("mysqli.default_host"),
    string username
        = =ini_get("mysqli.default_user"),
    string passwd
        = =ini_get("mysqli.default_pw"),
    string dbname
        = "",
    int port
        = =ini_get("mysqli.default_port"),
    string socket
        = =ini_get("mysqli.default_socket"));
```

Opens a connection to the MySQL Server running on.

## Parameters

<i>host</i>	Can be either a host name or an IP address. Passing the <b>NULL</b> value or the string "localhost" to this parameter, the local host is assumed. When possible, pipes will be used instead of the TCP/IP protocol.  Prepending <i>host</i> by <b>p:</b> opens a persistent connection. <i>mysqli_change_user</i> is automatically called on connections opened from the connection pool.
<i>username</i>	The MySQL user name.
<i>passwd</i>	If not provided or <b>NULL</b> , the MySQL server will attempt to authenticate the user against those user records which have no password only. This allows one username to be used with different permissions (depending on if a password as provided or not).
<i>dbname</i>	If provided will specify the default database to be used when performing queries.
<i>port</i>	Specifies the port number to attempt to connect to the MySQL server.
<i>socket</i>	Specifies the socket or named pipe that should be used.

**Note**

Specifying the *socket* parameter will not explicitly determine the type of connection to be used when connecting to the MySQL server. How the connection is made to the

MySQL database is determined by the *host* parameter.

## Return Values

Returns an object which represents the connection to a MySQL Server.

## Changelog

Version	Description
5.3.0	Added the ability of persistent connections.

## Examples

### Example 21.115. *mysqli::\_\_construct* example

Object oriented style

```
<?php
$mysqli = new mysqli('localhost', 'my_user', 'my_password', 'my_db');

/*
 * This is the "official" OO way to do it,
 * BUT $connect_error was broken until PHP 5.2.9 and 5.3.0.
 */
if ($mysqli->connect_error) {
    die('Connect Error (' . $mysqli->connect_errno . ') '
        . $mysqli->connect_error);
}

/*
 * Use this instead of $connect_error if you need to ensure
 * compatibility with PHP versions prior to 5.2.9 and 5.3.0.
 */
if (mysqli_connect_error()) {
    die('Connect Error (' . mysqli_connect_errno() . ') '
        . mysqli_connect_error());
}

echo 'Success... ' . $mysqli->host_info . "\n";

$mysqli->close();
?>
```

Object oriented style when extending *mysqli* class

```
<?php

class foo_mysqli extends mysqli {
    public function __construct($host, $user, $pass, $db) {
        parent::__construct($host, $user, $pass, $db);

        if (mysqli_connect_error()) {
            die('Connect Error (' . mysqli_connect_errno() . ') '
                . mysqli_connect_error());
        }
    }
}

$db = new foo_mysqli('localhost', 'my_user', 'my_password', 'my_db');

echo 'Success... ' . $db->host_info . "\n";

$db->close();
?>
```

## Procedural style

```
<?php
$link = mysqli_connect('localhost', 'my_user', 'my_password', 'my_db');

if (!$link) {
    die('Connect Error (' . mysqli_connect_errno() . ') '
        . mysqli_connect_error());
}

echo 'Success... ' . mysqli_get_host_info($link) . "\n";

mysqli_close($link);
?>
```

The above examples will output:

```
Success... MySQL host info: localhost via TCP/IP
```

## Notes

### Note

MySQLnd always assumes the server default charset. This charset is sent during connection hand-shake/authentication, which MySQLnd will use.

Libmysqlclient uses the default charset set in the `my.cnf` or by an explicit call to `mysqli_options` prior to calling `mysqli_real_connect`, but after `mysqli_init`.

### Note

OO syntax only: If a connection fails an object is still returned. To check if the connection failed then use either the `mysqli_connect_error` function or the `mysqli->connect_error` property as in the preceding examples.

### Note

If it is necessary to set options, such as the connection timeout, `mysqli_real_connect` must be used instead.

### Note

Calling the constructor with no parameters is the same as calling `mysqli_init`.

### Note

Error "Can't create TCP/IP socket (10106)" usually means that the `variables_order` configure directive doesn't contain character `E`. On Windows, if the environment is not copied the `SYSTEMROOT` environment variable won't be available and PHP will have problems loading Winsock.

[mysqli\\_debug](#)

Performs debugging operations

#### Description

Object oriented style

```
bool mysqli::debug(  
    string message);
```

Procedural style

```
bool mysqli_debug(  
    string message);
```

Performs debugging operations using the Fred Fish debugging library.

#### Parameters

*message* A string representing the debugging operation to perform

#### Return Values

Returns [TRUE](#) .

#### Notes

#### Note

To use the [mysqli\\_debug](#) function you must compile the MySQL client library to support debugging.

#### Examples

##### Example 21.116. Generating a Trace File

```
<?php  
  
/* Create a trace file in '/tmp/client.trace' on the local (client) machine: */  
mysqli_debug("d:t:o,/tmp/client.trace");  
  
?>
```

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::dump_debug_info`

`mysqli_dump_debug_info`

Dump debugging information into the log

### Description

Object oriented style

```
bool mysqli::dump_debug_info();
```

Procedural style

```
bool mysqli_dump_debug_info(  
    mysqli link);
```

This function is designed to be executed by an user with the SUPER privilege and is used to dump debugging information into the log for the MySQL Server relating to the connection.

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### 21.9.3.9.14. `mysqli::$errno`, `mysqli_errno`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$errno`

`mysqli_errno`

Returns the error code for the most recent function call

### Description

Object oriented style

```
int  
mysqli->errno ;
```

Procedural style

```
int mysqli_errno(  
    mysqli link);
```

Returns the last error code for the most recent MySQLi function call that can succeed or fail.

Client error message numbers are listed in the MySQL `errmsg.h` header file, server error message numbers are listed in `mysqld_error.h`. In the MySQL source distribution you can find a complete list of error messages and error numbers in the file `Docs/mysqld_error.txt`.

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

## Return Values

An error code value for the last call, if it failed. zero means no error occurred.

## Examples

### Example 21.117. `$mysqli->errno` example

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if ($mysqli->connect_errno) {
    printf("Connect failed: %s\n", $mysqli->connect_error);
    exit();
}

if (!$mysqli->query("SET a=1")) {
    printf("Errorcode: %d\n", $mysqli->errno);
}

/* close connection */
$mysqli->close();
?>
```

Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if (!mysqli_query($link, "SET a=1")) {
    printf("Errorcode: %d\n", mysqli_errno($link));
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Errorcode: 1193
```

### 21.9.3.9.15. `mysqli::$error_list`, `mysqli_error_list`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$error_list`

`mysqli_error_list`

Returns a list of errors from the last command executed

## Description

Object oriented style

```
array
mysqli->error_list ;
```

Procedural style

```
array mysqli_error_list(
mysqli link);
```

Returns a array of errors for the most recent MySQLi function call that can succeed or fail.

## Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

## Return Values

A list of errors, each as an associative array containing the errno, error, and sqlstate.

## Examples

### Example 21.118. `$mysqli->error_list` example

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "nobody", "");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if (!$mysqli->query("SET a=1")) {
    print_r($mysqli->error_list);
}

/* close connection */
$mysqli->close();
?>
```

Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if (!mysqli_query($link, "SET a=1")) {
```

```
print_r(mysqli_error_list($link));
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Array
(
    [0] => Array
        (
            [errno] => 1193
            [sqlstate] => HY000
            [error] => Unknown system variable 'a'
        )
)
```

#### 21.9.3.9.16. [mysqli::\\$error](#), [mysqli\\_error](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\$error](#)

[mysqli\\_error](#)

Returns a string description of the last error

### Description

Object oriented style

```
string
mysqli->error ;
```

Procedural style

```
string mysqli_error(
    mysqli link);
```

Returns the last error message for the most recent MySQLi function call that can succeed or fail.

### Parameters

[link](#) Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

A string that describes the error. An empty string if no error occurred.

### Examples

**Example 21.119. `$mysqli->error` example**

## Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if ($mysqli->connect_errno) {
    printf("Connect failed: %s\n", $mysqli->connect_error);
    exit();
}

if (!$mysqli->query("SET a=1")) {
    printf("Errormessage: %s\n", $mysqli->error);
}

/* close connection */
$mysqli->close();
?>
```

## Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if (!mysqli_query($link, "SET a=1")) {
    printf("Errormessage: %s\n", mysqli_error($link));
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Errormessage: Unknown system variable 'a'
```

**21.9.3.9.17. `mysqli::$field_count`, `mysqli_field_count`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\$field\\_count](#)  
[mysqli\\_field\\_count](#)

Returns the number of columns for the most recent query

## Description

Object oriented style

```
int
mysqli->field_count ;
```

Procedural style

```
int mysqli_field_count(
mysqli link);
```

Returns the number of columns for the most recent query on the connection represented by the [link](#) parameter. This function can be useful when using the [mysqli\\_store\\_result](#) function to determine if the query should have produced a non-empty result set or not without knowing the nature of the query.

## Parameters

[link](#) Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

## Return Values

An integer representing the number of fields in a result set.

## Examples

### Example 21.120. [\\$mysqli->field\\_count](#) example

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

$mysqli->query( "DROP TABLE IF EXISTS friends");
$mysqli->query( "CREATE TABLE friends (id int, name varchar(20))");

$mysqli->query( "INSERT INTO friends VALUES (1,'Hartmut'), (2, 'Ulf')");

$mysqli->real_query("SELECT * FROM friends");

if ($mysqli->field_count) {
    /* this was a select/show or describe query */
    $result = $mysqli->store_result();

    /* process resultset */
    $row = $result->fetch_row();

    /* free resultset */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "test");
```

```
mysqli_query($link, "DROP TABLE IF EXISTS friends");
mysqli_query($link, "CREATE TABLE friends (id int, name varchar(20))");

mysqli_query($link, "INSERT INTO friends VALUES (1,'Hartmut'), (2, 'Ulf')");

mysqli_real_query($link, "SELECT * FROM friends");

if (mysqli_field_count($link)) {
    /* this was a select/show or describe query */
    $result = mysqli_store_result($link);

    /* process resultset */
    $row = mysqli_fetch_row($result);

    /* free resultset */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

### 21.9.3.9.18. [mysqli::get\\_charset](#), [mysqli\\_get\\_charset](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::get\\_charset](#)  
[mysqli\\_get\\_charset](#)

Returns a character set object

#### Description

Object oriented style

```
object mysqli::get_charset();
```

Procedural style

```
object mysqli_get_charset(
    mysqli link);
```

Returns a character set object providing several properties of the current active character set.

#### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

#### Return Values

The function returns a character set object with the following properties:

<i>charset</i>	Character set name
<i>collation</i>	Collation name
<i>dir</i>	Directory the charset description was fetched from (?) or "" for built-in character sets
<i>min_length</i>	Minimum character length in bytes
<i>max_length</i>	Maximum character length in bytes

---

<code>number</code>	Internal character set number
<code>state</code>	Character set status (?)

## Examples

### Example 21.121. `mysqli::get_charset` example

Object oriented style

```
<?php
$db = mysqli_init();
$db->real_connect("localhost","root","","test");
var_dump($db->get_charset());
?>
```

Procedural style

```
<?php
$db = mysqli_init();
mysqli_real_connect($db, "localhost","root","","test");
var_dump(mysqli_get_charset($db));
?>
```

The above examples will output:

```
object(stdClass)#2 (7) {
  ["charset"]=>
  string(6) "latin1"
  ["collation"]=>
  string(17) "latin1_swedish_ci"
  ["dir"]=>
  string(0) ""
  ["min_length"]=>
  int(1)
  ["max_length"]=>
  int(1)
  ["number"]=>
  int(8)
  ["state"]=>
  int(801)
}
```

### 21.9.3.9.19. `mysqli::get_client_info`, `mysqli_get_client_info`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::get\\_client\\_info](#)

[mysqli\\_get\\_client\\_info](#)

Get MySQL client info

## Description

### Object oriented style

```
string mysqli::get_client_info();
```

### Procedural style

```
string mysqli_get_client_info(  
    mysqli link);
```

Returns a string that represents the MySQL client library version.

### Return Values

A string that represents the MySQL client library version

### Examples

#### Example 21.122. `mysqli_get_client_info`

```
<?php  
  
/* We don't need a connection to determine  
   the version of mysql client library */  
  
printf("Client library version: %s\n", mysqli_get_client_info());  
?>
```

#### 21.9.3.9.20. `mysqli_get_client_stats`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_get\\_client\\_stats](#)

Returns client per-process statistics

### Description

```
array mysqli_get_client_stats();
```

Returns client per-process statistics. Available only with [mysqlnd](#).

### Parameters

### Return Values

Returns an array with client stats if success, [FALSE](#) otherwise.

### Examples

#### Example 21.123. A `mysqli_get_client_stats` example

```
<?php  
$link = mysqli_connect();  
print_r(mysqli_get_client_stats());  
?>
```

The above example will output something similar to:

```
Array
(
    [bytes_sent] => 43

[Stats description](#)

#### 21.9.3.9.21. `mysqli_get_client_version`, `mysqli::$client_version`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_get_client_version`

`mysqli::$client_version`

Returns the MySQL client version as a string

## Description

Object oriented style

```
int
mysqli->client_version ;
```

Procedural style

```
int mysqli_get_client_version(
mysqli link);
```

Returns client version number as an integer.

## Return Values

A number that represents the MySQL client library version in format: `main_version*10000 + minor_version *100 + sub_version`. For example, 4.1.0 is returned as 40100.

This is useful to quickly determine the version of the client library to know if some capability exists.

## Examples

### Example 21.124. `mysqli_get_client_version`

```
<?php
/* We don't need a connection to determine
   the version of mysql client library */

printf("Client library version: %d\n", mysqli_get_client_version());
?>
```

### 21.9.3.9.22. [mysqli::get\\_connection\\_stats](#), [mysqli\\_get\\_connection\\_stats](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::get\\_connection\\_stats](#)

[mysqli\\_get\\_connection\\_stats](#)

Returns statistics about the client connection

## Description

Object oriented style

```
bool mysqli::get_connection_stats();
```

Procedural style

```
array mysqli_get_connection_stats(
mysqli link);
```

Returns statistics about the client connection. Available only with [mysqlnd](#).

## Parameters

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

## Return Values

Returns an array with connection stats if success, `FALSE` otherwise.

## Examples

### Example 21.125. A `mysqli_get_connection_stats` example

```
<?php
$link = mysqli_connect();
print_r(mysqli_get_connection_stats($link));
?>
```

The above example will output something similar to:

**See Also**[Stats description](#)**21.9.3.9.23. [mysqli::\\$host\\_info](#), [mysqli\\_get\\_host\\_info](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\$host\\_info](#)

[mysqli\\_get\\_host\\_info](#)

Returns a string representing the type of connection used

**Description**

Object oriented style

```
string  
mysqli->host_info ;
```

Procedural style

```
string mysqli_get_host_info(  
mysqli link);
```

Returns a string describing the connection represented by the [link](#) parameter (including the server host name).**Parameters**

[link](#) Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

**Return Values**

A character string representing the server hostname and the connection type.

**Examples****Example 21.126. [\\$mysqli->host\\_info](#) example**

Object oriented style

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* print host information */  
printf("Host info: %s\n", $mysqli->host_info);  
  
/* close connection */  
$mysqli->close();  
?>
```

Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print host information */
printf("Host info: %s\n", mysqli_get_host_info($link));

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Host info: Localhost via UNIX socket
```

### See Also

[mysqli\\_get\\_proto\\_info](#)

### 21.9.3.9.24. [mysqli::\\$protocol\\_version](#), [mysqli\\_get\\_proto\\_info](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\$protocol\\_version](#)

[mysqli\\_get\\_proto\\_info](#)

Returns the version of the MySQL protocol used

### Description

Object oriented style

```
string
mysqli->protocol_version ;
```

Procedural style

```
int mysqli_get_proto_info(
    mysqli link);
```

Returns an integer representing the MySQL protocol version used by the connection represented by the *link* parameter.

### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

Returns an integer representing the protocol version.

### Examples

**Example 21.127. `$mysqli->protocol_version` example**

## Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print protocol version */
printf("Protocol version: %d\n", $mysqli->protocol_version);

/* close connection */
$mysqli->close();
?>
```

## Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print protocol version */
printf("Protocol version: %d\n", mysqli_get_proto_info($link));

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Protocol version: 10
```

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\$server\\_info](#)

[mysqli\\_get\\_server\\_info](#)

Returns the version of the MySQL server

**Description**

Object oriented style

```
string  
mysqli->server_info ;
```

### Procedural style

```
string mysqli_get_server_info(  
    mysqli link);
```

Returns a string representing the version of the MySQL server that the MySQLi extension is connected to.

### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

A character string representing the server version.

### Examples

#### Example 21.128. `$mysqli->server_info` example

##### Object oriented style

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* print server version */  
printf("Server version: %s\n", $mysqli->server_info);  
  
/* close connection */  
$mysqli->close();  
?>
```

##### Procedural style

```
<?php  
$link = mysqli_connect("localhost", "my_user", "my_password");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* print server version */  
printf("Server version: %s\n", mysqli_get_server_info($link));  
  
/* close connection */  
mysqli_close($link);  
?>
```

The above examples will output:

```
Server version: 4.1.2-alpha-debug
```

### See Also

```

#### 21.9.3.9.26. `mysqli::$server_version`, `mysqli_get_server_version`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$server_version`  
`mysqli_get_server_version`

Returns the version of the MySQL server as an integer

### Description

Object oriented style

```
int  
mysqli->server_version ;
```

Procedural style

```
int mysqli_get_server_version(  
mysqli link);
```

The `mysqli_get_server_version` function returns the version of the server connected to (represented by the *link* parameter) as an integer.

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

### Return Values

An integer representing the server version.

The form of this version number is `main_version * 10000 + minor_version * 100 + sub_version` (i.e. version 4.1.0 is 40100).

### Examples

#### Example 21.129. `$mysqli->server_version` example

Object oriented style

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* print server version */
```

```
printf("Server version: %d\n", $mysqli->server_version);

/* close connection */
$mysqli->close();
?>
```

### Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print server version */
printf("Server version: %d\n", mysqli_get_server_version($link));

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Server version: 40102
```

[mysqli\\_get\\_warnings](#)

Get result of SHOW WARNINGS

### Description

Object oriented style

```
mysqli_warning mysqli::get_warnings();
```

Procedural style

```
mysqli_warning mysqli_get_warnings(
    mysqli link);
```

### Warning

This function is currently not documented; only its argument list is available.

**21.9.3.9.28. *mysqli::\$info*, *mysqli\_info***

Copyright 1997-2012 the PHP Documentation Group. [2906]

- *mysqli::\$info*

*mysqli\_info*

Retrieves information about the most recently executed query

**Description**

Object oriented style

```
string
mysqli->info ;
```

Procedural style

```
string mysqli_info(
    mysqli link);
```

The *mysqli\_info* function returns a string providing information about the last query executed. The nature of this string is provided below:

**Table 21.46. Possible *mysqli\_info* return values**

Query type	Example result string
INSERT INTO...SELECT...	Records: 100 Duplicates: 0 Warnings: 0
INSERT INTO...VALUES (...),(...),(...)	Records: 3 Duplicates: 0 Warnings: 0
LOAD DATA INFILE ...	Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
ALTER TABLE ...	Records: 3 Duplicates: 0 Warnings: 0
UPDATE ...	Rows matched: 40 Changed: 40 Warnings: 0

**Note**

Queries which do not fall into one of the preceding formats are not supported. In these situations, *mysqli\_info* will return an empty string.

**Parameters**

*link*

Procedural style only: A link identifier returned by *mysqli\_connect* or *mysqli\_init*

**Return Values**

A character string representing additional information about the most recently executed query.

**Examples****Example 21.130. *\$mysqli->info* example**

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
```

```
printf("Connect failed: %s\n", mysqli_connect_error());
exit();
}

$mysqli->query("CREATE TEMPORARY TABLE t1 LIKE City");

/* INSERT INTO .. SELECT */
$mysqli->query("INSERT INTO t1 SELECT * FROM City ORDER BY ID LIMIT 150");
printf("%s\n", $mysqli->info);

/* close connection */
$mysqli->close();
?>
```

### Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TEMPORARY TABLE t1 LIKE City");

/* INSERT INTO .. SELECT */
mysqli_query($link, "INSERT INTO t1 SELECT * FROM City ORDER BY ID LIMIT 150");
printf("%s\n", mysqli_info($link));

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Records: 150 Duplicates: 0 Warnings: 0
```

[mysqli\\_num\\_rows](#)

### 21.9.3.9.29. [mysqli::init](#), [mysqli\\_init](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::init](#)

[mysqli\\_init](#)

Initializes MySQLi and returns a resource for use with [mysqli\\_real\\_connect\(\)](#)

### Description

Object oriented style

```
mysqli mysqli::init();
```

## Procedural style

```
mysqli mysqli_init();
```

Allocates or initializes a MySQL object suitable for [mysqli\\_options](#) and [mysqli\\_real\\_connect](#).

### Note

Any subsequent calls to any mysqli function (except [mysqli\\_options](#)) will fail until [mysqli\\_real\\_connect](#) was called.

## Return Values

Returns an object.

## Examples

See [mysqli\\_real\\_connect](#).

## See Also

```
mysqli_options  
mysqli_close  
mysqli_real_connect  
mysqli_connect
```

### 21.9.3.9.30. [mysqli::\\$insert\\_id](#), [mysqli\\_insert\\_id](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::\\$insert\\_id](#)

```
mysqli_insert_id
```

Returns the auto generated id used in the last query

## Description

Object oriented style

```
mixed  
mysqli->insert_id ;
```

Procedural style

```
mixed mysqli_insert_id(  
mysqli link);
```

The [mysqli\\_insert\\_id](#) function returns the ID generated by a query on a table with a column having the AUTO\_INCREMENT attribute. If the last query wasn't an INSERT or UPDATE statement or if the modified table does not have a column with the AUTO\_INCREMENT attribute, this function will return zero.

### Note

Performing an INSERT or UPDATE statement using the [LAST\\_INSERT\\_ID\(\)](#) function will also modify the value returned by the [mysqli\\_insert\\_id](#) function.

## Parameters

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

## Return Values

The value of the [AUTO\\_INCREMENT](#) field that was updated by the previous query. Returns zero if there was no previous query on the connection or if the query did not update an [AUTO\\_INCREMENT](#) value.

### Note

If the number is greater than maximal int value, `mysqli_insert_id` will return a string.

## Examples

### Example 21.131. `$mysqli->insert_id` example

#### Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCity LIKE City");

$query = "INSERT INTO myCity VALUES (NULL, 'Stuttgart', 'DEU', 'Stuttgart', 617000)";
$mysqli->query($query);

printf ("New Record has id %d.\n", $mysqli->insert_id);

/* drop table */
$mysqli->query("DROP TABLE myCity");

/* close connection */
$mysqli->close();
?>
```

#### Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCity LIKE City");

$query = "INSERT INTO myCity VALUES (NULL, 'Stuttgart', 'DEU', 'Stuttgart', 617000)";
mysqli_query($link, $query);

printf ("New Record has id %d.\n", mysqli_insert_id($link));

/* drop table */
mysqli_query($link, "DROP TABLE myCity");

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
New Record has id 1.
```

### 21.9.3.9.31. [mysqli::kill](#), [mysqli\\_kill](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::kill](#)

[mysqli\\_kill](#)

Asks the server to kill a MySQL thread

#### Description

Object oriented style

```
bool mysqli::kill(  
    int processid);
```

Procedural style

```
bool mysqli_kill(  
    mysqli link,  
    int processid);
```

This function is used to ask the server to kill a MySQL thread specified by the *processid* parameter. This value must be retrieved by calling the [mysqli\\_thread\\_id](#) function.

To stop a running query you should use the SQL command `KILL QUERY processid`.

#### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### Examples

##### Example 21.132. [mysqli::kill](#) example

Object oriented style

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* determine our thread id */  
$thread_id = $mysqli->thread_id;  
  
/* Kill connection */
```

```
$mysqli->kill($thread_id);

/* This should produce an error */
if (!$mysqli->query("CREATE TABLE myCity LIKE City")) {
    printf("Error: %s\n", $mysqli->error);
    exit;
}

/* close connection */
$mysqli->close();
?>
```

### Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* determine our thread id */
$thread_id = mysqli_thread_id($link);

/* Kill connection */
mysqli_kill($link, $thread_id);

/* This should produce an error */
if (!mysqli_query($link, "CREATE TABLE myCity LIKE City")) {
    printf("Error: %s\n", mysqli_error($link));
    exit;
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Error: MySQL server has gone away
```

### See Also

### 21.9.3.9.32. [mysqli::more\\_results](#), [mysqli\\_more\\_results](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::more\\_results](#)

[mysqli\\_more\\_results](#)

Check if there are any more query results from a multi query

### Description

Object oriented style

```
bool mysqli::more_results();
```

Procedural style

```
bool mysqli_more_results(  
    mysqli link);
```

Indicates if one or more result sets are available from a previous call to [mysqli\\_multi\\_query](#).

#### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

#### Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

#### Examples

See [mysqli\\_multi\\_query](#).

#### See Also

[mysqli\\_multi\\_query](#)  
[mysqli\\_next\\_result](#)  
[mysqli\\_store\\_result](#)  
[mysqli\\_use\\_result](#)

### 21.9.3.9.33. [mysqli::multi\\_query](#), [mysqli\\_multi\\_query](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::multi\\_query](#)

[mysqli\\_multi\\_query](#)

Performs a query on the database

#### Description

Object oriented style

```
bool mysqli::multi_query(  
    string query);
```

Procedural style

```
bool mysqli_multi_query(  
    mysqli link,  
    string query);
```

Executes one or multiple queries which are concatenated by a semicolon.

To retrieve the resultset from the first query you can use [mysqli\\_use\\_result](#) or [mysqli\\_store\\_result](#). All subsequent query results can be processed using [mysqli\\_more\\_results](#) and [mysqli\\_next\\_result](#).

#### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

*query*

The query, as a string.

Data inside the query should be [properly escaped](#).

## Return Values

Returns [FALSE](#) if the first statement failed. To retrieve subsequent errors from other statements you have to call [mysqli\\_next\\_result](#) first.

## Examples

### Example 21.133. [mysqli::multi\\_query](#) example

#### Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT CURRENT_USER()";
$query .= "SELECT Name FROM City ORDER BY ID LIMIT 20, 5";

/* execute multi query */
if ($mysqli->multi_query($query)) {
    do {
        /* store first result set */
        if ($result = $mysqli->store_result()) {
            while ($row = $result->fetch_row()) {
                printf("%s\n", $row[0]);
            }
            $result->free();
        }
        /* print divider */
        if ($mysqli->more_results()) {
            printf("-----\n");
        }
    } while ($mysqli->next_result());
}

/* close connection */
$mysqli->close();
?>
```

#### Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT CURRENT_USER()";
$query .= "SELECT Name FROM City ORDER BY ID LIMIT 20, 5";

/* execute multi query */
if (mysqli_multi_query($link, $query)) {
    do {
```

```
/* store first result set */
if ($result = mysqli_store_result($link)) {
    while ($row = mysqli_fetch_row($result)) {
        printf("%s\n", $row[0]);
    }
    mysqli_free_result($result);
}
/* print divider */
if (mysqli_more_results($link)) {
    printf("-----\n");
}
} while (mysqli_next_result($link));
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output something similar to:

```
my_user@localhost
-----
Amersfoort
Maastricht
Dordrecht
Leiden
Haarlemmermeer
```

#### 21.9.3.9.34. [mysqli::next\\_result](#), [mysqli\\_next\\_result](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::next\\_result](#)

[mysqli\\_next\\_result](#)

Prepare next result from `multi_query`

### Description

Object oriented style

```
bool mysqli::next_result();
```

Procedural style

```
bool mysqli_next_result(
    mysqli link);
```

Prepares next result set from a previous call to [mysqli\\_multi\\_query](#) which can be retrieved by [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#).

### Parameters

*link*Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`**Return Values**Returns `TRUE` on success or `FALSE` on failure.**Examples**See `mysqli_multi_query`.**See Also**

`mysqli_multi_query`  
`mysqli_more_results`  
`mysqli_store_result`  
`mysqli_use_result`

**21.9.3.9.35. `mysqli::options`, `mysqli_options`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::options`

`mysqli_options`

Set options

**Description**

Object oriented style

```
bool mysqli::options(
    int option,
    mixed value);
```

Procedural style

```
bool mysqli_options(
    mysqli link,
    int option,
    mixed value);
```

Used to set extra connect options and affect behavior for a connection.

This function may be called multiple times to set several options.

`mysqli_options` should be called after `mysqli_init` and before `mysqli_real_connect`.**Parameters***link*Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`*option*

The option that you want to set. It can be one of the following values:

**Table 21.47. Valid options**

Name	Description
<code>MYSQLI_OPT_CONNECT_TIMEOUT</code>	connection timeout in seconds (supported on Windows with TCP/IP since PHP 5.3.1)

Name	Description
<code>MYSQLI_OPT_LOCAL_INFILE</code>	enable/disable use of <code>LOAD LOCAL INFILE</code>
<code>MYSQLI_INIT_COMMAND</code>	command to execute after when connecting to MySQL server
<code>MYSQLI_READ_DEFAULT_FILE</code>	Read options from named option file instead of <code>my.cnf</code>
<code>MYSQLI_READ_DEFAULT_GROUP</code>	Read options from the named group from <code>my.cnf</code> or the file specified with <code>MYSQLI_READ_DEFAULT_FILE</code> .
<code>MYSQLI_SERVER_PUBLIC_KEY</code>	RSA public key file used with the SHA-256 based authentication.

*value* The value for the option.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Changelog

Version	Description
5.5.0	The <code>MYSQLI_SERVER_PUBLIC_KEY</code> option was added.

### Examples

See `mysqli_real_connect`.

### Notes

#### Note

MySQLnd always assumes the server default charset. This charset is sent during connection hand-shake/authentication, which mysqlnd will use.

Libmysqlclient uses the default charset set in the `my.cnf` or by an explicit call to `mysqli_options` prior to calling `mysqli_real_connect`, but after `mysqli_init`.

### See Also

`mysqli_init`  
`mysqli_real_connect`

#### 21.9.3.9.36. `mysqli::ping`, `mysqli_ping`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::ping`

`mysqli_ping`

Pings a server connection, or tries to reconnect if the connection has gone down

### Description

## Object oriented style

```
bool mysqli::ping();
```

## Procedural style

```
bool mysqli_ping(  
    mysqli link);
```

Checks whether the connection to the server is working. If it has gone down, and global option [mysqli.reconnect](#) is enabled an automatic reconnection is attempted.

This function can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

## Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

## Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

## Examples

### Example 21.134. [mysqli::ping](#) example

#### Object oriented style

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* check if server is alive */  
if ($mysqli->ping()) {  
    printf ("Our connection is ok!\n");  
} else {  
    printf ("Error: %s\n", $mysqli->error);  
}  
  
/* close connection */  
$mysqli->close();  
?>
```

#### Procedural style

```
<?php  
$link = mysqli_connect("localhost", "my_user", "my_password", "world");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* check if server is alive */  
if (mysqli_ping($link)) {
```

```
    printf ("Our connection is ok!\n");
} else {
    printf ("Error: %s\n", mysqli_error($link));
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Our connection is ok!
```

### 21.9.3.9.37. [mysqli::poll](#), [mysqli\\_poll](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::poll](#)

[mysqli\\_poll](#)

Poll connections

#### Description

Object oriented style

```
public int mysqli::poll(
    array read,
    array error,
    array reject,
    int sec,
    int usec);
```

Procedural style

```
int mysqli_poll(
    array read,
    array error,
    array reject,
    int sec,
    int usec);
```

#### Warning

This function is currently not documented; only its argument list is available.

Poll connections. Available only with [mysqlind](#). The method can be used as [static](#).

#### Parameters

*read*

*error*

*reject*

*sec*

Number of seconds to wait, must be non-negative.

*usec*

Number of microseconds to wait, must be non-negative.

## Return Values

Returns number of ready connections upon success, [FALSE](#) otherwise.

## Examples

### Example 21.135. A `mysqli_poll` example

```
<?php
$link1 = mysqli_connect();
$link1->query("SELECT 'test'", MYSQLI_ASYNC);
$all_links = array($link1);
$processed = 0;
do {
    $links = $errors = $reject = array();
    foreach ($all_links as $link) {
        $links[] = $errors[] = $reject[] = $link;
    }
    if (!mysqli_poll($links, $errors, $reject, 1)) {
        continue;
    }
    foreach ($links as $link) {
        if ($result = $link->reap_async_query()) {
            print_r($result->fetch_row());
            if (is_object($result))
                mysqli_free_result($result);
        } else die(sprintf("MySQLi Error: %s", mysqli_error($link)));
        $processed++;
    }
} while ($processed < count($all_links));
?>
```

The above example will output:

```
Array
(
    [0] => test
)
```

### 21.9.3.9.38. `mysqli::prepare`, `mysqli_prepare`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::prepare](#)

[mysqli\\_prepare](#)

Prepare an SQL statement for execution

## Description

Object oriented style

```
mysqli_stmt mysqli::prepare(
    string query);
```

## Procedural style

```
mysqli_stmt mysqli_prepare(  
    mysqli link,  
    string query);
```

Prepares the SQL query, and returns a statement handle to be used for further operations on the statement. The query must consist of a single SQL statement.

The parameter markers must be bound to application variables using [mysqli\\_stmt\\_bind\\_param](#) and/or [mysqli\\_stmt\\_bind\\_result](#) before executing the statement or fetching rows.

### Parameters

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

*query*

The query, as a string.

#### Note

You should not add a terminating semicolon or `\g` to the statement.

This parameter can include one or more parameter markers in the SQL statement by embedding question mark (?) characters at the appropriate positions.

#### Note
