The markers are legal only in certain places in SQL statements. For example, they are allowed in the `VALUES ( )` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value.

However, they are not allowed for identifiers (such as table or column names), in the select list that names the columns to be returned by a `SELECT` statement, or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. It's not allowed to compare marker with `NULL` by `? IS NULL` too. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

### Return Values

[mysqli\\_prepare](#) returns a statement object or `FALSE` if an error occurred.

### Examples

#### Example 21.136. `mysqli::prepare` example

Object oriented style

```

<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$city = "Amersfoort";

/* create a prepared statement */
if ($stmt = $mysqli->prepare("SELECT District FROM City WHERE Name=?")) {

    /* bind parameters for markers */
    $stmt->bind_param("s", $city);

    /* execute query */
    $stmt->execute();

    /* bind result variables */
    $stmt->bind_result($district);

    /* fetch value */
    $stmt->fetch();

    printf("%s is in district %s\n", $city, $district);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>

```

### Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$city = "Amersfoort";

/* create a prepared statement */
if ($stmt = mysqli_prepare($link, "SELECT District FROM City WHERE Name=?")) {

    /* bind parameters for markers */
    mysqli_stmt_bind_param($stmt, "s", $city);

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* bind result variables */
    mysqli_stmt_bind_result($stmt, $district);

    /* fetch value */
    mysqli_stmt_fetch($stmt);

    printf("%s is in district %s\n", $city, $district);

    /* close statement */
    mysqli_stmt_close($stmt);
}

```

```
}  
  
/* close connection */  
mysqli_close($link);  
?>
```

The above examples will output:

```
Amersfoort is in district Utrecht
```

### See Also

```

### 21.9.3.9.39. [mysqli::query](#), [mysqli\\_query](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::query](#)

[mysqli\\_query](#)

Performs a query on the database

### Description

Object oriented style

```
mixed mysqli::query(  
    string query,  
    int resultmode  
    = MYSQLI_STORE_RESULT);
```

Procedural style

```
mixed mysqli_query(  
    mysqli link,  
    string query,  
    int resultmode  
    = MYSQLI_STORE_RESULT);
```

Performs a *query* against the database.

For non-DML queries (not INSERT, UPDATE or DELETE), this function is similar to calling [mysqli\\_real\\_query](#) followed by either [mysqli\\_use\\_result](#) or [mysqli\\_store\\_result](#).

### Note

In the case where you pass a statement to [mysqli\\_query](#) that is longer than [max\\_allowed\\_packet](#) of the server, the returned error codes are different depending on whether you are using MySQL Native Driver ([mysqlnd](#)) or MySQL Client Library ([libmysqlclient](#)). The behavior is as follows:

- [mysqlnd](#) on Linux returns an error code of 1153. The error message means “got a packet bigger than [max\\_allowed\\_packet](#) bytes”.

- [mysqlnd](#) on Windows returns an error code 2006. This error message means “server has gone away”.
- [libmysqlclient](#) on all platforms returns an error code 2006. This error message means “server has gone away”.

## Parameters

<i>link</i>	Procedural style only: A link identifier returned by <a href="#">mysqli_connect</a> or <a href="#">mysqli_init</a>
<i>query</i>	The query string.  Data inside the query should be <a href="#">properly escaped</a> .
<i>resultmode</i>	Either the constant <a href="#">MYSQLI_USE_RESULT</a> or <a href="#">MYSQLI_STORE_RESULT</a> depending on the desired behavior. By default, <a href="#">MYSQLI_STORE_RESULT</a> is used.  If you use <a href="#">MYSQLI_USE_RESULT</a> all subsequent calls will return error <a href="#">Commands out of sync</a> unless you call <a href="#">mysqli_free_result</a>  With <a href="#">MYSQLI_ASYNC</a> (available with <a href="#">mysqlnd</a> ), it is possible to perform query asynchronously. <a href="#">mysqli_poll</a> is then used to get results from such queries.

## Return Values

Returns [FALSE](#) on failure. For successful [SELECT](#), [SHOW](#), [DESCRIBE](#) or [EXPLAIN](#) queries [mysqli\\_query](#) will return a [mysqli\\_result](#) object. For other successful queries [mysqli\\_query](#) will return [TRUE](#) .

## Changelog

Version	Description
5.3.0	Added the ability of async queries.

## Examples

### Example 21.137. [mysqli::query](#) example

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if ($mysqli->connect_errno) {
    printf("Connect failed: %s\n", $mysqli->connect_error);
    exit();
}

/* Create table doesn't return a resultset */
if ($mysqli->query("CREATE TEMPORARY TABLE myCity LIKE City") === TRUE) {
    printf("Table myCity successfully created.\n");
}

/* Select queries return a resultset */
if ($result = $mysqli->query("SELECT Name FROM City LIMIT 10")) {
    printf("Select returned %d rows.\n", $result->num_rows);
}
```

```

    /* free result set */
    $result->close();
}

/* If we have to retrieve large amount of data we use MYSQLI_USE_RESULT */
if ($result = $mysqli->query("SELECT * FROM City", MYSQLI_USE_RESULT)) {

    /* Note, that we can't execute any functions which interact with the
       server until result set was closed. All calls will return an
       'out of sync' error */
    if (!$mysqli->query("SET @a='this will not work'")) {
        printf("Error: %s\n", $mysqli->error);
    }
    $result->close();
}

$mysqli->close();
?>

```

### Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Create table doesn't return a resultset */
if (mysqli_query($link, "CREATE TEMPORARY TABLE myCity LIKE City") === TRUE) {
    printf("Table myCity successfully created.\n");
}

/* Select queries return a resultset */
if ($result = mysqli_query($link, "SELECT Name FROM City LIMIT 10")) {
    printf("Select returned %d rows.\n", mysqli_num_rows($result));

    /* free result set */
    mysqli_free_result($result);
}

/* If we have to retrieve large amount of data we use MYSQLI_USE_RESULT */
if ($result = mysqli_query($link, "SELECT * FROM City", MYSQLI_USE_RESULT)) {

    /* Note, that we can't execute any functions which interact with the
       server until result set was closed. All calls will return an
       'out of sync' error */
    if (!mysqli_query($link, "SET @a='this will not work'")) {
        printf("Error: %s\n", mysqli_error($link));
    }
    mysqli_free_result($result);
}

mysqli_close($link);
?>

```

The above examples will output:

```

Table myCity successfully created.
Select returned 10 rows.
Error: Commands out of sync; You can't run this command now

```

---

[mysqli\\_multi\\_query](#)  
[mysqli\\_free\\_result](#)

**21.9.3.9.40. [mysqli::real\\_connect](#), [mysqli\\_real\\_connect](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::real\\_connect](#)

[mysqli\\_real\\_connect](#)

Opens a connection to a mysql server

**Description**

Object oriented style

```
bool mysqli::real_connect(  
    string host,  
    string username,  
    string passwd,  
    string dbname,  
    int port,  
    string socket,  
    int flags);
```

Procedural style

```
bool mysqli_real_connect(  
    mysqli link,  
    string host,  
    string username,  
    string passwd,  
    string dbname,  
    int port,  
    string socket,  
    int flags);
```

Establish a connection to a MySQL database engine.

This function differs from [mysqli\\_connect](#):

- [mysqli\\_real\\_connect](#) needs a valid object which has to be created by function [mysqli\\_init](#).
- With the [mysqli\\_options](#) function you can set various options for connection.
- There is a *flags* parameter.

**Parameters**

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

*host*

Can be either a host name or an IP address. Passing the [NULL](#) value or the string "localhost" to this parameter, the local host is assumed. When possible, pipes will be used instead of the TCP/IP protocol.

*username*

The MySQL user name.

*passwd*

If provided or [NULL](#), the MySQL server will attempt to authenticate the user against those user records which have no password only.

This allows one username to be used with different permissions (depending on if a password as provided or not).

*dbname*

If provided will specify the default database to be used when performing queries.

*port*

Specifies the port number to attempt to connect to the MySQL server.

*socket*

Specifies the socket or named pipe that should be used.

#### Note

Specifying the *socket* parameter will not explicitly determine the type of connection to be used when connecting to the MySQL server. How the connection is made to the MySQL database is determined by the *host* parameter.

*flags*

With the parameter *flags* you can set different connection options:

**Table 21.48. Supported flags**

Name	Description
<code>MYSQLI_CLIENT_COMPRESS</code>	Use compression protocol
<code>MYSQLI_CLIENT_FOUND_ROWS</code>	return number of matched rows, not the number of affected rows
<code>MYSQLI_CLIENT_IGNORE_SPACE</code>	Allow spaces after function names. Makes all function names reserved words.
<code>MYSQLI_CLIENT_INTERACTIVE</code>	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection
<code>MYSQLI_CLIENT_SSL</code>	Use SSL (encryption)

#### Note

For security reasons the `MULTI_STATEMENT` flag is not supported in PHP. If you want to execute multiple queries use the `mysqli_multi_query` function.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 21.138. `mysqli::real_connect` example

Object oriented style

```
<?php
$mysqli = mysqli_init();
if (!$mysqli) {
```

```
die('mysqli_init failed');
}

if (!$mysqli->options(MYSQLI_INIT_COMMAND, 'SET AUTOCOMMIT = 0')) {
    die('Setting MYSQLI_INIT_COMMAND failed');
}

if (!$mysqli->options(MYSQLI_OPT_CONNECT_TIMEOUT, 5)) {
    die('Setting MYSQLI_OPT_CONNECT_TIMEOUT failed');
}

if (!$mysqli->real_connect('localhost', 'my_user', 'my_password', 'my_db')) {
    die('Connect Error (' . mysqli_connect_errno() . ') '
        . mysqli_connect_error());
}

echo 'Success... ' . $mysqli->host_info . "\n";

$mysqli->close();
?>
```

### Object oriented style when extending mysqli class

```
<?php

class foo_mysqli extends mysqli {
    public function __construct($host, $user, $pass, $db) {
        parent::init();

        if (!$parent::options(MYSQLI_INIT_COMMAND, 'SET AUTOCOMMIT = 0')) {
            die('Setting MYSQLI_INIT_COMMAND failed');
        }

        if (!$parent::options(MYSQLI_OPT_CONNECT_TIMEOUT, 5)) {
            die('Setting MYSQLI_OPT_CONNECT_TIMEOUT failed');
        }

        if (!$parent::real_connect($host, $user, $pass, $db)) {
            die('Connect Error (' . mysqli_connect_errno() . ') '
                . mysqli_connect_error());
        }
    }
}

$db = new foo_mysqli('localhost', 'my_user', 'my_password', 'my_db');

echo 'Success... ' . $db->host_info . "\n";

$db->close();
?>
```

### Procedural style

```
<?php

$link = mysqli_init();
if (!$link) {
    die('mysqli_init failed');
}

if (!mysqli_options($link, MYSQLI_INIT_COMMAND, 'SET AUTOCOMMIT = 0')) {
    die('Setting MYSQLI_INIT_COMMAND failed');
}

if (!mysqli_options($link, MYSQLI_OPT_CONNECT_TIMEOUT, 5)) {
    die('Setting MYSQLI_OPT_CONNECT_TIMEOUT failed');
}
```

```

}

if (!mysqli_real_connect($link, 'localhost', 'my_user', 'my_password', 'my_db')) {
    die('Connect Error (' . mysqli_connect_errno() . ') '
        . mysqli_connect_error());
}

echo 'Success... ' . mysqli_get_host_info($link) . "\n";

mysqli_close($link);
?>

```

The above examples will output:

```
Success... MySQL host info: localhost via TCP/IP
```

## Notes

### Note

MySQLnd always assumes the server default charset. This charset is sent during connection hand-shake/authentication, which mysqlnd will use.

Libmysqlclient uses the default charset set in the `my.cnf` or by an explicit call to `mysqli_options` prior to calling `mysqli_real_connect`, but after `mysqli_init`.

### 21.9.3.9.41. `mysqli::real_escape_string`, `mysqli_real_escape_string`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::real_escape_string`

```
mysqli_real_escape_string
```

Escapes special characters in a string for use in an SQL statement, taking into account the current charset of the connection

## Description

Object oriented style

```
string mysqli::escape_string(
    string escapestr);
```

```
string mysqli::real_escape_string(
    string escapestr);
```

Procedural style

```
string mysqli_real_escape_string(
    mysqli link,
```

```
string escapestr);
```

This function is used to create a legal SQL string that you can use in an SQL statement. The given string is encoded to an escaped SQL string, taking into account the current character set of the connection.

### Security: the default character set

The character set must be set either at the server level, or with the API function [mysqli\\_set\\_charset](#) for it to affect [mysqli\\_real\\_escape\\_string](#). See the concepts section on [character sets](#) for more information.

### Parameters

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

*escapestr*

The string to be escaped.

Characters encoded are NUL (ASCII 0), \n, \r, \, ', ", and Control-Z.

### Return Values

Returns an escaped string.

### Examples

#### Example 21.139. [mysqli::real\\_escape\\_string](#) example

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TEMPORARY TABLE myCity LIKE City");

$city = "'s Hertogenbosch";

/* this query will fail, cause we didn't escape $city */
if (!$mysqli->query("INSERT into myCity (Name) VALUES ('$city')")) {
    printf("Error: %s\n", $mysqli->sqlstate);
}

$city = $mysqli->real_escape_string($city);

/* this query with escaped $city will work */
if ($mysqli->query("INSERT into myCity (Name) VALUES ('$city')")) {
    printf("%d Row inserted.\n", $mysqli->affected_rows);
}

$mysqli->close();
?>
```

Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TEMPORARY TABLE myCity LIKE City");

$city = "'s Hertogenbosch";

/* this query will fail, cause we didn't escape $city */
if (!mysqli_query($link, "INSERT into myCity (Name) VALUES ('$city')")) {
    printf("Error: %s\n", mysqli_sqlstate($link));
}

$city = mysqli_real_escape_string($link, $city);

/* this query with escaped $city will work */
if (mysqli_query($link, "INSERT into myCity (Name) VALUES ('$city')")) {
    printf("%d Row inserted.\n", mysqli_affected_rows($link));
}

mysqli_close($link);
?>
```

The above examples will output:

```
Error: 42000
1 Row inserted.
```

## Notes

### Note

For those accustomed to using `mysql_real_escape_string`, note that the arguments of `mysqli_real_escape_string` differ from what `mysql_real_escape_string` expects. The `link` identifier comes first in `mysqli_real_escape_string`, whereas the string to be escaped comes first in `mysql_real_escape_string`.

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::real\\_query](#)

[mysqli\\_real\\_query](#)

Execute an SQL query

## Description

Object oriented style

```
bool mysqli::real_query(  
    string query);
```

### Procedural style

```
bool mysqli_real_query(  
    mysqli link,  
    string query);
```

Executes a single query against the database whose result can then be retrieved or stored using the [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#) functions.

In order to determine if a given query should return a result set or not, see [mysqli\\_field\\_count](#).

### Parameters

<i>link</i>	Procedural style only: A link identifier returned by <a href="#">mysqli_connect</a> or <a href="#">mysqli_init</a>
<i>query</i>	The query, as a string.  Data inside the query should be <a href="#">properly escaped</a> .

### Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

### See Also

[mysqli\\_query](#)  
[mysqli\\_store\\_result](#)  
[mysqli\\_use\\_result](#)

#### 21.9.3.9.43. [mysqli::reap\\_async\\_query](#), [mysqli\\_reap\\_async\\_query](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::reap\\_async\\_query](#)

[mysqli\\_reap\\_async\\_query](#)

Get result from async query

### Description

Object oriented style

```
public mysqli_result mysqli::reap_async_query();
```

### Procedural style

```
mysqli_result mysqli_reap_async_query(  
    mysqli link);
```

#### Warning

This function is currently not documented; only its argument list is available.

Get result from async query. Available only with [mysqlnd](#).

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

### Return Values

Returns `mysqli_result` in success, `FALSE` otherwise.

### See Also

`mysqli_poll`

#### 21.9.3.9.44. `mysqli::refresh`, `mysqli_refresh`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::refresh`

`mysqli_refresh`

Refreshes

### Description

Object oriented style

```
public bool mysqli::refresh(  
    int options);
```

Procedural style

```
int mysqli_refresh(  
    resource link,  
    int options);
```

Flushes tables or caches, or resets the replication server information.

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

*options* The options to refresh, using the `MYSQLI_REFRESH_*` constants as documented within the [MySQLi constants](#) documentation.

See also the official [MySQL Refresh](#) documentation.

### Return Values

`TRUE` if the refresh was a success, otherwise `FALSE`

### See Also

`mysqli_poll`

#### 21.9.3.9.45. `mysqli::rollback`, `mysqli_rollback`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::rollback`

`mysqli_rollback`

Rolls back current transaction

## Description

Object oriented style

```
bool mysqli::rollback();
```

Procedural style

```
bool mysqli_rollback(  
    mysqli link);
```

Rollbacks the current transaction for the database.

## Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

## Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

## Examples

### Example 21.140. [mysqli::rollback](#) example

Object oriented style

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* disable autocommit */  
$mysqli->autocommit(FALSE);  
  
$mysqli->query("CREATE TABLE myCity LIKE City");  
$mysqli->query("ALTER TABLE myCity Type=InnoDB");  
$mysqli->query("INSERT INTO myCity SELECT * FROM City LIMIT 50");  
  
/* commit insert */  
$mysqli->commit();  
  
/* delete all rows */  
$mysqli->query("DELETE FROM myCity");  
  
if ($result = $mysqli->query("SELECT COUNT(*) FROM myCity")) {  
    $row = $result->fetch_row();  
    printf("%d rows in table myCity.\n", $row[0]);  
    /* Free result */  
    $result->close();  
}  
  
/* Rollback */  
$mysqli->rollback();  
  
if ($result = $mysqli->query("SELECT COUNT(*) FROM myCity")) {  
    $row = $result->fetch_row();  
    printf("%d rows in table myCity (after rollback).\n", $row[0]);
```

```

    /* Free result */
    $result->close();
}

/* Drop table myCity */
mysqli->query("DROP TABLE myCity");

mysqli->close();
?>

```

### Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* disable autocommit */
mysqli_autocommit($link, FALSE);

mysqli_query($link, "CREATE TABLE myCity LIKE City");
mysqli_query($link, "ALTER TABLE myCity Type=InnoDB");
mysqli_query($link, "INSERT INTO myCity SELECT * FROM City LIMIT 50");

/* commit insert */
mysqli_commit($link);

/* delete all rows */
mysqli_query($link, "DELETE FROM myCity");

if ($result = mysqli_query($link, "SELECT COUNT(*) FROM myCity")) {
    $row = mysqli_fetch_row($result);
    printf("%d rows in table myCity.\n", $row[0]);
    /* Free result */
    mysqli_free_result($result);
}

/* Rollback */
mysqli_rollback($link);

if ($result = mysqli_query($link, "SELECT COUNT(*) FROM myCity")) {
    $row = mysqli_fetch_row($result);
    printf("%d rows in table myCity (after rollback).\n", $row[0]);
    /* Free result */
    mysqli_free_result($result);
}

/* Drop table myCity */
mysqli_query($link, "DROP TABLE myCity");

mysqli_close($link);
?>

```

The above examples will output:

```

0 rows in table myCity.
50 rows in table myCity (after rollback).

```

```

#### 21.9.3.9.46. `mysqli::rpl_query_type`, `mysqli_rpl_query_type`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::rpl_query_type`

```
mysqli_rpl_query_type
```

Returns RPL query type

##### Description

Object oriented style

```
int mysqli::rpl_query_type(  
    string query);
```

Procedural style

```
int mysqli_rpl_query_type(  
    mysqli link,  
    string query);
```

Returns `MYSQLI_RPL_MASTER`, `MYSQLI_RPL_SLAVE` or `MYSQLI_RPL_ADMIN` depending on a query type. `INSERT`, `UPDATE` and similar are *master* queries, `SELECT` is *slave*, and `FLUSH`, `REPAIR` and similar are *admin*.

##### Warning

This function is currently not documented; only its argument list is available.

##### Warning

This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.

#### 21.9.3.9.47. `mysqli::select_db`, `mysqli_select_db`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::select_db`

```
mysqli_select_db
```

Selects the default database for database queries

##### Description

Object oriented style

```
bool mysqli::select_db(  
    string dbname);
```

Procedural style

```
bool mysqli_select_db(  
    mysqli link,  
    string dbname);
```

Selects the default database to be used when performing queries against the database connection.

**Note**

This function should only be used to change the default database for the connection. You can select the default database with 4th parameter in [mysqli\\_connect](#).

**Parameters**

<i>link</i>	Procedural style only: A link identifier returned by <a href="#">mysqli_connect</a> or <a href="#">mysqli_init</a>
<i>dbname</i>	The database name.

**Return Values**

Returns [TRUE](#) on success or [FALSE](#) on failure.

**Examples****Example 21.141. [mysqli::select\\_db](#) example**

## Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* return name of current default database */
if ($result = $mysqli->query("SELECT DATABASE())) {
    $row = $result->fetch_row();
    printf("Default database is %s.\n", $row[0]);
    $result->close();
}

/* change db to world db */
$mysqli->select_db("world");

/* return name of current default database */
if ($result = $mysqli->query("SELECT DATABASE())) {
    $row = $result->fetch_row();
    printf("Default database is %s.\n", $row[0]);
    $result->close();
}

$mysqli->close();
?>
```

## Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}
```

```
/* return name of current default database */
if ($result = mysqli_query($link, "SELECT DATABASE()")) {
    $row = mysqli_fetch_row($result);
    printf("Default database is %s.\n", $row[0]);
    mysqli_free_result($result);
}

/* change db to world db */
mysqli_select_db($link, "world");

/* return name of current default database */
if ($result = mysqli_query($link, "SELECT DATABASE()")) {
    $row = mysqli_fetch_row($result);
    printf("Default database is %s.\n", $row[0]);
    mysqli_free_result($result);
}

mysqli_close($link);
?>
```

The above examples will output:

```
Default database is test.
Default database is world.
```

- [mysqli::send\\_query](#)

[mysqli\\_send\\_query](#)

Send the query and return

### Description

Object oriented style

```
bool mysqli::send_query(
    string query);
```

Procedural style

```
bool mysqli_send_query(
    mysqli link,
    string query);
```

#### Warning

This function is currently not documented; only its argument list is available.

#### Warning

This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.

**21.9.3.9.49. *mysqli::set\_charset*, *mysqli\_set\_charset***

Copyright 1997-2012 the PHP Documentation Group. [2906]

- *mysqli::set\_charset*

*mysqli\_set\_charset*

Sets the default client character set

**Description**

Object oriented style

```
bool mysqli::set_charset(
    string charset);
```

Procedural style

```
bool mysqli_set_charset(
    mysqli link,
    string charset);
```

Sets the default character set to be used when sending data from and to the database server.

**Parameters***link*Procedural style only: A link identifier returned by *mysqli\_connect* or *mysqli\_init**charset*

The charset to be set as default.

**Return Values**Returns **TRUE** on success or **FALSE** on failure.**Notes****Note**

To use this function on a Windows platform you need MySQL client library version 4.1.11 or above (for MySQL 5.0 you need 5.0.6 or above).

**Note**This is the preferred way to change the charset. Using *mysqli\_query* to set it (such as **SET NAMES utf8**) is not recommended. See the [MySQL character set concepts](#) section for more information.**Examples****Example 21.142. *mysqli::set\_charset* example**

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}
```

```
/* change character set to utf8 */
if (!$mysqli->set_charset("utf8")) {
    printf("Error loading character set utf8: %s\n", $mysqli->error);
} else {
    printf("Current character set: %s\n", $mysqli->character_set_name());
}

$mysqli->close();
?>
```

### Procedural style

```
<?php
$link = mysqli_connect('localhost', 'my_user', 'my_password', 'test');

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* change character set to utf8 */
if (!mysqli_set_charset($link, "utf8")) {
    printf("Error loading character set utf8: %s\n", mysqli_error($link));
} else {
    printf("Current character set: %s\n", mysqli_character_set_name($link));
}

mysqli_close($link);
?>
```

The above examples will output:

```
Current character set: utf8
```

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::set\\_local\\_infile\\_default](#)  
[mysqli\\_set\\_local\\_infile\\_default](#)

Unsets user defined handler for load local infile command

### Description

```
void mysqli_set_local_infile_default(
    mysqli link);
```

Deactivates a [LOAD DATA INFILE LOCAL](#) handler previously set with [mysqli\\_set\\_local\\_infile\\_handler](#).

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

No value is returned.

**Examples**

See `mysqli_set_local_infile_handler` examples

**See Also**

`mysqli_set_local_infile_handler`

**21.9.3.9.51. `mysqli::set_local_infile_handler`, `mysqli_set_local_infile_handler`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::set_local_infile_handler`

`mysqli_set_local_infile_handler`

Set callback function for LOAD DATA LOCAL INFILE command

**Description**

Object oriented style

```
bool mysqli::set_local_infile_handler(
    mysqli link,
    callable read_func);
```

Procedural style

```
bool mysqli_set_local_infile_handler(
    mysqli link,
    callable read_func);
```

Set callback function for LOAD DATA LOCAL INFILE command

The callbacks task is to read input from the file specified in the `LOAD DATA LOCAL INFILE` and to reformat it into the format understood by `LOAD DATA INFILE`.

The returned data needs to match the format specified in the `LOAD DATA`

**Parameters**

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

*read\_func* A callback function or object method taking the following parameters:

- stream* A PHP stream associated with the SQL commands INFILE
- &buffer* A string buffer to store the rewritten input into
- buflen* The maximum number of characters to be stored in the buffer

*&errmsg*

If an error occurs you can store an error message in here

The callback function should return the number of characters stored in the *buffer* or a negative value if an error occurred.

### Return Values

Returns **TRUE** on success or **FALSE** on failure.

### Examples

#### Example 21.143. *mysqli::set\_local\_infile\_handler* example

Object oriented style

```
<?php
$db = mysqli_init();
$db->real_connect("localhost","root","","test");

function callme($stream, &$buffer, $buflen, &$errmsg)
{
    $buffer = fgets($stream);

    echo $buffer;

    // convert to upper case and replace "," delimiter with [TAB]
    $buffer = strtoupper(str_replace(",","\\t", $buffer));

    return strlen($buffer);
}

echo "Input:\\n";

$db->set_local_infile_handler("callme");
$db->query("LOAD DATA LOCAL INFILE 'input.txt' INTO TABLE t1");
$db->set_local_infile_default();

$res = $db->query("SELECT * FROM t1");

echo "\\nResult:\\n";
while ($row = $res->fetch_assoc()) {
    echo join(",", $row). "\\n";
}
?>
```

Procedural style

```
<?php
$db = mysqli_init();
mysqli_real_connect($db, "localhost","root","","test");

function callme($stream, &$buffer, $buflen, &$errmsg)
{
    $buffer = fgets($stream);

    echo $buffer;

    // convert to upper case and replace "," delimiter with [TAB]
    $buffer = strtoupper(str_replace(",","\\t", $buffer));

    return strlen($buffer);
}
```

```

echo "Input:\n";

mysqli_set_local_infile_handler($db, "callme");
mysqli_query($db, "LOAD DATA LOCAL INFILE 'input.txt' INTO TABLE t1");
mysqli_set_local_infile_default($db);

$res = mysqli_query($db, "SELECT * FROM t1");

echo "\nResult:\n";
while ($row = mysqli_fetch_assoc($res)) {
    echo join(", ", $row)."\n";
}
?>

```

The above examples will output:

```

Input :
23,foo
42,bar

Output:
23,FOO
42,BAR

```

#### 21.9.3.9.52. `mysqli::$sqlstate`, `mysqli_sqlstate`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$sqlstate`

`mysqli_sqlstate`

Returns the SQLSTATE error from previous MySQL operation

### Description

Object oriented style

```

string
mysqli->sqlstate ;

```

Procedural style

```

string mysqli_sqlstate(
    mysqli link);

```

Returns a string containing the SQLSTATE error code for the last error. The error code consists of five characters. '00000' means no error. The values are specified by ANSI SQL and ODBC. For a list of possible values, see <http://dev.mysql.com/doc/mysql/en/error-handling.html>.

### Note

Note that not all MySQL errors are yet mapped to SQLSTATE's. The value `HY000` (general error) is used for unmapped errors.

## Parameters

[link](#) Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

## Return Values

Returns a string containing the SQLSTATE error code for the last error. The error code consists of five characters. '00000' means no error.

## Examples

### Example 21.144. [\\$mysqli->sqlstate](#) example

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Table City already exists, so we should get an error */
if (!$mysqli->query("CREATE TABLE City (ID INT, Name VARCHAR(30))")) {
    printf("Error - SQLSTATE %s.\n", $mysqli->sqlstate);
}

$mysqli->close();
?>
```

Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Table City already exists, so we should get an error */
if (!mysqli_query($link, "CREATE TABLE City (ID INT, Name VARCHAR(30))")) {
    printf("Error - SQLSTATE %s.\n", mysqli_sqlstate($link));
}

mysqli_close($link);
?>
```

The above examples will output:

```
Error - SQLSTATE 42S01.
```

`mysqli_error`

### 21.9.3.9.53. `mysqli::ssl_set`, `mysqli_ssl_set`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::ssl_set`

`mysqli_ssl_set`

Used for establishing secure connections using SSL

#### Description

Object oriented style

```
bool mysqli::ssl_set(  
    string key,  
    string cert,  
    string ca,  
    string capath,  
    string cipher);
```

Procedural style

```
bool mysqli_ssl_set(  
    mysqli link,  
    string key,  
    string cert,  
    string ca,  
    string capath,  
    string cipher);
```

Used for establishing secure connections using SSL. It must be called before `mysqli_real_connect`. This function does nothing unless OpenSSL support is enabled.

Note that MySQL Native Driver does not support SSL before PHP 5.3.3, so calling this function when using MySQL Native Driver will result in an error. MySQL Native Driver is enabled by default on Microsoft Windows from PHP version 5.3 onwards.

#### Parameters

<i>link</i>	Procedural style only: A link identifier returned by <code>mysqli_connect</code> or <code>mysqli_init</code>
<i>key</i>	The path name to the key file.
<i>cert</i>	The path name to the certificate file.
<i>ca</i>	The path name to the certificate authority file.
<i>capath</i>	The pathname to a directory that contains trusted SSL CA certificates in PEM format.
<i>cipher</i>	A list of allowable ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`

#### Return Values

This function always returns `TRUE` value. If SSL setup is incorrect `mysqli_real_connect` will return an error when you attempt to connect.

#### See Also

```
mysqli_options  
mysqli_real_connect
```

### 21.9.3.9.54. *mysqli::stat*, *mysqli\_stat*

Copyright 1997-2012 the PHP Documentation Group. [2906]

- *mysqli::stat*

```
mysqli_stat
```

Gets the current system status

#### Description

Object oriented style

```
string mysqli::stat();
```

Procedural style

```
string mysqli_stat(  
    mysqli link);
```

*mysqli\_stat* returns a string containing information similar to that provided by the 'mysqladmin status' command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

#### Parameters

*link*

Procedural style only: A link identifier returned by *mysqli\_connect* or *mysqli\_init*

#### Return Values

A string describing the server status. *FALSE* if an error occurred.

#### Examples

##### Example 21.145. *mysqli::stat* example

Object oriented style

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
printf ("System status: %s\n", $mysqli->stat());  
  
$mysqli->close();  
?>
```

Procedural style

```
<?php  
$link = mysqli_connect("localhost", "my_user", "my_password", "world");
```

```
/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

printf("System status: %s\n", mysqli_stat($link));

mysqli_close($link);
?>
```

The above examples will output:

```
System status: Uptime: 272  Threads: 1  Questions: 5340  Slow queries: 0
Opens: 13  Flush tables: 1  Open tables: 0  Queries per second avg: 19.632
Memory in use: 8496K  Max memory used: 8560K
```

### See Also

#### 21.9.3.9.55. [mysqli::stmt\\_init](#), [mysqli\\_stmt\\_init](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::stmt\\_init](#)

[mysqli\\_stmt\\_init](#)

Initializes a statement and returns an object for use with [mysqli\\_stmt\\_prepare](#)

### Description

Object oriented style

```
mysqli_stmt $stmt = mysqli::stmt_init();
```

Procedural style

```
mysqli_stmt $stmt = mysqli_stmt_init(
    mysqli $link);
```

Allocates and initializes a statement object suitable for [mysqli\\_stmt\\_prepare](#).

#### Note

Any subsequent calls to any [mysqli\\_stmt](#) function will fail until [mysqli\\_stmt\\_prepare](#) was called.

### Parameters

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

Returns an object.

### See Also

```
mysqli_stmt_prepare
```

### 21.9.3.9.56. [mysqli::store\\_result](#), [mysqli\\_store\\_result](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::store\\_result](#)

```
mysqli_store_result
```

Transfers a result set from the last query

#### Description

Object oriented style

```
mysqli_result mysqli::store_result();
```

Procedural style

```
mysqli_result mysqli_store_result(  
    mysqli link);
```

Transfers the result set from the last query on the database connection represented by the [link](#) parameter to be used with the [mysqli\\_data\\_seek](#) function.

#### Parameters

[link](#) Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

#### Return Values

Returns a buffered result object or [FALSE](#) if an error occurred.

#### Note

[mysqli\\_store\\_result](#) returns [FALSE](#) in case the query didn't return a result set (if the query was, for example an INSERT statement). This function also returns [FALSE](#) if the reading of the result set failed. You can check if you have got an error by checking if [mysqli\\_error](#) doesn't return an empty string, if [mysqli\\_errno](#) returns a non zero value, or if [mysqli\\_field\\_count](#) returns a non zero value. Also possible reason for this function returning [FALSE](#) after successful call to [mysqli\\_query](#) can be too large result set (memory for it cannot be allocated). If [mysqli\\_field\\_count](#) returns a non-zero value, the statement should have produced a non-empty result set.

#### Notes

#### Note

Although it is always good practice to free the memory used by the result of a query using the [mysqli\\_free\\_result](#) function, when transferring large result sets using the [mysqli\\_store\\_result](#) this becomes particularly important.

#### Examples

See [mysqli\\_multi\\_query](#).

#### See Also

[mysqli\\_real\\_query](#)

`mysqli_use_result`

### 21.9.3.9.57. `mysqli::$thread_id, mysqli_thread_id`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$thread_id`

`mysqli_thread_id`

Returns the thread ID for the current connection

#### Description

Object oriented style

```
int
mysqli->thread_id ;
```

Procedural style

```
int mysqli_thread_id(
mysqli link);
```

The `mysqli_thread_id` function returns the thread ID for the current connection which can then be killed using the `mysqli_kill` function. If the connection is lost and you reconnect with `mysqli_ping`, the thread ID will be other. Therefore you should get the thread ID only when you need it.

#### Note

The thread ID is assigned on a connection-by-connection basis. Hence, if the connection is broken and then re-established a new thread ID will be assigned.

To kill a running query you can use the SQL command `KILL QUERY processid`.

#### Parameters

`link` Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

#### Return Values

Returns the Thread ID for the current connection.

#### Examples

##### Example 21.146. `$mysqli->thread_id` example

Object oriented style

```
<?php
mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* determine our thread id */
$thread_id = $mysqli->thread_id;
```

```
/* Kill connection */
$mysqli->kill($thread_id);

/* This should produce an error */
if (!$mysqli->query("CREATE TABLE myCity LIKE City")) {
    printf("Error: %s\n", $mysqli->error);
    exit;
}

/* close connection */
$mysqli->close();
?>
```

### Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* determine our thread id */
$thread_id = mysqli_thread_id($link);

/* Kill connection */
mysqli_kill($link, $thread_id);

/* This should produce an error */
if (!mysqli_query($link, "CREATE TABLE myCity LIKE City")) {
    printf("Error: %s\n", mysqli_error($link));
    exit;
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Error: MySQL server has gone away
```

### See Also

[mysqli\\_kill](#)

#### 21.9.3.9.58. [mysqli::thread\\_safe](#), [mysqli\\_thread\\_safe](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli::thread\\_safe](#)

[mysqli\\_thread\\_safe](#)

Returns whether thread safety is given or not

### Description

Procedural style

```
bool mysqli_thread_safe();
```

Tells whether the client library is compiled as thread-safe.

### Return Values

`TRUE` if the client library is thread-safe, otherwise `FALSE`.

#### 21.9.3.9.59. `mysqli::use_result`, `mysqli_use_result`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::use_result`

`mysqli_use_result`

Initiate a result set retrieval

### Description

Object oriented style

```
mysqli_result mysqli::use_result();
```

Procedural style

```
mysqli_result mysqli_use_result(
    mysqli link);
```

Used to initiate the retrieval of a result set from the last query executed using the `mysqli_real_query` function on the database connection.

Either this or the `mysqli_store_result` function must be called before the results of a query can be retrieved, and one or the other must be called to prevent the next query on that database connection from failing.

#### Note

The `mysqli_use_result` function does not transfer the entire result set from the database and hence cannot be used functions such as `mysqli_data_seek` to move to a particular row within the set. To use this functionality, the result set must be stored using `mysqli_store_result`. One should not use `mysqli_use_result` if a lot of processing on the client side is performed, since this will tie up the server and prevent other threads from updating any tables from which the data is being fetched.

### Return Values

Returns an unbuffered result object or `FALSE` if an error occurred.

### Examples

#### Example 21.147. `mysqli::use_result` example

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
```

```
printf("Connect failed: %s\n", mysqli_connect_error());
exit();
}

$query = "SELECT CURRENT_USER()";
$query .= "SELECT Name FROM City ORDER BY ID LIMIT 20, 5";

/* execute multi query */
if ($mysqli->multi_query($query)) {
    do {
        /* store first result set */
        if ($result = $mysqli->use_result()) {
            while ($row = $result->fetch_row()) {
                printf("%s\n", $row[0]);
            }
            $result->close();
        }
        /* print divider */
        if ($mysqli->more_results()) {
            printf("-----\n");
        }
    } while ($mysqli->next_result());
}

/* close connection */
$mysqli->close();
?>
```

### Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT CURRENT_USER()";
$query .= "SELECT Name FROM City ORDER BY ID LIMIT 20, 5";

/* execute multi query */
if (mysqli_multi_query($link, $query)) {
    do {
        /* store first result set */
        if ($result = mysqli_use_result($link)) {
            while ($row = mysqli_fetch_row($result)) {
                printf("%s\n", $row[0]);
            }
            mysqli_free_result($result);
        }
        /* print divider */
        if (mysqli_more_results($link)) {
            printf("-----\n");
        }
    } while (mysqli_next_result($link));
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
my_user@localhost
```

```
-----
Amersfoort
Maastricht
Dordrecht
Leiden
Haarlemmermeer
```

**21.9.3.9.60. `mysqli::$warning_count`, `mysqli_warning_count`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli::$warning_count`

`mysqli_warning_count`

Returns the number of warnings from the last query for the given link

**Description**

Object oriented style

```
int
mysqli->warning_count ;
```

Procedural style

```
int mysqli_warning_count(
    mysqli link);
```

Returns the number of warnings from the last query in the connection.

**Note**

For retrieving warning messages you can use the SQL command `SHOW WARNINGS [limit row_count]`.

**Parameters**

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

Number of warnings or zero if there are no warnings.

**Examples****Example 21.148. `$mysqli->warning_count` example**

Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
```

```

if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCity LIKE City");

/* a remarkable city in Wales */
$query = "INSERT INTO myCity (CountryCode, Name) VALUES('GBR',
    'Llanfairpwllgwyngyllgogerychwyrndrobwlllllantysiliogogoch')";

$mysqli->query($query);

if ($mysqli->warning_count) {
    if ($result = $mysqli->query("SHOW WARNINGS")) {
        $row = $result->fetch_row();
        printf("%s (%d): %s\n", $row[0], $row[1], $row[2]);
        $result->close();
    }
}

/* close connection */
$mysqli->close();
?>

```

### Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCity LIKE City");

/* a remarkable long city name in Wales */
$query = "INSERT INTO myCity (CountryCode, Name) VALUES('GBR',
    'Llanfairpwllgwyngyllgogerychwyrndrobwlllllantysiliogogoch')";

mysqli_query($link, $query);

if (mysqli_warning_count($link)) {
    if ($result = mysqli_query($link, "SHOW WARNINGS")) {
        $row = mysqli_fetch_row($result);
        printf("%s (%d): %s\n", $row[0], $row[1], $row[2]);
        mysqli_free_result($result);
    }
}

/* close connection */
mysqli_close($link);
?>

```

The above examples will output:

```
Warning (1264): Data truncated for column 'Name' at row 1
```

### 21.9.3.10.1. [mysqli\\_stmt::\\$affected\\_rows](#), [mysqli\\_stmt\\_affected\\_rows](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::\\$affected\\_rows](#)

[mysqli\\_stmt\\_affected\\_rows](#)

Returns the total number of rows changed, deleted, or inserted by the last executed statement

#### Description

Object oriented style

```
int
mysqli_stmt->affected_rows ;
```

Procedural style

```
int mysqli_stmt_affected_rows(
    mysqli_stmt stmt);
```

Returns the number of rows affected by [INSERT](#), [UPDATE](#), or [DELETE](#) query.

This function only works with queries which update a table. In order to get the number of rows from a [SELECT](#) query, use [mysqli\\_stmt\\_num\\_rows](#) instead.

#### Parameters

*stmt*

Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an [UPDATE](#)/[DELETE](#) statement, no rows matched the [WHERE](#) clause in the query or that no query has yet been executed. -1 indicates that the query has returned an error. [NULL](#) indicates an invalid argument was supplied to the function.

#### Note

If the number of affected rows is greater than maximal PHP int value, the number of affected rows will be returned as a string value.

## Examples

### Example 21.149. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* create temp table */
$mysqli->query("CREATE TEMPORARY TABLE myCountry LIKE Country");

$query = "INSERT INTO myCountry SELECT * FROM Country WHERE Code LIKE ?";

/* prepare statement */
if ($stmt = $mysqli->prepare($query)) {

    /* Bind variable for placeholder */
    $code = 'A%';
    $stmt->bind_param("s", $code);

    /* execute statement */
    $stmt->execute();

    printf("rows inserted: %d\n", $stmt->affected_rows);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.150. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* create temp table */
mysqli_query($link, "CREATE TEMPORARY TABLE myCountry LIKE Country");

$query = "INSERT INTO myCountry SELECT * FROM Country WHERE Code LIKE ?";

/* prepare statement */
if ($stmt = mysqli_prepare($link, $query)) {

    /* Bind variable for placeholder */
    $code = 'A%';
    mysqli_stmt_bind_param($stmt, "s", $code);

    /* execute statement */
    mysqli_stmt_execute($stmt);

    printf("rows inserted: %d\n", mysqli_stmt_affected_rows($stmt));

    /* close statement */
```

```
mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
rows inserted: 17
```

[mysqli\\_prepare](#)

#### 21.9.3.10.2. [mysqli\\_stmt::attr\\_get](#), [mysqli\\_stmt\\_attr\\_get](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::attr\\_get](#)

[mysqli\\_stmt\\_attr\\_get](#)

Used to get the current value of a statement attribute

### Description

Object oriented style

```
int mysqli_stmt::attr_get(
    int attr);
```

Procedural style

```
int mysqli_stmt_attr_get(
    mysqli_stmt stmt,
    int attr);
```

Gets the current value of a statement attribute.

### Parameters

*stmt* Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

*attr* The attribute that you want to get.

### Return Values

Returns [FALSE](#) if the attribute is not found, otherwise returns the value of the attribute.

#### 21.9.3.10.3. [mysqli\\_stmt::attr\\_set](#), [mysqli\\_stmt\\_attr\\_set](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::attr\\_set](#)

[mysqli\\_stmt\\_attr\\_set](#)

Used to modify the behavior of a prepared statement

**Description**

Object oriented style

```
bool mysqli_stmt::attr_set(
    int attr,
    int mode);
```

Procedural style

```
bool mysqli_stmt_attr_set(
    mysqli_stmt stmt,
    int attr,
    int mode);
```

Used to modify the behavior of a prepared statement. This function may be called multiple times to set several attributes.

**Parameters**

*stmt* Procedural style only: A statement identifier returned by *mysqli\_stmt\_init*.

*attr* The attribute that you want to set. It can have one of the following values:

**Table 21.49. Attribute values**

Character	Description
MYSQLI_STMT_ATTR_UPDATE_MAX_LENGTH	Use to enable <i>mysqli_stmt_store_result</i> to update the metadata <i>MYSQL_FIELD-&gt;max_length</i> value.
MYSQLI_STMT_ATTR_CURSOR_TYPE	Type of cursor to open for statement when <i>mysqli_stmt_execute</i> is invoked. <i>mode</i> can be <i>MYSQLI_CURSOR_TYPE_NO_CURSOR</i> (the default) or <i>MYSQLI_CURSOR_TYPE_READ_ONLY</i> .
MYSQLI_STMT_ATTR_PREFETCH_ROWS	Number of rows to fetch from server at a time when using a cursor. <i>mode</i> can be in the range from 1 to the maximum value of unsigned long. The default is 1.

If you use the *MYSQLI\_STMT\_ATTR\_CURSOR\_TYPE* option with *MYSQLI\_CURSOR\_TYPE\_READ\_ONLY*, a cursor is opened for the statement when you invoke *mysqli\_stmt\_execute*. If there is already an open cursor from a previous *mysqli\_stmt\_execute* call, it closes the cursor before opening a new one. *mysqli\_stmt\_reset* also closes any open cursor before preparing the statement for re-execution. *mysqli\_stmt\_free\_result* closes any open cursor.

If you open a cursor for a prepared statement, *mysqli\_stmt\_store\_result* is unnecessary.

*mode*

The value to assign to the attribute.

**21.9.3.10.4. *mysqli\_stmt::bind\_param*, *mysqli\_stmt\_bind\_param***

Copyright 1997-2012 the PHP Documentation Group. [2906]

- *mysqli\_stmt::bind\_param*

*mysqli\_stmt\_bind\_param*

Binds variables to a prepared statement as parameters

**Description**

Object oriented style

```
bool mysqli_stmt::bind_param(
    string types,
    mixed var1,
    mixed ...);
```

Procedural style

```
bool mysqli_stmt_bind_param(
    mysqli_stmt stmt,
    string types,
    mixed var1,
    mixed ...);
```

Bind variables for the parameter markers in the SQL statement that was passed to *mysqli\_prepare*.**Note**

If data size of a variable exceeds max. allowed packet size (*max\_allowed\_packet*), you have to specify *b* in *types* and use *mysqli\_stmt\_send\_long\_data* to send the data in packets.

**Note**

Care must be taken when using *mysqli\_stmt\_bind\_param* in conjunction with *call\_user\_func\_array*. Note that *mysqli\_stmt\_bind\_param* requires parameters to be passed by reference, whereas *call\_user\_func\_array* can accept as a parameter a list of variables that can represent references or values.

**Parameters***stmt*Procedural style only: A statement identifier returned by *mysqli\_stmt\_init*.*types*

A string that contains one or more characters which specify the types for the corresponding bind variables:

**Table 21.50. Type specification chars**

Character	Description
i	corresponding variable has type integer
d	corresponding variable has type double
s	corresponding variable has type string

Character	Description
b	corresponding variable is a blob and will be sent in packets

*var1*

The number of variables and length of string *types* must match the parameters in the statement.

## Return Values

Returns **TRUE** on success or **FALSE** on failure.

## Examples

### Example 21.151. Object oriented style

```
<?php
$mysqli = new mysqli('localhost', 'my_user', 'my_password', 'world');

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$stmt = $mysqli->prepare("INSERT INTO CountryLanguage VALUES (?, ?, ?, ?)");
$stmt->bind_param('sssd', $code, $language, $official, $percent);

$code = 'DEU';
$language = 'Bavarian';
$official = "F";
$percent = 11.2;

/* execute prepared statement */
$stmt->execute();

printf("%d Row inserted.\n", $stmt->affected_rows);

/* close statement and connection */
$stmt->close();

/* Clean up table CountryLanguage */
$mysqli->query("DELETE FROM CountryLanguage WHERE Language='Bavarian'");
printf("%d Row deleted.\n", $mysqli->affected_rows);

/* close connection */
$mysqli->close();
?>
```

### Example 21.152. Procedural style

```
<?php
$link = mysqli_connect('localhost', 'my_user', 'my_password', 'world');

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$stmt = mysqli_prepare($link, "INSERT INTO CountryLanguage VALUES (?, ?, ?, ?)");
mysqli_stmt_bind_param($stmt, 'sssd', $code, $language, $official, $percent);

$code = 'DEU';
```

```
$language = 'Bavarian';
$official = "F";
$percent = 11.2;

/* execute prepared statement */
mysqli_stmt_execute($stmt);

printf("%d Row inserted.\n", mysqli_stmt_affected_rows($stmt));

/* close statement and connection */
mysqli_stmt_close($stmt);

/* Clean up table CountryLanguage */
mysqli_query($link, "DELETE FROM CountryLanguage WHERE Language='Bavarian'");
printf("%d Row deleted.\n", mysqli_affected_rows($link));

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
1 Row inserted.
1 Row deleted.
```

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::bind\\_result](#)

[mysqli\\_stmt\\_bind\\_result](#)

Binds variables to a prepared statement for result storage

#### Description

Object oriented style

```
bool mysqli_stmt::bind_result(
    mixed var1,
    mixed ...);
```

Procedural style

```
bool mysqli_stmt_bind_result(
    mysqli_stmt stmt,
    mixed var1,
    mixed ...);
```

Binds columns in the result set to variables.

When `mysqli_stmt_fetch` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified variables `var1`, ....

### Note

Note that all columns must be bound after `mysqli_stmt_execute` and prior to calling `mysqli_stmt_fetch`. Depending on column types bound variables can silently change to the corresponding PHP type.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysqli_stmt_fetch` is called.

### Parameters

<code>stmt</code>	Procedural style only: A statement identifier returned by <code>mysqli_stmt_init</code> .
<code>var1</code>	The variable to be bound.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 21.153. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* prepare statement */
if ($stmt = $mysqli->prepare("SELECT Code, Name FROM Country ORDER BY Name LIMIT 5")) {
    $stmt->execute();

    /* bind variables to prepared statement */
    $stmt->bind_result($col1, $col2);

    /* fetch values */
    while ($stmt->fetch()) {
        printf("%s %s\n", $col1, $col2);
    }

    /* close statement */
    $stmt->close();
}
/* close connection */
$mysqli->close();

?>
```

#### Example 21.154. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (!$link) {
```

```
printf("Connect failed: %s\n", mysqli_connect_error());
exit();
}

/* prepare statement */
if ($stmt = mysqli_prepare($link, "SELECT Code, Name FROM Country ORDER BY Name LIMIT 5")) {
    mysqli_stmt_execute($stmt);

    /* bind variables to prepared statement */
    mysqli_stmt_bind_result($stmt, $col1, $col2);

    /* fetch values */
    while (mysqli_stmt_fetch($stmt)) {
        printf("%s %s\n", $col1, $col2);
    }

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
AFG Afghanistan
ALB Albania
DZA Algeria
ASM American Samoa
AND Andorra
```

#### 21.9.3.10.6. [mysqli\\_stmt::close](#), [mysqli\\_stmt\\_close](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::close](#)

[mysqli\\_stmt\\_close](#)

Closes a prepared statement

### Description

Object oriented style

```
bool mysqli_stmt::close();
```

Procedural style

```
bool mysqli_stmt_close(
```

```
mysqli_stmt stmt);
```

Closes a prepared statement. [mysqli\\_stmt\\_close](#) also deallocates the statement handle. If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

### Parameters

*stmt* Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

### Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

### See Also

[mysqli\\_prepare](#)

#### 21.9.3.10.7. [mysqli\\_stmt::data\\_seek](#), [mysqli\\_stmt\\_data\\_seek](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::data\\_seek](#)

[mysqli\\_stmt\\_data\\_seek](#)

Seeks to an arbitrary row in statement result set

### Description

Object oriented style

```
void mysqli_stmt::data_seek(  
    int offset);
```

Procedural style

```
void mysqli_stmt_data_seek(  
    mysqli_stmt stmt,  
    int offset);
```

Seeks to an arbitrary result pointer in the statement result set.

[mysqli\\_stmt\\_store\\_result](#) must be called prior to [mysqli\\_stmt\\_data\\_seek](#).

### Parameters

*stmt* Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

*offset* Must be between zero and the total number of rows minus one (0.. [mysqli\\_stmt\\_num\\_rows](#) - 1).

### Return Values

No value is returned.

### Examples

#### Example 21.155. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name";
if ($stmt = $mysqli->prepare($query)) {

    /* execute query */
    $stmt->execute();

    /* bind result variables */
    $stmt->bind_result($name, $code);

    /* store result */
    $stmt->store_result();

    /* seek to row no. 400 */
    $stmt->data_seek(399);

    /* fetch values */
    $stmt->fetch();

    printf ("City: %s Countrycode: %s\n", $name, $code);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.156. Procedural style

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* bind result variables */
    mysqli_stmt_bind_result($stmt, $name, $code);

    /* store result */
    mysqli_stmt_store_result($stmt);

    /* seek to row no. 400 */
    mysqli_stmt_data_seek($stmt, 399);

    /* fetch values */
    mysqli_stmt_fetch($stmt);

    printf ("City: %s Countrycode: %s\n", $name, $code);
}
```

```
    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
City: Benin City Countrycode: NGA
```

### See Also

#### 21.9.3.10.8. [mysqli\\_stmt::\\$errno](#), [mysqli\\_stmt\\_errno](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::\\$errno](#)

[mysqli\\_stmt\\_errno](#)

Returns the error code for the most recent statement call

### Description

Object oriented style

```
int
mysqli_stmt->errno ;
```

Procedural style

```
int mysqli_stmt_errno(
mysqli_stmt stmt);
```

Returns the error code for the most recently invoked statement function that can succeed or fail.

Client error message numbers are listed in the MySQL [errmsg.h](#) header file, server error message numbers are listed in [mysqld\\_error.h](#). In the MySQL source distribution you can find a complete list of error messages and error numbers in the file [Docs/mysqld\\_error.txt](#).

### Parameters

*stmt*

Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

### Return Values

An error code value. Zero means no error occurred.

### Examples

#### Example 21.157. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCountry LIKE Country");
$mysqli->query("INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = $mysqli->prepare($query)) {

    /* drop table */
    $mysqli->query("DROP TABLE myCountry");

    /* execute query */
    $stmt->execute();

    printf("Error: %d.\n", $stmt->errno);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.158. Procedural style

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCountry LIKE Country");
mysqli_query($link, "INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* drop table */
    mysqli_query($link, "DROP TABLE myCountry");

    /* execute query */
    mysqli_stmt_execute($stmt);

    printf("Error: %d.\n", mysqli_stmt_errno($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Error: 1146.
```

### See Also

#### 21.9.3.10.9. [mysqli\\_stmt::\\$error\\_list](#), [mysqli\\_stmt\\_error\\_list](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::\\$error\\_list](#)

[mysqli\\_stmt\\_error\\_list](#)

Returns a list of errors from the last statement executed

### Description

Object oriented style

```
array  
mysqli_stmt->error_list ;
```

Procedural style

```
array mysqli_stmt_error_list(  
    mysqli_stmt stmt);
```

Returns an array of errors for the most recently invoked statement function that can succeed or fail.

### Parameters

*stmt* Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

### Return Values

A list of errors, each as an associative array containing the errno, error, and sqlstate.

### Examples

#### Example 21.159. Object oriented style

```
<?php  
/* Open a connection */  
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
$mysqli->query("CREATE TABLE myCountry LIKE Country");  
$mysqli->query("INSERT INTO myCountry SELECT * FROM Country");  
  
$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
```

```

if ($stmt = $mysqli->prepare($query)) {

    /* drop table */
    $mysqli->query("DROP TABLE myCountry");

    /* execute query */
    $stmt->execute();

    echo "Error:\n";
    print_r($stmt->error_list);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>

```

**Example 21.160. Procedural style**

```

<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCountry LIKE Country");
mysqli_query($link, "INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* drop table */
    mysqli_query($link, "DROP TABLE myCountry");

    /* execute query */
    mysqli_stmt_execute($stmt);

    echo "Error:\n";
    print_r(mysqli_stmt_error_list($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above examples will output:

```

Array
(
    [0] => Array
        (
            [errno] => 1146
            [sqlstate] => 42S02
            [error] => Table 'world.myCountry' doesn't exist
        )
)

```

)

**21.9.3.10.10. `mysqli_stmt::$error`, `mysqli_stmt_error`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_stmt::$error`

`mysqli_stmt_error`

Returns a string description for last statement error

**Description**

Object oriented style

```
string
mysqli_stmt->error ;
```

Procedural style

```
string mysqli_stmt_error(
    mysqli_stmt stmt);
```

Returns a containing the error message for the most recently invoked statement function that can succeed or fail.

**Parameters**

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

**Return Values**

A string that describes the error. An empty string if no error occurred.

**Examples****Example 21.161. Object oriented style**

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCountry LIKE Country");
$mysqli->query("INSERT INTO myCountry SELECT * FROM Country");
```

```

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = $mysqli->prepare($query)) {

    /* drop table */
    $mysqli->query("DROP TABLE myCountry");

    /* execute query */
    $stmt->execute();

    printf("Error: %s.\n", $stmt->error);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>

```

**Example 21.162. Procedural style**

```

<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCountry LIKE Country");
mysqli_query($link, "INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* drop table */
    mysqli_query($link, "DROP TABLE myCountry");

    /* execute query */
    mysqli_stmt_execute($stmt);

    printf("Error: %s.\n", mysqli_stmt_error($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above examples will output:

```
Error: Table 'world.myCountry' doesn't exist.
```

**21.9.3.10.11. *mysqli\_stmt::execute*, *mysqli\_stmt\_execute***

Copyright 1997-2012 the PHP Documentation Group. [2906]

- *mysqli\_stmt::execute*

*mysqli\_stmt\_execute*

Executes a prepared Query

**Description**

Object oriented style

```
bool mysqli_stmt::execute();
```

Procedural style

```
bool mysqli_stmt_execute(
    mysqli_stmt stmt);
```

Executes a query that has been previously prepared using the *mysqli\_prepare* function. When executed any parameter markers which exist will automatically be replaced with the appropriate data.

If the statement is *UPDATE*, *DELETE*, or *INSERT*, the total number of affected rows can be determined by using the *mysqli\_stmt\_affected\_rows* function. Likewise, if the query yields a result set the *mysqli\_stmt\_fetch* function is used.

**Note**

When using *mysqli\_stmt\_execute*, the *mysqli\_stmt\_fetch* function must be used to fetch the data prior to performing any additional queries.

**Parameters**

*stmt* Procedural style only: A statement identifier returned by *mysqli\_stmt\_init*.

**Return Values**

Returns *TRUE* on success or *FALSE* on failure.

**Examples****Example 21.163. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCity LIKE City");

/* Prepare an insert statement */
$query = "INSERT INTO myCity (Name, CountryCode, District) VALUES (?, ?, ?)";
$stmt = $mysqli->prepare($query);

$stmt->bind_param("sss", $val1, $val2, $val3);

$val1 = 'Stuttgart';
```

```

$val2 = 'DEU';
$val3 = 'Baden-Wuerttemberg';

/* Execute the statement */
$stmt->execute();

$val1 = 'Bordeaux';
$val2 = 'FRA';
$val3 = 'Aquitaine';

/* Execute the statement */
$stmt->execute();

/* close statement */
$stmt->close();

/* retrieve all rows from myCity */
$query = "SELECT Name, CountryCode, District FROM myCity";
if ($result = $mysqli->query($query)) {
    while ($row = $result->fetch_row()) {
        printf("%s (%s,%s)\n", $row[0], $row[1], $row[2]);
    }
    /* free result set */
    $result->close();
}

/* remove table */
$mysqli->query("DROP TABLE myCity");

/* close connection */
$mysqli->close();
?>

```

**Example 21.164. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCity LIKE City");

/* Prepare an insert statement */
$query = "INSERT INTO myCity (Name, CountryCode, District) VALUES (?, ?, ?)";
$stmt = mysqli_prepare($link, $query);

mysqli_stmt_bind_param($stmt, "sss", $val1, $val2, $val3);

$val1 = 'Stuttgart';
$val2 = 'DEU';
$val3 = 'Baden-Wuerttemberg';

/* Execute the statement */
mysqli_stmt_execute($stmt);

$val1 = 'Bordeaux';
$val2 = 'FRA';
$val3 = 'Aquitaine';

/* Execute the statement */
mysqli_stmt_execute($stmt);

/* close statement */
mysqli_stmt_close($stmt);

```

```
/* retrieve all rows from myCity */
$query = "SELECT Name, CountryCode, District FROM myCity";
if ($result = mysqli_query($link, $query)) {
    while ($row = mysqli_fetch_row($result)) {
        printf("%s (%s,%s)\n", $row[0], $row[1], $row[2]);
    }
    /* free result set */
    mysqli_free_result($result);
}

/* remove table */
mysqli_query($link, "DROP TABLE myCity");

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Stuttgart (DEU,Baden-Wuerttemberg)
Bordeaux (FRA,Aquitaine)
```

### See Also

[mysqli\\_prepare](#)  
[mysqli\\_stmt\\_bind\\_param](#)

#### 21.9.3.10.12. [mysqli\\_stmt::fetch](#), [mysqli\\_stmt\\_fetch](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::fetch](#)

[mysqli\\_stmt\\_fetch](#)

Fetch results from a prepared statement into the bound variables

### Description

Object oriented style

```
bool mysqli_stmt::fetch();
```

Procedural style

```
bool mysqli_stmt_fetch(
    mysqli_stmt stmt);
```

Fetch the result from a prepared statement into the variables bound by [mysqli\\_stmt\\_bind\\_result](#).

#### Note

Note that all columns must be bound by the application before calling [mysqli\\_stmt\\_fetch](#).

#### Note

Data are transferred unbuffered without calling [mysqli\\_stmt\\_store\\_result](#) which can decrease performance (but reduces memory cost).

### Parameters

*stmt*Procedural style only: A statement identifier returned by `mysqli_stmt_init`.**Return Values****Table 21.51. Return Values**

Value	Description
TRUE	Success. Data has been fetched
FALSE	Error occurred
NULL	No more rows/data exists or data truncation occurred

**Examples****Example 21.165. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 150,5";

if ($stmt = $mysqli->prepare($query)) {

    /* execute statement */
    $stmt->execute();

    /* bind result variables */
    $stmt->bind_result($name, $code);

    /* fetch values */
    while ($stmt->fetch()) {
        printf ("%s (%s)\n", $name, $code);
    }

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 21.166. Procedural style**

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 150,5";
```

```
if ($stmt = mysqli_prepare($link, $query)) {  
  
    /* execute statement */  
    mysqli_stmt_execute($stmt);  
  
    /* bind result variables */  
    mysqli_stmt_bind_result($stmt, $name, $code);  
  
    /* fetch values */  
    while (mysqli_stmt_fetch($stmt)) {  
        printf ("%s (%s)\n", $name, $code);  
    }  
  
    /* close statement */  
    mysqli_stmt_close($stmt);  
}  
  
/* close connection */  
mysqli_close($link);  
?>
```

The above examples will output:

```
Rockford (USA)  
Tallahassee (USA)  
Salinas (USA)  
Santa Clarita (USA)  
Springfield (USA)
```

- [mysqli\\_stmt::\\$field\\_count](#)

[mysqli\\_stmt\\_field\\_count](#)

Returns the number of field in the given statement

### Description

Object oriented style

```
int  
mysqli_stmt->field_count ;
```

Procedural style

```
int mysqli_stmt_field_count(  
    mysqli_stmt stmt);
```

### Warning

This function is currently not documented; only its argument list is available.

**21.9.3.10.14. `mysqli_stmt::free_result`, `mysqli_stmt_free_result`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_stmt::free_result`

`mysqli_stmt_free_result`

Frees stored result memory for the given statement handle

**Description**

Object oriented style

```
void mysqli_stmt::free_result();
```

Procedural style

```
void mysqli_stmt_free_result(  
    mysqli_stmt stmt);
```

Frees the result memory associated with the statement, which was allocated by `mysqli_stmt_store_result`.

**Parameters**

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

**Return Values**

No value is returned.

**See Also**

`mysqli_stmt_store_result`

**21.9.3.10.15. `mysqli_stmt::get_result`, `mysqli_stmt_get_result`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_stmt::get_result`

`mysqli_stmt_get_result`

Gets a result set from a prepared statement

**Description**

Object oriented style

```
mysqli_result mysqli_stmt::get_result();
```

Procedural style

```
mysqli_result mysqli_stmt_get_result(  
    mysqli_stmt stmt);
```

Call to return a result set from a prepared statement query.

**Parameters**

*stmt*Procedural style only: A statement identifier returned by *mysqli\_stmt\_init*.**Return Values**Returns a resultset or **FALSE** on failure.**MySQL Native Driver Only**Available only with *mysqlnd*.**Examples****Example 21.167. Object oriented style**

```
<?php
$mysqli = new mysqli("127.0.0.1", "user", "password", "world");

if($mysqli->connect_error)
{
    die("$mysqli->connect_errno: $mysqli->connect_error");
}

$query = "SELECT Name, Population, Continent FROM Country WHERE Continent=? ORDER BY Name LIMIT 1";

$stmt = $mysqli->stmt_init();
if(!$stmt->prepare($query))
{
    print "Failed to prepare statement\n";
}
else
{
    $stmt->bind_param("s", $continent);

    $continent_array = array('Europe', 'Africa', 'Asia', 'North America');

    foreach($continent_array as $continent)
    {
        $stmt->execute();
        $result = $stmt->get_result();
        while ($row = $result->fetch_array(MYSQLI_NUM))
        {
            foreach ($row as $r)
            {
                print "$r ";
            }
            print "\n";
        }
    }

    $stmt->close();
    $mysqli->close();
?>
```

**Example 21.168. Procedural style**

```
<?php

$link = mysqli_connect("127.0.0.1", "user", "password", "world");

if (!$link)
{
```

```
$error = mysqli_connect_error();
$errorno = mysqli_connect_errno();
print "$errorno: $error\n";
exit();
}

$query = "SELECT Name, Population, Continent FROM Country WHERE Continent=? ORDER BY Name LIMIT 1";

$stmt = mysqli_stmt_init($link);
if(!mysqli_stmt_prepare($stmt, $query))
{
    print "Failed to prepare statement\n";
}
else
{
    mysqli_stmt_bind_param($stmt, "s", $continent);

    $continent_array = array('Europe','Africa','Asia','North America');

    foreach($continent_array as $continent)
    {
        mysqli_stmt_execute($stmt);
        $result = mysqli_stmt_get_result($stmt);
        while ($row = mysqli_fetch_array($result, MYSQLI_NUM))
        {
            foreach ($row as $r)
            {
                print "$r ";
            }
            print "\n";
        }
    }
}
mysqli_stmt_close($stmt);
mysqli_close($link);
?>
```

The above examples will output:

```
Albania 3401200 Europe
Algeria 31471000 Africa
Afghanistan 22720000 Asia
Anguilla 8000 North America
```

mysqli_stmt->insert_id ;
```

## Procedural style

```
mixed mysqli_stmt_insert_id(
    mysqli_stmt $stmt);
```

**Warning**

This function is currently not documented; only its argument list is available.

**21.9.3.10.18. *mysqli\_stmt::\$more\_results*, *mysqli\_stmt\_more\_results***

Copyright 1997-2012 the PHP Documentation Group. [2906]

- *mysqli\_stmt::\$more\_results*  
*mysqli\_stmt\_more\_results*

Check if there are more query results from a multiple query

**Description**

## Object oriented style (method):

```
public bool mysqli_stmt::$more_results();
```

## Procedural style:

```
bool mysqli_stmt_more_results(
    mysqli_stmt $stmt);
```

Checks if there are more query results from a multiple query.

**Parameters**

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

**Return Values**

Returns `TRUE` if more results exist, otherwise `FALSE` .

**See Also**

`mysqli_stmt::next_result`  
`mysqli::multi_query`

**21.9.3.10.19. `mysqli_stmt::next_result`, `mysqli_stmt_next_result`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_stmt::next_result`

`mysqli_stmt_next_result`

Reads the next result from a multiple query

**Description**

Object oriented style (method):

```
public bool mysqli_stmt::next_result();
```

Procedural style:

```
bool mysqli_stmt_next_result(
    mysqli_stmt stmt);
```

Reads the next result from a multiple query.

**Parameters**

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Errors/Exceptions**

Emits an `E_STRICT` level error if a result set does not exist, and suggests using `mysqli_stmt::more_results` in these cases, before calling `mysqli_stmt::next_result`.

**See Also**

`mysqli_stmt::more_results`  
`mysqli::multi_query`

**21.9.3.10.20. `mysqli_stmt::$num_rows`, `mysqli_stmt_num_rows`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_stmt::$num_rows`

`mysqli_stmt_num_rows`

Return the number of rows in statements result set

## Description

Object oriented style

```
int
mysqli_stmt->num_rows ;
```

Procedural style

```
int mysqli_stmt_num_rows(
mysqli_stmt stmt);
```

Returns the number of rows in the result set. The use of `mysqli_stmt_num_rows` depends on whether or not you used `mysqli_stmt_store_result` to buffer the entire result set in the statement handle.

If you use `mysqli_stmt_store_result`, `mysqli_stmt_num_rows` may be called immediately.

## Parameters

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

## Return Values

An integer representing the number of rows in result set.

## Examples

### Example 21.169. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name LIMIT 20";
if ($stmt = $mysqli->prepare($query)) {

    /* execute query */
    $stmt->execute();

    /* store result */
    $stmt->store_result();

    printf("Number of rows: %d.\n", $stmt->num_rows);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 21.170. Procedural style**

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name LIMIT 20";
if ($stmt = mysqli_prepare($link, $query)) {

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* store result */
    mysqli_stmt_store_result($stmt);

    printf("Number of rows: %d.\n", mysqli_stmt_num_rows($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Number of rows: 20.
```

**See Also**

[mysqli\\_prepare](#)  
[mysqli\\_stmt\\_store\\_result](#)

**21.9.3.10.21. [mysqli\\_stmt::\\$param\\_count](#), [mysqli\\_stmt\\_param\\_count](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::\\$param\\_count](#)

[mysqli\\_stmt\\_param\\_count](#)

Returns the number of parameter for the given statement

**Description**

Object oriented style

```
int
mysqli_stmt->param_count ;
```

Procedural style

```
int mysqli_stmt_param_count(
    mysqli_stmt stmt);
```

Returns the number of parameter markers present in the prepared statement.

### Parameters

*stmt* Procedural style only: A statement identifier returned by *mysqli\_stmt\_init*.

### Return Values

Returns an integer representing the number of parameters.

### Examples

#### Example 21.171. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($stmt = $mysqli->prepare("SELECT Name FROM Country WHERE Name=? OR Code=?")) {

    $marker = $stmt->param_count;
    printf("Statement has %d markers.\n", $marker);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

#### Example 21.172. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($stmt = mysqli_prepare($link, "SELECT Name FROM Country WHERE Name=? OR Code=?")) {

    $marker = mysqli_stmt_param_count($stmt);
    printf("Statement has %d markers.\n", $marker);

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Statement has 2 markers.
```

### See Also

`mysqli_prepare`

#### 21.9.3.10.22. `mysqli_stmt::prepare`, `mysqli_stmt_prepare`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_stmt::prepare`

`mysqli_stmt_prepare`

Prepare an SQL statement for execution

### Description

Object oriented style

```
mixed mysqli_stmt::prepare(
    string query);
```

Procedural style

```
bool mysqli_stmt_prepare(
    mysqli_stmt stmt,
    string query);
```

Prepares the SQL query pointed to by the null-terminated string query.

The parameter markers must be bound to application variables using `mysqli_stmt_bind_param` and/or `mysqli_stmt_bind_result` before executing the statement or fetching rows.

#### Note

In the case where you pass a statement to `mysqli_stmt_prepare` that is longer than `max_allowed_packet` of the server, the returned error codes are different depending on whether you are using MySQL Native Driver (`mysqlnd`) or MySQL Client Library (`libmysqlclient`). The behavior is as follows:

- `mysqlnd` on Linux returns an error code of 1153. The error message means “got a packet bigger than `max_allowed_packet` bytes”.
- `mysqlnd` on Windows returns an error code 2006. This error message means “server has gone away”.
- `libmysqlclient` on all platforms returns an error code 2006. This error message means “server has gone away”.

### Parameters

`stmt`

Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

`query`

The query, as a string. It must consist of a single SQL statement.

You can include one or more parameter markers in the SQL statement by embedding question mark (?) characters at the appropriate positions.

**Note**

You should not add a terminating semicolon or `\g` to the statement.

**Note**

The markers are legal only in certain places in SQL statements. For example, they are allowed in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value.

However, they are not allowed for identifiers (such as table or column names), in the select list that names the columns to be returned by a `SELECT` statement), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples****Example 21.173. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$city = "Amersfoort";

/* create a prepared statement */
$stmt = $mysqli->stmt_init();
if ($stmt->prepare("SELECT District FROM City WHERE Name=?")) {

    /* bind parameters for markers */
    $stmt->bind_param("s", $city);

    /* execute query */
    $stmt->execute();

    /* bind result variables */
```

```
$stmt->bind_result($district);

/* fetch value */
$stmt->fetch();

printf("%s is in district %s\n", $city, $district);

/* close statement */
$stmt->close();
}

/* close connection */
mysqli->close();
?>
```

### Example 21.174. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$city = "Amersfoort";

/* create a prepared statement */
$stmt = mysqli_stmt_init($link);
if (mysqli_stmt_prepare($stmt, 'SELECT District FROM City WHERE Name=?')) {

    /* bind parameters for markers */
    mysqli_stmt_bind_param($stmt, "s", $city);

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* bind result variables */
    mysqli_stmt_bind_result($stmt, $district);

    /* fetch value */
    mysqli_stmt_fetch($stmt);

    printf("%s is in district %s\n", $city, $district);

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Amersfoort is in district Utrecht
```

```

### 21.9.3.10.23. `mysqli_stmt::reset`, `mysqli_stmt_reset`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_stmt::reset`

```
mysqli_stmt_reset
```

Resets a prepared statement

#### Description

Object oriented style

```
bool mysqli_stmt::reset();
```

Procedural style

```
bool mysqli_stmt_reset(  
    mysqli_stmt stmt);
```

Resets a prepared statement on client and server to state after prepare.

It resets the statement on the server, data sent using `mysqli_stmt_send_long_data`, unbuffered result sets and current errors. It does not clear bindings or stored result sets. Stored result sets will be cleared when executing the prepared statement (or closing it).

To prepare a statement with another query use function `mysqli_stmt_prepare`.

#### Parameters

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### See Also

`mysqli_prepare`

### 21.9.3.10.24. `mysqli_stmt::result_metadata`, `mysqli_stmt_result_metadata`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_stmt::result_metadata`

```
mysqli_stmt_result_metadata
```

Returns result set metadata from a prepared statement

#### Description

Object oriented style

```
mysqli_result mysqli_stmt::result_metadata();
```

## Procedural style

```
mysqli_result mysqli_stmt_result_metadata(
    mysqli_stmt stmt);
```

If a statement passed to `mysqli_prepare` is one that produces a result set, `mysqli_stmt_result_metadata` returns the result object that can be used to process the meta information such as total number of fields and individual field information.

**Note**

This result set pointer can be passed as an argument to any of the field-based functions that process result set metadata, such as:

- `mysqli_num_fields`
- `mysqli_fetch_field`
- `mysqli_fetch_field_direct`
- `mysqli_fetch_fields`
- `mysqli_field_count`
- `mysqli_field_seek`
- `mysqli_field_tell`
- `mysqli_free_result`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysqli_free_result`

**Note**

The result set returned by `mysqli_stmt_result_metadata` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysqli_stmt_fetch`.

**Parameters**

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

**Return Values**

Returns a result object or `FALSE` if an error occurred.

**Examples****Example 21.175. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

$mysqli->query("DROP TABLE IF EXISTS friends");
$mysqli->query("CREATE TABLE friends (id int, name varchar(20))");

$mysqli->query("INSERT INTO friends VALUES (1, 'Hartmut'), (2, 'Ulf')");

$stmt = $mysqli->prepare("SELECT id, name FROM friends");
$stmt->execute();
```

```
/* get resultset for metadata */
$result = $stmt->result_metadata();

/* retrieve field information from metadata result set */
$field = $result->fetch_field();

printf("Fieldname: %s\n", $field->name);

/* close resultset */
$result->close();

/* close connection */
mysqli->close();
?>
```

### Example 21.176. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

mysqli_query($link, "DROP TABLE IF EXISTS friends");
mysqli_query($link, "CREATE TABLE friends (id int, name varchar(20))");
mysqli_query($link, "INSERT INTO friends VALUES (1,'Hartmut'), (2, 'Ulf')");

$stmt = mysqli_prepare($link, "SELECT id, name FROM friends");
mysqli_stmt_execute($stmt);

/* get resultset for metadata */
$result = mysqli_stmt_result_metadata($stmt);

/* retrieve field information from metadata result set */
$field = mysqli_fetch_field($result);

printf("Fieldname: %s\n", $field->name);

/* close resultset */
mysqli_free_result($result);

/* close connection */
mysqli_close($link);
?>
```

### 21.9.3.10.25. [mysqli\\_stmt::send\\_long\\_data](#), [mysqli\\_stmt\\_send\\_long\\_data](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::send\\_long\\_data](#)

[mysqli\\_stmt\\_send\\_long\\_data](#)

Send data in blocks

### Description

Object oriented style

```
bool mysqli_stmt::send_long_data(
    int param_nr,
```

```
string data);
```

### Procedural style

```
bool mysqli_stmt_send_long_data(  
    mysqli_stmt stmt,  
    int param_nr,  
    string data);
```

Allows to send parameter data to the server in pieces (or chunks), e.g. if the size of a blob exceeds the size of [max\\_allowed\\_packet](#). This function can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the TEXT or BLOB datatypes.

### Parameters

<i>stmt</i>	Procedural style only: A statement identifier returned by <a href="#">mysqli_stmt_init</a> .
<i>param_nr</i>	Indicates which parameter to associate the data with. Parameters are numbered beginning with 0.
<i>data</i>	A string containing data to be sent.

### Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

### Examples

#### Example 21.177. Object oriented style

```
<?php  
$stmt = $mysqli->prepare("INSERT INTO messages (message) VALUES (?)");  
$null = NULL;  
$stmt->bind_param("b", $null);  
$fp = fopen("messages.txt", "r");  
while (!feof($fp)) {  
    $stmt->send_long_data(0, fread($fp, 8192));  
}  
fclose($fp);  
$stmt->execute();  
?>
```

#### 21.9.3.10.26. [mysqli\\_stmt::\\$sqlstate](#), [mysqli\\_stmt\\_sqlstate](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::\\$sqlstate](#)

[mysqli\\_stmt\\_sqlstate](#)

Returns SQLSTATE error from previous statement operation

### Description

Object oriented style

```
string
mysqli_stmt->sqlstate ;
```

### Procedural style

```
string mysqli_stmt_sqlstate(
    mysqli_stmt stmt);
```

Returns a string containing the SQLSTATE error code for the most recently invoked prepared statement function that can succeed or fail. The error code consists of five characters. '00000' means no error. The values are specified by ANSI SQL and ODBC. For a list of possible values, see <http://dev.mysql.com/doc/mysq/en/error-handling.html>.

### Parameters

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

### Return Values

Returns a string containing the SQLSTATE error code for the last error. The error code consists of five characters. '00000' means no error.

### Notes

#### Note

Note that not all MySQL errors are yet mapped to SQLSTATE's. The value `HY000` (general error) is used for unmapped errors.

### Examples

#### Example 21.178. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCountry LIKE Country");
$mysqli->query("INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = $mysqli->prepare($query)) {

    /* drop table */
    $mysqli->query("DROP TABLE myCountry");

    /* execute query */
    $stmt->execute();

    printf("Error: %s.\n", $stmt->sqlstate);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 21.179. Procedural style**

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCountry LIKE Country");
mysqli_query($link, "INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* drop table */
    mysqli_query($link, "DROP TABLE myCountry");

    /* execute query */
    mysqli_stmt_execute($stmt);

    printf("Error: %s.\n", mysqli_stmt_sqlstate($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Error: 42S02.
```

**See Also**

[mysqli\\_stmt\\_errno](#)  
[mysqli\\_stmt\\_error](#)

**21.9.3.10.27. [mysqli\\_stmt::store\\_result](#), [mysqli\\_stmt\\_store\\_result](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_stmt::store\\_result](#)

[mysqli\\_stmt\\_store\\_result](#)

Transfers a result set from a prepared statement

**Description**

Object oriented style

```
bool mysqli_stmt::store_result();
```

## Procedural style

```
bool mysqli_stmt_store_result(
    mysqli_stmt stmt);
```

You must call `mysqli_stmt_store_result` for every query that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`), and only if you want to buffer the complete result set by the client, so that the subsequent `mysqli_stmt_fetch` call returns buffered data.

### Note

It is unnecessary to call `mysqli_stmt_store_result` for other queries, but if you do, it will not harm or cause any notable performance in all cases. You can detect whether the query produced a result set by checking if `mysqli_stmt_result_metadata` returns `NULL`.

## Parameters

*stmt*

Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Examples

### Example 21.180. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name LIMIT 20";
if ($stmt = $mysqli->prepare($query)) {

    /* execute query */
    $stmt->execute();

    /* store result */
    $stmt->store_result();

    printf("Number of rows: %d.\n", $stmt->num_rows);

    /* free result */
    $stmt->free_result();

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.181. Procedural style

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name LIMIT 20";
if ($stmt = mysqli_prepare($link, $query)) {

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* store result */
    mysqli_stmt_store_result($stmt);

    printf("Number of rows: %d.\n", mysqli_stmt_num_rows($stmt));

    /* free result */
    mysqli_stmt_free_result($stmt);

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Number of rows: 20.
```

#### 21.9.3.11.1. `mysqli_result::$current_field`, `mysqli_field_tell`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_result::$current_field`  
`mysqli_field_tell`

Get current field offset of a result pointer

#### Description

Object oriented style

```

int
    mysqli_result->current_field ;

```

## Procedural style

```
int mysqli_field_tell(
    mysqli_result result);
```

Returns the position of the field cursor used for the last `mysqli_fetch_field` call. This value can be used as an argument to `mysqli_field_seek`.

## Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

## Return Values

Returns current offset of field cursor.

## Examples

### Example 21.182. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";

if ($result = $mysqli->query($query)) {

    /* Get field information for all columns */
    while ($finfo = $result->fetch_field()) {

        /* get fieldpointer offset */
        $currentfield = $result->current_field;

        printf("Column %d:\n", $currentfield);
        printf("Name:      %s\n", $finfo->name);
        printf("Table:     %s\n", $finfo->table);
        printf("max. Len:  %d\n", $finfo->max_length);
        printf("Flags:     %d\n", $finfo->flags);
        printf("Type:      %d\n\n", $finfo->type);
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.183. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
```

```
        exit();
    }

    $query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";

    if ($result = mysqli_query($link, $query)) {

        /* Get field information for all fields */
        while ($finfo = mysqli_fetch_field($result)) {

            /* get fieldpointer offset */
            $currentfield = mysqli_field_tell($result);

            printf("Column %d:\n", $currentfield);
            printf("Name:      %s\n", $finfo->name);
            printf("Table:     %s\n", $finfo->table);
            printf("max. Len:  %d\n", $finfo->max_length);
            printf("Flags:     %d\n", $finfo->flags);
            printf("Type:      %d\n\n", $finfo->type);
        }
        mysqli_free_result($result);
    }

    /* close connection */
    mysqli_close($link);
?>
```

The above examples will output:

```
Column 1:
Name:      Name
Table:     Country
max. Len:  11
Flags:     1
Type:      254

Column 2:
Name:      SurfaceArea
Table:     Country
max. Len:  10
Flags:     32769
Type:      4
```

## See Also

[mysqli\\_fetch\\_field](#)  
[mysqli\\_field\\_seek](#)

### 21.9.3.11.2. [mysqli\\_result::data\\_seek](#), [mysqli\\_data\\_seek](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_result::data\\_seek](#)

[mysqli\\_data\\_seek](#)

Adjusts the result pointer to an arbitrary row in the result

## Description

Object oriented style

```
bool mysqli_result::data_seek(
```

```
int offset);
```

### Procedural style

```
bool mysqli_data_seek(
    mysqli_result result,
    int offset);
```

The `mysqli_data_seek` function seeks to an arbitrary result pointer specified by the `offset` in the result set.

### Parameters

*result*

Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

*offset*

The field offset. Must be between zero and the total number of rows minus one (`0..mysqli_num_rows - 1`).

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Notes

#### Note

This function can only be used with buffered results attained from the use of the `mysqli_store_result` or `mysqli_query` functions.

### Examples

#### Example 21.184. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name";
if ($result = $mysqli->query( $query)) {

    /* seek to row no. 400 */
    $result->data_seek(399);

    /* fetch row */
    $row = $result->fetch_row();

    printf ("City: %s Countrycode: %s\n", $row[0], $row[1]);

    /* free result set*/
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 21.185. Procedural style**

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name";

if ($result = mysqli_query($link, $query)) {

    /* seek to row no. 400 */
    mysqli_data_seek($result, 399);

    /* fetch row */
    $row = mysqli_fetch_row($result);

    printf ("City: %s Countrycode: %s\n", $row[0], $row[1]);

    /* free result set*/
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
City: Benin City Countrycode: NGA
```

**See Also**

[mysqli\\_store\\_result](#)  
[mysqli\\_fetch\\_row](#)  
[mysqli\\_fetch\\_array](#)  
[mysqli\\_fetch\\_assoc](#)  
[mysqli\\_fetch\\_object](#)  
[mysqli\\_query](#)  
[mysqli\\_num\\_rows](#)

**21.9.3.11.3. [mysqli\\_result::fetch\\_all](#), [mysqli\\_fetch\\_all](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_result::fetch\\_all](#)

[mysqli\\_fetch\\_all](#)

Fetches all result rows as an associative array, a numeric array, or both

**Description**

Object oriented style

```
mixed mysqli_result::fetch_all(
```

```
int resulttype
= =MYSQLI_NUM);
```

### Procedural style

```
mixed mysqli_fetch_all(
    mysqli_result result,
    int resulttype
    = =MYSQLI_NUM);
```

[mysqli\\_fetch\\_all](#) fetches all result rows and returns the result set as an associative array, a numeric array, or both.

### Parameters

*result*

Procedural style only: A result set identifier returned by [mysqli\\_query](#), [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#).

*resulttype*

This optional parameter is a constant indicating what type of array should be produced from the current row data. The possible values for this parameter are the constants [MYSQLI\\_ASSOC](#) , [MYSQLI\\_NUM](#) , or [MYSQLI\\_BOTH](#) .

### Return Values

Returns an array of associative or numeric arrays holding result rows.

### MySQL Native Driver Only

Available only with [mysqlnd](#).

As [mysqli\\_fetch\\_all](#) returns all the rows as an array in a single step, it may consume more memory than some similar functions such as [mysqli\\_fetch\\_array](#), which only returns one row at a time from the result set. Further, if you need to iterate over the result set, you will need a looping construct that will further impact performance. For these reasons [mysqli\\_fetch\\_all](#) should only be used in those situations where the fetched result set will be sent to another layer for processing.

- [mysqli\\_result::fetch\\_array](#)

[mysqli\\_fetch\\_array](#)

Fetch a result row as an associative, a numeric array, or both

### Description

Object oriented style

```
mixed mysqli_result::fetch_array(
    int resulttype
    = =MYSQLI_BOTH);
```

Procedural style

```
mixed mysqli_fetch_array(
    mysqli_result result,
    int resulttype
    = =MYSQLI_BOTH);
```

Returns an array that corresponds to the fetched row or `NULL` if there are no more rows for the resultset represented by the `result` parameter.

`mysqli_fetch_array` is an extended version of the `mysqli_fetch_row` function. In addition to storing the data in the numeric indices of the result array, the `mysqli_fetch_array` function can also store the data in associative indices, using the field names of the result set as keys.

#### Note

Field names returned by this function are *case-sensitive*.

#### Note

This function sets `NULL` fields to the PHP `NULL` value.

If two or more columns of the result have the same field names, the last column will take precedence and overwrite the earlier data. In order to access multiple columns with the same name, the numerically indexed version of the row must be used.

### Parameters

`result`

Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

`resulttype`

This optional parameter is a constant indicating what type of array should be produced from the current row data. The possible values for this parameter are the constants `MYSQLI_ASSOC`, `MYSQLI_NUM`, or `MYSQLI_BOTH`.

By using the `MYSQLI_ASSOC` constant this function will behave identically to the `mysqli_fetch_assoc`, while `MYSQLI_NUM` will behave identically to the `mysqli_fetch_row` function. The final option `MYSQLI_BOTH` will create a single array with the attributes of both.

### Return Values

Returns an array of strings that corresponds to the fetched row or `NULL` if there are no more rows in resultset.

### Examples

#### Example 21.186. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID LIMIT 3";
```

```

$result = $mysqli->query($query);

/* numeric array */
$row = $result->fetch_array(MYSQLI_NUM);
printf ("%s (%s)\n", $row[0], $row[1]);

/* associative array */
$row = $result->fetch_array(MYSQLI_ASSOC);
printf ("%s (%s)\n", $row["Name"], $row["CountryCode"]);

/* associative and numeric array */
$row = $result->fetch_array(MYSQLI_BOTH);
printf ("%s (%s)\n", $row[0], $row["CountryCode"]);

/* free result set */
$result->free();

/* close connection */
$mysqli->close();
?>

```

**Example 21.187. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID LIMIT 3";
$result = mysqli_query($link, $query);

/* numeric array */
$row = mysqli_fetch_array($result, MYSQLI_NUM);
printf ("%s (%s)\n", $row[0], $row[1]);

/* associative array */
$row = mysqli_fetch_array($result, MYSQLI_ASSOC);
printf ("%s (%s)\n", $row["Name"], $row["CountryCode"]);

/* associative and numeric array */
$row = mysqli_fetch_array($result, MYSQLI_BOTH);
printf ("%s (%s)\n", $row[0], $row["CountryCode"]);

/* free result set */
mysqli_free_result($result);

/* close connection */
mysqli_close($link);
?>

```

The above examples will output:

```

Kabul (AFG)
Qandahar (AFG)
Herat (AFG)

```

**See Also**

[mysqli\\_fetch\\_assoc](#)

```
mysqli_fetch_row
mysqli_fetch_object
mysqli_query
mysqli_data_seek
```

### 21.9.3.11.5. `mysqli_result::fetch_assoc`, `mysqli_fetch_assoc`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_result::fetch_assoc`

```
mysqli_fetch_assoc
```

Fetch a result row as an associative array

#### Description

Object oriented style

```
array mysqli_result::fetch_assoc();
```

Procedural style

```
array mysqli_fetch_assoc(
    mysqli_result result);
```

Returns an associative array that corresponds to the fetched row or `NULL` if there are no more rows.

#### Note

Field names returned by this function are *case-sensitive*.

#### Note

This function sets `NULL` fields to the PHP `NULL` value.

#### Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

#### Return Values

Returns an associative array of strings representing the fetched row in the result set, where each key in the array represents the name of one of the result set's columns or `NULL` if there are no more rows in resultset.

If two or more columns of the result have the same field names, the last column will take precedence. To access the other column(s) of the same name, you either need to access the result with numeric indices by using `mysqli_fetch_row` or add alias names.

#### Examples

##### Example 21.188. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");
```

```
/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";

if ($result = $mysqli->query($query)) {

    /* fetch associative array */
    while ($row = $result->fetch_assoc()) {
        printf ("%s (%s)\n", $row["Name"], $row["CountryCode"]);
    }

    /* free result set */
    $result->free();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.189. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";

if ($result = mysqli_query($link, $query)) {

    /* fetch associative array */
    while ($row = mysqli_fetch_assoc($result)) {
        printf ("%s (%s)\n", $row["Name"], $row["CountryCode"]);
    }

    /* free result set */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Pueblo (USA)
Arvada (USA)
Cape Coral (USA)
Green Bay (USA)
Santa Clara (USA)
```

### Example 21.190. A `mysqli_result` example comparing `iterator` usage

```

<?php
$c = mysqli_connect('127.0.0.1','user', 'pass');

// Using iterators (support was added with PHP 5.4)
foreach ( $c->query('SELECT user,host FROM mysql.user') as $row ) {
    printf("%s'@'%s'\n", $row['user'], $row['host']);
}

echo "\n=====\n";

// Not using iterators
$result = $c->query('SELECT user,host FROM mysql.user');
while ($row = $result->fetch_assoc()) {
    printf("%s'@'%s'\n", $row['user'], $row['host']);
}

?>

```

The above example will output something similar to:

```

'root'@'192.168.1.1'
'root'@'127.0.0.1'
'dude'@'localhost'
'lebowski'@'localhost'

=====

'root'@'192.168.1.1'
'root'@'127.0.0.1'
'dude'@'localhost'
'lebowski'@'localhost'

```

#### 21.9.3.11.6. `mysqli_result::fetch_field_direct`, `mysqli_fetch_field_direct`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_result::fetch_field_direct`

`mysqli_fetch_field_direct`

Fetch meta-data for a single field

### Description

Object oriented style

```
object mysqli_result::fetch_field_direct(
    int fieldnr);
```

Procedural style

```
object mysqli_fetch_field_direct(
    mysqli_result result,
    int fieldnr);
```

Returns an object which contains field definition information from the specified result set.

### Parameters

*result*

Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

*fieldnr*

The field number. This value must be in the range from 0 to `number of fields - 1`.

### Return Values

Returns an object which contains field definition information or `FALSE` if no field information for specified `fieldnr` is available.

**Table 21.53. Object attributes**

Attribute	Description
name	The name of the column
orgname	Original column name if an alias was specified
table	The name of the table this field belongs to (if not calculated)
orgtable	Original table name if an alias was specified
def	The default value for this field, represented as a string
max_length	The maximum width of the field for the result set.
length	The width of the field, as specified in the table definition.
charsetnr	The character set number for the field.
flags	An integer representing the bit-flags for the field.
type	The data type used for this field
decimals	The number of decimals used (for integer fields)

### Examples

#### Example 21.191. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Name LIMIT 5";

if ($result = $mysqli->query($query)) {

    /* Get field information for column 'SurfaceArea' */
    $finfo = $result->fetch_field_direct(1);

    printf("Name:      %s\n", $finfo->name);
    printf("Table:     %s\n", $finfo->table);
    printf("max. Len:  %d\n", $finfo->max_length);
    printf("Flags:     %d\n", $finfo->flags);
}
```

```
    printf("Type:      %d\n", $finfo->type);

    $result->close();
}

/* close connection */
mysqli->close();
?>
```

### Example 21.192. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Name LIMIT 5";

if ($result = mysqli_query($link, $query)) {

    /* Get field information for column 'SurfaceArea' */
    $finfo = mysqli_fetch_field_direct($result, 1);

    printf("Name:      %s\n", $finfo->name);
    printf("Table:      %s\n", $finfo->table);
    printf("max. Len:  %d\n", $finfo->max_length);
    printf("Flags:      %d\n", $finfo->flags);
    printf("Type:      %d\n", $finfo->type);

    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Name:      SurfaceArea
Table:      Country
max. Len:  10
Flags:      32769
Type:      4
```

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_result::fetch\\_field](#)  
[mysqli\\_fetch\\_field](#)

Returns the next field in the result set

## Description

Object oriented style

```
object mysqli_result::fetch_field();
```

Procedural style

```
object mysqli_fetch_field(
    mysqli_result result);
```

Returns the definition of one column of a result set as an object. Call this function repeatedly to retrieve information about all columns in the result set.

## Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

## Return Values

Returns an object which contains field definition information or `FALSE` if no field information is available.

**Table 21.54. Object properties**

Property	Description
name	The name of the column
orgname	Original column name if an alias was specified
table	The name of the table this field belongs to (if not calculated)
orgtable	Original table name if an alias was specified
def	Reserved for default value, currently always ""
db	Database (since PHP 5.3.6)
catalog	The catalog name, always "def" (since PHP 5.3.6)
max_length	The maximum width of the field for the result set.
length	The width of the field, as specified in the table definition.
charsetnr	The character set number for the field.
flags	An integer representing the bit-flags for the field.
type	The data type used for this field
decimals	The number of decimals used (for integer fields)

## Examples

### Example 21.193. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
```

```

    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";

if ($result = $mysqli->query($query)) {

    /* Get field information for all columns */
    while ($finfo = $result->fetch_field()) {

        printf("Name:      %s\n", $finfo->name);
        printf("Table:     %s\n", $finfo->table);
        printf("max. Len:  %d\n", $finfo->max_length);
        printf("Flags:     %d\n", $finfo->flags);
        printf("Type:      %d\n\n", $finfo->type);
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>

```

**Example 21.194. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";

if ($result = mysqli_query($link, $query)) {

    /* Get field information for all fields */
    while ($finfo = mysqli_fetch_field($result)) {

        printf("Name:      %s\n", $finfo->name);
        printf("Table:     %s\n", $finfo->table);
        printf("max. Len:  %d\n", $finfo->max_length);
        printf("Flags:     %d\n", $finfo->flags);
        printf("Type:      %d\n\n", $finfo->type);
    }
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above examples will output:

```

Name:      Name
Table:     Country
max. Len:  11
Flags:     1
Type:      254

Name:      SurfaceArea
Table:     Country
max. Len:  10

```

```
Flags: 32769
Type: 4
```

**See Also**

**21.9.3.11.8. [mysqli\\_result::fetch\\_fields](#), [mysqli\\_fetch\\_fields](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_result::fetch\\_fields](#)

```
mysqli_fetch_fields
```

Returns an array of objects representing the fields in a result set

**Description**

Object oriented style

```
array mysqli_result::fetch_fields();
```

Procedural style

```
array mysqli_fetch_fields(
    mysqli_result result);
```

This function serves an identical purpose to the [mysqli\\_fetch\\_field](#) function with the single difference that, instead of returning one object at a time for each field, the columns are returned as an array of objects.

**Parameters**

*result* Procedural style only: A result set identifier returned by [mysqli\\_query](#), [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#).

**Return Values**

Returns an array of objects which contains field definition information or [FALSE](#) if no field information is available.

**Table 21.55. Object properties**

Property	Description
name	The name of the column
orgname	Original column name if an alias was specified
table	The name of the table this field belongs to (if not calculated)
orgtable	Original table name if an alias was specified
max_length	The maximum width of the field for the result set.
length	The width of the field, as specified in the table definition.

Property	Description
charsetnr	The character set number for the field.
flags	An integer representing the bit-flags for the field.
type	The data type used for this field
decimals	The number of decimals used (for integer fields)

## Examples

### Example 21.195. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";

if ($result = $mysqli->query($query)) {

    /* Get field information for all columns */
    $finfo = $result->fetch_fields();

    foreach ($finfo as $val) {
        printf("Name:      %s\n", $val->name);
        printf("Table:      %s\n", $val->table);
        printf("max. Len: %d\n", $val->max_length);
        printf("Flags:      %d\n", $val->flags);
        printf("Type:       %d\n\n", $val->type);
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.196. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";

if ($result = mysqli_query($link, $query)) {

    /* Get field information for all columns */
    $finfo = mysqli_fetch_fields($result);

    foreach ($finfo as $val) {
        printf("Name:      %s\n", $val->name);
        printf("Table:      %s\n", $val->table);
        printf("max. Len: %d\n", $val->max_length);
        printf("Flags:      %d\n", $val->flags);
        printf("Type:       %d\n\n", $val->type);
    }
}
```

```
}
mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Name:      Name
Table:     Country
max. Len:  11
Flags:     1
Type:      254

Name:      SurfaceArea
Table:     Country
max. Len:  10
Flags:     32769
Type:      4
```

### See Also

[mysqli\\_fetch\\_field](#)

#### 21.9.3.11.9. [mysqli\\_result::fetch\\_object](#), [mysqli\\_fetch\\_object](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_result::fetch\\_object](#)

[mysqli\\_fetch\\_object](#)

Returns the current row of a result set as an object

### Description

Object oriented style

```
object mysqli_result::fetch_object(
    string class_name,
    array params);
```

Procedural style

```
object mysqli_fetch_object(
    mysqli_result result,
    string class_name,
    array params);
```

The [mysqli\\_fetch\\_object](#) will return the current row result set as an object where the attributes of the object represent the names of the fields found within the result set.

Note that [mysqli\\_fetch\\_object](#) sets the properties of the object before calling the object constructor.

### Parameters

<i>result</i>	Procedural style only: A result set identifier returned by <code>mysqli_query</code> , <code>mysqli_store_result</code> or <code>mysqli_use_result</code> .
<i>class_name</i>	The name of the class to instantiate, set the properties of and return. If not specified, a <code>stdClass</code> object is returned.
<i>params</i>	An optional array of parameters to pass to the constructor for <i>class_name</i> objects.

## Return Values

Returns an object with string properties that corresponds to the fetched row or `NULL` if there are no more rows in resultset.

### Note

Field names returned by this function are *case-sensitive*.

### Note

This function sets `NULL` fields to the PHP `NULL` value.

## Changelog

Version	Description
5.0.0	Added the ability to return as a different object.

## Examples

### Example 21.197. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";

if ($result = $mysqli->query($query)) {

    /* fetch object array */
    while ($obj = $result->fetch_object()) {
        printf ("%s (%s)\n", $obj->Name, $obj->CountryCode);
    }

    /* free result set */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.198. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";

if ($result = mysqli_query($link, $query)) {

    /* fetch associative array */
    while ($obj = mysqli_fetch_object($result)) {
        printf ("%s (%s)\n", $obj->Name, $obj->CountryCode);
    }

    /* free result set */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Pueblo (USA)
Arvada (USA)
Cape Coral (USA)
Green Bay (USA)
Santa Clara (USA)
```

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_result::fetch\\_row](#)

[mysqli\\_fetch\\_row](#)

Get a result row as an enumerated array

### Description

Object oriented style

```
mixed mysqli_result::fetch_row();
```

Procedural style

```
mixed mysqli_fetch_row(
    mysqli_result result);
```

Fetches one row of data from the result set and returns it as an enumerated array, where each column is stored in an array offset starting from 0 (zero). Each subsequent call to this function will return the next row within the result set, or `NULL` if there are no more rows.

### Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

### Return Values

`mysqli_fetch_row` returns an array of strings that corresponds to the fetched row or `NULL` if there are no more rows in result set.

#### Note

This function sets NULL fields to the PHP `NULL` value.

### Examples

#### Example 21.199. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";

if ($result = $mysqli->query($query)) {

    /* fetch object array */
    while ($row = $result->fetch_row()) {
        printf ("%s (%s)\n", $row[0], $row[1]);
    }

    /* free result set */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

#### Example 21.200. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";
```

```
if ($result = mysqli_query($link, $query)) {  
  
    /* fetch associative array */  
    while ($row = mysqli_fetch_row($result)) {  
        printf ("%s (%s)\n", $row[0], $row[1]);  
    }  
  
    /* free result set */  
    mysqli_free_result($result);  
}  
  
/* close connection */  
mysqli_close($link);  
?>
```

The above examples will output:

```
Pueblo (USA)  
Arvada (USA)  
Cape Coral (USA)  
Green Bay (USA)  
Santa Clara (USA)
```

### 21.9.3.11.11. [mysqli\\_result::\\$field\\_count](#), [mysqli\\_num\\_fields](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_result::\\$field\\_count](#)

[mysqli\\_num\\_fields](#)

Get the number of fields in a result

#### Description

Object oriented style

```
int  
mysqli_result->field_count ;
```

Procedural style

```
int mysqli_num_fields(  
    mysqli_result result);
```

Returns the number of fields from specified result set.

#### Parameters

*result*

Procedural style only: A result set identifier returned by [mysqli\\_query](#), [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#).

## Return Values

The number of fields from a result set.

## Examples

### Example 21.201. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($result = $mysqli->query("SELECT * FROM City ORDER BY ID LIMIT 1")) {

    /* determine number of fields in result set */
    $field_cnt = $result->field_count;

    printf("Result set has %d fields.\n", $field_cnt);

    /* close result set */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.202. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($result = mysqli_query($link, "SELECT * FROM City ORDER BY ID LIMIT 1")) {

    /* determine number of fields in result set */
    $field_cnt = mysqli_num_fields($result);

    printf("Result set has %d fields.\n", $field_cnt);

    /* close result set */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Result set has 5 fields.
```

## See Also

[mysqli\\_fetch\\_field](#)

### 21.9.3.11.12. [mysqli\\_result::field\\_seek](#), [mysqli\\_field\\_seek](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqli\\_result::field\\_seek](#)

[mysqli\\_field\\_seek](#)

Set result pointer to a specified field offset

## Description

Object oriented style

```
bool mysqli_result::field_seek(  
    int fieldnr);
```

Procedural style

```
bool mysqli_field_seek(  
    mysqli_result result,  
    int fieldnr);
```

Sets the field cursor to the given offset. The next call to [mysqli\\_fetch\\_field](#) will retrieve the field definition of the column associated with that offset.

### Note

To seek to the beginning of a row, pass an offset value of zero.

## Parameters

*result*

Procedural style only: A result set identifier returned by [mysqli\\_query](#), [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#).

*fieldnr*

The field number. This value must be in the range from 0 to [number of fields](#) - 1.

## Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

## Examples

### Example 21.203. Object oriented style

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}
```

```
$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";

if ($result = $mysqli->query($query)) {

    /* Get field information for 2nd column */
    $result->field_seek(1);
    $finfo = $result->fetch_field();

    printf("Name:      %s\n", $finfo->name);
    printf("Table:     %s\n", $finfo->table);
    printf("max. Len:  %d\n", $finfo->max_length);
    printf("Flags:     %d\n", $finfo->flags);
    printf("Type:      %d\n\n", $finfo->type);

    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.204. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";

if ($result = mysqli_query($link, $query)) {

    /* Get field information for 2nd column */
    mysqli_field_seek($result, 1);
    $finfo = mysqli_fetch_field($result);

    printf("Name:      %s\n", $finfo->name);
    printf("Table:     %s\n", $finfo->table);
    printf("max. Len:  %d\n", $finfo->max_length);
    printf("Flags:     %d\n", $finfo->flags);
    printf("Type:      %d\n\n", $finfo->type);

    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Name:      SurfaceArea
Table:     Country
max. Len:  10
Flags:     32769
Type:      4
```

**See Also**

`mysqli_fetch_field`

### 21.9.3.11.13. `mysqli_result::free`, `mysqli_free_result`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_result::free`

`mysqli_free_result`

Frees the memory associated with a result

#### Description

Object oriented style

```
void mysqli_result::free();
```

```
void mysqli_result::close();
```

```
void mysqli_result::free_result();
```

Procedural style

```
void mysqli_free_result(  
    mysqli_result result);
```

Frees the memory associated with the result.

#### Note

You should always free your result with `mysqli_free_result`, when your result object is not needed anymore.

#### Parameters

*result*

Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

#### Return Values

No value is returned.

#### See Also

`mysqli_query`  
`mysqli_stmt_store_result`  
`mysqli_store_result`  
`mysqli_use_result`

### 21.9.3.11.14. `mysqli_result::$lengths`, `mysqli_fetch_lengths`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_result::$lengths`

`mysqli_fetch_lengths`

Returns the lengths of the columns of the current row in the result set

#### Description

## Object oriented style

```
array
mysqli_result->lengths ;
```

## Procedural style

```
array mysqli_fetch_lengths(
mysqli_result result);
```

The `mysqli_fetch_lengths` function returns an array containing the lengths of every column of the current row within the result set.

## Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

## Return Values

An array of integers representing the size of each column (not including any terminating null characters). `FALSE` if an error occurred.

`mysqli_fetch_lengths` is valid only for the current row of the result set. It returns `FALSE` if you call it before calling `mysqli_fetch_row/array/object` or after retrieving all rows in the result.

## Examples

### Example 21.205. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT * from Country ORDER BY Code LIMIT 1";

if ($result = $mysqli->query($query)) {

    $row = $result->fetch_row();

    /* display column lengths */
    foreach ($result->lengths as $i => $val) {
        printf("Field %2d has Length %2d\n", $i+1, $val);
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.206. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");
```

```
/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT * from Country ORDER BY Code LIMIT 1";

if ($result = mysqli_query($link, $query)) {

    $row = mysqli_fetch_row($result);

    /* display column lengths */
    foreach (mysqli_fetch_lengths($result) as $i => $val) {
        printf("Field %2d has Length %2d\n", $i+1, $val);
    }
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Field 1 has Length 3
Field 2 has Length 5
Field 3 has Length 13
Field 4 has Length 9
Field 5 has Length 6
Field 6 has Length 1
Field 7 has Length 6
Field 8 has Length 4
Field 9 has Length 6
Field 10 has Length 6
Field 11 has Length 5
Field 12 has Length 44
Field 13 has Length 7
Field 14 has Length 3
Field 15 has Length 2
```

#### 21.9.3.11.15. `mysqli_result::$num_rows, mysqli_num_rows`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_result::$num_rows`

`mysqli_num_rows`

Gets the number of rows in a result

#### Description

Object oriented style

```
int
mysqli_result->num_rows ;
```

Procedural style

```
int mysqli_num_rows(
    mysqli_result result);
```

Returns the number of rows in the result set.

The behaviour of `mysqli_num_rows` depends on whether buffered or unbuffered result sets are being used. For unbuffered result sets, `mysqli_num_rows` will not return the correct number of rows until all the rows in the result have been retrieved.

## Parameters

`result` Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

## Return Values

Returns number of rows in the result set.

### Note

If the number of rows is greater than `MAXINT`, the number will be returned as a string.

## Examples

### Example 21.207. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($result = $mysqli->query("SELECT Code, Name FROM Country ORDER BY Name")) {

    /* determine number of rows result set */
    $row_cnt = $result->num_rows;

    printf("Result set has %d rows.\n", $row_cnt);

    /* close result set */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 21.208. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($result = mysqli_query($link, "SELECT Code, Name FROM Country ORDER BY Name")) {

    /* determine number of rows result set */
    $row_cnt = mysqli_num_rows($result);
}
```

```
printf("Result set has %d rows.\n", $row_cnt);

/* close result set */
mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above examples will output:

```
Result set has 239 rows.
```

mysqli_driver {
    mysqli_driver

    Properties

    public readonly string
        client_info ;

    public readonly string
        client_version ;

    public readonly string
        driver_version ;

    public readonly string
        embedded ;

    public bool
        reconnect ;

    public int
        report_mode ;

    Methods

    void mysqli_driver::embedded_server_end();

    bool mysqli_driver::embedded_server_start(
        bool start,
        array arguments,
        array groups);
}
```

<code>client_info</code>	The Client API header version
<code>client_version</code>	The Client version
<code>driver_version</code>	The MySQLi Driver version
<code>embedded</code>	Whether MySQLi Embedded support is enabled
<code>reconnect</code>	Allow or prevent reconnect (see the <code>mysqli.reconnect</code> INI directive)
<code>report_mode</code>	Set to <code>MYSQLI_REPORT_OFF</code> , <code>MYSQLI_REPORT_ALL</code> or any combination of <code>MYSQLI_REPORT_STRICT</code> (throw Exceptions for errors), <code>MYSQLI_REPORT_ERROR</code> (report errors) and <code>MYSQLI_REPORT_INDEX</code> (errors regarding indexes). See also <code>mysqli_report</code> .

#### 21.9.3.12.1. `mysqli_driver::embedded_server_end`, `mysqli_embedded_server_end`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_driver::embedded_server_end`

`mysqli_embedded_server_end`

Stop embedded server

#### Description

Object oriented style

```
void mysqli_driver::embedded_server_end();
```

Procedural style

```
void mysqli_embedded_server_end();
```

#### Warning

This function is currently not documented; only its argument list is available.

#### 21.9.3.12.2. `mysqli_driver::embedded_server_start`, `mysqli_embedded_server_start`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_driver::embedded_server_start`

`mysqli_embedded_server_start`

Initialize and start embedded server

#### Description

Object oriented style

```
bool mysqli_driver::embedded_server_start(
    bool start,
    array arguments,
    array groups);
```

Procedural style

```
bool mysqli_embedded_server_start(
    bool start,
```

```
array arguments,
array groups);
```

**Warning**

This function is currently not documented; only its argument list is available.

**21.9.3.12.3. `mysqli_driver::$report_mode`, `mysqli_report`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_driver::$report_mode`

`mysqli_report`

Enables or disables internal report functions

**Description**

Object oriented style

```
int
mysqli_driver->report_mode ;
```

Procedural style

```
bool mysqli_report(
int flags);
```

A function helpful in improving queries during code development and testing. Depending on the flags, it reports errors from `mysqli` function calls or queries that don't use an index (or use a bad index).

**Parameters**

*flags*

**Table 21.56. Supported flags**

Name	Description
<code>MYSQLE_REPORT_OFF</code>	Turns reporting off
<code>MYSQLE_REPORT_ERROR</code>	Report errors from <code>mysqli</code> function calls
<code>MYSQLE_REPORT_STRICT</code>	Throw <code>mysqli_sql_exception</code> for errors instead of warnings
<code>MYSQLE_REPORT_INDEX</code>	Report if no index or bad index was used in a query
<code>MYSQLE_REPORT_ALL</code>	Set all options (report all)

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Changelog**

Version	Description
5.3.4	Changing the reporting mode is now be per-request, rather than per-process.
5.2.15	Changing the reporting mode is now be per-request, rather than per-process.

## Examples

### Example 21.209. Object oriented style

```
<?php

$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* activate reporting */
$driver = new mysqli_driver();
$driver->report_mode = MYSQLI_REPORT_ALL;

try {

    /* this query should report an error */
    $result = $mysqli->query("SELECT Name FROM Nonexistingtable WHERE population > 50000");

    /* this query should report a bad index */
    $result = $mysqli->query("SELECT Name FROM City WHERE population > 50000");

    $result->close();

    $mysqli->close();

} catch (mysqli_sql_exception $e) {

    echo $e->__toString();
}
?>
```

### Example 21.210. Procedural style

```
<?php
/* activate reporting */
mysqli_report(MYSQLI_REPORT_ALL);

$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* this query should report an error */
$result = mysqli_query("SELECT Name FROM Nonexistingtable WHERE population > 50000");

/* this query should report a bad index */
$result = mysqli_query("SELECT Name FROM City WHERE population > 50000");

mysqli_free_result($result);

mysqli_close($link);
?>
```

The `__construct` purpose

#### Description

```
public mysqli_warning::__construct();
```

#### Warning

This function is currently not documented; only its argument list is available.

#### Parameters

This function has no parameters.

#### Return Values

### 21.9.3.13.2. `mysqli_warning::next`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_warning::next`

The next purpose

#### Description

```
public void mysqli_warning::next();
```

#### Warning

This function is currently not documented; only its argument list is available.

#### Parameters

This function has no parameters.

#### Return Values

### 21.9.3.14. The `mysqli_sql_exception` class (`mysqli_sql_exception`)

Copyright 1997-2012 the PHP Documentation Group. [2906]

The `mysqli` exception handling class.

```
mysqli_sql_exception {
mysqli_sql_exception extends RuntimeException

    Properties

    protected
    code ;

    protected
    sqlstate ;
}
```

<code>message</code>	The error message.
<code>file</code>	The file with the error.
<code>line</code>	The line with the error.
<code>code</code>	The code causing the error.
<code>sqlstate</code>	The sql state with the error.

## Notes

### Note

`mysqli_execute` is deprecated and will be removed.

## See Also

`mysqli_stmt_execute`

### 21.9.3.15.11. `mysqli_fetch`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_fetch`

Alias for `mysqli_stmt_fetch`

## Description

This function is an alias of `mysqli_stmt_fetch`.

### Warning

This function has been *DEPRECATED* as of PHP 5.3.0 and *REMOVED* as of PHP 5.4.0.

## See Also

`mysqli_stmt_fetch`

### 21.9.3.15.12. `mysqli_get_cache_stats`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqli_get_cache_stats`

Returns client Zval cache statistics

## Description

```
array mysqli_get_cache_stats();
```

### Warning

This function is currently not documented; only its argument list is available.

Returns client Zval cache statistics. Available only with `mysqlnd`.

## Parameters

## Return Values

Returns an array with client Zval cache stats if success, `FALSE` otherwise.

## Examples

### Example 21.211. A `mysqli_get_cache_stats` example

```
<?php
$link = mysqli_connect();
print_r(mysqli_get_cache_stats());
```

```
?>
```

The above example will output something similar to:

```
Array
(
    [bytes_sent] => 43
    [bytes_received] => 80
    [packets_sent] => 1

**Warning**This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.**21.9.3.16. Changelog**[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The following changes have been made to classes/functions/methods of this extension.

**21.9.4. MySQL Functions (PDO\_MYSQL) (MySQL (PDO))**[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)PDO\_MYSQL is a driver that implements the [PHP Data Objects \(PDO\) interface](#) to enable access from PHP to MySQL 3.x, 4.x and 5.x databases.

PDO\_MYSQL will take advantage of native prepared statement support present in MySQL 4.1 and higher. If you're using an older version of the mysql client libraries, PDO will emulate them for you.

**Warning**

Beware: Some MySQL table types (storage engines) do not support transactions. When writing transactional database code using a table type that does not support transactions, MySQL will pretend that a transaction was

initiated successfully. In addition, any DDL queries issued will implicitly commit any pending transactions.

Use `--with-pdo-mysql[=DIR]` to install the PDO MySQL extension, where the optional `[=DIR]` is the MySQL base install directory. If `mysqlnd` is passed as `[=DIR]`, then the MySQL native driver will be used.

Optionally, the `--with-mysql-sock[=DIR]` sets to location to the MySQL unix socket pointer for all MySQL extensions, including PDO\_MYSQL. If unspecified, the default locations are searched.

Optionally, the `--with-zlib-dir[=DIR]` is used to set the path to the libz install prefix.

```
$ ./configure --with-pdo-mysql --with-mysql-sock=/var/mysql/mysql.sock
```

SSL support is enabled using the appropriate [PDO\\_MySQL constants \[3197\]](#), which is equivalent to calling the [MySQL C API function `mysql\_ssl\_set\(\)`](#). Also, SSL cannot be enabled with `PDO::setAttribute` because the connection already exists. See also the MySQL documentation about [connecting to MySQL with SSL](#).

**Table 21.57. Changelog**

Version	Description
5.4.0	MySQL client libraries 4.1 and below are no longer supported.
5.3.9	Added SSL support with <code>mysqlnd</code> and OpenSSL.
5.3.7	Added SSL support with <code>libmysqlclient</code> and OpenSSL.

The constants below are defined by this driver, and will only be available when the extension has been either compiled into PHP or dynamically loaded at runtime. In addition, these driver-specific constants should only be used if you are using this driver. Using driver-specific attributes with another driver may result in unexpected behaviour. `PDO::getAttribute` may be used to obtain the `PDO_ATTR_DRIVER_NAME` attribute to check the driver, if your code can run against multiple drivers.

`PDO::MYSQL_ATTR_USE_BUFFERED_QUERY` (integer) If this attribute is set to `TRUE` on a `PDOStatement`, the MySQL driver will use the buffered versions of the MySQL API. If you're writing portable code, you should use `PDOStatement::fetchAll` instead.

**Example 21.212. Forcing queries to be buffered in mysql**

```
<?php
if ($db->getAttribute(PDO::ATTR_DRIVER_NAME) == 'mysql') {
    $stmt = $db->prepare('select * from foo',
        array(PDO::MYSQL_ATTR_USE_BUFFERED_QUERY => true));
} else {
    die("my application only works with mysql; I should use \$stmt->fet
}
?>
```

`PDO::MYSQL_ATTR_LOCAL_INFILE` (integer) Enable `LOAD LOCAL INFILE`.

Note, this constant can only be used in the `driver_options` array when constructing a new database handle.

- `PDO::MYSQL_ATTR_INIT_COMMAND` (integer) Command to execute when connecting to the MySQL server. Will automatically be re-executed when reconnecting.
- Note, this constant can only be used in the `driver_options` array when constructing a new database handle.
- `PDO::MYSQL_ATTR_READ_DEFAULT_GROUP` (integer) Read options from the named option file instead of from `my.cnf`. This option is not available if `mysqlnd` is used, because `mysqlnd` does not read the `mysql` configuration files.
- `PDO::MYSQL_ATTR_READ_DEFAULT_SECTION` (integer) Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`. This option is not available if `mysqlnd` is used, because `mysqlnd` does not read the `mysql` configuration files.
- `PDO::MYSQL_ATTR_MAX_BUFFER_SIZE` (integer) Maximum buffer size. Defaults to 1 MiB. This constant is not supported when compiled against `mysqlnd`.
- `PDO::MYSQL_ATTR_DIRECT_QUERY` (integer) Perform direct queries, don't use prepared statements.
- `PDO::MYSQL_ATTR_FOUND_ROWS` (integer) Return the number of found (matched) rows, not the number of changed rows.
- `PDO::MYSQL_ATTR_IGNORE_SPACE` (integer) Permit spaces after function names. Makes all functions names reserved words.
- `PDO::MYSQL_ATTR_COMPRESS` (integer) Enable network communication compression. This is not supported when compiled against `mysqlnd`.
- `PDO::MYSQL_ATTR_SSL_CA` (integer) The file path to the SSL certificate authority.
- This exists as of PHP 5.3.7.
- `PDO::MYSQL_ATTR_SSL_CAPATH` (integer) The file path to the directory that contains the trusted SSL CA certificates, which are stored in PEM format.
- This exists as of PHP 5.3.7.
- `PDO::MYSQL_ATTR_SSL_CERT` (integer) The file path to the SSL certificate.
- This exists as of PHP 5.3.7.
- `PDO::MYSQL_ATTR_SSL_CIPHER` (integer) A list of one or more permissible ciphers to use for SSL encryption, in a format understood by OpenSSL. For example: `DHE-RSA-AES256-SHA:AES128-SHA`
- This exists as of PHP 5.3.7.
- `PDO::MYSQL_ATTR_SSL_KEY` (integer) The file path to the SSL key.
- This exists as of PHP 5.3.7.

The behaviour of these functions is affected by settings in `php.ini`.

**Table 21.58. PDO\_MYSQL Configuration Options**

Name	Default	Changeable
<code>pdo_mysql.default_socket</code>	<code>"/tmp/mysql.sock"</code>	PHP_INI_SYSTEM
<code>pdo_mysql.debug</code>	NULL	PHP_INI_SYSTEM

For further details and definitions of the PHP\_INI\_\* modes, see the <http://www.php.net/manual/en/configuration.changes.modes>.

Here's a short explanation of the configuration directives.

<code>pdo_mysql.default_socket</code> string	Sets a Unix domain socket. This value can either be set at compile time if a domain socket is found at configure. This ini setting is Unix only.
<code>pdo_mysql.debug</code> boolean	Enables debugging for PDO_MYSQL. This setting is only available when PDO_MYSQL is compiled against mysqlnd and in PDO debug mode.

### 21.9.4.1. PDO\_MYSQL DSN

Copyright 1997-2012 the PHP Documentation Group. [2906]

- PDO\_MYSQL DSN

Connecting to MySQL databases

#### Description

The PDO\_MYSQL Data Source Name (DSN) is composed of the following elements:

DSN prefix	The DSN prefix is <code>mysql:</code> .
<code>host</code>	The hostname on which the database server resides.
<code>port</code>	The port number where the database server is listening.
<code>dbname</code>	The name of the database.
<code>unix_socket</code>	The MySQL Unix socket (shouldn't be used with <code>host</code> or <code>port</code> ).
<code>charset</code>	The character set. See the <a href="#">character set</a> concepts documentation for more information.  Prior to PHP 5.3.6, this element was silently ignored. The same behaviour can be partly replicated with the <code>PDO::MYSQL_ATTR_INIT_COMMAND</code> driver option, as the following example shows.

#### Warning

The method in the below example can only be used with character sets that share the same lower 7 bit representation as ASCII, such as ISO-8859-1 and UTF-8. Users using character sets that have different representations (such as UTF-16 or Big5) *must* use the `charset` option provided in PHP 5.3.6 and later versions.

#### Example 21.213. Setting the connection character set to UTF-8 prior to PHP 5.3.6

```
<?php
$dsn = 'mysql:host=localhost;dbname=testdb';
$username = 'username';
$password = 'password';
$options = array(
```

```

PDO::MYSQL_ATTR_INIT_COMMAND => 'SET NAMES utf8',
);

$dbh = new PDO($dsn, $username, $password, $options);
?>

```

## Changelog

Version	Description
5.3.6	Prior to version 5.3.6, <code>charset</code> was ignored.

## Examples

### Example 21.214. PDO\_MYSQL DSN examples

The following example shows a PDO\_MYSQL DSN for connecting to MySQL databases:

```
mysql:host=localhost;dbname=testdb
```

More complete examples:

```
mysql:host=localhost;port=3307;dbname=testdb
mysql:unix_socket=/tmp/mysql.sock;dbname=testdb
```

## Notes

### Unix only:

When the host name is set to "`localhost`", then the connection to the server is made thru a domain socket. If PDO\_MYSQL is compiled against `libmysqlclient` then the location of the socket file is at `libmysqlclient`'s compiled in location. If PDO\_MYSQL is compiled against `mysqlnd` a default socket can be set thru the `pdo_mysql.default_socket` setting.

## 21.9.5. MySQL Native Driver ([Mysqlnd](#))

Copyright 1997-2012 the PHP Documentation Group. [2906]

MySQL Native Driver is a replacement for the MySQL Client Library (`libmysqlclient`). MySQL Native Driver is part of the official PHP sources as of PHP 5.3.0.

The MySQL database extensions MySQL extension, `mysqli` and PDO MYSQL all communicate with the MySQL server. In the past, this was done by the extension using the services provided by the MySQL Client Library. The extensions were compiled against the MySQL Client Library in order to use its client-server protocol.

With MySQL Native Driver there is now an alternative, as the MySQL database extensions can be compiled to use MySQL Native Driver instead of the MySQL Client Library.

MySQL Native Driver is written in C as a PHP extension.

### 21.9.5.1. Overview

Copyright 1997-2012 the PHP Documentation Group. [2906]

### *What it is not*

Although MySQL Native Driver is written as a PHP extension, it is important to note that it does not provide a new API to the PHP programmer. The programmer APIs for MySQL database connectivity are provided by the MySQL extension, `mysqli` and PDO MySQL. These extensions can now use the services of MySQL Native Driver to communicate with the MySQL Server. Therefore, you should not think of MySQL Native Driver as an API.

### *Why use it?*

Using the MySQL Native Driver offers a number of advantages over using the MySQL Client Library.

The older MySQL Client Library was written by MySQL AB (now Oracle Corporation) and so was released under the MySQL license. This ultimately led to MySQL support being disabled by default in PHP. However, the MySQL Native Driver has been developed as part of the PHP project, and is therefore released under the PHP license. This removes licensing issues that have been problematic in the past.

Also, in the past, you needed to build the MySQL database extensions against a copy of the MySQL Client Library. This typically meant you needed to have MySQL installed on a machine where you were building the PHP source code. Also, when your PHP application was running, the MySQL database extensions would call down to the MySQL Client library file at run time, so the file needed to be installed on your system. With MySQL Native Driver that is no longer the case as it is included as part of the standard distribution. So you do not need MySQL installed in order to build PHP or run PHP database applications.

Because MySQL Native Driver is written as a PHP extension, it is tightly coupled to the workings of PHP. This leads to gains in efficiency, especially when it comes to memory usage, as the driver uses the PHP memory management system. It also supports the PHP memory limit. Using MySQL Native Driver leads to comparable or better performance than using MySQL Client Library, it always ensures the most efficient use of memory. One example of the memory efficiency is the fact that when using the MySQL Client Library, each row is stored in memory twice, whereas with the MySQL Native Driver each row is only stored once in memory.

#### **Reporting memory usage**

Because MySQL Native Driver uses the PHP memory management system, its memory usage can be tracked with `memory_get_usage`. This is not possible with `libmysqlclient` because it uses the C function `malloc()` instead.

### *Special features*

MySQL Native Driver also provides some special features not available when the MySQL database extensions use MySQL Client Library. These special features are listed below:

- Improved persistent connections
- The special function `mysqli_fetch_all`
- Performance statistics calls: `mysqli_get_cache_stats`, `mysqli_get_client_stats`, `mysqli_get_connection_stats`

The performance statistics facility can prove to be very useful in identifying performance bottlenecks.

MySQL Native Driver also allows for persistent connections when used with the `mysqli` extension.

### *SSL Support*

MySQL Native Driver has supported SSL since PHP version 5.3.3

### *Compressed Protocol Support*

As of PHP 5.3.2 MySQL Native Driver supports the compressed client server protocol. MySQL Native Driver did not support this in 5.3.0 and 5.3.1. Extensions such as [ext/mysql](#), [ext/mysqli](#), that are configured to use MySQL Native Driver, can also take advantage of this feature. Note that [PDO\\_MYSQL](#) does *NOT* support compression when used together with [mysqlnd](#).

#### *Named Pipes Support*

Named pipes support for Windows was added in PHP version 5.4.0.

### 21.9.5.2. Installation

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### *Changelog*

**Table 21.59. Changelog**

Version	Description
5.3.0	The MySQL Native Driver was added, with support for all MySQL extensions (i.e., <a href="#">mysql</a> , <a href="#">mysqli</a> and <a href="#">PDO_MYSQL</a> ). Passing in <a href="#">mysqlnd</a> to the appropriate configure switch enables this support.
5.4.0	The MySQL Native Driver is now the default for all MySQL extensions (i.e., <a href="#">mysql</a> , <a href="#">mysqli</a> and <a href="#">PDO_MYSQL</a> ). Passing in <a href="#">mysqlnd</a> to configure is now optional.
5.5.0	SHA-256 Authentication Plugin support was added

#### *Installation on Unix*

The MySQL database extensions must be configured to use the MySQL Client Library. In order to use the MySQL Native Driver, PHP needs to be built specifying that the MySQL database extensions are compiled with MySQL Native Driver support. This is done through configuration options prior to building the PHP source code.

For example, to build the MySQL extension, [mysqli](#) and PDO MYSQL using the MySQL Native Driver, the following command would be given:

```
./configure --with-mysql=mysqlnd \  
--with-mysqli=mysqlnd \  
--with-pdo-mysql=mysqlnd \  
[other options]
```

#### *Installation on Windows*

In the official PHP Windows distributions from 5.3 onwards, MySQL Native Driver is enabled by default, so no additional configuration is required to use it. All MySQL database extensions will use MySQL Native Driver in this case.

#### *SHA-256 Authentication Plugin support*

The MySQL Native Driver requires the OpenSSL functionality of PHP to be loaded and enabled to connect to MySQL through accounts that use the MySQL SHA-256 Authentication Plugin. For example, PHP could be configured using:

```
./configure --with-mysql=mysqlnd \  
--with-mysqli=mysqlnd \  
--with-openssl=
```

```
--with-pdo-mysql=mysqlnd \
--with-openssl
[other options]
```

### 21.9.5.3. Runtime Configuration

Copyright 1997-2012 the PHP Documentation Group. [2906]

The behaviour of these functions is affected by settings in `php.ini`.

**Table 21.60. MySQL Native Driver Configuration Options**

Name	Default	Changeable	Changelog
<code>mysqlnd.collect_statistics</code>	"1"	PHP_INI_SYSTEM	Available since PHP 5.3.0.
<code>mysqlnd.collect_memory_statistics</code>	"0"	PHP_INI_SYSTEM	Available since PHP 5.3.0.
<code>mysqlnd.debug</code>	"0"	PHP_INI_SYSTEM	Available since PHP 5.3.0.
<code>mysqlnd.log_mask</code>	0	PHP_INI_ALL	Available since PHP 5.3.0
<code>mysqlnd.mempool_default_size</code>	16000	PHP_INI_ALL	Available since PHP 5.3.3
<code>mysqlnd.net_read_timeout</code>	31536000"	PHP_INI_SYSTEM	Available since PHP 5.3.0.
<code>mysqlnd.net_cmd_buffer_size</code>	512 - "2048", 5.3.1 - "4096"	PHP_INI_SYSTEM	Available since PHP 5.3.0.
<code>mysqlnd.net_read_buffer_size</code>	32768"	PHP_INI_SYSTEM	Available since PHP 5.3.0.
<code>mysqlnd.sha256_server_public_key</code>	"public_key"	PHP_INI_PERDIR	Available since PHP 5.5.0.

For further details and definitions of the `PHP_INI_*` modes, see the <http://www.php.net/manual/en/configuration.changes.modes>.

Here's a short explanation of the configuration directives.

`mysqlnd.collect_statistics` **boolean** Enables the collection of various client statistics which can be accessed through `mysqli_get_client_stats`, `mysqli_get_connection_stats`, `mysqli_get_cache_stats` and are shown in `mysqlnd` section of the output of the `phpinfo` function as well.

This configuration setting enables all [MySQL Native Driver statistics](#) except those relating to memory management.

`mysqlnd.collect_memory_statistics` **boolean** Enable the collection of various memory statistics which can be accessed through `mysqli_get_client_stats`, `mysqli_get_connection_stats`, `mysqli_get_cache_stats` and are shown in `mysqlnd` section of the output of the `phpinfo` function as well.

This configuration setting enables the memory management statistics within the overall set of [MySQL Native Driver statistics](#).

`mysqlnd.debug` **string** Records communication from all extensions using `mysqlnd` to the specified log file.

The format of the directive is `mysqlnd.debug = "option1[,parameter_option1] [:option2[,parameter_option2]]"`.

The options for the format string are as follows:

- `A[,file]` - Appends trace output to specified file. Also ensures that data is written after each write. This is done by closing and reopening the trace file (this is slow). It helps ensure a complete log file should the application crash.
- `a[,file]` - Appends trace output to the specified file.
- `d` - Enables output from `DEBUG_<N>` macros for the current state. May be followed by a list of keywords which selects output only for the `DEBUG` macros with that keyword. An empty list of keywords implies output for all macros.
- `f[,functions]` - Limits debugger actions to the specified list of functions. An empty list of functions implies that all functions are selected.
- `F` - Marks each debugger output line with the name of the source file containing the macro causing the output.
- `i` - Marks each debugger output line with the PID of the current process.
- `L` - Marks each debugger output line with the name of the source file line number of the macro causing the output.
- `n` - Marks each debugger output line with the current function nesting depth
- `o[,file]` - Similar to `a[,file]` but overwrites old file, and does not append.
- `O[,file]` - Similar to `A[,file]` but overwrites old file, and does not append.
- `t[,N]` - Enables function control flow tracing. The maximum nesting depth is specified by `N`, and defaults to 200.
- `x` - This option activates profiling.

Example:

```
d:t:x:0,/tmp/mysqlnd.trace
```

#### Note

This feature is only available with a debug build of PHP. Works on Microsoft Windows if using a debug build of PHP and PHP was built using Microsoft Visual C version 9 and above.

`mysqlnd.log_mask` integer

Defines which queries will be logged. The default 0, which disables logging. Define using an integer, and not with PHP constants. For

example, a value of 48 (16 + 32) will log slow queries which either use 'no good index' (`SERVER_QUERY_NO_GOOD_INDEX_USED = 16`) or no index at all (`SERVER_QUERY_NO_INDEX_USED = 32`). A value of 2043 (1 + 2 + 8 + ... + 1024) will log all slow query types.

The types are as follows: `SERVER_STATUS_IN_TRANS=1`, `SERVER_STATUS_AUTOCOMMIT=2`, `SERVER_MORE_RESULTS_EXISTS=8`, `SERVER_QUERY_NO_GOOD_INDEX_USED=16`, `SERVER_QUERY_NO_INDEX_USED=32`, `SERVER_STATUS_CURSOR_EXISTS=64`, `SERVER_STATUS_LAST_ROW_SENT=128`, `SERVER_STATUS_DB_DROPPED=256`, `SERVER_STATUS_NO_BACKSLASH_ESCAPES=512`, and `SERVER_QUERY_WAS_SLOW=1024`.

[mysqlnd.mempool\\_default\\_size](#) integer Default size of the mysqlnd memory pool, which is used by result sets.

[mysqlnd.net\\_read\\_timeout](#) integer [mysqlnd](#) and the MySQL Client Library, [libmysqlclient](#) use different networking APIs. [mysqlnd](#) uses PHP streams, whereas [libmysqlclient](#) uses its own wrapper around the operating level network calls. PHP, by default, sets a read timeout of 60s for streams. This is set via [php.ini](#), [default\\_socket\\_timeout](#). This default applies to all streams that set no other timeout value. [mysqlnd](#) does not set any other value and therefore connections of long running queries can be disconnected after [default\\_socket\\_timeout](#) seconds resulting in an error message "2006 - MySQL Server has gone away". The MySQL Client Library sets a default timeout of 365 \* 24 \* 3600 seconds (1 year) and waits for other timeouts to occur, such as TCP/IP timeouts. [mysqlnd](#) now uses the same very long timeout. The value is configurable through a new [php.ini](#) setting: [mysqlnd.net\\_read\\_timeout](#). [mysqlnd.net\\_read\\_timeout](#) gets used by any extension ([ext/mysql](#), [ext/mysql\\_i](#), [PDO\\_MySQL](#)) that uses [mysqlnd](#). [mysqlnd](#) tells PHP Streams to use [mysqlnd.net\\_read\\_timeout](#). Please note that there may be subtle differences between [MYSQL\\_OPT\\_READ\\_TIMEOUT](#) from the MySQL Client Library and PHP Streams, for example [MYSQL\\_OPT\\_READ\\_TIMEOUT](#) is documented to work only for TCP/IP connections and, prior to MySQL 5.1.2, only for Windows. PHP streams may not have this limitation. Please check the streams documentation, if in doubt.

[mysqlnd.net\\_cmd\\_buffer\\_size](#) long [mysqlnd](#) allocates an internal command/network buffer of [mysqlnd.net\\_cmd\\_buffer\\_size](#) (in [php.ini](#)) bytes for every connection. If a MySQL Client Server protocol command, for example, `COM_QUERY` ("normal" query), does not fit into the buffer, [mysqlnd](#) will grow the buffer to the size required for sending the command. Whenever the buffer gets extended for one connection, [command\\_buffer\\_too\\_small](#) will be incremented by one.

If [mysqlnd](#) has to grow the buffer beyond its initial size of [mysqlnd.net\\_cmd\\_buffer\\_size](#) bytes for almost every connection, you should consider increasing the default size to avoid re-allocations.

The default buffer size is 2048 bytes in PHP 5.3.0. In later versions the default is 4096 bytes. The default can be changed either through the `php.ini` setting `mysqlnd.net_cmd_buffer_size` or using `mysqli_options(MYSQLI_OPT_NET_CMD_BUFFER_SIZE, int size)`.

It is recommended that the buffer size be set to no less than 4096 bytes because `mysqlnd` also uses it when reading certain communication packets from MySQL. In PHP 5.3.0, `mysqlnd` will not grow the buffer if MySQL sends a packet that is larger than the current size of the buffer. As a consequence, `mysqlnd` is unable to decode the packet and the client application will get an error. There are only two situations when the packet can be larger than the 2048 bytes default of `mysqlnd.net_cmd_buffer_size` in PHP 5.3.0: the packet transports a very long error message, or the packet holds column meta data from `COM_LIST_FIELD` (`mysql_list_fields()`) and the meta data come from a string column with a very long default value (>1900 bytes).

As of PHP 5.3.2 `mysqlnd` does not allow setting buffers smaller than 4096 bytes.

The value can also be set using `mysqli_options(link, MYSQLI_OPT_NET_CMD_BUFFER_SIZE, size)`.

`mysqlnd.net_read_buffer_size`  
long

Maximum read chunk size in bytes when reading the body of a MySQL command packet. The MySQL client server protocol encapsulates all its commands in packets. The packets consist of a small header and a body with the actual payload. The size of the body is encoded in the header. `mysqlnd` reads the body in chunks of `MIN(header.size, mysqlnd.net_read_buffer_size)` bytes. If a packet body is larger than `mysqlnd.net_read_buffer_size` bytes, `mysqlnd` has to call `read()` multiple times.

The value can also be set using `mysqli_options(link, MYSQLI_OPT_NET_READ_BUFFER_SIZE, size)`.

`mysqlnd.sha256_server_public_key`  
string

SHA-256 Authentication Plugin related. File with the MySQL server public RSA key.

Clients can either omit setting a public RSA key, specify the key through this PHP configuration setting or set the key at runtime using `mysqli_options`. If not public RSA key file is given by the client, then the key will be exchanged as part of the standard SHA-256 Authentication Plugin authentication procedure.

#### 21.9.5.4. Persistent Connections

Copyright 1997-2012 the PHP Documentation Group. [2906]

##### *Using Persistent Connections*

If `mysqli` is used with `mysqlnd`, when a persistent connection is created it generates a `COM_CHANGE_USER` (`mysql_change_user()`) call on the server. This ensures that re-authentication of the connection takes place.

As there is some overhead associated with the `COM_CHANGE_USER` call, it is possible to switch this off at compile time. Reusing a persistent connection will then generate a `COM_PING` (`mysql_ping`) call to simply test the connection is reusable.

Generation of `COM_CHANGE_USER` can be switched off with the compile flag `MYSQLI_NO_CHANGE_USER_ON_PCONNECT`. For example:

```
shell# CFLAGS="-DMYSQLI_NO_CHANGE_USER_ON_PCONNECT" ./configure --with-mysql=/usr/local/mysql/ --with-m
```

Or alternatively:

```
shell# export CFLAGS="-DMYSQLI_NO_CHANGE_USER_ON_PCONNECT"
shell# configure --whatever-option
shell# make clean
shell# make
```

Note that only `mysqli` on `mysqlnd` uses `COM_CHANGE_USER`. Other extension-driver combinations use `COM_PING` on initial use of a persistent connection.

### 21.9.5.5. Statistics

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### *Using Statistical Data*

MySQL Native Driver contains support for gathering statistics on the communication between the client and the server. The statistics gathered are of three main types:

- Client statistics
- Connection statistics
- Zval cache statistics

If you are using the `mysqli` extension, these statistics can be obtained through three API calls:

- `mysqli_get_client_stats`
- `mysqli_get_connection_stats`
- `mysqli_get_cache_stats`

#### **Note**

Statistics are aggregated among all extensions that use MySQL Native Driver. For example, when compiling both `ext/mysql` and `ext/mysqli` against MySQL Native Driver, both function calls of `ext/mysql` and `ext/mysqli` will change the statistics. There is no way to find out how much a certain API call of any extension that has been compiled against MySQL Native Driver has impacted a certain statistic. You can configure the PDO MySQL Driver, `ext/mysql` and `ext/mysqli` to optionally use the MySQL Native Driver. When doing so, all three extensions will change the statistics.

#### *Accessing Client Statistics*

To access client statistics, you need to call `mysqli_get_client_stats`. The function call does not require any parameters.

The function returns an associative array that contains the name of the statistic as the key and the statistical data as the value.

Client statistics can also be accessed by calling the `phpinfo` function.

#### *Accessing Connection Statistics*

To access connection statistics call `mysqli_get_connection_stats`. This takes the database connection handle as the parameter.

The function returns an associative array that contains the name of the statistic as the key and the statistical data as the value.

*Accessing Zval Cache Statistics*

The MySQL Native Driver also collects statistics from its internal Zval cache. These statistics can be accessed by calling `mysqli_get_cache_stats`.

The Zval cache statistics obtained may lead to a tweaking of `php.ini` settings related to the Zval cache, resulting in better performance.

*Buffered and Unbuffered Result Sets*

Result sets can be buffered or unbuffered. Using default settings, `ext/mysql` and `ext/mysqli` work with buffered result sets for normal (non prepared statement) queries. Buffered result sets are cached on the client. After the query execution all results are fetched from the MySQL Server and stored in a cache on the client. The big advantage of buffered result sets is that they allow the server to free all resources allocated to a result set, once the results have been fetched by the client.

Unbuffered result sets on the other hand are kept much longer on the server. If you want to reduce memory consumption on the client, but increase load on the server, use unbuffered results. If you experience a high server load and the figures for unbuffered result sets are high, you should consider moving the load to the clients. Clients typically scale better than servers. "Load" does not only refer to memory buffers - the server also needs to keep other resources open, for example file handles and threads, before a result set can be freed.

Prepared Statements use unbuffered result sets by default. However, you can use `mysqli_stmt_store_result` to enable buffered result sets.

*Statistics returned by MySQL Native Driver*

The following tables show a list of statistics returned by the `mysqli_get_client_stats`, `mysqli_get_connection_stats` and `mysqli_get_cache_stats` functions.

**Table 21.61. Returned mysqlnd statistics: Network**

Statistic	Scope	Description	Notes
<code>bytes_sent</code>	Connection	Number of bytes sent from PHP to the MySQL server	Can be used to check the efficiency of the compression protocol
<code>bytes_received</code>	Connection	Number of bytes received from MySQL server	Can be used to check the efficiency of the compression protocol
<code>packets_sent</code>	Connection	Number of MySQL Client Server protocol packets sent	Used for debugging Client Server protocol implementation
<code>packets_received</code>	Connection	Number of MySQL Client Server protocol packets received	Used for debugging Client Server protocol implementation
<code>protocol_overhead_in</code>	Connection	MySQL Client Server protocol overhead in bytes for incoming traffic. Currently only the Packet Header (4 bytes) is considered as overhead. <code>protocol_overhead_in = packets_received * 4</code>	Used for debugging Client Server protocol implementation
<code>protocol_overhead_out</code>	Connection	MySQL Client Server protocol overhead in bytes for outgoing traffic. Currently only the Packet Header (4 bytes) is considered as overhead. <code>protocol_overhead_out = packets_sent * 4</code>	Used for debugging Client Server protocol implementation
<code>bytes_received_ok</code>	Connection	Total size of bytes of MySQL Client Server protocol OK packets received.	Used for debugging CS protocol implementation. Note that the total

Statistic	Scope	Description	Notes
		OK packets can contain a status message. The length of the status message can vary and thus the size of an OK packet is not fixed.	size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">packets_received</a>	Connection	Number of MySQL Client Server protocol OK packets received.	Used for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">bytes_received</a>	Connection	Total size in bytes of MySQL Client Server protocol EOF packets received. EOF can vary in size depending on the server version. Also, EOF can transport an error message.	Used for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">packets_received</a>	Connection	Number of MySQL Client Server protocol EOF packets. Like with other packet statistics the number of packets will be increased even if PHP does not receive the expected packet but, for example, an error message.	Used for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">bytes_received</a>	Connection	Total size in bytes of MySQL Client Server protocol result set header packets. The size of the packets varies depending on the payload ( <a href="#">LOAD LOCAL INFILE</a> , <a href="#">INSERT</a> , <a href="#">UPDATE</a> , <a href="#">SELECT</a> , error message).	Used for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">packets_received</a>	Connection	Number of MySQL Client Server protocol result set header packets.	Used for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">bytes_received</a>	Connection	Total size in bytes of MySQL Client Server protocol result set meta data (field information) packets. Of course the size varies with the fields in the result set. The packet may also transport an error or an EOF packet in case of <a href="#">COM_LIST_FIELDS</a> .	Only useful for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">packets_received</a>	Connection	Number of MySQL Client Server protocol result set meta data (field information) packets.	Only useful for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">bytes_received</a>	Connection	Total size in bytes of MySQL Client Server protocol result set row data packets. The packet may also transport an error or an EOF packet. You can reverse engineer the number of error and EOF packets by subtracting <a href="#">rows_fetched_from_server_normal</a> and <a href="#">rows_fetched_from_server_ps</a>	Only useful for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).

Statistic	Scope	Description	Notes
		from <a href="#">bytes_received_rset_row_packet</a> .	
<a href="#">packets_received_rset_row_data</a>	Connection	Number of MySQL Client Server protocol result set row data packets and their total size in bytes.	Only useful for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">bytes_received_prepare_response</a>	Connection	Total size in bytes of MySQL Client Server protocol OK for Prepared Statement Initialization packets (prepared statement init packets). The packet may also transport an error. The packet size depends on the MySQL version: 9 bytes with MySQL 4.1 and 12 bytes from MySQL 5.0 on. There is no safe way to know how many errors happened. You may be able to guess that an error has occurred if, for example, you always connect to MySQL 5.0 or newer and, <a href="#">bytes_received_prepare_response_packet</a> != <a href="#">packets_received_prepare_response</a> * 12. See also <a href="#">ps_prepared_never_executed</a> , <a href="#">ps_prepared_once_executed</a> .	Only useful for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">packets_received_prepare_init</a>	Connection	Number of MySQL Client Server protocol OK for Prepared Statement Initialization packets (prepared statement init packets).	Only useful for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">bytes_received_change_user</a>	Connection	Total size in bytes of MySQL Client Server protocol COM_CHANGE_USER packets. The packet may also transport an error or EOF.	Only useful for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">packets_received_change_user</a>	Connection	Number of MySQL Client Server protocol COM_CHANGE_USER packets	Only useful for debugging CS protocol implementation. Note that the total size in bytes includes the size of the header packet (4 bytes, see protocol overhead).
<a href="#">packets_received_commands</a>	Connection	Number of MySQL Client Server protocol commands sent from PHP to MySQL. There is no way to know which specific commands and how many of them have been sent. At its best you can use it to check if PHP has sent any commands to MySQL to know if you can consider to disable MySQL support in your PHP binary. There is also no way to reverse engineer the number of errors that may have occurred while sending data to MySQL. The only error that is recorded is	Only useful for debugging CS protocol implementation.

Statistic	Scope	Description	Notes
		command_buffer_too_small (see below).	
<a href="#">bytes_received</a>	Connection	Number of bytes of payload fetched by the PHP client from <a href="#">mysqlnd</a> using the text protocol.	<p>This is the size of the actual data contained in result sets that do not originate from prepared statements and which have been fetched by the PHP client. Note that although a full result set may have been pulled from MySQL by <a href="#">mysqlnd</a>, this statistic only counts actual data pulled from <a href="#">mysqlnd</a> by the PHP client. An example of a code sequence that will increase the value is as follows:</p> <pre>\$mysqli = new mysqli(); \$res = \$mysqli-&gt;query("SELECT 'abc'"); \$res-&gt;fetch_assoc(); \$res-&gt;close();</pre> <p>Every fetch operation will increase the value.</p> <p>The statistic will not be increased if the result set is only buffered on the client, but not fetched, such as in the following example:</p> <pre>\$mysqli = new mysqli(); \$res = \$mysqli-&gt;query("SELECT 'abc'"); \$res-&gt;close();</pre> <p>This statistic is available as of PHP version 5.3.4.</p>
<a href="#">bytes_received_real_data</a>	Connection	Number of bytes of the payload fetched by the PHP client from <a href="#">mysqlnd</a> using the prepared statement protocol.	<p>This is the size of the actual data contained in result sets that originate from prepared statements and which has been fetched by the PHP client. The value will not be increased if the result set is not subsequently read by the PHP client. Note that although a full result set may have been pulled from MySQL by <a href="#">mysqlnd</a>, this statistic only counts actual data pulled from <a href="#">mysqlnd</a> by the PHP client. See also <a href="#">bytes_received_real_data_normal</a>. This statistic is available as of PHP version 5.3.4.</p>

*Result Set*

**Table 21.62. Returned mysqlnd statistics: Result Set**

Statistic	Scope	Description	Notes
<a href="#">result_queries</a>	Connection	Number of queries that have generated a result set. Examples of queries that generate a result set: <a href="#">SELECT</a> , <a href="#">SHOW</a> . The statistic will not be incremented if	You may use it as an indirect measure for the number of queries PHP has sent to MySQL, for example, to identify a client that causes a high database load.

Statistic	Scope	Description	Notes
		there is an error reading the result set header packet from the line.	
<a href="#">non_res</a>	Connection	Number of queries that did not generate a result set. Examples of queries that do not generate a result set: <a href="#">INSERT</a> , <a href="#">UPDATE</a> , <a href="#">LOAD DATA</a> , <a href="#">SHOW</a> . The statistic will not be incremented if there is an error reading the result set header packet from the line.	You may use it as an indirect measure for the number of queries PHP has sent to MySQL, for example, to identify a client that causes a high database load.
<a href="#">no_index</a>	Connection	Number of queries that have generated a result set but did not use an index (see also <a href="#">mysqld</a> start option <code>–log-queries-not-using-indexes</code> ). If you want these queries to be reported you can use <code>mysqli_report(MYSQLI_REPORT_INDEX)</code> to make <code>ext/mysqli</code> throw an exception. If you prefer a warning instead of an exception use <code>mysqli_report(MYSQLI_REPORT_INDEX ^ MYSQLI_REPORT_STRICT)</code> .	
<a href="#">bad_index</a>	Connection	Number of queries that have generated a result set and did not use a good index (see also <a href="#">mysqld</a> start option <code>–log-slow-queries</code> ).	If you want these queries to be reported you can use <code>mysqli_report(MYSQLI_REPORT_INDEX)</code> to make <code>ext/mysqli</code> throw an exception. If you prefer a warning instead of an exception use <code>mysqli_report(MYSQLI_REPORT_INDEX ^ MYSQLI_REPORT_STRICT)</code>
<a href="#">slow_query</a>	Connection	SQL statements that took more than <a href="#">long_query_time</a> seconds to execute and required at least <a href="#">min_examined_row_limit</a> rows to be examined.	Not reported through <code>mysqli_report</code>
<a href="#">buffered</a>	Connection	Number of buffered result sets returned by “normal” queries. “Normal” means “not prepared statement” in the following notes.	Examples of API calls that will buffer result sets on the client: <code>mysql_query</code> , <code>mysqli_query</code> , <code>mysqli_store_result</code> , <code>mysqli_stmt_get_result</code> . Buffering result sets on the client ensures that server resources are freed as soon as possible and it makes result set scrolling easier. The downside is the additional memory consumption on the client for buffering data. Note that <code>mysqlnd</code> (unlike the MySQL Client Library) respects the PHP memory limit because it uses PHP internal memory management functions to allocate memory. This is also the reason why <code>memory_get_usage</code> reports a higher memory consumption when using <code>mysqlnd</code> instead of the MySQL Client Library. <code>memory_get_usage</code> does not

Statistic	Scope	Description	Notes
			measure the memory consumption of the MySQL Client Library at all because the MySQL Client Library does not use PHP internal memory management functions monitored by the function!
<a href="#">unbuffered</a>	Connection	Number of unbuffered result sets returned by normal (non prepared statement) queries.	Examples of API calls that will not buffer result sets on the client: <a href="#">mysqli_use_result</a>
<a href="#">ps_buffered</a>	Connection	Number of buffered result sets returned by prepared statements. By default prepared statements are unbuffered.	Examples of API calls that will not buffer result sets on the client: <a href="#">mysqli_stmt_store_result</a>
<a href="#">ps_unbuffered</a>	Connection	Number of unbuffered result sets returned by prepared statements.	By default prepared statements are unbuffered.
<a href="#">flushed_normal</a>	Connection	Number of result sets from normal (non prepared statement) queries with unread data which have been flushed silently for you. Flushing happens only with unbuffered result sets.	Unbuffered result sets must be fetched completely before a new query can be run on the connection otherwise MySQL will throw an error. If the application does not fetch all rows from an unbuffered result set, <a href="#">mysqlnd</a> does implicitly fetch the result set to clear the line. See also <a href="#">rows_skipped_normal</a> , <a href="#">rows_skipped_ps</a> . Some possible causes for an implicit flush: <ul style="list-style-type: none"> <li>• Faulty client application</li> <li>• Client stopped reading after it found what it was looking for but has made MySQL calculate more records than needed</li> <li>• Client application has stopped unexpectedly</li> </ul>
<a href="#">flushed_ps</a>	Connection	Number of result sets from prepared statements with unread data which have been flushed silently for you. Flushing happens only with unbuffered result sets.	Unbuffered result sets must be fetched completely before a new query can be run on the connection otherwise MySQL will throw an error. If the application does not fetch all rows from an unbuffered result set, <a href="#">mysqlnd</a> does implicitly fetch the result set to clear the line. See also <a href="#">rows_skipped_normal</a> , <a href="#">rows_skipped_ps</a> . Some possible causes for an implicit flush: <ul style="list-style-type: none"> <li>• Faulty client application</li> <li>• Client stopped reading after it found what it was looking for but has made MySQL calculate more records than needed</li> <li>• Client application has stopped unexpectedly</li> </ul>

Statistic	Scope	Description	Notes
<a href="#">ps_prepared_statements</a>	Connection	Number of statements prepared but never executed.	Prepared statements occupy server resources. You should not prepare a statement if you do not plan to execute it.
<a href="#">ps_prepared_statements_executed</a>	Connection	Number of prepared statements executed only once.	One of the ideas behind prepared statements is that the same query gets executed over and over again (with different parameters) and some parsing and other preparation work can be saved, if statement execution is split up in separate prepare and execute stages. The idea is to prepare once and “cache” results, for example, the parse tree to be reused during multiple statement executions. If you execute a prepared statement only once the two stage processing can be inefficient compared to “normal” queries because all the caching means extra work and it takes (limited) server resources to hold the cached information. Consequently, prepared statements that are executed only once may cause performance hurts.
<a href="#">rows_fetched_from_result_set</a> <a href="#">rows_fetched_from_result_set_implicit</a>	Connection	Total number of result set rows successfully fetched from MySQL regardless if the client application has consumed them or not. Some of the rows may not have been fetched by the client application but have been flushed implicitly.	See also <a href="#">packets_received_rset_row</a>
<a href="#">rows_buffered_fetching</a> <a href="#">rows_buffered_fetching_implicit</a>	Connection	Total number of successfully buffered rows originating from a “normal” query or a prepared statement. This is the number of rows that have been fetched from MySQL and buffered on client. Note that there are two distinct statistics on rows that have been buffered (MySQL to <i>mysqld</i> internal buffer) and buffered rows that have been fetched by the client application ( <i>mysqld</i> internal buffer to client application). If the number of buffered rows is higher than the number of fetched buffered rows it can mean that the client application runs queries that cause larger result sets than needed resulting in rows not read by the client.	Examples of queries that will buffer results: <a href="#">mysql_query</a> , <a href="#">mysql_store_result</a>
<a href="#">rows_fetched_from_result_set_buffered</a> <a href="#">rows_fetched_from_result_set_buffered_implicit</a>	Connection	Total number of rows fetched by the client from a buffered result set created by a normal query or a prepared statement.	
<a href="#">rows_fetched_from_result_set_unbuffered</a> <a href="#">rows_fetched_from_result_set_unbuffered_implicit</a>	Connection	Total number of rows fetched by the client from a unbuffered result set	

Statistic	Scope	Description	Notes
		created by a "normal" query or a prepared statement.	
<code>rows_fetched</code>	Connection	Total number of rows fetched by the client from a cursor created by a prepared statement.	
<code>rows_skipped</code> <code>rows_skipped_ps</code>	Connection	Reserved for future use (currently not supported)	
<code>copy_on_write_enabled</code> <code>copy_on_write_percent</code>	Process	With mysqlnd, variables returned by the extensions point into mysqlnd internal network result buffers. If you do not change the variables, fetched data will be kept only once in memory. If you change the variables, mysqlnd has to perform a copy-on-write to protect the internal network result buffers from being changed. With the MySQL Client Library you always hold fetched data twice in memory. Once in the internal MySQL Client Library buffers and once in the variables returned by the extensions. In theory mysqlnd can save up to 40% memory. However, note that the memory saving cannot be measured using <code>memory_get_usage</code> .	
<code>explicit_result_set_free</code> <code>implicit_result_set_free</code>	Connection Process (only during prepared statement cleanup)	Total number of freed result sets.	The free is always considered explicit but for result sets created by an init command, for example, <code>mysql_options(MYSQLI_INIT_COMMAND, ...)</code>
<code>proto_text_fetched</code> <code>proto_text_fetched_int</code> <code>proto_text_fetched_short</code> <code>proto_text_fetched_int24</code> <code>proto_text_fetched_int</code> <code>proto_text_fetched_bigint</code> <code>proto_text_fetched_decimal</code> <code>proto_text_fetched_float</code> <code>proto_text_fetched_double</code> <code>proto_text_fetched_date</code> <code>proto_text_fetched_year</code> <code>proto_text_fetched_time</code> <code>proto_text_fetched_datetime</code> <code>proto_text_fetched_timestamp</code> <code>proto_text_fetched_string</code> <code>proto_text_fetched_blob</code> <code>proto_text_fetched_enum</code> <code>proto_text_fetched_set</code> <code>proto_text_fetched_geometry</code> <code>proto_text_fetched_other</code>	Connection	Total number of columns of a certain type fetched from a normal query (MySQL text protocol).	Mapping from C API / MySQL meta data type to statistics name: <ul style="list-style-type: none"> <li><code>MYSQL_TYPE_NULL</code> - <code>proto_text_fetched_null</code></li> <li><code>MYSQL_TYPE_BIT</code> - <code>proto_text_fetched_bit</code></li> <li><code>MYSQL_TYPE_TINY</code> - <code>proto_text_fetched_tinyint</code></li> <li><code>MYSQL_TYPE_SHORT</code> - <code>proto_text_fetched_short</code></li> <li><code>MYSQL_TYPE_INT24</code> - <code>proto_text_fetched_int24</code></li> <li><code>MYSQL_TYPE_LONG</code> - <code>proto_text_fetched_int</code></li> <li><code>MYSQL_TYPE_LONGLONG</code> - <code>proto_text_fetched_bigint</code></li> </ul>

Statistic	Scope	Description	Notes
			<ul style="list-style-type: none"> <li>• <code>MYSQL_TYPE_DECIMAL</code>, <code>MYSQL_TYPE_NEWDECIMAL</code> - <code>proto_text_fetched_decimal</code></li> <li>• <code>MYSQL_TYPE_FLOAT</code> - <code>proto_text_fetched_float</code></li> <li>• <code>MYSQL_TYPE_DOUBLE</code> - <code>proto_text_fetched_double</code></li> <li>• <code>MYSQL_TYPE_DATE</code>, <code>MYSQL_TYPE_NEWDATE</code> - <code>proto_text_fetched_date</code></li> <li>• <code>MYSQL_TYPE_YEAR</code> - <code>proto_text_fetched_year</code></li> <li>• <code>MYSQL_TYPE_TIME</code> - <code>proto_text_fetched_time</code></li> <li>• <code>MYSQL_TYPE_DATETIME</code> - <code>proto_text_fetched_datetime</code></li> <li>• <code>MYSQL_TYPE_TIMESTAMP</code> - <code>proto_text_fetched_timestamp</code></li> <li>• <code>MYSQL_TYPE_STRING</code>, <code>MYSQL_TYPE_VARSTRING</code>, <code>MYSQL_TYPE_VARCHAR</code> - <code>proto_text_fetched_string</code></li> <li>• <code>MYSQL_TYPE_TINY_BLOB</code>, <code>MYSQL_TYPE_MEDIUM_BLOB</code>, <code>MYSQL_TYPE_LONG_BLOB</code>, <code>MYSQL_TYPE_BLOB</code> - <code>proto_text_fetched_blob</code></li> <li>• <code>MYSQL_TYPE_ENUM</code> - <code>proto_text_fetched_enum</code></li> <li>• <code>MYSQL_TYPE_SET</code> - <code>proto_text_fetched_set</code></li> <li>• <code>MYSQL_TYPE_GEOMETRY</code> - <code>proto_text_fetched_geometry</code></li> <li>• Any <code>MYSQL_TYPE_*</code> not listed before (there should be none) - <code>proto_text_fetched_other</code></li> </ul> <p>Note that the <code>MYSQL_*</code>-type constants may not be associated with the very same SQL column types in every version of MySQL.</p>
<code>proto_binary_fetched</code> , <code>proto_binary_fetched_long</code> , <code>proto_binary_fetched_medium</code> , <code>proto_binary_fetched_short</code> ,	<b>Connection</b>	<b>Total number</b> , of columns of a certain type fetched from a prepared statement (MySQL binary protocol).	For type mapping see <code>proto_text_*</code> described in the preceding text.

Statistic	Scope	Description	Notes
proto_binary_fetched_int24, proto_binary_fetched_int, proto_binary_fetched_bigint, proto_binary_fetched_decimal, proto_binary_fetched_float, proto_binary_fetched_double, proto_binary_fetched_date, proto_binary_fetched_year, proto_binary_fetched_time, proto_binary_fetched_datetime, proto_binary_fetched_timestamp, proto_binary_fetched_string, proto_binary_fetched_blob, proto_binary_fetched_enum, proto_binary_fetched_set, proto_binary_fetched_geometry, proto_binary_fetched_other			

**Table 21.63. Returned mysqlnd statistics: Connection**

Statistic	Scope	Description	Notes
<code>connect_success</code> , <code>connect_failure</code>	Connection	Total number of successful / failed connection attempt.	Reused connections and all other kinds of connections are included.
<code>reconnect</code>	Process	Total number of (real_)connect attempts made on an already opened connection handle.	The code sequence <code>\$link = new mysqli(...); \$link-&gt;real_connect(...)</code> will cause a reconnect. But <code>\$link = new mysqli(...); \$link-&gt;connect(...)</code> will not because <code>\$link-&gt;connect(...)</code> will explicitly close the existing connection before a new connection is established.
<code>pconnect_success</code>	Connection	Total number of successful persistent connection attempts.	Note that <code>connect_success</code> holds the sum of successful persistent and non-persistent connection attempts. The number of successful non-persistent connection attempts is <code>connect_success - pconnect_success</code> .
<code>active_connections</code>	Connection	Total number of active persistent and non-persistent connections.	
<code>active_persistent_connections</code>	Connection	Total number of active persistent connections.	The total number of active non-persistent connections is <code>active_connections - active_persistent_connections</code> .
<code>explicit_closes</code>	Connection	Total number of explicitly closed connections (ext/mysqli only).	Examples of code snippets that cause an explicit close :  <pre>\$link = new mysqli(...); \$link-&gt;close(...) \$link = new mysqli(...); \$link-&gt;connect(...)</pre>
<code>implicit_closes</code>	Connection	Total number of implicitly closed connections (ext/mysqli only).	Examples of code snippets that cause an implicit close :

Statistic	Scope	Description	Notes
			<ul style="list-style-type: none"> <li><code>\$link = new mysqli(...);</code> <code>\$link-&gt;real_connect(...)</code></li> <li><code>unset(\$link)</code></li> <li>Persistent connection: pooled connection has been created with <code>real_connect</code> and there may be unknown options set - close implicitly to avoid returning a connection with unknown options</li> <li>Persistent connection: <code>ping/change_user</code> fails and <code>ext/mysqli</code> closes the connection</li> <li>end of script execution: close connections that have not been closed by the user</li> </ul>
<code>disconnect</code>	Connection	Connection failures indicated by the C API call <code>mysql_real_connect</code> during an attempt to establish a connection.	It is called <code>disconnect_close</code> because the connection handle passed to the C API call will be closed.
<code>in_middle</code>	Process	A connection has been closed in the middle of a command execution (outstanding result sets not fetched, after sending a query and before retrieving an answer, while fetching data, while transferring data with LOAD DATA).	Unless you use asynchronous queries this should only happen if your script stops unexpectedly and PHP shuts down the connections for you.
<code>init_command</code>	Connection	Total number of init command executions, for example, <code>mysqli_options(MYSQLI_INIT_COMMAND)</code>	The number of successful executions is <code>init_command_executed_count - init_command_failed_count</code> .
<code>init_command</code>	Connection	Total number of failed init commands.	

**Table 21.64. Returned mysqlnd statistics: COM\_\* Command**

Statistic	Scope	Description	Notes
<code>com_quit</code> , <code>com_init_db</code> , <code>com_query</code> , <code>com_field_list</code> , <code>com_create_db</code> , <code>com_drop_db</code> , <code>com_refresh</code> , <code>com_shutdown</code> , <code>com_statistics</code> , <code>com_process_info</code> , <code>com_connect</code> , <code>com_process_kill</code> , <code>com_debug</code> , <code>com_ping</code> , <code>com_time</code> , <code>com_delayed_insert</code> , <code>com_change_user</code> , <code>com_binlog_dump</code> ,	Connection	Total number of attempts to send a certain COM_* command from PHP to MySQL.	<p>The statistics are incremented after checking the line and immediately before sending the corresponding MySQL client server protocol packet. If <code>mysqlnd</code> fails to send the packet over the wire the statistics will not be decremented. In case of a failure <code>mysqlnd</code> emits a PHP warning "Error while sending %s packet. PID=%d."</p> <p>Usage examples:</p> <ul style="list-style-type: none"> <li>Check if PHP sends certain commands to MySQL, for example, check if a client sends <code>COM_PROCESS_KILL</code></li> </ul>

Statistic	Scope	Description	Notes
<code>com_table_dump</code> , <code>com_connect_out</code> , <code>com_register_slave</code> , <code>com_stmt_prepare</code> , <code>com_stmt_execute</code> , <code>com_stmt_send_long_data</code> , <code>com_stmt_close</code> , <code>com_stmt_reset</code> , <code>com_stmt_set_option</code> , <code>com_stmt_fetch</code> , <code>com_daemon</code>			<ul style="list-style-type: none"> <li>Calculate the average number of prepared statement executions by comparing <code>COM_EXECUTE</code> with <code>COM_PREPARE</code></li> <li>Check if PHP has run any non-prepared SQL statements by checking if <code>COM_QUERY</code> is zero</li> <li>Identify PHP scripts that run an excessive number of SQL statements by checking <code>COM_QUERY</code> and <code>COM_EXECUTE</code></li> </ul>

*Miscellaneous*

**Table 21.65. Returned mysqlnd statistics: Miscellaneous**

Statistic	Scope	Description	Notes
<code>explicit_close</code> , <code>implicit_stmt_close</code>	Process	Total number of close prepared statements.	A close is always considered explicit but for a failed prepare.
<code>mem_emalloc_count</code> , <code>mem_emalloc_ammount</code> , <code>mem_ecalloc_count</code> , <code>mem_ecalloc_ammount</code> , <code>mem_erealloc_count</code> , <code>mem_erealloc_ammount</code> , <code>mem_efree_count</code> , <code>mem_malloc_count</code> , <code>mem_malloc_ammount</code> , <code>mem_calloc_count</code> , <code>mem_calloc_ammount</code> , <code>mem_realloc_count</code> , <code>mem_realloc_ammount</code> , <code>mem_free_count</code>	Process	Memory management calls.	Development only.
<code>command_buffer_too_small</code>	Connection	Number of network command buffer extensions while sending commands from PHP to MySQL.	<p>mysqlnd allocates an internal command/network buffer of <code>mysqlnd.net_cmd_buffer_size</code> (<code>php.ini</code>) bytes for every connection. If a MySQL Client Server protocol command, for example, <code>COM_QUERY</code> (normal query), does not fit into the buffer, mysqlnd will grow the buffer to what is needed for sending the command. Whenever the buffer gets extended for one connection <code>command_buffer_too_small</code> will be incremented by one.</p> <p>If mysqlnd has to grow the buffer beyond its initial size of <code>mysqlnd.net_cmd_buffer_size</code> (<code>php.ini</code>) bytes for almost every connection, you should consider to increase the default size to avoid re-allocations.</p>

Statistic	Scope	Description	Notes
			<p>The default buffer size is 2048 bytes in PHP 5.3.0. In future versions the default will be 4kB or larger. The default can be changed either through the <code>php.ini</code> setting <code>mysqlnd.net_cmd_buffer_size</code> or using <code>mysqli_options(MYSQLI_OPT_NET_CMD_BUFFER_SIZE, int size)</code>.</p> <p>It is recommended to set the buffer size to no less than 4096 bytes because <code>mysqlnd</code> also uses it when reading certain communication packet from MySQL. In PHP 5.3.0, <code>mysqlnd</code> will not grow the buffer if MySQL sends a packet that is larger than the current size of the buffer. As a consequence <code>mysqlnd</code> is unable to decode the packet and the client application will get an error. There are only two situations when the packet can be larger than the 2048 bytes default of <code>mysqlnd.net_cmd_buffer_size</code> in PHP 5.3.0: the packet transports a very long error message or the packet holds column meta data from <code>COM_LIST_FIELD</code> (<code>mysql_list_fields</code>) and the meta data comes from a string column with a very long default value (&gt;1900 bytes). No bug report on this exists - it should happen rarely.</p> <p>As of PHP 5.3.2 <code>mysqlnd</code> does not allow setting buffers smaller than 4096 bytes.</p>
<code>connection_reused</code>			

### 21.9.5.6. Notes

Copyright 1997-2012 the PHP Documentation Group. [2906]

This section provides a collection of miscellaneous notes on MySQL Native Driver usage.

- Using `mysqlnd` means using PHP streams for underlying connectivity. For `mysqlnd`, the PHP streams documentation (<http://www.php.net/manual/en/book.stream>) should be consulted on such details as timeout settings, not the documentation for the MySQL Client Library.

### 21.9.5.7. MySQL Native Driver Plugin API

Copyright 1997-2012 the PHP Documentation Group. [2906]

The MySQL Native Driver Plugin API is a feature of MySQL Native Driver, or `mysqlnd`. `mysqlnd` plugins operate in the layer between PHP applications and the MySQL server. This is comparable to MySQL Proxy. MySQL Proxy operates on a layer between any MySQL client application, for example, a PHP application and, the MySQL server. `mysqlnd` plugins can undertake typical MySQL Proxy tasks such as load balancing, monitoring and performance optimizations. Due to the different architecture

and location, `mysqlnd` plugins do not have some of MySQL Proxy's disadvantages. For example, with plugins, there is no single point of failure, no dedicated proxy server to deploy, and no new programming language to learn (Lua).

A `mysqlnd` plugin can be thought of as an extension to `mysqlnd`. Plugins can intercept the majority of `mysqlnd` functions. The `mysqlnd` functions are called by the PHP MySQL extensions such as `ext/mysql`, `ext/mysqli`, and `PDO_MYSQL`. As a result, it is possible for a `mysqlnd` plugin to intercept all calls made to these extensions from the client application.

Internal `mysqlnd` function calls can also be intercepted, or replaced. There are no restrictions on manipulating `mysqlnd` internal function tables. It is possible to set things up so that when certain `mysqlnd` functions are called by the extensions that use `mysqlnd`, the call is directed to the appropriate function in the `mysqlnd` plugin. The ability to manipulate `mysqlnd` internal function tables in this way allows maximum flexibility for plugins.

`mysqlnd` plugins are in fact PHP Extensions, written in C, that use the `mysqlnd` plugin API (which is built into MySQL Native Driver, `mysqlnd`). Plugins can be made 100% transparent to PHP applications. No application changes are needed because plugins operate on a different layer. The `mysqlnd` plugin can be thought of as operating in a layer below `mysqlnd`.

The following list represents some possible applications of `mysqlnd` plugins.

- Load Balancing
  - Read/Write Splitting. An example of this is the `PECL/mysqlnd_ms` (Master Slave) extension. This extension splits read/write queries for a replication setup.
  - Failover
  - Round-Robin, least loaded
- Monitoring
  - Query Logging
  - Query Analysis
  - Query Auditing. An example of this is the `PECL/mysqlnd_sip` (SQL Injection Protection) extension. This extension inspects queries and executes only those that are allowed according to a ruleset.
- Performance
  - Caching. An example of this is the `PECL/mysqlnd_qc` (Query Cache) extension.
  - Throttling
  - Sharding. An example of this is the `PECL/mysqlnd_mc` (Multi Connect) extension. This extension will attempt to split a `SELECT` statement into `n`-parts, using `SELECT ... LIMIT part_1, SELECT LIMIT part_n`. It sends the queries to distinct MySQL servers and merges the result at the client.

#### *MySQL Native Driver Plugins Available*

There are a number of `mysqlnd` plugins already available. These include:

- `PECL/mysqlnd_mc` - Multi Connect plugin.
- `PECL/mysqlnd_ms` - Master Slave plugin.
- `PECL/mysqlnd_qc` - Query Cache plugin.
- `PECL/mysqlnd_pscache` - Prepared Statement Handle Cache plugin.
- `PECL/mysqlnd_sip` - SQL Injection Protection plugin.

- [PECL/mysqlnd\\_uh](#) - User Handler plugin.

#### 21.9.5.7.1. A comparison of `mysqlnd` plugins with MySQL Proxy

Copyright 1997-2012 the PHP Documentation Group. [2906]

`mysqlnd` plugins and MySQL Proxy are different technologies using different approaches. Both are valid tools for solving a variety of common tasks such as load balancing, monitoring, and performance enhancements. An important difference is that MySQL Proxy works with all MySQL clients, whereas `mysqlnd` plugins are specific to PHP applications.

As a PHP Extension, a `mysqlnd` plugin gets installed on the PHP application server, along with the rest of PHP. MySQL Proxy can either be run on the PHP application server or can be installed on a dedicated machine to handle multiple PHP application servers.

Deploying MySQL Proxy on the application server has two advantages:

1. No single point of failure
2. Easy to scale out (horizontal scale out, scale by client)

MySQL Proxy (and `mysqlnd` plugins) can solve problems easily which otherwise would have required changes to existing applications.

However, MySQL Proxy does have some disadvantages:

- MySQL Proxy is a new component and technology to master and deploy.
- MySQL Proxy requires knowledge of the Lua scripting language.

MySQL Proxy can be customized with C and Lua programming. Lua is the preferred scripting language of MySQL Proxy. For most PHP experts Lua is a new language to learn. A `mysqlnd` plugin can be written in C. It is also possible to write plugins in PHP using [PECL/mysqlnd\\_uh](#).

MySQL Proxy runs as a daemon - a background process. MySQL Proxy can recall earlier decisions, as all state can be retained. However, a `mysqlnd` plugin is bound to the request-based lifecycle of PHP. MySQL Proxy can also share one-time computed results among multiple application servers. A `mysqlnd` plugin would need to store data in a persistent medium to be able to do this. Another daemon would need to be used for this purpose, such as Memcache. This gives MySQL Proxy an advantage in this case.

MySQL Proxy works on top of the wire protocol. With MySQL Proxy you have to parse and reverse engineer the MySQL Client Server Protocol. Actions are limited to those that can be achieved by manipulating the communication protocol. If the wire protocol changes (which happens very rarely) MySQL Proxy scripts would need to be changed as well.

`mysqlnd` plugins work on top of the C API, which mirrors the `libmysqlclient` client and Connector/C APIs. This C API is basically a wrapper around the MySQL Client Server protocol, or wire protocol, as it is sometimes called. You can intercept all C API calls. PHP makes use of the C API, therefore you can hook all PHP calls, without the need to program at the level of the wire protocol.

`mysqlnd` implements the wire protocol. Plugins can therefore parse, reverse engineer, manipulate and even replace the communication protocol. However, this is usually not required.

As plugins allow you to create implementations that use two levels (C API and wire protocol), they have greater flexibility than MySQL Proxy. If a `mysqlnd` plugin is implemented using the C API, any subsequent changes to the wire protocol do not require changes to the plugin itself.

#### 21.9.5.7.2. Obtaining the `mysqlnd` plugin API

Copyright 1997-2012 the PHP Documentation Group. [2906]

The [mysqlnd](#) plugin API is simply part of the MySQL Native Driver PHP extension, [ext/mysqlnd](#). Development started on the [mysqlnd](#) plugin API in December 2009. It is developed as part of the PHP source repository, and as such is available to the public either via Git, or through source snapshot downloads.

The following table shows PHP versions and the corresponding [mysqlnd](#) version contained within.

**Table 21.66. The bundled mysqlnd version per PHP release**

PHP Version	MySQL Native Driver version
5.3.0	5.0.5
5.3.1	5.0.5
5.3.2	5.0.7
5.3.3	5.0.7
5.3.4	5.0.7

Plugin developers can determine the [mysqlnd](#) version through accessing `MYSQLND_VERSION`, which is a string of the format “mysqlnd 5.0.7-dev - 091210 - \$Revision: 300535”, or through `MYSQLND_VERSION_ID`, which is an integer such as 50007. Developers can calculate the version number as follows:

**Table 21.67. MYSQLND\_VERSION\_ID calculation table**

Version (part)	Example
Major*10000	5*10000 = 50000
Minor*100	0*100 = 0
Patch	7 = 7
MYSQLND_VERSION_ID	50007

During development, developers should refer to the [mysqlnd](#) version number for compatibility and version tests, as several iterations of [mysqlnd](#) could occur during the lifetime of a PHP development branch with a single PHP version number.

### 21.9.5.7.3. MySQL Native Driver Plugin Architecture

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

This section provides an overview of the [mysqlnd](#) plugin architecture.

*MySQL Native Driver Overview*

Before developing [mysqlnd](#) plugins, it is useful to know a little of how [mysqlnd](#) itself is organized. [Mysqlnd](#) consists of the following modules:

**Table 21.68. The mysqlnd organization chart, per module**

Modules Statistics	mysqlnd_statistics.c
Connection	mysqlnd.c
Resultset	mysqlnd_result.c
Resultset Metadata	mysqlnd_result_meta.c
Statement	mysqlnd_ps.c
Network	mysqlnd_net.c
Wire protocol	mysqlnd_wireprotocol.c

*C Object Oriented Paradigm*

At the code level, *mysqlnd* uses a C pattern for implementing object orientation.

In C you use a *struct* to represent an object. Members of the struct represent object properties. Struct members pointing to functions represent methods.

Unlike with other languages such as C++ or Java, there are no fixed rules on inheritance in the C object oriented paradigm. However, there are some conventions that need to be followed that will be discussed later.

### *The PHP Life Cycle*

When considering the PHP life cycle there are two basic cycles:

- PHP engine startup and shutdown cycle
- Request cycle

When the PHP engine starts up it will call the module initialization (MINIT) function of each registered extension. This allows each module to setup variables and allocate resources that will exist for the lifetime of the PHP engine process. When the PHP engine shuts down it will call the module shutdown (MSHUTDOWN) function of each extension.

During the lifetime of the PHP engine it will receive a number of requests. Each request constitutes another life cycle. On each request the PHP engine will call the request initialization function of each extension. The extension can perform any variable setup and resource allocation required for request processing. As the request cycle ends the engine calls the request shutdown (RSHUTDOWN) function of each extension so the extension can perform any cleanup required.

### *How a plugin works*

A *mysqlnd* plugin works by intercepting calls made to *mysqlnd* by extensions that use *mysqlnd*. This is achieved by obtaining the *mysqlnd* function table, backing it up, and replacing it by a custom function table, which calls the functions of the plugin as required.

The following code shows how the *mysqlnd* function table is replaced:

```
/* a place to store original function table */
struct st_mysqlnd_conn_methods org_methods;

void minit_register_hooks(TSRMLS_D) {
    /* active function table */
    struct st_mysqlnd_conn_methods * current_methods
        = mysqlnd_conn_get_methods();

    /* backup original function table */
    memcpy(&org_methods, current_methods,
        sizeof(struct st_mysqlnd_conn_methods));

    /* install new methods */
    current_methods->query = MYSQLND_METHOD(my_conn_class, query);
}
```

Connection function table manipulations must be done during Module Initialization (MINIT). The function table is a global shared resource. In an multi-threaded environment, with a TSRM build, the manipulation of a global shared resource during the request processing will almost certainly result in conflicts.

#### **Note**

Do not use any fixed-size logic when manipulating the *mysqlnd* function table: new methods may be added at the end of the function table. The function table may change at any time in the future.

*Calling parent methods*

If the original function table entries are backed up, it is still possible to call the original function table entries - the parent methods.

In some cases, such as for `Connection::stmt_init()`, it is vital to call the parent method prior to any other activity in the derived method.

```
MYSQLND_METHOD(my_conn_class, query)(MYSQLND *conn,
    const char *query, unsigned int query_len TSRMLS_DC) {

    php_printf("my_conn_class::query(query = %s)\n", query);

    query = "SELECT 'query rewritten' FROM DUAL";
    query_len = strlen(query);

    return org_methods.query(conn, query, query_len); /* return with call to parent */
}
```

*Extending properties*

A `mysqlnd` object is represented by a C struct. It is not possible to add a member to a C struct at run time. Users of `mysqlnd` objects cannot simply add properties to the objects.

Arbitrary data (properties) can be added to a `mysqlnd` objects using an appropriate function of the `mysqlnd_plugin_get_plugin_<object>_data()` family. When allocating an object `mysqlnd` reserves space at the end of the object to hold a `void *` pointer to arbitrary data. `mysqlnd` reserves space for one `void *` pointer per plugin.

The following table shows how to calculate the position of the pointer for a specific plugin:

**Table 21.69. Pointer calculations for `mysqlnd`**

Memory address	Contents
0	Beginning of the <code>mysqlnd</code> object C struct
n	End of the <code>mysqlnd</code> object C struct
n + (m x sizeof(void*))	<code>void*</code> to object data of the m-th plugin

If you plan to subclass any of the `mysqlnd` object constructors, which is allowed, you must keep this in mind!

The following code shows extending properties:

```
/* any data we want to associate */
typedef struct my_conn_properties {
    unsigned long query_counter;
} MY_CONN_PROPERTIES;

/* plugin id */
unsigned int my_plugin_id;

void minit_register_hooks(TSRMLS_D) {
    /* obtain unique plugin ID */
    my_plugin_id = mysqlnd_plugin_register();
    /* snip - see Extending Connection: methods */
}

static MY_CONN_PROPERTIES** get_conn_properties(const MYSQLND *conn TSRMLS_DC) {
    MY_CONN_PROPERTIES** props;
    props = (MY_CONN_PROPERTIES**)mysqlnd_plugin_get_plugin_connection_data(
        conn, my_plugin_id);
    if (!props || !(*props)) {
```

```

*props = mnd_pecalloc(1, sizeof(MY_CONN_PROPERTIES), conn->persistent);
(*props)->query_counter = 0;
}
return props;
}

```

The plugin developer is responsible for the management of plugin data memory.

Use of the *mysqlnd* memory allocator is recommended for plugin data. These functions are named using the convention: `mnd_*loc()`. The *mysqlnd* allocator has some useful features, such as the ability to use a debug allocator in a non-debug build.

**Table 21.70. When and how to subclass**

	When to subclass?	Each instance has its own private function table?	How to subclass?
Connection (MYSQLND)	MINIT	No	<code>mysqlnd_conn_get_methods()</code>
Resultset (MYSQLND_RES)	MINIT or later	Yes	<code>mysqlnd_result_get_methods()</code> or object method function table manipulation
Resultset Meta (MYSQLND_RES_METADATA)	MINIT	No	<code>mysqlnd_result_metadata_get_methods()</code>
Statement (MYSQLND_STMT)	MINIT	No	<code>mysqlnd_stmt_get_methods()</code>
Network (MYSQLND_NET)	MINIT or later	Yes	<code>mysqlnd_net_get_methods()</code> or object method function table manipulation
Wire protocol (MYSQLND_PROTOCOL)	MINIT or later	Yes	<code>mysqlnd_protocol_get_methods()</code> or object method function table manipulation

You must not manipulate function tables at any time later than MINIT if it is not allowed according to the above table.

Some classes contain a pointer to the method function table. All instances of such a class will share the same function table. To avoid chaos, in particular in threaded environments, such function tables must only be manipulated during MINIT.

Other classes use copies of a globally shared function table. The class function table copy is created together with the object. Each object uses its own function table. This gives you two options: you can manipulate the default function table of an object at MINIT, and you can additionally refine methods of an object without impacting other instances of the same class.

The advantage of the shared function table approach is performance. There is no need to copy a function table for each and every object.

**Table 21.71. Constructor status**

	Allocation, construction, reset	Can be modified?	Caller
Connection (MYSQLND)	<code>mysqlnd_init()</code>	No	<code>mysqlnd_connect()</code>
Resultset (MYSQLND_RES)	Allocation:	Yes, but call parent!	<ul style="list-style-type: none"> <li>• <code>Connection::list_fields()</code></li> </ul>

	<ul style="list-style-type: none"> <li>• Connection::result_init()</li> </ul> <p>Reset and re-initialized during:</p> <ul style="list-style-type: none"> <li>• Result::use_result()</li> <li>• Result::store_result</li> </ul>		<ul style="list-style-type: none"> <li>• Statement::get_result()</li> <li>• Statement::prepare() (Metadata only)</li> <li>• Statement::resultMetadata()</li> </ul>
Resultset Meta (MYSQLND_RES_METADATA)	Connection::result_metadata()	Yes, but call parent!	Result::read_result_metadata()
Statement (MYSQLND_STMT)	Connection::stmt_init()	Yes, but call parent!	Connection::stmt_init()
Network (MYSQLND_NET)	mysqlnd_net_init()	No	Connection::init()
Wire protocol (MYSQLND_PROTOCOL)	mysqlnd_protocol_init()	No	Connection::init()

It is strongly recommended that you do not entirely replace a constructor. The constructors perform memory allocations. The memory allocations are vital for the *mysqlnd* plugin API and the object logic of *mysqlnd*. If you do not care about warnings and insist on hooking the constructors, you should at least call the parent constructor before doing anything in your constructor.

Regardless of all warnings, it can be useful to subclass constructors. Constructors are the perfect place for modifying the function tables of objects with non-shared object tables, such as Resultset, Network, Wire Protocol.

**Table 21.72. Destruction status**

	Derived method must call parent?	Destructor
Connection	yes, after method execution	free_contents(), end_psession()
Resultset	yes, after method execution	free_result()
Resultset Meta	yes, after method execution	free()
Statement	yes, after method execution	dtor(), free_stmt_content()
Network	yes, after method execution	free()
Wire protocol	yes, after method execution	free()

The destructors are the appropriate place to free properties, `mysqlnd_plugin_get_plugin_<object>_data()`.

The listed destructors may not be equivalent to the actual *mysqlnd* method freeing the object itself. However, they are the best possible place for you to hook in and free your plugin data. As with constructors you may replace the methods entirely but this is not recommended. If multiple methods are listed in the above table you will need to hook all of the listed methods and free your plugin data in whichever method is called first by *mysqlnd*.

The recommended method for plugins is to simply hook the methods, free your memory and call the parent implementation immediately following this.

**Caution**

Due to a bug in PHP versions 5.3.0 to 5.3.3, plugins do not associate plugin data with a persistent connection. This is because `ext/mysql` and `ext/mysqli` do not trigger all the necessary `mysqlnd_end_psession()` method calls and the plugin may therefore leak memory. This has been fixed in PHP 5.3.4.

**21.9.5.7.4. The *mysqlnd* plugin API**

Copyright 1997-2012 the PHP Documentation Group. [2906]

The following is a list of functions provided in the *mysqlnd* plugin API:

- *mysqlnd\_plugin\_register()*
- *mysqlnd\_plugin\_count()*
- *mysqlnd\_plugin\_get\_plugin\_connection\_data()*
- *mysqlnd\_plugin\_get\_plugin\_result\_data()*
- *mysqlnd\_plugin\_get\_plugin\_stmt\_data()*
- *mysqlnd\_plugin\_get\_plugin\_net\_data()*
- *mysqlnd\_plugin\_get\_plugin\_protocol\_data()*
- *mysqlnd\_conn\_get\_methods()*
- *mysqlnd\_result\_get\_methods()*
- *mysqlnd\_result\_meta\_get\_methods()*
- *mysqlnd\_stmt\_get\_methods()*
- *mysqlnd\_net\_get\_methods()*
- *mysqlnd\_protocol\_get\_methods()*

There is no formal definition of what a plugin is and how a plugin mechanism works.

Components often found in plugins mechanisms are:

- A plugin manager
- A plugin API
- Application services (or modules)
- Application service APIs (or module APIs)

The *mysqlnd* plugin concept employs these features, and additionally enjoys an open architecture.

*No Restrictions*

A plugin has full access to the inner workings of *mysqlnd*. There are no security limits or restrictions. Everything can be overwritten to implement friendly or hostile algorithms. It is recommended you only deploy plugins from a trusted source.

As discussed previously, plugins can use pointers freely. These pointers are not restricted in any way, and can point into another plugin's data. Simple offset arithmetic can be used to read another plugin's data.

It is recommended that you write cooperative plugins, and that you always call the parent method. The plugins should always cooperate with *mysqlnd* itself.

**Table 21.73. Issues: an example of chaining and cooperation**

Extension	<i>mysqlnd.query()</i> pointer	call stack if calling parent
ext/ <i>mysqlnd</i>	<i>mysqlnd.query()</i>	<i>mysqlnd.query</i>

<code>ext/mysqlnd_cache</code>	<code>mysqlnd_cache.query()</code>	<ol style="list-style-type: none"> <li>1. <code>mysqlnd_cache.query()</code></li> <li>2. <code>mysqlnd.query</code></li> </ol>
<code>ext/mysqlnd_monitor</code>	<code>mysqlnd_monitor.query()</code>	<ol style="list-style-type: none"> <li>1. <code>mysqlnd_monitor.query()</code></li> <li>2. <code>mysqlnd_cache.query()</code></li> <li>3. <code>mysqlnd.query</code></li> </ol>

In this scenario, a cache (`ext/mysqlnd_cache`) and a monitor (`ext/mysqlnd_monitor`) plugin are loaded. Both subclass `Connection::query()`. Plugin registration happens at `MINIT` using the logic shown previously. PHP calls extensions in alphabetical order by default. Plugins are not aware of each other and do not set extension dependencies.

By default the plugins call the parent implementation of the query method in their derived version of the method.

### PHP Extension Recap

This is a recap of what happens when using an example plugin, `ext/mysqlnd_plugin`, which exposes the `mysqlnd` C plugin API to PHP:

- Any PHP MySQL application tries to establish a connection to 192.168.2.29
- The PHP application will either use `ext/mysql`, `ext/mysqli` or `PDO_MYSQL`. All three PHP MySQL extensions use `mysqlnd` to establish the connection to 192.168.2.29.
- `Mysqlnd` calls its connect method, which has been subclassed by `ext/mysqlnd_plugin`.
- `ext/mysqlnd_plugin` calls the userspace hook `proxy::connect()` registered by the user.
- The userspace hook changes the connection host IP from 192.168.2.29 to 127.0.0.1 and returns the connection established by `parent::connect()`.
- `ext/mysqlnd_plugin` performs the equivalent of `parent::connect(127.0.0.1)` by calling the original `mysqlnd` method for establishing a connection.
- `ext/mysqlnd` establishes a connection and returns to `ext/mysqlnd_plugin`. `ext/mysqlnd_plugin` returns as well.
- Whatever PHP MySQL extension had been used by the application, it receives a connection to 127.0.0.1. The PHP MySQL extension itself returns to the PHP application. The circle is closed.

### 21.9.5.7.5. Getting started building a mysqlnd plugin

Copyright 1997-2012 the PHP Documentation Group. [2906]

It is important to remember that a `mysqlnd` plugin is itself a PHP extension.

The following code shows the basic structure of the `MINIT` function that will be used in the typical `mysqlnd` plugin:

```
/* my_php_mysqlnd_plugin.c */

static PHP_MINIT_FUNCTION(mysqlnd_plugin) {
    /* globals, ini entries, resources, classes */

    /* register mysqlnd plugin */
    mysqlnd_plugin_id = mysqlnd_plugin_register();

    conn_m = mysqlnd_get_conn_methods();
    memcpy(org_conn_m, conn_m,
```

```

sizeof(struct st_mysqlnd_conn_methods));

conn_m->query = MYSQLND_METHOD(mysqlnd_plugin_conn, query);
conn_m->connect = MYSQLND_METHOD(mysqlnd_plugin_conn, connect);
}

```

```

/* my_mysqlnd_plugin.c */

enum_func_status MYSQLND_METHOD(mysqlnd_plugin_conn, query)(/* ... */) {
    /* ... */
}
enum_func_status MYSQLND_METHOD(mysqlnd_plugin_conn, connect)(/* ... */) {
    /* ... */
}

```

### Task analysis: from C to userspace

```

class proxy extends mysqlnd_plugin_connection {
    public function connect($host, ...) { .. }
}
mysqlnd_plugin_set_conn_proxy(new proxy());

```

#### Process:

1. PHP: user registers plugin callback
2. PHP: user calls any PHP MySQL API to connect to MySQL
3. C: ext/\*mysql\* calls mysqlnd method
4. C: mysqlnd ends up in ext/mysqlnd\_plugin
5. C: ext/mysqlnd\_plugin
  - a. Calls userspace callback
  - b. Or original [mysqlnd](#) method, if userspace callback not set

You need to carry out the following:

1. Write a class "mysqlnd\_plugin\_connection" in C
2. Accept and register proxy object through "mysqlnd\_plugin\_set\_conn\_proxy()"
3. Call userspace proxy methods from C (optimization - zend\_interfaces.h)

Userspace object methods can either be called using [call\\_user\\_function\(\)](#) or you can operate at a level closer to the Zend Engine and use [zend\\_call\\_method\(\)](#).

#### Optimization: calling methods from C using [zend\\_call\\_method](#)

The following code snippet shows the prototype for the [zend\\_call\\_method](#) function, taken from [zend\\_interfaces.h](#).

```

ZEND_API zval* zend_call_method(
    zval **object_pp, zend_class_entry *obj_ce,
    zend_function **fn_proxy, char *function_name,
    int function_name_len, zval **retval_ptr_ptr,
    int param_count, zval* arg1, zval* arg2 TSRMLS_DC
);

```

Zend API supports only two arguments. You may need more, for example:

```
enum_func_status (*func_mysqlnd_conn_connect)(
    MYSQLND *conn, const char *host,
    const char * user, const char * passwd,
    unsigned int passwd_len, const char * db,
    unsigned int db_len, unsigned int port,
    const char * socket, unsigned int mysql_flags TSRMLS_DC
);
```

To get around this problem you will need to make a copy of `zend_call_method()` and add a facility for additional parameters. You can do this by creating a set of `MY_ZEND_CALL_METHOD_WRAPPER` macros.

### Calling PHP userspace

This code snippet shows the optimized method for calling a userspace function from C:

```
/* my_mysqlnd_plugin.c */
MYSQLND_METHOD(my_conn_class, connect)(
    MYSQLND *conn, const char *host /* ... */ TSRMLS_DC) {
    enum_func_status ret = FAIL;
    zval * global_user_conn_proxy = fetch_userspace_proxy();
    if (global_user_conn_proxy) {
        /* call userspace proxy */
        ret = MY_ZEND_CALL_METHOD_WRAPPER(global_user_conn_proxy, host, /*...*/);
    } else {
        /* or original mysqlnd method = do nothing, be transparent */
        ret = org_methods.connect(conn, host, user, passwd,
            passwd_len, db, db_len, port,
            socket, mysql_flags TSRMLS_CC);
    }
    return ret;
}
```

### Calling userspace: simple arguments

```
/* my_mysqlnd_plugin.c */
MYSQLND_METHOD(my_conn_class, connect)(
    /* ... */, const char *host, /* ... */) {
    /* ... */
    if (global_user_conn_proxy) {
        /* ... */
        zval* zv_host;
        MAKE_STD_ZVAL(zv_host);
        ZVAL_STRING(zv_host, host, 1);
        MY_ZEND_CALL_METHOD_WRAPPER(global_user_conn_proxy, zv_retval, zv_host /*, ...*/);
        zval_ptr_dtor(&zv_host);
        /* ... */
    }
    /* ... */
}
```

### Calling userspace: structs as arguments

```
/* my_mysqlnd_plugin.c */
MYSQLND_METHOD(my_conn_class, connect)(
    MYSQLND *conn, /* ... */) {
    /* ... */
    if (global_user_conn_proxy) {
        /* ... */
        zval* zv_conn;
        ZEND_REGISTER_RESOURCE(zv_conn, (void *)conn, le_mysqlnd_plugin_conn);
        MY_ZEND_CALL_METHOD_WRAPPER(global_user_conn_proxy, zv_retval, zv_conn, zv_host /*, ...*/);
        zval_ptr_dtor(&zv_conn);
        /* ... */
    }
}
```

```
/* ... */
}
```

The first argument of many [mysqlnd](#) methods is a C "object". For example, the first argument of the `connect()` method is a pointer to `MYSQLND`. The struct `MYSQLND` represents a [mysqlnd](#) connection object.

The [mysqlnd](#) connection object pointer can be compared to a standard I/O file handle. Like a standard I/O file handle a [mysqlnd](#) connection object shall be linked to the userspace using the PHP resource variable type.

*From C to userspace and back*

```
class proxy extends mysqlnd_plugin_connection {
    public function connect($conn, $host, ...) {
        /* "pre" hook */
        printf("Connecting to host = '%s'\n", $host);
        debug_print_backtrace();
        return parent::connect($conn);
    }

    public function query($conn, $query) {
        /* "post" hook */
        $ret = parent::query($conn, $query);
        printf("Query = '%s'\n", $query);
        return $ret;
    }
}
mysqlnd_plugin_set_conn_proxy(new proxy());
```

PHP users must be able to call the parent implementation of an overwritten method.

As a result of subclassing it is possible to refine only selected methods and you can choose to have "pre" or "post" hooks.

*Buildin class: `mysqlnd_plugin_connection::connect()`*

```
/* my_mysqlnd_plugin_classes.c */

PHP_METHOD("mysqlnd_plugin_connection", connect) {
    /* ... simplified! ... */
    zval* mysqlnd_rsrc;
    MYSQLND* conn;
    char* host; int host_len;
    if (zend_parse_parameters(ZEND_NUM_ARGS() TSRMLS_CC, "rs",
        &mysqlnd_rsrc, &host, &host_len) == FAILURE) {
        RETURN_NULL();
    }
    ZEND_FETCH_RESOURCE(conn, MYSQLND* conn, &mysqlnd_rsrc, -1,
        "MySQLnd Connection", le_mysqlnd_plugin_conn);
    if (PASS == org_methods.connect(conn, host, /* simplified! */ TSRMLS_CC))
        RETVAL_TRUE;
    else
        RETVAL_FALSE;
}
```

## 21.9.6. MySQLnd replication and load balancing plugin ([mysqlnd\\_ms](#))

Copyright 1997-2012 the PHP Documentation Group. [2906]

The [mysqlnd](#) replication and load balancing plugin ([mysqlnd\\_ms](#)) adds easy to use MySQL replication support to all PHP MySQL extensions that use [mysqlnd](#).

As of version PHP 5.3.3 the MySQL native driver for PHP ([mysqlnd](#)) features an internal plugin C API. C plugins, such as the replication and load balancing plugin, can extend the functionality of [mysqlnd](#).

The MySQL native driver for PHP is a C library that ships together with PHP as of PHP 5.3.0. It serves as a drop-in replacement for the MySQL Client Library (libmysqlclient). Using `mysqld` has several advantages: no extra downloads are required because it's bundled with PHP, it's under the PHP license, there is lower memory consumption in certain cases, and it contains new functionality such as asynchronous queries.

Mysqld plugins like `mysqld_ms` operate, for the most part, transparently from a user perspective. The replication and load balancing plugin supports all PHP applications, and all MySQL PHP extensions. It does not change existing APIs. Therefore, it can easily be used with existing PHP applications.

### 21.9.6.1. Key Features

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The key features of PECL/`mysqld_ms` are as follows.

- Transparent and therefore easy to use.
  - Supports all of the PHP MySQL extensions.
  - SSL support.
  - A consistent API.
  - Little to no application changes required, dependent on the required usage scenario.
  - Lazy connections: connections to master and slave servers are not opened before a SQL statement is executed.
  - Optional: automatic use of master after the first write in a web request, to lower the possible impact of replication lag.
- Can be used with any MySQL clustering solution.
  - MySQL Replication: Read-write splitting is done by the plugin. Primary focus of the plugin.
  - MySQL Cluster: Read-write splitting can be disabled. Configuration of multiple masters possible
  - Third-party solutions: the plugin is optimized for MySQL Replication but can be used with any other kind of MySQL clustering solution.
- Featured read-write split strategies
  - Automatic detection of SELECT.
  - Supports SQL hints to overrule automatism.
  - User-defined.
  - Can be disabled for, for example, when using synchronous clusters such as MySQL Cluster.
- Featured load balancing strategies
  - Round Robin: choose a different slave in round-robin fashion for every slave request.
  - Random: choose a random slave for every slave request.
  - Random once (sticky): choose a random slave once to run all slave requests for the duration of a web request.
  - User-defined. The application can register callbacks with `mysqld_ms`.

- PHP 5.4.0 or newer: transaction aware when using API calls only to control transactions.
- Weighted load balancing: servers can be assigned different priorities, for example, to direct more requests to a powerful machine than to another less powerful machine. Or, to prefer nearby machines to reduce latency.
- Global transaction ID
- Client-side emulation. Makes manual master server failover and slave promotion easier with asynchronous clusters, such as MySQL Replication.
- Support for built-in global transaction identifier feature of MySQL 5.6.5 or newer.
- Supports using transaction ids to identify up-to-date asynchronous slaves for reading when session consistency is required.
- Throttling: optionally, the plugin can wait for a slave to become "synchronous" before continuing.
- Service and consistency levels
  - Applications can request eventual, session and strong consistency service levels for connections. Appropriate cluster nodes will be searched automatically.
  - Eventual consistent MySQL Replication slave accesses can be replaced with fast local cache accesses transparently to reduce server load.
- Partitioning and sharding
  - Servers of a replication cluster can be organized into groups. SQL hints can be used to manually direct queries to a specific group. Grouping can be used to partition (shard) the data, or to cure the issue of hotspots with updates.
  - MySQL Replication filters are supported through the table filter.

### 21.9.6.2. Limitations

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The built-in read-write-split mechanism is very basic. Every query which starts with `SELECT` is considered a read request to be sent to a MySQL slave server. All other queries (such as `SHOW` statements) are considered as write requests that are sent to the MySQL master server. The build-in behavior can be overruled using [SQL hints](#), or a user-defined [callback function](#).

The read-write splitter is not aware of multi-statements. Multi-statements are considered as one statement. The decision of where to run the statement will be based on the beginning of the statement string. For example, if using `mysqli_multi_query` to execute the multi-statement `SELECT id FROM test ; INSERT INTO test(id) VALUES (1)`, the statement will be redirected to a slave server because it begins with `SELECT`. The `INSERT` statement, which is also part of the multi-statement, will not be redirected to a master server.

#### Note

Applications must be aware of the consequences of connection switches that are performed for load balancing purposes. Please check the documentation on [connection pooling and switching](#), [transaction handling](#), [failover load balancing](#) and [read-write splitting](#).

### 21.9.6.3. On the name

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The shortcut `mysqlnd_ms` stands for `mysqlnd master slave plugin`. The name was chosen for a quick-and-dirty proof-of-concept. In the beginning the developers did not expect to continue using the code base.

#### 21.9.6.4. Quickstart and Examples

Copyright 1997-2012 the PHP Documentation Group. [2906]

The mysqlnd replication load balancing plugin is easy to use. This quickstart will demo typical use-cases, and provide practical advice on getting started.

It is strongly recommended to read the reference sections in addition to the quickstart. The quickstart tries to avoid discussing theoretical concepts and limitations. Instead, it will link to the reference sections. It is safe to begin with the quickstart. However, before using the plugin in mission critical environments we urge you to read additionally the background information from the reference sections.

The focus is on using PECL `mysqlnd_ms` for work with an asynchronous MySQL cluster, namely MySQL replication. Generally speaking an asynchronous cluster is more difficult to use than a synchronous one. Thus, users of, for example, MySQL Cluster will find more information than needed.

##### 21.9.6.4.1. Setup

Copyright 1997-2012 the PHP Documentation Group. [2906]

The plugin is implemented as a PHP extension. See also the [installation instructions](#) to install the `PECL/mysqlnd_ms` extension.

Compile or configure the PHP MySQL extension (API) (`mysqli`, `PDO_MYSQL`, `mysql`) that you plan to use with support for the `mysqlnd` library. `PECL/mysqlnd_ms` is a plugin for the `mysqlnd` library. To use the plugin with any of the PHP MySQL extensions, the extension has to use the `mysqlnd` library.

Then, load the extension into PHP and activate the plugin in the PHP configuration file using the PHP configuration directive named `mysqlnd_ms.enable`.

##### Example 21.215. Enabling the plugin (`php.ini`)

```
mysqlnd_ms.enable=1
mysqlnd_ms.config_file=/path/to/mysqlnd_ms_plugin.ini
```

The plugin uses its own configuration file. Use the PHP configuration directive `mysqlnd_ms.config_file` to set the full file path to the plugin-specific configuration file. This file must be readable by PHP (e.g., the web server user). Please note, the configuration directive `mysqlnd_ms.config_file` supersedes `mysqlnd_ms.ini_file` since 1.4.0. It is a common pitfall to use the old, no longer available configuration directive.

Create a plugin-specific configuration file. Save the file to the path set by the PHP configuration directive `mysqlnd_ms.config_file`.

The plugin's [configuration file](#) is JSON based. It is divided into one or more sections. Each section has a name, for example, `myapp`. Every section makes its own set of configuration settings.

A section must, at a minimum, list the MySQL replication master server, and set a list of slaves. The plugin supports using only one master server per section. Multi-master MySQL replication setups are not yet fully supported. Use the configuration setting `master` to set the hostname, and the port or socket of the MySQL master server. MySQL slave servers are configured using the `slave` keyword.

##### Example 21.216. Minimal plugin-specific configuration file (`mysqlnd_ms_plugin.ini`)

```
{
  "myapp": {
```

```

"master": {
  "master_0": {
    "host": "localhost"
  }
},
"slave": [
]
}

```

Configuring a MySQL slave server list is required, although it may contain an empty list. It is recommended to always configure at least one slave server.

Server lists can use [anonymous or non-anonymous syntax \[3280\]](#). Non-anonymous lists include alias names for the servers, such as `master_0` for the master in the above example. The quickstart uses the more verbose non-anonymous syntax.

#### Example 21.217. Recommended minimal plugin-specific config (`mysqlnd_ms_plugin.ini`)

```

{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\\tmp\\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.2.27",
        "port": "3306"
      }
    }
  }
}

```

If there are at least two servers in total, the plugin can start to load balance and switch connections. Switching connections is not always transparent and can cause issues in certain cases. The reference sections about [connection pooling and switching](#), [transaction handling](#), [fail over load balancing](#) and [read-write splitting](#) all provide more details. And potential pitfalls are described later in this guide.

It is the responsibility of the application to handle potential issues caused by connection switches, by configuring a master with at least one slave server, which allows switching to work therefore related problems can be found.

The MySQL master and MySQL slave servers, which you configure, do not need to be part of MySQL replication setup. For testing purpose you can use single MySQL server and make it known to the plugin as a master and slave server as shown below. This could help you to detect many potential issues with connection switches. However, such a setup will not be prone to the issues caused by replication lag.

#### Example 21.218. Using one server as a master and as a slave (testing only!)

```

{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\\tmp\\mysql.sock"
      }
    },
  },
}

```

```

    "slave": {
      "slave_0": {
        "host": "127.0.0.1",
        "port": "3306"
      }
    }
  }
}

```

The plugin attempts to notify you of invalid configurations. Since 1.5.0 it will throw a warning during PHP startup if the configuration file cannot be read, is empty or parsing the JSON failed. Depending on your PHP settings those errors may appear in some log files only. Further validation is done when a connection is to be established and the configuration file is searched for valid sections. Setting [mysqlnd\\_ms.force\\_config\\_usage](#) may help debugging a faulty setup. Please, see also [configuration file debugging notes \[3282\]](#).

#### 21.9.6.4.2. Running statements

Copyright 1997-2012 the PHP Documentation Group. [2906]

The plugin can be used with any PHP MySQL extension (`mysqli`, `mysql`, and `PDO_MYSQL`) that is compiled to use the `mysqlnd` library. PECL/`mysqlnd_ms` plugs into the `mysqlnd` library. It does not change the API or behavior of those extensions.

Whenever a connection to MySQL is being opened, the plugin compares the host parameter value of the connect call, with the section names from the plugin specific configuration file. If, for example, the plugin specific configuration file has a section `myapp` then the section should be referenced by opening a MySQL connection to the host `myapp`

#### Example 21.219. Plugin specific configuration file (`mysqlnd_ms_plugin.ini`)

```

{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.2.27",
        "port": "3306"
      }
    }
  }
}

```

#### Example 21.220. Opening a load balanced connection

```

<?php
/* Load balanced following "myapp" section rules from the plugins config file */
$mysqli = new mysqli("myapp", "username", "password", "database");
$pdo = new PDO('mysql:host=myapp;dbname=database', 'username', 'password');
$mysql = mysql_connect("myapp", "username", "password");
?>

```

The connection examples above will be load balanced. The plugin will send read-only statements to the MySQL slave server with the IP `192.168.2.27` and will listen on port `3306` for the MySQL client connection. All other statements will be directed to the MySQL master server running on the host

[localhost](#). If on Unix like operating systems, the master on [localhost](#) will be accepting MySQL client connections on the Unix domain socket `/tmp/mysql.sock`, while TCP/IP is the default port on Windows. The plugin will use the user name [username](#) and the password [password](#) to connect to any of the MySQL servers listed in the section [myapp](#) of the plugins configuration file. Upon connect, the plugin will select [database](#) as the current schemata.

The username, password and schema name are taken from the connect API calls and used for all servers. In other words: you must use the same username and password for every MySQL server listed in a plugin configuration file section. This is not a general limitation. As of PECL/mysqlnd\_ms 1.1.0, it is possible to set the [username \[3284\]](#) and [password \[3284\]](#) for any server in the plugins configuration file, to be used instead of the credentials passed to the API call.

The plugin does not change the API for running statements. [Read-write splitting](#) works out of the box. The following example assumes that there is no significant replication lag between the master and the slave.

### Example 21.221. Executing statements

```
<?php
/* Load balanced following "myapp" section rules from the plugins config file */
$mysqli = new mysqli("myapp", "username", "password", "database");
if (mysqli_connect_errno())
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Statements will be run on the master */
if (!$mysqli->query("DROP TABLE IF EXISTS test")) {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}
if (!$mysqli->query("CREATE TABLE test(id INT)")) {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}
if (!$mysqli->query("INSERT INTO test(id) VALUES (1)")) {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}

/* read-only: statement will be run on a slave */
if (!$res = $mysqli->query("SELECT id FROM test")) {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
} else {
    $row = $res->fetch_assoc();
    $res->close();
    printf("Slave returns id = '%s'\n", $row['id']);
}
$mysqli->close();
?>
```

The above example will output something similar to:

```
Slave returns id = '1'
```

#### 21.9.6.4.3. Connection state

Copyright 1997-2012 the PHP Documentation Group. [2906]

The plugin changes the semantics of a PHP MySQL connection handle. A new connection handle represents a connection pool, instead of a single MySQL client-server network connection. The connection pool consists of a master connection, and optionally any number of slave connections.

Every connection from the connection pool has its own state. For example, SQL user variables, temporary tables and transactions are part of the state. For a complete list of items that belong to the

state of a connection, see the [connection pooling and switching](#) concepts documentation. If the plugin decides to switch connections for load balancing, the application could be given a connection which has a different state. Applications must be made aware of this.

#### Example 21.222. Plugin config with one slave and one master

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.2.27",
        "port": "3306"
      }
    }
  }
}
```

#### Example 21.223. Pitfall: connection state and SQL user variables

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Connection 1, connection bound SQL user variable, no SELECT thus run on master */
if (!$mysqli->query("SET @myrole='master'")) {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}

/* Connection 2, run on slave because SELECT */
if (!($res = $mysqli->query("SELECT @myrole AS _role"))) {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
} else {
    $row = $res->fetch_assoc();
    $res->close();
    printf("@myrole = '%s'\n", $row['_role']);
}
$mysqli->close();
?>
```

The above example will output:

```
@myrole = ''
```

The example opens a load balanced connection and executes two statements. The first statement `SET @myrole='master'` does not begin with the string `SELECT`. Therefore the plugin does not recognize it as a read-only query which shall be run on a slave. The plugin runs the statement on the connection to the master. The statement sets a SQL user variable which is bound to the master connection. The state of the master connection has been changed.

The next statement is `SELECT @myrole AS _role`. The plugin does recognize it as a read-only query and sends it to the slave. The statement is run on a connection to the slave. This second connection does not have any SQL user variables bound to it. It has a different state than the first

connection to the master. The requested SQL user variable is not set. The example script prints `@myrole = ''`.

It is the responsibility of the application developer to take care of the connection state. The plugin does not monitor all connection state changing activities. Monitoring all possible cases would be a very CPU intensive task, if it could be done at all.

The pitfalls can easily be worked around using SQL hints.

#### 21.9.6.4.4. SQL Hints

Copyright 1997-2012 the PHP Documentation Group. [2906]

SQL hints can force a query to choose a specific server from the connection pool. It gives the plugin a hint to use a designated server, which can solve issues caused by connection switches and connection state.

SQL hints are standard compliant SQL comments. Because SQL comments are supposed to be ignored by SQL processing systems, they do not interfere with other programs such as the MySQL Server, the MySQL Proxy, or a firewall.

Three SQL hints are supported by the plugin: The `MYSQLND_MS_MASTER_SWITCH` hint makes the plugin run a statement on the master, `MYSQLND_MS_SLAVE_SWITCH` enforces the use of the slave, and `MYSQLND_MS_LAST_USED_SWITCH` will run a statement on the same server that was used for the previous statement.

The plugin scans the beginning of a statement for the existence of an SQL hint. SQL hints are only recognized if they appear at the beginning of the statement.

#### Example 21.224. Plugin config with one slave and one master

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.2.27",
        "port": "3306"
      }
    }
  }
}
```

#### Example 21.225. SQL hints to prevent connection switches

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (mysqli_connect_errno())
  /* Of course, your error handling is nicer... */
  die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Connection 1, connection bound SQL user variable, no SELECT thus run on master */
if (!$mysqli->query("SET @myrole='master'")) {
  printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}

/* Connection 1, run on master because of SQL hint */
if (!$res = $mysqli->query(sprintf("/*%s*/SELECT @myrole AS _role", MYSQLND_MS_LAST_USED_SWITCH))) {
  printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}
```

```

} else {
    $row = $res->fetch_assoc();
    $res->close();
    printf("@myrole = '%s'\n", $row['_role']);
}
$mysqli->close();
?>

```

The above example will output:

```
@myrole = 'master'
```

In the above example, using `MYSQLND_MS_LAST_USED_SWITCH` prevents session switching from the master to a slave when running the `SELECT` statement.

SQL hints can also be used to run `SELECT` statements on the MySQL master server. This may be desired if the MySQL slave servers are typically behind the master, but you need current data from the cluster.

In version 1.2.0 the concept of a service level has been introduced to address cases when current data is required. Using a service level requires less attention and removes the need of using SQL hints for this use case. Please, find more information below in the service level and consistency section.

#### Example 21.226. Fighting replication lag

```

<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Force use of master, master has always fresh and current data */
if (!$mysqli->query(sprintf("/*%s*/SELECT critical_data FROM important_table", MYSQLND_MS_MASTER_SWITCH)))
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}
?>

```

A use case may include the creation of tables on a slave. If an SQL hint is not given, then the plugin will send `CREATE` and `INSERT` statements to the master. Use the SQL hint `MYSQLND_MS_SLAVE_SWITCH` if you want to run any such statement on a slave, for example, to build temporary reporting tables.

#### Example 21.227. Table creation on a slave

```

<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Force use of slave */
if (!$mysqli->query(sprintf("/*%s*/CREATE TABLE slave_reporting(id INT)", MYSQLND_MS_SLAVE_SWITCH))) {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}
/* Continue using this particular slave connection */
if (!$mysqli->query(sprintf("/*%s*/INSERT INTO slave_reporting(id) VALUES (1), (2), (3)", MYSQLND_MS_SLAVE_SWITCH)))
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}
/* Don't use MYSQLND_MS_SLAVE_SWITCH which would allow switching to another slave! */
if ($res = $mysqli->query(sprintf("/*%s*/SELECT COUNT(*) AS _num FROM slave_reporting", MYSQLND_MS_SLAVE_SWITCH)))

```

```

$row = $res->fetch_assoc();
$res->close();
printf("There are %d rows in the table 'slave_reporting'", $row['_num']);
} else {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}
$mysqli->close();
?>

```

The SQL hint `MYSQLND_MS_LAST_USED` forbids switching a connection, and forces use of the previously used connection.

#### 21.9.6.4.5. Transactions

Copyright 1997-2012 the PHP Documentation Group. [2906]

The current version of the plugin is not transaction safe by default, because it is not aware of running transactions in all cases. SQL transactions are units of work to be run on a single server. The plugin does not always know when the unit of work starts and when it ends. Therefore, the plugin may decide to switch connections in the middle of a transaction.

No kind of MySQL load balancer can detect transaction boundaries without any kind of hint from the application.

You can either use SQL hints to work around this limitation. Alternatively, you can activate transaction API call monitoring. In the latter case you must use API calls only to control transactions, see below.

#### Example 21.228. Plugin config with one slave and one master

```

[myapp]
{
    "myapp": {
        "master": {
            "master_0": {
                "host": "localhost",
                "socket": "\tmp\mysql.sock"
            }
        },
        "slave": {
            "slave_0": {
                "host": "192.168.2.27",
                "port": "3306"
            }
        }
    }
}

```

#### Example 21.229. Using SQL hints for transactions

```

<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Not a SELECT, will use master */
if (!$mysqli->query("START TRANSACTION")) {
    /* Please use better error handling in your code */
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}

/* Prevent connection switch! */
if (!$mysqli->query(sprintf("/*%s*/INSERT INTO test(id) VALUES (1)", MYSQLND_MS_LAST_USED_SWITCH))) {

```

```

/* Please do proper ROLLBACK in your code, don't just die */
die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}
if ($res = $mysqli->query(sprintf("/*%s*/SELECT COUNT(*) AS _num FROM test", MYSQLND_MS_LAST_USED_SWITCH))) {
    $row = $res->fetch_assoc();
    $res->close();
    if ($row['_num'] > 1000) {
        if (!$mysqli->query(sprintf("/*%s*/INSERT INTO events(task) VALUES ('cleanup'", MYSQLND_MS_LAST_USED_SWITCH))) {
            die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
        }
    }
} else {
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}
if (!$mysqli->query(sprintf("/*%s*/UPDATE log SET last_update = NOW()", MYSQLND_MS_LAST_USED_SWITCH))) {
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}
if (!$mysqli->query(sprintf("/*%s*/COMMIT", MYSQLND_MS_LAST_USED_SWITCH))) {
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}

$mysqli->close();
?>

```

Starting with PHP 5.4.0, the `mysqlnd` library allows the plugin to monitor the status of the `autocommit` mode, if the mode is set by API calls instead of using SQL statements such as `SET AUTOCOMMIT=0`. This makes it possible for the plugin to become transaction aware. In this case, you do not need to use SQL hints.

If using PHP 5.4.0 or newer, API calls that enable `autocommit` mode, and when setting the plugin configuration option `trx_stickiness=master`, the plugin can automatically disable load balancing and connection switches for SQL transactions. In this configuration, the plugin stops load balancing if `autocommit` is disabled and directs all statements to the master. This prevents connection switches in the middle of a transaction. Once `autocommit` is re-enabled, the plugin starts to load balance statements again.

API based transaction boundary detection has been improved with PHP 5.5.0 and PECL/`mysqlnd_ms` 1.5.0 to cover not only calls to `mysqli_autocommit` but also `mysqli_begin`, `mysqli_commit` and `mysqli_rollback`.

#### Example 21.230. Transaction aware load balancing: `trx_stickiness` setting

```

{
    "myapp": {
        "master": {
            "master_0": {
                "host": "localhost",
                "socket": "\tmp\mysql.sock"
            }
        },
        "slave": {
            "slave_0": {
                "host": "127.0.0.1",
                "port": "3306"
            }
        },
        "trx_stickiness": "master"
    }
}

```

#### Example 21.231. Transaction aware

```
<?php
```

```

$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Disable autocommit, plugin will run all statements on the master */
$mysqli->autocommit(FALSE);

if (!$mysqli->query("INSERT INTO test(id) VALUES (1)") {
    /* Please do proper ROLLBACK in your code, don't just die */
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}
if ($res = $mysqli->query("SELECT COUNT(*) AS _num FROM test")) {
    $row = $res->fetch_assoc();
    $res->close();
    if ($row['_num'] > 1000) {
        if (!$mysqli->query("INSERT INTO events(task) VALUES ('cleanup')")) {
            die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
        }
    }
} else {
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}
if (!$mysqli->query("UPDATE log SET last_update = NOW()") {
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}
if (!$mysqli->commit()) {
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}

/* Plugin assumes that the transaction has ended and starts load balancing again */
$mysqli->autocommit(TRUE);
$mysqli->close();
?>

```

#### Version requirement

The plugin configuration option `trx_stickiness=master` requires PHP 5.4.0 or newer.

Please note the restrictions outlined in the [transaction handling](#) concepts section.

#### 21.9.6.4.6. Service level and consistency

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### Version requirement

Service levels have been introduced in PECL `mysqlnd_ms` version 1.2.0-alpha. `mysqlnd_ms_set_qos` is available with PHP 5.4.0 or newer.

Different types of MySQL cluster solutions offer different service and data consistency levels to their users. An asynchronous MySQL replication cluster offers eventual consistency by default. A read executed on an asynchronous slave may return current, stale or no data at all, depending on whether the slave has replayed all changesets from the master or not.

Applications using an MySQL replication cluster need to be designed to work correctly with eventual consistent data. In some cases, however, stale data is not acceptable. In those cases only certain slaves or even only master accesses are allowed to achieve the required quality of service from the cluster.

As of PECL `mysqlnd_ms` 1.2.0 the plugin is capable of selecting MySQL replication nodes automatically that deliver session consistency or strong consistency. Session consistency means that one client can read its writes. Other clients may or may not see the clients' write. Strong consistency means that all clients will see all writes from the client.

**Example 21.232. Session consistency: read your writes**

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "127.0.0.1",
        "port": "3306"
      }
    }
  }
}
```

**Example 21.233. Requesting session consistency**

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* read-write splitting: master used */
if (!$mysqli->query("INSERT INTO orders(order_id, item) VALUES (1, 'christmas tree, 1.8m')")) {
    /* Please use better error handling in your code */
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}

/* Request session consistency: read your writes */
if (!mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_SESSION))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Plugin picks a node which has the changes, here: master */
if (!$res = $mysqli->query("SELECT item FROM orders WHERE order_id = 1"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

var_dump($res->fetch_assoc());

/* Back to eventual consistency: stale data allowed */
if (!mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Plugin picks any slave, stale data is allowed */
if (!$res = $mysqli->query("SELECT item, price FROM specials"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
?>
```

Service levels can be set in the plugins configuration file and at runtime using [mysqlnd\\_ms\\_set\\_qos](#). In the example the function is used to enforce session consistency (read your writes) for all future statements until further notice. The `SELECT` statement on the `orders` table is run on the master to ensure the previous write can be seen by the client. Read-write splitting logic has been adapted to fulfill the service level.

After the application has read its changes from the `orders` table it returns to the default service level, which is eventual consistency. Eventual consistency puts no restrictions on choosing a node for statement execution. Thus, the `SELECT` statement on the `specials` table is executed on a slave.

The new functionality supersedes the use of SQL hints and the [master\\_on\\_write](#) configuration option. In many cases [mysqlnd\\_ms\\_set\\_qos](#) is easier to use, more powerful improves portability.

### Example 21.234. Maximum age/slave lag

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "127.0.0.1",
        "port": "3306"
      }
    },
    "failover" : "master"
  }
}
```

### Example 21.235. Limiting slave lag

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Read from slaves lagging no more than four seconds */
$ret = mysqlnd_ms_set_qos($mysqli,
    MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL,
    MYSQLND_MS_QOS_OPTION_AGE, 4);

if (!$ret)
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Plugin picks any slave, which may or may not have the changes */
if (!$res = $mysqli->query("SELECT item, price FROM daytrade"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Back to default: use of all slaves and masters permitted */
if (!mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
?>
```

The eventual consistency service level can be used with an optional parameter to set a maximum slave lag for choosing slaves. If set, the plugin checks `SHOW SLAVE STATUS` for all configured slaves. In case of the example, only slaves for which `Slave_IO_Running=Yes`, `Slave_SQL_Running=Yes` and `Seconds_Behind_Master <= 4` is true are considered for executing the statement `SELECT item, price FROM daytrade`.

Checking `SHOW SLAVE STATUS` is done transparently from an applications perspective. Errors, if any, are reported as warnings. No error will be set on the connection handle. Even if all `SHOW SLAVE STATUS` SQL statements executed by the plugin fail, the execution of the users statement is not stopped, given that master fail over is enabled. Thus, no application changes are required.

#### Expensive and slow operation

Checking `SHOW SLAVE STATUS` for all slaves adds overhead to the application. It is an expensive and slow background operation. Try to minimize the use of it. Unfortunately, a MySQL replication cluster does not give clients the possibility to

request a list of candidates from a central instance. Thus, a more efficient way of checking the slaves lag is not available.

Please, note the limitations and properties of `SHOW SLAVE STATUS` as explained in the MySQL reference manual.

To prevent `mysqLnd_ms` from emitting a warning if no slaves can be found that lag no more than the defined number of seconds behind the master, it is necessary to enable master fail over in the plugins configuration file. If no slaves can be found and fail over is turned on, the plugin picks a master for executing the statement.

If no slave can be found and fail over is turned off, the plugin emits a warning, it does not execute the statement and it sets an error on the connection.

#### Example 21.236. Fail over not set

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "127.0.0.1",
        "port": "3306"
      }
    }
  }
}
```

#### Example 21.237. No slave within time limit

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
  /* Of course, your error handling is nicer... */
  die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Read from slaves lagging no more than four seconds */
$ret = mysqlnd_ms_set_qos($mysqli,
  MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL,
  MYSQLND_MS_QOS_OPTION_AGE, 4);

if (!$ret)
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Plugin picks any slave, which may or may not have the changes */
if (!$res = $mysqli->query("SELECT item, price FROM daytrade"))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Back to default: use of all slaves and masters permitted */
if (!mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
?>
```

The above example will output:

```
PHP Warning: mysqli::query(): (mysqlnd_ms) Couldn't find the appropriate slave connection. 0 slaves to
```

```
PHP Warning: mysqli::query(): (mysqlnd_ms) No connection selected by the last filter in %s on line %d
[2000] (mysqlnd_ms) No connection selected by the last filter
```

### 21.9.6.4.7. Global transaction IDs

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### Version requirement

A client-side global transaction ID injection has been introduced in `mysqlnd_ms` version 1.2.0-alpha. The feature is not required for synchronous clusters, such as MySQL Cluster. Use it with asynchronous clusters such as classical MySQL replication.

As of MySQL 5.6.5-m8 the MySQL server features built-in global transaction identifiers. The MySQL built-in global transaction ID feature is supported by PECL/`mysqlnd_ms` 1.3.0-alpha or later.

PECL/`mysqlnd_ms` can either use its own global transaction ID emulation or the global transaction ID feature built-in to MySQL 5.6.5-m8 or later. From a developer perspective the client-side and server-side approach offer the same features with regards to service levels provided by PECL/`mysqlnd_ms`. Their differences are discussed in the [concepts section](#).

The quickstart first demonstrates the use of the client-side global transaction ID emulation built-in to PECL/`mysqlnd_ms` before it shows how to use the server-side counterpart. The order ensures that the underlying idea is discussed first.

#### *Idea and client-side emulation*

In its most basic form a global transaction ID (GTID) is a counter in a table on the master. The counter is incremented whenever a transaction is committed on the master. Slaves replicate the table. The counter serves two purposes. In case of a master failure, it helps the database administrator to identify the most recent slave for promoting it to the new master. The most recent slave is the one with the highest counter value. Applications can use the global transaction ID to search for slaves which have replicated a certain write (identified by a global transaction ID) already.

PECL/`mysqlnd_ms` can inject SQL for every committed transaction to increment a GTID counter. The so created GTID is accessible by the application to identify an applications write operation. This enables the plugin to deliver session consistency (read your writes) service level by not only querying masters but also slaves which have replicated the change already. Read load is taken away from the master.

Client-side global transaction ID emulation has some limitations. Please, read the [concepts section](#) carefully to fully understand the principles and ideas behind it, before using in production environments. The background knowledge is not required to continue with the quickstart.

First, create a counter table on your master server and insert a record into it. The plugin does not assist creating the table. Database administrators must make sure it exists. Depending on the error reporting mode, the plugin will silently ignore the lack of the table or bail out.

#### **Example 21.238. Create counter table on master**

```
CREATE TABLE `trx` (
  `trx_id` int(11) DEFAULT NULL,
  `last_update` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
) ENGINE=InnoDB DEFAULT CHARSET=latin1
INSERT INTO `trx`(`trx_id`) VALUES (1);
```

In the plugins configuration file set the SQL to update the global transaction ID table using `on_commit` from the `global_transaction_id_injection` section. Make sure the table name used for the `UPDATE` statement is fully qualified. In the example, `test.trx` is used to refer to table `trx` in the schema (database) `test`. Use the table that was created in the previous step. It is important to set the fully qualified table name because the connection on which the injection is done may use a different default database. Make sure the user that opens the connection is allowed to execute the `UPDATE`.

Enable reporting of errors that may occur when `mysqld_ms` does global transaction ID injection.

### Example 21.239. Plugin config: SQL for client-side GTID injection

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\/tmp\/mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "127.0.0.1",
        "port": "3306"
      }
    },
    "global_transaction_id_injection": {
      "on_commit": "UPDATE test.trx SET trx_id = trx_id + 1",
      "report_error": true
    }
  }
}
```

### Example 21.240. Transparent global transaction ID injection

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
  /* Of course, your error handling is nicer... */
  die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* auto commit mode, transaction on master, GTID must be incremented */
if (!$mysqli->query("DROP TABLE IF EXISTS test"))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* auto commit mode, transaction on master, GTID must be incremented */
if (!$mysqli->query("CREATE TABLE test(id INT)"))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* auto commit mode, transaction on master, GTID must be incremented */
if (!$mysqli->query("INSERT INTO test(id) VALUES (1)"))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* auto commit mode, read on slave, no increment */
if (!($res = $mysqli->query("SELECT id FROM test")))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

var_dump($res->fetch_assoc());
?>
```

The above example will output:

```
array(1) {
  ["id"]=>
```

```
string(1) "1"
}
```

The example runs three statements in auto commit mode on the master, causing three transactions on the master. For every such statement, the plugin will inject the configured `UPDATE` transparently before executing the users SQL statement. When the script ends the global transaction ID counter on the master has been incremented by three.

The fourth SQL statement executed in the example, a `SELECT`, does not trigger an increment. Only transactions (writes) executed on a master shall increment the GTID counter.

#### SQL for global transaction ID: efficient solution wanted!

The SQL used for the client-side global transaction ID emulation is inefficient. It is optimized for clarity not for performance. Do not use it for production environments. Please, help finding an efficient solution for inclusion in the manual. We appreciate your input.

#### Example 21.241. Plugin config: SQL for fetching GTID

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "127.0.0.1",
        "port": "3306"
      }
    },
    "global_transaction_id_injection": {
      "on_commit": "UPDATE test.trx SET trx_id = trx_id + 1",
      "fetch_last_gtid" : "SELECT MAX(trx_id) FROM test.trx",
      "report_error": true
    }
  }
}
```

#### Example 21.242. Obtaining GTID after injection

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
  /* Of course, your error handling is nicer... */
  die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* auto commit mode, transaction on master, GTID must be incremented */
if (!$mysqli->query("DROP TABLE IF EXISTS test"))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

printf("GTID after transaction %s\n", mysqlnd_ms_get_last_gtid($mysqli));

/* auto commit mode, transaction on master, GTID must be incremented */
if (!$mysqli->query("CREATE TABLE test(id INT)"))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

printf("GTID after transaction %s\n", mysqlnd_ms_get_last_gtid($mysqli));
?>
```

The above example will output:

```
GTID after transaction 7
GTID after transaction 8
```

Applications can ask PECL `mysqlnd_ms` for a global transaction ID which belongs to the last write operation performed by the application. The function `mysqlnd_ms_get_last_gtid` returns the GTID obtained when executing the SQL statement from the `fetch_last_gtid` entry of the `global_transaction_id_injection` section from the plugins configuration file. The function may be called after the GTID has been incremented.

Applications are advised not to run the SQL statement themselves as this bares the risk of accidentally causing an implicit GTID increment. Also, if the function is used, it is easy to migrate an application from one SQL statement for fetching a transaction ID to another, for example, if any MySQL server ever features built-in global transaction ID support.

The quickstart shows a SQL statement which will return a GTID equal or greater to that created for the previous statement. It is exactly the GTID created for the previous statement if no other clients have incremented the GTID in the time span between the statement execution and the `SELECT` to fetch the GTID. Otherwise, it is greater.

#### Example 21.243. Plugin config: Checking for a certain GTID

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "127.0.0.1",
        "port": "3306"
      }
    },
    "global_transaction_id_injection":{
      "on_commit":"UPDATE test.trx SET trx_id = trx_id + 1",
      "fetch_last_gtid" : "SELECT MAX(trx_id) FROM test.trx",
      "check_for_gtid" : "SELECT trx_id FROM test.trx WHERE trx_id >= #GTID",
      "report_error":true
    }
  }
}
```

#### Example 21.244. Session consistency service level and GTID combined

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
  /* Of course, your error handling is nicer... */
  die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* auto commit mode, transaction on master, GTID must be incremented */
if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT)") ||
    !$mysqli->query("INSERT INTO test(id) VALUES (1)"))
  die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
```

```

/* GTID as an identifier for the last write */
$gtid = mysqlnd_ms_get_last_gtid($mysqli);

/* Session consistency (read your writes): try to read from slaves not only master */
if (false == mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_SESSION, MYSQLND_MS_QOS_OPTION_GTID, $gtid)) {
    die(sprintf("[006] [%d] %s\n", $mysqli->errno, $mysqli->error));
}

/* Either run on master or a slave which has replicated the INSERT */
if (!($res = $mysqli->query("SELECT id FROM test"))) {
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}

var_dump($res->fetch_assoc());
?>

```

A GTID returned from `mysqlnd_ms_get_last_gtid` can be used as an option for the session consistency service level. Session consistency delivers read your writes. Session consistency can be requested by calling `mysqlnd_ms_set_qos`. In the example, the plugin will execute the `SELECT` statement either on the master or on a slave which has replicated the previous `INSERT` already.

PECL `mysqlnd_ms` will transparently check every configured slave if it has replicated the `INSERT` by checking the slaves GTID table. The check is done running the SQL set with the `check_for_gtid` option from the `global_transaction_id_injection` section of the plugins configuration file. Please note, that this is a slow and expensive procedure. Applications should try to use it sparsely and only if read load on the master becomes to high otherwise.

#### *Use of the server-side global transaction ID feature*

Starting with MySQL 5.6.5-m8 the MySQL Replication system features server-side global transaction IDs. Transaction identifiers are automatically generated and maintained by the server. Users do not need to take care of maintaining them. There is no need to setup any tables in advance, or for setting `on_commit`. A client-side emulation is no longer needed.

Clients can continue to use global transaction identifier to achieve session consistency when reading from MySQL Replication slaves. The algorithm works as described above. Different SQL statements must be configured for `fetch_last_gtid` and `check_for_gtid`. The statements are given below. Please note, MySQL 5.6.5-m8 is a development version. Details of the server implementation may change in the future and require adoption of the SQL statements shown.

Using the following configuration any of the above described functionality can be used together with the server-side global transaction ID feature. `mysqlnd_ms_get_last_gtid` and `mysqlnd_ms_set_qos` continue to work as described above. The only difference is that the server does not use a simple sequence number but a string containing of a server identifier and a sequence number. Thus, users cannot easily derive an order from GTIDs returned by `mysqlnd_ms_get_last_gtid`.

#### **Example 21.245. Plugin config: using MySQL 5.6.5-m8 built-in GTID feature**

```

{
    "myapp": {
        "master": {
            "master_0": {
                "host": "localhost",
                "socket": "\\tmp\\mysql.sock"
            }
        },
        "slave": {
            "slave_0": {
                "host": "127.0.0.1",
                "port": "3306"
            }
        },
        "global_transaction_id_injection":{

```

```

        "fetch_last_gtid" : "SELECT @@GLOBAL.GTID_DONE AS trx_id FROM DUAL",
        "check_for_gtid"  : "SELECT GTID_SUBSET('#GTID', @@GLOBAL.GTID_DONE) AS trx_id FROM DUAL",
        "report_error":true
    }
}

```

### 21.9.6.4.8. Cache integration

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### Version requirement, dependencies and status

Please, find more about version requirements, extension load order dependencies and the current status in the [concepts section](#)!

Databases clusters can deliver different levels of consistency. As of PECL/mysqlnd\_ms 1.2.0 it is possible to advice the plugin to consider only cluster nodes that can deliver the consistency level requested. For example, if using asynchronous MySQL Replication with its cluster-wide eventual consistency, it is possible to request session consistency (read your writes) at any time using `mysqlnd_ms_set_qos`. Please, see also the [service level and consistency](#) introduction.

#### Example 21.246. Recap: quality of service to request read your writes

```

/* Request session consistency: read your writes */
if (!mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_SESSION))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

```

Assuming PECL/mysqlnd has been explicitly told to deliver no consistency level higher than eventual consistency, it is possible to replace a database node read access with a client-side cache using time-to-live (TTL) as its invalidation strategy. Both the database node and the cache may or may not serve current data as this is what eventual consistency defines.

Replacing a database node read access with a local cache access can improve overall performance and lower the database load. If the cache entry is every reused by other clients than the one creating the cache entry, a database access is saved and thus database load is lowered. Furthermore, system performance can become better if computation and delivery of a database query is slower than a local cache access.

#### Example 21.247. Plugin config: no special entries for caching

```

{
    "myapp": {
        "master": {
            "master_0": {
                "host": "localhost",
                "socket": "\/tmp\/mysql.sock"
            }
        },
        "slave": {
            "slave_0": {
                "host": "127.0.0.1",
                "port": "3306"
            }
        }
    }
}

```

#### Example 21.248. Caching a slave request

```

<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT)") ||
    !$mysqli->query("INSERT INTO test(id) VALUES (1)"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Explicitly allow eventual consistency and caching (TTL <= 60 seconds) */
if (false == mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL, MYSQLND_MS_QOS_OPTION_CACHE,
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}

/* To make this example work, we must wait for a slave to catch up. Brute force style. */
$attempts = 0;
do {
    /* check if slave has the table */
    if ($res = $mysqli->query("SELECT id FROM test")) {
        break;
    } else if ($mysqli->errno) {
        die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
    }
    /* wait for slave to catch up */
    usleep(200000);
} while ($attempts++ < 10);

/* Query has been run on a slave, result is in the cache */
assert($res);
var_dump($res->fetch_assoc());

/* Served from cache */
$res = $mysqli->query("SELECT id FROM test");
?>
    
```

The example shows how to use the cache feature. First, you have to set the quality of service to eventual consistency and explicitly allow for caching. This is done by calling `mysqlnd_ms_set_qos`. Then, the result set of every read-only statement is cached for upto that many seconds as allowed with `mysqlnd_ms_set_qos`.

The actual TTL is lower or equal to the value set with `mysqlnd_ms_set_qos`. The value passed to the function sets the maximum age (seconds) of the data delivered. To calculate the actual TTL value the replication lag on a slave is checked and subtracted from the given value. If, for example, the maximum age is set to 60 seconds and the slave reports a lag of 10 seconds the resulting TTL is 50 seconds. The TTL is calculated individually for every cached query.

#### Example 21.249. Read your writes and caching combined

```

<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

if (!$mysqli->query("DROP TABLE IF EXISTS test") ||
    !$mysqli->query("CREATE TABLE test(id INT)") ||
    !$mysqli->query("INSERT INTO test(id) VALUES (1)"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Explicitly allow eventual consistency and caching (TTL <= 60 seconds) */
if (false == mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL, MYSQLND_MS_QOS_OPTION_CACHE,
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}

/* To make this example work, we must wait for a slave to catch up. Brute force style. */
    
```

```

$attempts = 0;
do {
    /* check if slave has the table */
    if ($res = $mysqli->query("SELECT id FROM test")) {
        break;
    } else if ($mysqli->errno) {
        die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
    }
    /* wait for slave to catch up */
    usleep(200000);
} while ($attempts++ < 10);

assert($res);

/* Query has been run on a slave, result is in the cache */
var_dump($res->fetch_assoc());

/* Served from cache */
if (!($res = $mysqli->query("SELECT id FROM test")))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
var_dump($res->fetch_assoc());

/* Update on master */
if (!$mysqli->query("UPDATE test SET id = 2"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Read your writes */
if (false == mysqlnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_SESSION)) {
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
}

/* Fetch latest data */
if (!($res = $mysqli->query("SELECT id FROM test")))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
var_dump($res->fetch_assoc());
?>
    
```

The quality of service can be changed at any time to avoid further cache usage. If needed, you can switch to read your writes (session consistency). In that case, the cache will not be used and fresh data is read.

#### 21.9.6.4.9. Failover

Copyright 1997-2012 the PHP Documentation Group. [2906]

By default, the plugin does not attempt to fail over if connecting to a host fails. This prevents pitfalls related to [connection state](#). It is recommended to manually handle connection errors in a way similar to a failed transaction. You should catch the error, rebuild the connection state and rerun your query as shown below.

If connection state is no issue to you, you can alternatively enable automatic and silent failover. Depending on the configuration, the automatic and silent failover will either attempt to fail over to the master before issuing an error or, try to connect to other slaves, given the query allows for it, before attempting to connect to a master. Because [automatic failover](#) is not fool-proof, it is not discussed in the quickstart. Instead, details are given in the [concepts](#) section below.

#### Example 21.250. Manual failover, automatic optional

```

{
    "myapp": {
        "master": {
            "master_0": {
                "host": "localhost",
                "socket": "\tmp\mysql.sock"
            }
        }
    },
}
    
```

```

    "slave": {
      "slave_0": {
        "host": "simulate_slave_failure",
        "port": "0"
      },
      "slave_1": {
        "host": "127.0.0.1",
        "port": 3311
      }
    },
    "filters": { "roundrobin": [] }
  }
}

```

### Example 21.251. Manual failover

```

<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

$sql = "SELECT 1 FROM DUAL";

/* error handling as it should be done regardless of the plugin */
if (!$res = $link->query($sql)) {
    /* plugin specific: check for connection error */
    switch ($link->errno) {
        case 2002:
        case 2003:
        case 2005:
            printf("Connection error - trying next slave!\n");
            /* load balancer will pick next slave */
            $res = $link->query($sql);
            break;
        default:
            /* no connection error, failover is unlikely to help */
            die(sprintf("SQL error: [%d] %s", $link->errno, $link->error));
            break;
    }
}
if ($res) {
    var_dump($res->fetch_assoc());
}
?>

```

## 21.9.6.4.10. Partitioning and Sharding

Copyright 1997-2012 the PHP Documentation Group. [2906]

Database clustering is done for various reasons. Clusters can improve availability, fault tolerance, and increase performance by applying a divide and conquer approach as work is distributed over many machines. Clustering is sometimes combined with partitioning and sharding to further break up a large complex task into smaller, more manageable units.

The `mysqlnd_ms` plugin aims to support a wide variety of MySQL database clusters. Some flavors of MySQL database clusters have built-in methods for partitioning and sharding, which could be transparent to use. The plugin supports the two most common approaches: MySQL Replication table filtering, and Sharding (application based partitioning).

MySQL Replication supports partitioning as filters that allow you to create slaves that replicate all or specific databases of the master, or tables. It is then in the responsibility of the application to choose a slave according to the filter rules. You can either use the `mysqlnd_ms` `node_groups` filter to manually support this, or use the experimental table filter.

Manual partitioning or sharding is supported through the node grouping filter, and SQL hints as of 1.5.0. The `node_groups` filter lets you assign a symbolic name to a group of master and slave servers. In the example, the master `master_0` and `slave_0` form a group with the name `Partition_A`. It is entirely up to you to decide what makes up a group. For example, you may use node groups for sharding, and use the group names to address shards like `Shard_A_Range_0_100`.

### Example 21.252. Cluster node groups

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\/tmp\/mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "simulate_slave_failure",
        "port": "0"
      },
      "slave_1": {
        "host": "127.0.0.1",
        "port": 3311
      }
    },
    "filters": {
      "node_groups": {
        "Partition_A": {
          "master": ["master_0"],
          "slave": ["slave_0"]
        }
      },
      "roundrobin": []
    }
  }
}
```

### Example 21.253. Manual partitioning using SQL hints

```
<?php
function select($mysqli, $msg, $hint = '') {
  /* Note: weak test, two connections to two servers may have the same thread id */
  $sql = sprintf("SELECT CONNECTION_ID() AS _thread, '%s' AS _hint FROM DUAL", $msg);
  if ($hint) {
    $sql = $hint . $sql;
  }
  if (!$res = $mysqli->query($sql)) {
    printf("[%d] %s", $mysqli->errno, $mysqli->error);
    return false;
  }
  $row = $res->fetch_assoc();
  printf("%d - %s - %s\n", $row['_thread'], $row['_hint'], $sql);
  return true;
}

$mysqli = new mysqli("myapp", "user", "password", "database");
if (!$mysqli)
  /* Of course, your error handling is nicer... */
  die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* All slaves allowed */
select($mysqli, "slave_0");
select($mysqli, "slave_1");

/* only servers of node group "Partition_A" allowed */
select($mysqli, "slave_1", "/*Partition_A*/");
```

```
select($mysqli, "slave_1", "/*Partition_A*/");
?>
```

```
6804 - slave_0 - SELECT CONNECTION_ID() AS _thread, 'slave1' AS _hint FROM DUAL
2442 - slave_1 - SELECT CONNECTION_ID() AS _thread, 'slave2' AS _hint FROM DUAL
6804 - slave_0 - /*Partition_A*/SELECT CONNECTION_ID() AS _thread, 'slave1' AS _hint FROM DUAL
6804 - slave_0 - /*Partition_A*/SELECT CONNECTION_ID() AS _thread, 'slave1' AS _hint FROM DUAL
```

By default, the plugin will use all configured master and slave servers for query execution. But if a query begins with a SQL hint like `/*node_group*/`, the plugin will only consider the servers listed in the `node_group` for query execution. Thus, `SELECT` queries prefixed with `/*Partition_A*/` will only be executed on `slave_0`.

### 21.9.6.5. Concepts

Copyright 1997-2012 the PHP Documentation Group. [2906]

This explains the architecture and related concepts for this plugin, and describes the impact that MySQL replication and this plugin have on developmental tasks while using a database cluster. Reading and understanding these concepts is required, in order to use this plugin with success.

#### 21.9.6.5.1. Architecture

Copyright 1997-2012 the PHP Documentation Group. [2906]

The `mysqlnd` replication and load balancing plugin is implemented as a PHP extension. It is written in C and operates under the hood of PHP. During the startup of the PHP interpreter, in the module init phase of the PHP engine, it gets registered as a `mysqlnd` plugin to replace selected `mysqlnd C` methods.

At PHP runtime, it inspects queries sent from `mysqlnd` (PHP) to the MySQL server. If a query is recognized as read-only, it will be sent to one of the configured slave servers. Statements are considered read-only if they either start with `SELECT`, the SQL hint `/*ms=slave*/` or a slave had been chosen for running the previous query, and the query started with the SQL hint `/*ms=last_used*/`. In all other cases, the query will be sent to the MySQL replication master server.

For better portability, applications should use the `MYSQLND_MS_MASTER_SWITCH`, `MYSQLND_MS_SLAVE_SWITCH`, and `MYSQLND_MS_LAST_USED_SWITCH` predefined `mysqlnd_ms constants`, instead of their literal values, such as `/*ms=slave*/`.

The plugin handles the opening and closing of database connections to both master and slave servers. From an application point of view, there continues to be only one connection handle. However, internally, this one public connection handle represents a pool of network connections that are managed by the plugin. The plugin proxies queries to the master server, and to the slaves using multiple connections.

Database connections have a state consisting of, for example, transaction status, transaction settings, character set settings, and temporary tables. The plugin will try to maintain the same state among all internal connections, whenever this can be done in an automatic and transparent way. In cases where it is not easily possible to maintain state among all connections, such as when using `BEGIN TRANSACTION`, the plugin leaves it to the user to handle.

#### 21.9.6.5.2. Connection pooling and switching

Copyright 1997-2012 the PHP Documentation Group. [2906]

The replication and load balancing plugin changes the semantics of a PHP MySQL connection handle. The existing API of the PHP MySQL extensions (`mysqli`, `mysql`, and `PDO_MYSQL`) are not changed

in a way that functions are added or removed. But their behaviour changes when using the plugin. Existing applications do not need to be adapted to a new API, but they may need to be modified because of the behaviour changes.

The plugin breaks the one-by-one relationship between a [mysqli](#), [mysql](#), and [PDO\\_MYSQL](#) connection handle and a MySQL network connection. And a [mysqli](#), [mysql](#), and [PDO\\_MYSQL](#) connection handle represents a local pool of connections to the configured MySQL replication master and MySQL replication slave servers. The plugin redirects queries to the master and slave servers. At some point in time one and the same PHP connection handle may point to the MySQL master server. Later on, it may point to one of the slave servers or still the master. Manipulating and replacing the network connection referenced by a PHP MySQL connection handle is not a transparent operation.

Every MySQL connection has a state. The state of the connections in the connection pool of the plugin can differ. Whenever the plugin switches from one wire connection to another, the current state of the user connection may change. The applications must be aware of this.

The following list shows what the connection state consists of. The list may not be complete.

- Transaction status
- Temporary tables
- Table locks
- Session system variables and session user variables
- The current database set using [USE](#) and other state chaining SQL commands
- Prepared statements
- [HANDLER](#) variables
- Locks acquired with [GET\\_LOCK\( \)](#)

Connection switches happen right before queries are executed. The plugin does not switch the current connection until the next statement is executed.

#### Replication issues

See also the MySQL reference manual chapter about [replication features](#) and related issues. Some restrictions may not be related to the PHP plugin, but are properties of the MySQL replication system.

#### Broadcasted messages

The plugins philosophy is to align the state of connections in the pool only if the state is under full control of the plugin, or if it is necessary for security reasons. Just a few actions that change the state of the connection fall into this category.

The following is a list of connection client library calls that change state, and are broadcasted to all open connections in the connection pool.

If any of the listed calls below are to be executed, the plugin loops over all open master and slave connections. The loop continues until all servers have been contacted, and the loop does not break if a server indicates a failure. If possible, the failure will propagate to the called user API function, which may be detected depending on which underlying library function was triggered.

Library call	Notes	Version
<a href="#">change_user()</a>	Called by the <a href="#">mysqli_change_user</a> user API call. Also triggered upon reuse of a persistent <a href="#">mysqli</a> connection.	Since 1.0.0.

Library call	Notes	Version
<code>select_db</code>	Called by the following user API calls: <code>mysql_select_db</code> , <code>mysql_list_tables</code> , <code>mysql_db_query</code> , <code>mysql_list_fields</code> , <code>mysqli_select_db</code> . Note, that SQL <code>USE</code> is not monitored.	Since 1.0.0.
<code>set_charset</code>	Called by the following user API calls: <code>mysql_set_charset</code> , <code>mysqli_set_charset</code> . Note, that SQL <code>SET NAMES</code> is not monitored.	Since 1.0.0.
<code>set_server_option</code>	Called by the following user API calls: <code>mysqli_multi_query</code> , <code>mysqli_real_query</code> , <code>mysqli_query</code> , <code>mysql_query</code> .	Since 1.0.0.
<code>set_client_option</code>	Called by the following user API calls: <code>mysqli_options</code> , <code>mysqli_ssl_set</code> , <code>mysqli_connect</code> , <code>mysql_connect</code> , <code>mysql_pconnect</code> .	Since 1.0.0.
<code>set_autocommit</code>	Called by the following user API calls: <code>mysqli_autocommit</code> , <code>PDO::setAttribute(PDO::ATTR_AUTOCOMMIT)</code> .	Since 1.0.0. PHP >= 5.4.0.
<code>ssl_set</code>	Called by the following user API calls: <code>mysqli_ssl_set</code> .	Since 1.1.0.

### Broadcasting and lazy connections

The plugin does not proxy or “remember” all settings to apply them on connections opened in the future. This is important to remember, if using [lazy connections](#). Lazy connections are connections which are not opened before the client sends the first connection. Use of lazy connections is the default plugin action.

The following connection library calls each changed state, and their execution is recorded for later use when lazy connections are opened. This helps ensure that the connection state of all connections in the connection pool are comparable.

Library call	Notes	Version
<code>change_user</code>	User, password and database recorded for future use.	Since 1.1.0.
<code>select_db</code>	Database recorded for future use.	Since 1.1.0.
<code>set_charset</code>	Calls <code>(set_client_option(MYSQL_SET_CHARSET_NAME, charset))</code> on lazy connection to ensure <code>charset</code> will be used upon opening the lazy connection.	Since 1.1.0.
<code>set_autocommit</code>	Adds <code>SET AUTOCOMMIT=0 1</code> to the list of init commands of a lazy connection using <code>set_client_option(MYSQL_INIT_COMMAND, "SET AUTOCOMMIT=...%quot;)</code> .	Since 1.1.0. PHP >= 5.4.0.

### Connection state

The connection state is not only changed by API calls. Thus, even if PECL `mysqlnd_ms` monitors all API calls, the application must still be aware. Ultimately, it is the applications responsibility to maintain the connection state, if needed.

### Charsets and string escaping

Due to the use of lazy connections, which are a default, it can happen that an application tries to escape a string for use within SQL statements before a connection has been established. In this case string escaping is not possible. The string escape function does not know what charset to use before a connection has been established.

To overcome the problem a new configuration setting `server_charset` has been introduced in version 1.4.0.

Attention has to be paid on escaping strings with a certain charset but using the result on a connection that uses a different charset. Please note, that PECL/mysqlnd\_ms manipulates connections and one application level connection represents a pool of multiple connections that all may have different default charsets. It is recommended to configure the servers involved to use the same default charsets. The configuration setting `server_charset` does help with this situation as well. If using `server_charset`, the plugin will set the given charset on all newly opened connections.

### 21.9.6.5.3. Transaction handling

Copyright 1997-2012 the PHP Documentation Group. [2906]

Transaction handling is fundamentally changed. An SQL transaction is a unit of work that is run on one database server. The unit of work consists of one or more SQL statements.

By default the plugin is not aware of SQL transactions. The plugin may switch connections for load balancing at any point in time. Connection switches may happen in the middle of a transaction. This is against the nature of an SQL transaction. By default, the plugin is not transaction safe.

Any kind of MySQL load balancer must be hinted about the begin and end of a transaction. Hinting can either be done implicitly by monitoring API calls or using SQL hints. Both options are supported by the plugin, depending on your PHP version. API monitoring requires PHP 5.4.0 or newer. The plugin, like any other MySQL load balancer, cannot detect transaction boundaries based on the MySQL Client Server Protocol. Thus, entirely transparent transaction aware load balancing is not possible. The least intrusive option is API monitoring, which requires little to no application changes, depending on your application.

Please, find examples of using SQL hints or the API monitoring in the [examples section](#). The details behind the API monitoring, which makes the plugin transaction aware, are described below.

Beginning with PHP 5.4.0, the [mysqlnd](#) library allows this plugin to subclass the library C API call `set_autocommit()`, to detect the status of `autocommit` mode.

The PHP MySQL extensions either issue a query (such as `SET AUTOCOMMIT=0|1`), or use the `mysqlnd` library call `set_autocommit()` to control the `autocommit` setting. If an extension makes use of `set_autocommit()`, the plugin can be made transaction aware. Transaction awareness cannot be achieved if using SQL to set the `autocommit` mode. The library function `set_autocommit()` is called by the `mysqli_autocommit` and `PDO::setAttribute(PDO::ATTR_AUTOCOMMIT)` user API calls.

The plugin configuration option `trx_stickiness=master` can be used to make the plugin transactional aware. In this mode, the plugin stops load balancing if `autocommit` becomes disabled, and directs all statements to the master until `autocommit` gets enabled.

An application that does not want to set SQL hints for transactions but wants to use the transparent API monitoring to avoid application changes must make sure that the `autocommit` settings is changed exclusively through the listed API calls.

API based transaction boundary detection has been improved with PHP 5.5.0 and PECL/mysqlnd\_ms 1.5.0 to cover not only calls to `mysqli_autocommit` but also `mysqli_begin`, `mysqli_commit` and `mysqli_rollback`.

### 21.9.6.5.4. Error handling

Copyright 1997-2012 the PHP Documentation Group. [2906]

Applications using PECL/mysqlnd\_ms should implement proper error handling for all user API calls. And because the plugin changes the semantics of a connection handle, API calls may return unexpected errors. If using the plugin on a connection handle that no longer represents an individual network connection, but a connection pool, an error code and error message will be set on the connection handle whenever an error occurs on any of the network connections behind.

If using lazy connections, which is the default, connections are not opened until they are needed for query execution. Therefore, an API call for a statement execution may return a connection error. In the example below, an error is provoked when trying to run a statement on a slave. Opening a slave connection fails because the plugin configuration file lists an invalid host name for the slave.

**Example 21.254. Provoking a connection error**

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost",
        "socket": "\tmp\mysql.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "invalid_host_name",
      }
    },
    "lazy_connections": 1
  }
}
```

The explicit activation of lazy connections is for demonstration purpose only.

**Example 21.255. Connection error on query execution**

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (mysqli_connect_errno())
  /* Of course, your error handling is nicer... */
  die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Connection 1, connection bound SQL user variable, no SELECT thus run on master */
if (!$mysqli->query("SET @myrole='master'")) {
  printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}

/* Connection 2, run on slave because SELECT, provoke connection error */
if (!$res = $mysqli->query("SELECT @myrole AS _role")) {
  printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
} else {
  $row = $res->fetch_assoc();
  $res->close();
  printf("@myrole = '%s'\n", $row['_role']);
}
$mysqli->close();
?>
```

The above example will output something similar to:

```
PHP Warning: mysqli::query(): php_network_getaddresses: getaddrinfo failed: Name or service not known in %
PHP Warning: mysqli::query(): [2002] php_network_getaddresses: getaddrinfo failed: Name or service not kno
[2002] php_network_getaddresses: getaddrinfo failed: Name or service not known
```

Applications are expected to handle possible connection errors by implementing proper error handling.

Depending on the use case, applications may want to handle connection errors differently from other errors. Typical connection errors are `2002 (CR_CONNECTION_ERROR) - Can't connect to local MySQL server through socket '%s' (%d)`, `2003 (CR_CONN_HOST_ERROR)`

- Can't connect to MySQL server on '%s' (%d) and 2005 (CR\_UNKNOWN\_HOST) - Unknown MySQL server host '%s' (%d). For example, the application may test for the error codes and manually perform a fail over. The plugins philosophy is not to offer automatic fail over, beyond master fail over, because fail over is not a transparent operation.

### Example 21.256. Provoking a connection error

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "invalid_host_name"
      },
      "slave_1": {
        "host": "192.168.78.136"
      }
    },
    "lazy_connections": 1,
    "filters": {
      "roundrobin": [
        ]
      ]
    }
  }
}
```

Explicitly activating lazy connections is done for demonstration purposes, as is round robin load balancing as opposed to the default `random once` type.

### Example 21.257. Most basic failover

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
if (mysqli_connect_errno())
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Connection 1, connection bound SQL user variable, no SELECT thus run on master */
if (!$mysqli->query("SET @myrole='master'")) {
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
}

/* Connection 2, first slave */
$res = $mysqli->query("SELECT VERSION() AS _version");
/* Hackish manual fail over */
if (2002 == $mysqli->errno || 2003 == $mysqli->errno || 2004 == $mysqli->errno) {
    /* Connection 3, first slave connection failed, trying next slave */
    $res = $mysqli->query("SELECT VERSION() AS _version");
}

if (!$res) {
    printf("ERROR, [%d] '%s'\n", $mysqli->errno, $mysqli->error);
} else {
    /* Error messages are taken from connection 3, thus no error */
    printf("SUCCESS, [%d] '%s'\n", $mysqli->errno, $mysqli->error);
    $row = $res->fetch_assoc();
    $res->close();
    printf("version = %s\n", $row['_version']);
}
$mysqli->close();
?>
```

The above example will output something similar to:

```
[1045] Access denied for user 'username'@'localhost' (using password: YES)
PHP Warning: mysqli::query(): php_network_getaddresses: getaddrinfo failed: Name or service not known in 3
PHP Warning: mysqli::query(): [2002] php_network_getaddresses: getaddrinfo failed: Name or service not known
SUCCESS, [0] ''
version = 5.6.2-m5-log
```

In some cases, it may not be easily possible to retrieve all errors that occur on all network connections through a connection handle. For example, let's assume a connection handle represents a pool of three open connections. One connection to a master and two connections to the slaves. The application changes the current database using the user API call `mysqli_select_db`, which then calls the `mysqld` library function to change the schemata. `mysqld_ms` monitors the function, and tries to change the current database on all connections to harmonize their state. Now, assume the master succeeds in changing the database, and both slaves fail. Upon the initial error from the first slave, the plugin will set an appropriate error on the connection handle. The same is done when the second slave fails to change the database. The error message from the first slave is lost.

Such cases can be debugged by either checking for errors of the type `E_WARNING` (see above) or, if no other option, investigation of the [mysqld\\_ms debug and trace log](#).

### 21.9.6.5.5. Failover

Copyright 1997-2012 the PHP Documentation Group. [2906]

By default, connection failover handling is left to the user. The application is responsible for checking return values of the database functions it calls and reacting to possible errors. If, for example, the plugin recognizes a query as a read-only query to be sent to the slave servers, and the slave server selected by the plugin is not available, the plugin will raise an error after not executing the statement.

*Default: manual failover*

It is up to the application to handle the error and, if required, re-issue the query to trigger the selection of another slave server for statement execution. The plugin will make no attempts to failover automatically, because the plugin cannot ensure that an automatic failover will not change the state of the connection. For example, the application may have issued a query which depends on SQL user variables which are bound to a specific connection. Such a query might return incorrect results if the plugin would switch the connection implicitly as part of automatic failover. To ensure correct results, the application must take care of the failover, and rebuild the required connection state. Therefore, by default, no automatic failover is performed by the plugin.

A user that does not change the connection state after opening a connection may activate automatic failover. Please note, that automatic failover logic is limited to connection attempts. Automatic failover is not used for already established connections. There is no way to instruct the plugin to attempt failover on a connection that has been connected to MySQL already in the past.

*Automatic failover*

The failover policy is configured in the plugins configuration file, by using the [failover](#) configuration directive.

Automatic and silent failover can be enabled through the [failover](#) configuration directive. Automatic failover can either be configured to try exactly one master after a slave failure or, alternatively, loop over slaves and masters before returning an error to the user. The number of connection attempts can be limited and failed hosts can be excluded from future load balancing attempts. Limiting the number of retries and remembering failed hosts are considered experimental features, albeit being reasonable stable. Syntax and semantics may change in future versions.

Please note, since version 1.5.0 automatic failover is disabled for the duration of a transaction if transaction stickiness is enabled and transaction boundaries have been detected. The plugin will not switch connections for the duration of a transaction. It will also not perform automatic and silent failover. Instead an error will be thrown. It is then left to the user to handle the failure of the transaction. Please check, the [trx\\_stickiness](#) documentation how to do this.

A basic manual failover example is provided within the [error handling](#) section.

#### *Standby servers*

Using [weighted load balancing](#), introduced in PECL/mysqld 1.4.0, it is possible to configure standby servers that are sparsely used during normal operations. A standby server that is primarily used as a worst-case standby failover target can be assigned a very low weight/priority in relation to all other servers. As long as all servers are up and running the majority of the workload is assigned to the servers which have high weight values. Few requests will be directed to the standby system which has a very low weight value.

Upon failure of the servers with a high priority, you can still failover to the standby, which has been given a low load balancing priority by assigning a low weight to it. Failover can be done manually or automatically. If done automatically, you may want to combine it with the [remember\\_failed](#) option.

At this point, it is not possible to instruct the load balancer to direct no requests at all to a standby. This may not be much of a limitation given that the highest weight you can assign to a server is 65535. Given two slaves, of which one shall act as a standby and has been assigned a weight of 1, the standby will have to handle far less than one percent of the overall workload.

#### *Failover and primary copy*

Please note, if using a primary copy cluster, such as MySQL Replication, it is difficult to do connection failover in case of a master failure. At any time there is only one master in the cluster for a given dataset. The master is a single point of failure. If the master fails, clients have no target to fail over write requests. In case of a master outage the database administrator must take care of the situation and update the client configurations, if need be.

### **21.9.6.5.6. Load balancing**

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

Four load balancing strategies are supported to distribute statements over the configured MySQL slave servers:

random	Chooses a random server whenever a statement is executed.
random once (default)	Chooses a random server after the first statement is executed, and uses the decision for the rest of the PHP request.  It is the default, and the lowest impact on the connection state.
round robin	Iterates over the list of configured servers.
user-defined via callback	Is used to implement any other strategy.

The load balancing policy is configured in the plugins configuration file using the [random](#), [roundrobin](#), and [user filters](#).

Servers can be prioritized assigning a weight. A server that has been given a weight of two will get twice as many requests as a server that has been given the default weight of one. Prioritization can be handy in heterogenous environments. For example, you may want to assign more requests to a powerful machine than to a less powerful. Or, you may have configured servers that are close or far from the client, thus expose different latencies.

### 21.9.6.5.7. Read-write splitting

Copyright 1997-2012 the PHP Documentation Group. [2906]

The plugin executes read-only statements on the configured MySQL slaves, and all other queries on the MySQL master. Statements are considered read-only if they either start with `SELECT`, the SQL hint `/*ms=slave*/`, or if a slave had been chosen for running the previous query and the query starts with the SQL hint `/*ms=last_used*/`. In all other cases, the query will be sent to the MySQL replication master server. It is recommended to use the constants `MYSQLND_MS_SLAVE_SWITCH`, `MYSQLND_MS_MASTER_SWITCH` and `MYSQLND_MS_LAST_USED_SWITCH` instead of `/*ms=slave*/`. See also the [list of `mysqld\_ms` constants](#).

SQL hints are a special kind of standard compliant SQL comments. The plugin does check every statement for certain SQL hints. The SQL hints are described within the [`mysqld\_ms` constants](#) documentation, constants that are exported by the extension. Other systems involved with the statement processing, such as the MySQL server, SQL firewalls, and SQL proxies, are unaffected by the SQL hints, because those systems are designed to ignore SQL comments.

The built-in read-write splitter can be replaced by a user-defined filter, see also the [user filter](#) documentation.

A user-defined read-write splitter can request the built-in logic to send a statement to a specific location, by invoking `mysqld_ms_is_select`.

#### Note

The built-in read-write splitter is not aware of multi-statements. Multi-statements are seen as one statement. The splitter will check the beginning of the statement to decide where to run the statement. If, for example, a multi-statement begins with `SELECT 1 FROM DUAL; INSERT INTO test(id) VALUES (1); ...` the plugin will run it on a slave although the statement is not read-only.

### 21.9.6.5.8. Filter

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### Version requirement

Filters exist as of `mysqld_ms` version 1.1.0-beta.

**filters.** PHP applications that implement a MySQL replication cluster must first identify a group of servers in the cluster which could execute a statement before the statement is executed by one of the candidates. In other words: a defined list of servers must be filtered until only one server is available.

The process of filtering may include using one or more filters, and filters can be chained. And they are executed in the order they are defined in the plugins configuration file.

#### Explanation: comparing filter chaining to pipes

The concept of chained filters can be compared to using pipes to connect command line utilities on an operating system command shell. For example, an input stream is passed to a processor, filtered, and then transferred to be output. Then, the output is passed as input to the next command, which is connected to the previous using the pipe operator.

Available filters:

- Load balancing filters: [random](#) and [roundrobin](#).
- Selection filter: [user](#), [user\\_multi](#), [quality\\_of\\_service](#).

The `random` filter implements the 'random' and 'random once' load balancing policies. The 'round robin' load balancing can be configured through the `roundrobin` filter. Setting a 'user defined callback' for server selection is possible with the `user` filter. The `quality_of_service` filter finds cluster nodes capable of delivering a certain service, for example, read-your-writes or, not lagging more seconds behind the master than allowed.

Filters can accept parameters to change their behaviour. The `random` filter accepts an optional `sticky` parameter. If set to true, the filter changes load balancing from random to random once. Random picks a random server every time a statement is to be executed. Random once picks a random server when the first statement is to be executed and uses the same server for the rest of the PHP request.

One of the biggest strength of the filter concept is the possibility to chain filters. This strength does not become immediately visible because the `random`, `roundrobin` and `user` filters are supposed to output no more than one server. If a filter reduces the list of candidates for running a statement to only one server, it makes little sense to use that one server as input for another filter for further reduction of the list of candidates.

An example filter sequence that will fail:

- Statement to be executed: `SELECT 1 FROM DUAL`. Passed to all filters.
- All configured nodes are passed as input to the first filter. Master nodes: `master_0`. Slave nodes: `slave_0`, `slave_1`
- Filter: `random`, argument `sticky=1`. Picks a random slave once to be used for the rest of the PHP request. Output: `slave_0`.
- Output of `slave_0` and the statement to be executed is passed as input to the next filter. Here: `roundrobin`, server list passed to filter is: `slave_0`.
- Filter: `roundrobin`. Server list consists of one server only, round robin will always return the same server.

If trying to use such a filter sequence, the plugin may emit a warning like `(mysqld_ms) Error while creating filter '%s' . Non-multi filter '%s' already created. Stopping in %s on line %d`. Furthermore, an appropriate error on the connection handle may be set.

A second type of filter exists: multi filter. A multi filter emits zero, one or multiple servers after processing. The `quality_of_service` filter is an example. If the service quality requested sets an upper limit for the slave lag and more than one slave is lagging behind less than the allowed number of seconds, the filter returns more than one cluster node. A multi filter must be followed by other to further reduce the list of candidates for statement execution until a candidate is found.

A filter sequence with the `quality_of_service` multi filter followed by a load balancing filter.

- Statement to be executed: `SELECT sum(price) FROM orders WHERE order_id = 1`. Passed to all filters.
- All configured nodes are passed as input to the first filter. Master nodes: `master_0`. Slave nodes: `slave_0`, `slave_1`, `slave_2`, `slave_3`
- Filter: `quality_of_service`, rule set: `session_consistency (read-your-writes)` Output: `master_0`
- Output of `master_0` and the statement to be executed is passed as input to the next filter, which is `roundrobin`.
- Filter: `roundrobin`. Server list consists of one server. Round robin selects `master_0`.

A filter sequence must not end with a multi filter. If trying to use a filter sequence which ends with a multi filter the plugin may emit a warning like `(mysqld_ms) Error in configuration. Last`

`filter` is multi filter. Needs to be non-multi one. Stopping in %s on line %d. Furthermore, an appropriate error on the connection handle may be set.

### Speculation towards the future: MySQL replication filtering

In future versions, there may be additional multi filters. For example, there may be a `table` filter to support MySQL replication filtering. This would allow you to define rules for which database or table is to be replicated to which node of a replication cluster. Assume your replication cluster consists of four slaves (`slave_0`, `slave_1`, `slave_2`, `slave_3`) two of which replicate a database named `sales` (`slave_0`, `slave_1`). If the application queries the database `sales`, the hypothetical `table` filter reduces the list of possible servers to `slave_0` and `slave_1`. Because the output and list of candidates consists of more than one server, it is necessary and possible to add additional filters to the candidate list, for example, using a load balancing filter to identify a server for statement execution.

#### 21.9.6.5.9. Service level and consistency

Copyright 1997-2012 the PHP Documentation Group. [2906]

### Version requirement

Service levels have been introduced in `mysqlnd_ms` version 1.2.0-alpha. `mysqlnd_ms_set_qos` requires PHP 5.4.0 or newer.

The plugin can be used with different kinds of MySQL database clusters. Different clusters can deliver different levels of service to applications. The service levels can be grouped by the data consistency levels that can be achieved. The plugin knows about:

- eventual consistency
- session consistency
- strong consistency

Depending how a cluster is used it may be possible to achieve higher service levels than the default one. For example, a read from an asynchronous MySQL replication slave is eventual consistent. Thus, one may say the default consistency level of a MySQL replication cluster is eventual consistency. However, if the master only is used by a client for reading and writing during a session, session consistency (read your writes) is given. PECL `mysqlnd` 1.2.0 abstracts the details of choosing an appropriate node for any of the above service levels from the user.

Service levels can be set through the qualify-of-service filter in the [plugins configuration file](#) and at runtime using the function `mysqlnd_ms_set_qos`.

The plugin defines the different service levels as follows.

Eventual consistency is the default service provided by an asynchronous cluster, such as classical MySQL replication. A read operation executed on an arbitrary node may or may not return stale data. The applications view of the data is eventual consistent.

Session consistency is given if a client can always read its own writes. An asynchronous MySQL replication cluster can deliver session consistency if clients always use the master after the first write or never query a slave which has not yet replicated the clients write operation.

The plugins understanding of strong consistency is that all clients always see the committed writes of all other clients. This is the default when using MySQL Cluster or any other cluster offering synchronous data distribution.

*Service level parameters*

Eventual consistency and session consistency service level accept parameters.

Eventual consistency is the service provided by classical MySQL replication. By default, all nodes qualify for read requests. An optional `age` parameter can be given to filter out nodes which lag more than a certain number of seconds behind the master. The plugin is using `SHOW SLAVE STATUS` to measure the lag. Please, see the MySQL reference manual to learn about accuracy and reliability of the `SHOW SLAVE STATUS` command.

Session consistency (read your writes) accepts an optional `GTID` parameter to consider reading not only from the master but also from slaves which already have replicated a certain write described by its transaction identifier. This way, when using asynchronous MySQL replication, read requests may be load balanced over slaves while still ensuring session consistency.

The latter requires the use of [client-side global transaction id injection](#).

#### *Advantages of the new approach*

The new approach supersedes the use of SQL hints and the configuration option `master_on_write` in some respects. If an application running on top of an asynchronous MySQL replication cluster cannot accept stale data for certain reads, it is easier to tell the plugin to choose appropriate nodes than prefixing all read statements in question with the SQL hint to enforce the use of the master. Furthermore, the plugin may be able to use selected slaves for reading.

The `master_on_write` configuration option makes the plugin use the master after the first write (session consistency, read your writes). In some cases, session consistency may not be needed for the rest of the session but only for some, few read operations. Thus, `master_on_write` may result in more read load on the master than necessary. In those cases it is better to request a higher than default service level only for those reads that actually need it. Once the reads are done, the application can return to default service level. Switching between service levels is only possible using `mysqLnd_ms_set_qos`.

#### *Performance considerations*

A MySQL replication cluster cannot tell clients which slaves are capable of delivering which level of service. Thus, in some cases, clients need to query the slaves to check their status. PECL `mysqLnd_ms` transparently runs the necessary SQL in the background. However, this is an expensive and slow operation. SQL statements are run if eventual consistency is combined with an `age` (slave lag) limit and if session consistency is combined with a global transaction ID.

If eventual consistency is combined with an maximum `age` (slave lag), the plugin selects candidates for statement execution and load balancing for each statement as follows. If the statement is a write all masters are considered as candidates. Slaves are not checked and not considered as candidates. If the statement is a read, the plugin transparently executes `SHOW SLAVE STATUS` on every slaves connection. It will loop over all connections, send the statement and then start checking for results. Usually, this is slightly faster than a loop over all connections in which for every connection a query is send and the plugin waits for its results. A slave is considered a candidate if `SHOW SLAVE STATUS` reports `Slave_IO_Running=Yes`, `Slave_SQL_Running=Yes` and `Seconds_Behind_Master` is less or equal than the allowed maximum `age`. In case of an SQL error, the plugin emits a warning but does not set an error on the connection. The error is not set to make it possible to use the plugin as a drop-in.

If session consistency is combined with a global transaction ID, the plugin executes the SQL statement set with the `fetch_last_gtid` entry of the `global_transaction_id_injection` section from the plugins configuration file. Further details are identical to those described above.

In version 1.2.0 no additional optimizations are done for executing background queries. Future versions may contain optimizations, depending on user demand.

If no parameters and options are set, no SQL is needed. In that case, the plugin consider all nodes of the type shown below.

- eventual consistency, no further options set: all masters, all slaves
- session consistency, no further options set: all masters
- strong consistency (no options allowed): all masters

#### *Throttling*

The quality of service filter can be combined with [Global transaction IDs](#) to throttle clients. Throttling does reduce the write load on the master by slowing down clients. If session consistency is requested and global transactions identifier are used to check the status of a slave, the check can be done in two ways. By default a slave is checked and skipped immediately if it does not match the criteria for session consistency. Alternatively, the plugin can wait for a slave to catch up to the master until session consistency is possible. To enable the throttling, you have to set [wait\\_for\\_gtid\\_timeout](#) configuration option.

### 21.9.6.5.10. Global transaction IDs

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### **Version requirement**

Client side global transaction ID injection exists as of `mysqLnd_ms` version 1.2.0-alpha. Transaction boundaries are detected by monitoring API calls. This is possible as of PHP 5.4.0. Please, see also [Transaction handling](#).

As of MySQL 5.6.5-m8 the MySQL server features built-in global transaction identifiers. The MySQL built-in global transaction ID feature is supported by PECL/`mysqLnd_ms` 1.3.0-alpha or later. Neither are client-side transaction boundary monitoring nor any setup activities required if using the server feature.

#### *Idea and client-side emulation*

PECL/`mysqLnd_ms` can do client-side transparent global transaction ID injection. In its most basic form, a global transaction identifier is a counter which is incremented for every transaction executed on the master. The counter is held in a table on the master. Slaves replicate the counter table.

In case of a master failure a database administrator can easily identify the most recent slave for promoting it as a new master. The most recent slave has the highest transaction identifier.

Application developers can ask the plugin for the global transaction identifier (GTID) for their last successful write operation. The plugin will return an identifier that refers to a transaction no older than that of the clients last write operation. Then, the GTID can be passed as a parameter to the quality of service (QoS) filter as an option for session consistency. Session consistency ensures read your writes. The filter ensures that all reads are either directed to a master or a slave which has replicated the write referenced by the GTID.

#### *When injection is done*

The plugin transparently maintains the GTID table on the master. In autocommit mode the plugin injects an `UPDATE` statement before executing the users statement for every master use. In manual transaction mode, the injection is done before the application calls `commit()` to close a transaction. The configuration option `report_error` of the GTID section in the plugins configuration file is used to control whether a failed injection shall abort the current operation or be ignored silently (default).

Please note, the PHP version requirements for [transaction boundary monitoring](#) and their limits.

#### *Limitations*

Client-side global transaction ID injection has shortcomings. The potential issues are not specific to PECL/`mysqLnd_ms` but are rather of general nature.

- Global transaction ID tables must be deployed on all masters and replicas.
- The GTID can have holes. Only PHP clients using the plugin will maintain the table. Other clients will not.
- Client-side transaction boundary detection is based on API calls only.
- Client-side transaction boundary detection does not take implicit commit into account. Some MySQL SQL statements cause an implicit commit and cannot be rolled back.

*Using server-side global transaction identifier*

Starting with PECL/mysqlnd\_ms 1.3.0-alpha the MySQL 5.6.5-m8 or newer built-in global transaction identifier feature is supported. Use of the server feature lifts all of the above listed limitations. Please, see the MySQL Reference Manual for limitations and preconditions for using server built-in global transaction identifiers.

Whether to use the client-side emulation or the server built-in functionality is a question not directly related to the plugin, thus it is not discussed in depth. There are no plans to remove the client-side emulation and you can continue to use it, if the server-side solution is no option. This may be the case in heterogenous environments with old MySQL server or, if any of the server-side solution limitations is not acceptable.

From an applications perspective there is hardly a difference in using one or the other approach. The following properties differ.

- Client-side emulation, as shown in the manual, is using an easy to compare sequence number for global transactions. Multi-master is not handled to keep the manual examples easy.

Server-side built-in feature is using a combination of a server identifier and a sequence number as a global transaction identifier. Comparison cannot use numeric algebra. Instead a SQL function must be used. Please, see the MySQL Reference Manual for details.

- Plugin global transaction ID statistics are only available with client-side emulation because they monitor the emulation.

**Global transaction identifiers in distributed systems**

Global transaction identifiers can serve multiple purposes in the context of distributed systems, such as a database cluster. Global transaction identifiers can be used for, for example, system wide identification of transactions, global ordering of transactions, heartbeat mechanism and for checking the replication status of replicas. PECL/mysqlnd\_ms, a clientside driver based software, does focus on using GTIDs for tasks that can be handled at the client, such as checking the replication status of replicas for asynchronous replication setups.

**21.9.6.5.11. Cache integration**

Copyright 1997-2012 the PHP Documentation Group. [2906]

**Version requirement**

The feature requires use of PECL/mysqlnd\_ms 1.3.0-beta or later, and PECL/mysqlnd\_qc 1.1.0-alpha or newer. PECL/mysqlnd\_ms must be compiled to support the feature. PHP 5.4.0 or newer is required.

**Setup: extension load order**

PECL/mysqlnd\_ms must be loaded before PECL/mysqlnd\_qc, when using shared extensions.

### Feature stability

The cache integration is of beta quality.

### Suitable MySQL clusters

The feature is targeted for use with MySQL Replication (primary copy). Currently, no other kinds of MySQL clusters are supported. Users of such cluster must control PECL/[mysqld\\_qc](#) manually if they are interested in client-side query caching.

Support for MySQL replication clusters (asynchronous primary copy) is the main focus of PECL/[mysqld\\_ms](#). The slaves of a MySQL replication cluster may or may not reflect the latest updates from the master. Slaves are asynchronous and can lag behind the master. A read from a slave is eventual consistent from a cluster-wide perspective.

The same level of consistency is offered by a local cache using time-to-live (TTL) invalidation strategy. Current data or stale data may be served. Eventually, data searched for in the cache is not available and the source of the cache needs to be accessed.

Given that both a MySQL Replication slave (asynchronous secondary) and a local TTL-driven cache deliver the same level of service it is possible to transparently replace a remote database access with a local cache access to gain better possibility.

As of PECL/[mysqld\\_ms](#) 1.3.0-beta the plugin is capable of transparently controlling PECL/[mysqld\\_ms](#) 1.1.0-alpha or newer to cache a read-only query if explicitly allowed by setting an appropriate quality of service through [mysqld\\_ms\\_set\\_qos](#). Please, see the [quickstart](#) for a code example. Both plugins must be installed, PECL/[mysqld\\_ms](#) must be compiled to support the cache feature and PHP 5.4.0 or newer has to be used.

Applications have full control of cache usage and can request fresh data at any time, if need be. The cache usage can be enabled and disabled time during the execution of a script. The cache will be used if [mysqld\\_ms\\_set\\_qos](#) sets the quality of service to eventual consistency and enables cache usage. Cache usage is disabled by requesting higher consistency levels, for example, session consistency (read your writes). Once the quality of service has been relaxed to eventual consistency the cache can be used again.

If caching is enabled for a read-only statement, PECL/[mysqld\\_ms](#) may inject [SQL hints to control caching](#) by PECL/[mysqld\\_qc](#). It may modify the SQL statement it got from the application. Subsequent SQL processors are supposed to ignore the SQL hints. A SQL hint is a SQL comment. Comments must not be ignored, for example, by the database server.

The TTL of a cache entry is computed on a per statement basis. Applications set an maximum age for the data they want to retrieve using [mysqld\\_ms\\_set\\_qos](#). The age sets an approximate upper limit of how many seconds the data returned may lag behind the master.

The following logic is used to compute the actual TTL if caching is enabled. The logic takes the estimated slave lag into account for choosing a TTL. If, for example, there are two slaves lagging 5 and 10 seconds behind and the maximum age allowed is 60 seconds, the TTL is set to 50 seconds. Please note, the age setting is no more than an estimated guess.

- Check whether the statement is read-only. If not, don't cache.
- If caching is enabled, check the slave lag of all configured slaves. Establish slave connections if none exist so far and lazy connections are used.
- Send [SHOW SLAVE STATUS](#) to all slaves. Do not wait for the first slave to reply before sending to the second slave. Clients often wait long for replies, thus we send out all requests in a burst before fetching in a second stage.

- Loop over all slaves. For every slave wait for its reply. Do not start checking another slave before the currently waited for slave has replied. Check for [Slave\\_IO\\_Running=Yes](#) and [Slave\\_SQL\\_Running=Yes](#). If both conditions hold true, fetch the value of [Seconds\\_Behind\\_Master](#). In case of any errors or if conditions fail, set an error on the slave connection. Skip any such slave connection for the rest of connection filtering.
- Search for the maximum value of [Seconds\\_Behind\\_Master](#) from all slaves that passed the previous conditions. Subtract the value from the maximum age provided by the user with [mysqLnd\\_ms\\_set\\_qos](#). Use the result as a TTL.
- The filtering may sort out all slaves. If so, the maximum age is used as TTL, because the maximum lag found equals zero. It is perfectly valid to sort out all slaves. In the following it is up to subsequent filter to decide what to do. The built-in load balancing filter will pick the master.
- Inject the appropriate SQL hints to enable caching by PECL/mysqLnd\_qc.
- Proceed with the connection filtering, e.g. apply load balancing rules to pick a slave.
- PECL/mysqLnd\_qc is loaded after PECL/mysqLnd\_ms by PHP. Thus, it will see all query modifications of PECL/mysqLnd\_ms and cache the query if instructed to do so.

The algorithm may seem expensive. [SHOW SLAVE STATUS](#) is a very fast operation. Given a sufficient number of requests and cache hits per second the cost of checking the slaves lag can easily outweigh the costs of the cache decision.

Suggestions on a better algorithm are always welcome.

#### 21.9.6.5.12. Supported clusters

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

Any application using any kind of MySQL cluster is faced with the same tasks:

- Identify nodes capable of executing a given statement with the required service level
- Load balance requests within the list of candidates
- Automatic fail over within candidates, if needed

The plugin is optimized for fulfilling these tasks in the context of a classical asynchronous MySQL replication cluster consisting of a single master and many slaves (primary copy). When using classical, asynchronous MySQL replication all of the above listed tasks need to be mastered at the client side.

Other types of MySQL cluster may have lower requirements on the application side. For example, if all nodes in the cluster can answer read and write requests, no read-write splitting needs to be done (multi-master, update-all). If all nodes in the cluster are synchronous, they automatically provide the highest possible quality of service which makes choosing a node easier. In this case, the plugin may serve the application after some reconfiguration to disable certain features, such as built-in read-write splitting.

#### Documentation focus

The documentation focusses describing the use of the plugin with classical asynchronous MySQL replication clusters (primary copy). Support for this kind of cluster has been the original development goal. Use of other clusters is briefly described below. Please note, that this is still work in progress.

*Primary copy (MySQL Replication)*

This is the primary use case of the plugin. Follow the hints given in the descriptions of each feature.

- Configure one master and one or more slaves. [Server configuration details \[3280\]](#) are given in the setup section.
- Use random load balancing policy together with the `sticky` flag.
- If you do not plan to use the `service level` API calls, add the `master on write` flag.
- Please, make yourself aware of the properties of automatic failover before adding a `failover` directive.
- Consider the use of `trx_stickiness` to execute transactions on the primary only. Please, read carefully how it works before you rely on it.

#### Example 21.258. Enabling the plugin (`php.ini`)

```
mysqlnd_ms.enable=1
mysqlnd_ms.config_file=/path/to/mysqlnd_ms_plugin.ini
```

#### Example 21.259. Basic plugin configuration (`mysqlnd_ms_plugin.ini`) for MySQL Replication

```
{
  "myapp": {
    "master": {
      "master_1": {
        "host": "localhost",
        "socket": "\tmp\mysql57.sock"
      }
    },
    "slave": {
      "slave_0": {
        "host": "127.0.0.1",
        "port": 3308
      },
      "slave_1": {
        "host": "192.168.2.28",
        "port": 3306
      }
    },
    "filters": {
      "random": {
        "sticky": "1"
      }
    }
  }
}
```

#### *Primary copy with multi primaries (MMM - MySQL Multi Master)*

MySQL Replication allows you to create cluster topologies with multiple masters (primaries). Write-write conflicts are not handled by the replication system. This is no update anywhere setup. Thus, data must be partitioned manually and clients must be redirected in accordance to the partitioning rules. The recommended setup is equal to the sharding setup below.

#### *Manual sharding, possibly combined with primary copy and multiple primaries*

Use SQL hints and the node group filter for clusters that use data partitioning but leave query redirection to the client. The example configuration shows a multi master setup with two shards.

#### Example 21.260. Multiple primaries - multi master (`php.ini`)

```
mysqlnd_ms.enable=1
```

```
mysqlnd_ms.config_file=/path/to/mysqlnd_ms_plugin.ini
mysqlnd_ms.multi_master=1
```

### Example 21.261. Primary copy with multiple primaries and partitioning

```
{
  "myapp": {
    "master": {
      "master_1": {
        "host": "localhost",
        "socket": "\tmp\mysql57.sock"
      }
      "master_2": {
        "host": "192.168.2.27",
        "socket": "3306"
      }
    },
    "slave": {
      "slave_1": {
        "host": "127.0.0.1",
        "port": 3308
      },
      "slave_2": {
        "host": "192.168.2.28",
        "port": 3306
      }
    },
    "filters": {
      "node_groups": {
        "Partition_A": {
          "master": ["master_1"],
          "slave": ["slave_1"]
        },
        "Partition_B": {
          "master": ["master_2"],
          "slave": ["slave_2"]
        }
      }
    },
    "roundrobin": []
  }
}
```

The plugin can also be used with a loose collection of unrelated shards. For such a cluster, configure masters only and disable read write splitting. The nodes of such a cluster are called masters in the plugin configuration as they accept both reads and writes for their partition.

#### *Using synchronous update everywhere clusters such as MySQL Cluster*

MySQL Cluster is a synchronous cluster solution. All cluster nodes accept read and write requests. In the context of the plugin, all nodes shall be considered as masters.

Use the load balancing and fail over features only.

- Disable the plugins [built-in read-write splitting](#).
- Configure masters only.
- Consider random once load balancing strategy, which is the plugins default. If random once is used, only masters are configured and no SQL hints are used to force using a certain node, no connection switches will happen for the duration of a web request. Thus, no special handling is required for transactions. The plugin will pick one master at the beginning of the PHP script and use it until the script terminates.

- Do not set the quality of service. All nodes have all the data. This automatically gives you the highest possible service quality (strong consistency).
- Do not enable client-side global transaction injection. It is neither required to help with server-side fail over nor to assist the quality of service filter choosing an appropriate node.

Disabling built-in read-write splitting.

- Set `mysqld_ms.disable_rw_split=1`
- Do not use [SQL hints](#) to enforce the use of slaves

Configure masters only.

- Set `mysqld_ms.multi_master=1`.
- Do not configure any slaves.
- Set `failover=loop_before_master` in the plugins configuration file to avoid warnings about the empty slave list and to make the failover logic loop over all configured masters before emitting an error.

Please, note the warnings about automatic failover given in the previous sections.

#### Example 21.262. Multiple primaries - multi master (`php.ini`)

```
mysqld_ms.enable=1
mysqld_ms.config_file=/path/to/mysqld_ms_plugin.ini
mysqld_ms.multi_master=1
mysqld_ms.disable_rw_split=1
```

#### Example 21.263. Synchronous update anywhere cluster

```
"myapp": {
  "master": {
    "master_1": {
      "host": "localhost",
      "socket": "\\tmp\\mysql57.sock"
    },
    "master_2": {
      "host": "192.168.2.28",
      "port": 3306
    }
  },
  "slave": {
  },
  "filters": {
    "roundrobin": {
    }
  },
  "failover": {
    "strategy": "loop_before_master",
    "remember_failed": true
  }
}
```

If running an update everywhere cluster that has no built-in partitioning to avoid hot spots and high collision rates, consider using the node groups filter to keep updates on a frequently accessed table on one of the nodes. This may help to reduce collision rates and thus improve performance.

## 21.9.6.6. Installing/Configuring

Copyright 1997-2012 the PHP Documentation Group. [2906]

### 21.9.6.6.1. Requirements

Copyright 1997-2012 the PHP Documentation Group. [2906]

PHP 5.3.6 or newer. Some advanced functionality requires PHP 5.4.0 or newer.

The [mysqlnd\\_ms](#) replication and load balancing plugin supports all PHP applications and all available PHP MySQL extensions ([mysqli](#), [mysql](#), [PDO\\_MYSQL](#)). The PHP MySQL extension must be configured to use [mysqlnd](#) in order to be able to use the [mysqlnd\\_ms](#) plugin for [mysqlnd](#).

### 21.9.6.6.2. Installation

Copyright 1997-2012 the PHP Documentation Group. [2906]

This [PECL](#) extension is not bundled with PHP.

Information for installing this PECL extension may be found in the manual chapter titled [Installation of PECL extensions](#). Additional information such as new releases, downloads, source files, maintainer information, and a CHANGELOG, can be located here: [http://pecl.php.net/package/mysqlnd\\_ms](http://pecl.php.net/package/mysqlnd_ms)

A DLL for this PECL extension is currently unavailable. See also the [building on Windows](#) section.

### 21.9.6.6.3. Runtime Configuration

Copyright 1997-2012 the PHP Documentation Group. [2906]

The behaviour of these functions is affected by settings in [php.ini](#).

**Table 21.74. Mysqlnd\_ms Configure Options**

Name	Default	Changeable	Changelog
<a href="#">mysqlnd_ms.enable</a>	0	PHP_INI_SYSTEM	
<a href="#">mysqlnd_ms.force_config_usage</a>	0	PHP_INI_SYSTEM	
<a href="#">mysqlnd_ms.ini_file</a>	""	PHP_INI_SYSTEM	
<a href="#">mysqlnd_ms.config_file</a>	""	PHP_INI_SYSTEM	
<a href="#">mysqlnd_ms.collect_statistics</a>	0	PHP_INI_SYSTEM	
<a href="#">mysqlnd_ms.multi_master</a>	0	PHP_INI_SYSTEM	
<a href="#">mysqlnd_ms.disable_rw_split</a>	0	PHP_INI_SYSTEM	

Here's a short explanation of the configuration directives.

[mysqlnd\\_ms.enable](#) integer Enables or disables the plugin. If disabled, the extension will not plug into [mysqlnd](#) to proxy internal [mysqlnd](#) C API calls.

[mysqlnd\\_ms.force\\_config\\_usage](#) integer If enabled, the plugin checks if the host (server) parameters value of any MySQL connection attempt, matches a section name from the plugin configuration file. If not, the connection attempt is blocked.

This setting is not only useful to restrict PHP to certain servers but also to debug configuration file problems. The configuration file validity is checked at two different stages. The first check is performed when PHP begins to handle a web request. At this point the plugin reads and decodes the configuration file. Errors thrown

at this early stage in an extensions life cycle may not be shown properly to the user. Thus, the plugin buffers the errors, if any, and additionally displays them when establishing a connection to MySQL. By default a buffered startup error will emit an error of type `E_WARNING`. If `force_config_usage` is set, the error type used is `E_RECOVERABLE_ERROR`.

Please, see also [configuration file debugging notes \[3282\]](#).

`mysqlnd_ms.ini_file` string Plugin specific configuration file. This setting has been renamed to `mysqlnd_ms.config_file` in version 1.4.0.

`mysqlnd_ms.config_file` string Plugin specific configuration file. This setting supersedes `mysqlnd_ms.ini_file` since 1.4.0.

`mysqlnd_ms.collect_statistics` integer Enables or disables the collection of statistics. The collection of statistics is disabled by default for performance reasons. Statistics are returned by the function `mysqlnd_ms_get_stats`.

`mysqlnd_ms.multi_master` integer Enables or disables support of MySQL multi master replication setups. Please, see also [supported clusters](#).

`mysqlnd_ms.disable_rw_splitting` integer Enables or disables built-in read write splitting.

Controls whether load balancing and lazy connection functionality can be used independently of read write splitting. If read write splitting is disabled, only servers from the master list will be used for statement execution. All configured slave servers will be ignored.

The SQL hint `MYSQLND_MS_USE_SLAVE` will not be recognized. If found, the statement will be redirected to a master.

Disabling read write splitting impacts the return value of `mysqlnd_ms_query_is_select`. The function will no longer propose query execution on slave servers.

#### Multiple master servers

Setting `mysqlnd_ms.multi_master=1` allows the plugin to use multiple master servers, instead of only the first master server of the master list.

Please, see also [supported clusters](#).

#### 21.9.6.6.4. Plugin configuration file (>=1.1.x)

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### Changelog: Feature was added in PECL/mysqlnd\_ms 1.1.0-beta

The below description applies to PECL/mysqlnd\_ms >= 1.1.0-beta. It is not valid for prior versions.

The plugin uses its own configuration file. The configuration file holds information about the MySQL replication master server, the MySQL replication slave servers, the server pick (load balancing) policy, the failover strategy, and the use of lazy connections.

The plugin loads its configuration file at the beginning of a web request. It is then cached in memory and used for the duration of the web request. This way, there is no need to restart PHP after deploying the configuration file. Configuration file changes will become active almost instantly.

The PHP configuration directive `mysqld_ms.config_file` is used to set the plugins configuration file. Please note, that the PHP configuration directive may not be evaluated for every web request. Therefore, changing the plugins configuration file name or location may require a PHP restart. However, no restart is required to read changes if an already existing plugin configuration file is updated.

Using and parsing JSON is efficient, and using JSON makes it easier to express hierarchical data structures than the standard `php.ini` format.

#### Example 21.264. Converting a PHP array (hash) into JSON format

Or alternatively, a developer may be more familiar with the PHP array syntax, and prefer it. This example demonstrates how a developer might convert a PHP array to JSON.

```
<?php
$config = array(
    "myapp" => array(
        "master" => array(
            "master_0" => array(
                "host" => "localhost",
                "socket" => "/tmp/mysql.sock",
            ),
        ),
        "slave" => array(),
    ),
);

file_put_contents("mysqld_ms.ini", json_encode($config, JSON_PRETTY_PRINT));
printf("mysqld_ms.ini file created...\n");
printf("Dumping file contents...\n");
printf("%s\n", str_repeat("-", 80));
echo file_get_contents("mysqld_ms.ini");
printf("\n%s\n", str_repeat("-", 80));
?>
```

The above example will output:

```
mysqld_ms.ini file created...
Dumping file contents...
-----
{
    "myapp": {
        "master": {
            "master_0": {
                "host": "localhost",
                "socket": "\\tmp\\mysql.sock"
            }
        },
        "slave": [
        ]
    }
}
-----
```

A plugin configuration file consists of one or more sections. Sections are represented by the top-level object properties of the object encoded in the JSON file. Sections could also be called *configuration names*.

Applications reference sections by their name. Applications use section names as the host (server) parameter to the various connect methods of the [mysqli](#), [mysql](#) and [PDO\\_MYSQL](#) extensions. Upon connect, the [mysqld](#) plugin compares the hostname with all of the section names from the plugin

configuration file. If the hostname and section name match, then the plugin will load the settings for that section.

### Example 21.265. Using section names example

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.2.27"
      },
      "slave_1": {
        "host": "192.168.2.27",
        "port": 3306
      }
    }
  },
  "localhost": {
    "master": [
      {
        "host": "localhost",
        "socket": "\path\to\mysql.sock"
      }
    ],
    "slave": [
      {
        "host": "192.168.3.24",
        "port": "3305"
      },
      {
        "host": "192.168.3.65",
        "port": "3309"
      }
    ]
  }
}
```

```
<?php
/* All of the following connections will be load balanced */
$mysqli = new mysqli("myapp", "username", "password", "database");
$pdo = new PDO('mysql:host=myapp;dbname=database', 'username', 'password');
$mysql = mysql_connect("myapp", "username", "password");

$mysqli = new mysqli("localhost", "username", "password", "database");
?>
```

Section names are strings. It is valid to use a section name such as `192.168.2.1`, `127.0.0.1` or `localhost`. If, for example, an application connects to `localhost` and a plugin configuration section `localhost` exists, the semantics of the connect operation are changed. The application will no longer only use the MySQL server running on the host `localhost`, but the plugin will start to load balance MySQL queries following the rules from the `localhost` configuration section. This way you can load balance queries from an application without changing the applications source code. Please keep in mind, that such a configuration may not contribute to overall readability of your applications source code. Using section names that can be mixed up with host names should be seen as a last resort.

Each configuration section contains, at a minimum, a list of master servers and a list of slave servers. The master list is configured with the keyword `master`, while the slave list is configured with the `slave` keyword. Failing to provide a slave list will result in a fatal `E_ERROR` level error, although a slave list

may be empty. It is possible to allow no slaves. However, this is only recommended with synchronous clusters, please see also [supported clusters](#). The main part of the documentation focusses on the use of asynchronous MySQL replication clusters.

The master and slave server lists can be optionally indexed by symbolic names for the servers they describe. Alternatively, an array of descriptions for slave and master servers may be used.

#### Example 21.266. List of anonymous slaves

```
"slave": [
  {
    "host": "192.168.3.24",
    "port": "3305"
  },
  {
    "host": "192.168.3.65",
    "port": "3309"
  }
]
```

An anonymous server list is encoded by the [JSON array](#) type. Optionally, symbolic names may be used for indexing the slave or master servers of a server list, and done so using the [JSON object](#) type.

#### Example 21.267. Master list using symbolic names

```
"master": {
  "master_0": {
    "host": "localhost"
  }
}
```

It is recommended to index the server lists with symbolic server names. The alias names will be shown in error messages.

The order of servers is preserved and taken into account by `mysqld_ms`. If, for example, you configure round robin load balancing strategy, the first `SELECT` statement will be executed on the slave that appears first in the slave server list.

A configured server can be described with the `host`, `port`, `socket`, `db`, `user`, `password` and `connect_flags`. It is mandatory to set the database server host using the `host` keyword. All other settings are optional.

#### Example 21.268. Keywords to configure a server

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "db_server_host",
        "port": "db_server_port",
        "socket": "db_server_socket",
        "db": "database_resp_schema",
        "user": "user",
        "password": "password",
        "connect_flags": 0
      }
    },
    "slave": {
      "slave_0": {
        "host": "db_server_host",
```

```

        "port": "db_server_port",
        "socket": "db_server_socket"
    }
}
}
}

```

If a setting is omitted, the plugin will use the value provided by the user API call used to open a connection. Please, see the [using section names example \[3280\]](#) above.

The configuration file format has been changed in version 1.1.0-beta to allow for chained filters. Filters are responsible for filtering the configured list of servers to identify a server for execution of a given statement. Filters are configured with the `filter` keyword. Filters are executed by `mysqlnd_ms` in the order of their appearance. Defining filters is optional. A configuration section in the plugins configuration file does not need to have a `filters` entry.

Filters replace the `pick[]` setting from prior versions. The new `random` and `roundrobin` provide the same functionality.

**Example 21.269. New `roundrobin` filter, old functionality**

```

{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      },
      "slave_1": {
        "host": "192.168.78.137",
        "port": "3306"
      }
    },
    "filters": {
      "roundrobin": [
      ]
    }
  }
}

```

The function `mysqlnd_ms_set_user_pick_server` has been removed. Setting a callback is now done with the `user` filter. Some filters accept parameters. The `user` filter requires and accepts a mandatory `callback` parameter to set the callback previously set through the function `mysqlnd_ms_set_user_pick_server`.

**Example 21.270. The `user` filter replaces `mysqlnd_ms_set_user_pick_server`**

```

"filters": {
  "user": {
    "callback": "pick_server"
  }
}

```

The validity of the configuration file is checked both when reading the configuration file and later when establishing a connection. The configuration file is read during PHP request startup. At this early stage

a PHP extension may not display error messages properly. In the worst case, no error is shown and a connection attempt fails without an adequate error message. This problem has been cured in version 1.5.0.

**Example 21.271. Common error message in case of configuration file issues (upto version 1.5.0)**

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
?>
```

The above example will output:

```
Warning: mysqli::mysqli(): (mysqlnd_ms) (mysqlnd_ms) Failed to parse config file [s1.json]. Please, ver
Warning: mysqli::mysqli(): (HY000/2002): php_network_getaddresses: getaddrinfo failed: Name or service
Warning: mysqli::query(): Couldn't fetch mysqli in Command line code on line 1
Fatal error: Call to a member function fetch_assoc() on a non-object in Command line code on line 1
```

Since version 1.5.0 startup errors are additionally buffered and emitted when a connection attempt is made. Use the configuration directive [mysqlnd\\_ms.force\\_config\\_usage](#) to set the error type used to display buffered errors. By default an error of type [E\\_WARNING](#) will be emitted.

**Example 21.272. Improved configuration file validation since 1.5.0**

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
?>
```

The above example will output:

```
Warning: mysqli::mysqli(): (mysqlnd_ms) (mysqlnd_ms) Failed to parse config file [s1.json]. Please, ver
```

It can be useful to set [mysqlnd\\_ms.force\\_config\\_usage = 1](#) when debugging potential configuration file errors. This will not only turn the type of buffered startup errors into [E\\_RECOVERABLE\\_ERROR](#) but also help detecting misspelled section names.

**Example 21.273. Possibly more precise error due to [mysqlnd\\_ms.force\\_config\\_usage=1](#)**

```
mysqlnd_ms.force_config_usage=1
```

```
<?php
$mysqli = new mysqli("invalid_section", "username", "password", "database");
?>
```

The above example will output:

```
Warning: mysqli::mysqli(): (mysqlnd_ms) Exclusive usage of configuration enforced but did not find the
```

Here is a short explanation of the configuration directives that can be used.

`master` array or object

List of MySQL replication master servers. The list of either of the `JSON type array` to declare an anonymous list of servers or of the `JSON type object`. Please, see [above \[3280\]](#) for examples.

Setting at least one master server is mandatory. The plugin will issue an error of type `E_ERROR` if the user has failed to provide a master server list for a configuration section. The fatal error may read `(mysqlnd_ms) Section [master] doesn't exist for host [name_of_a_config_section] in %s on line %d`.

A server is described with the `host`, `port`, `socket`, `db`, `user`, `password` and `connect_flags`. It is mandatory to provide at a value for `host`. If any of the other values is not given, it will be taken from the user API connect call, please, see also: [using section names example \[3280\]](#).

Table of server configuration keywords.

Keyword	Description	Version
<code>host</code>	Database server host. This is a mandatory setting. Failing to provide, will cause an error of type <code>E_RECOVERABLE_ERROR</code> when the plugin tries to connect to the server. The error message may read <code>(mysqlnd_ms) Cannot find [host] in [%s] section in config in %s on line %d</code> .	Since 1.1.0.
<code>port</code>	Database server TCP/IP port.	Since 1.1.0.
<code>socket</code>	Database server Unix domain socket.	Since 1.1.0.
<code>db</code>	Database (schemata).	Since 1.1.0.
<code>user</code>	MySQL database user.	Since 1.1.0.
<code>password</code>	MySQL database user password.	Since 1.1.0.
<code>connect_flags</code>	Connection flags.	Since 1.1.0.

The plugin supports using only one master server. An experimental setting exists to enable multi-master support. The details are not documented. The setting is meant for development only.

`slave` array or object

List of one or more MySQL replication slave servers. The syntax is identical to setting master servers, please, see `master` above for details.

The plugin supports using one or more slave servers.

Setting a list of slave servers is mandatory. The plugin will report an error of the type `E_ERROR` if `slave` is not given for a configuration section. The fatal error message may read `(mysqlnd_ms) Section [slave] doesn't exist for host [%s] in %s on line %d`. Note, that it is valid to use an empty slave server list. The error has been introduced to prevent accidentally setting no slaves by forgetting about the `slave` setting. A master-only setup is still possible using an empty slave server list.

If an empty slave list is configured and an attempt is made to execute a statement on a slave the plugin may emit a warning like `(mysqld_ms) Couldn't find the appropriate slave connection. 0 slaves to choose from.` upon statement execution. It is possible that another warning follows such as `(mysqld_ms) No connection selected by the last filter.`

`global_transaction_id_injection` Global transaction identifier configuration related to both the use of the server built-in global transaction ID feature and the client-side emulation.

Keyword	Description	Version
<code>fetch_global_transaction_id</code>	SQL statement for accessing the latest global transaction identifier. The SQL statement is run if the plugin needs to know the most recent global transaction identifier. This can be the case, for example, when checking MySQL Replication slave status. Also used with <code>mysqld_ms_get_last_gtid</code> .	Since 1.2.0.
<code>check_replica_consistency</code>	SQL statement for checking if a replica has replicated all transactions up to and including ones searched for. The SQL statement is run when searching for replicas which can offer a higher level of consistency than eventual consistency. The statement must contain a placeholder <code>#GTID</code> which is to be replaced with the global transaction identifier searched for by the plugin. Please, check the <a href="#">quickstart</a> for examples.	Since 1.2.0.
<code>report_errors</code>	Whether to emit an error of type warning if an issue occurs while executing any of the configured SQL statements.	Since 1.2.0.
<code>on_completion</code>	Client-side global transaction ID emulation only. SQL statement to run when a transaction finished to update the global transaction identifier sequence number on the master. Please, see the <a href="#">quickstart</a> for examples.	Since 1.2.0.
<code>wait_for_slave</code>	Instructs the plugin to wait up to <code>wait_for_gtid_timeout</code> seconds for a slave to catch up when searching for slaves that can deliver session consistency. The setting limits the time spend for polling the slave status. If polling the status takes very long, the total clock time spend waiting may exceed <code>wait_for_gtid_timeout</code> . The plugin calls <code>sleep(1)</code> to sleep one second between each two polls.  The setting can be used both with the plugins client-side emulation and the server-side global transaction identifier feature of MySQL 5.6.  Waiting for a slave to replicate a certain GTID needed for session consistency also means	Since 1.4.0.

Keyword	Description	Version
	throttling the client. By throttling the client the write load on the master is reduced indirectly. A primary copy based replication system, such as MySQL Replication, is given more time to reach a consistent state. This can be desired, for example, to increase the number of data copies for high availability considerations or to prevent the master from being overloaded.	

`filters` object

List of filters. A filter is responsible to filter the list of available servers for executing a given statement. Filters can be chained. The `random` and `roundrobin` filter replace the `pick[ ]` directive used in prior version to select a load balancing policy. The `user` filter replaces the `mysqlnd_ms_set_user_pick_server` function.

Filters may accept parameters to refine their actions.

If no load balancing policy is set, the plugin will default to `random_once`. The `random_once` policy picks a random slave server when running the first read-only statement. The slave server will be used for all read-only statements until the PHP script execution ends. No load balancing policy is set and thus, defaulting takes place, if neither the `random` nor the `roundrobin` are part of a configuration section.

If a filter chain is configured so that a filter which output no more than once server is used as input for a filter which should be given more than one server as input, the plugin may emit a warning upon opening a connection. The warning may read: (`mysqlnd_ms`) `Error while creating filter '%s' . Non-multi filter '%s' already created. Stopping in %s on line %d`. Furthermore, an error of the error code `2000`, the sql state `HY000` and an error message similar to the warning may be set on the connection handle.

**Example 21.274. Invalid filter sequence**

```

{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "filters": [
      "roundrobin",
      "random"
    ]
  }
}

```

```
<?php
```

```
$link = new mysqli("myapp", "root", "", "test");
printf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error());
$link->query("SELECT 1 FROM DUAL");
?>
```

The above example will output:

```
PHP Warning: mysqli::mysqli(): (HY000/2000): (mysqlnd_ms) Error while
[2000] (mysqlnd_ms) Error while creating filter 'random' . Non-multi fi
PHP Warning: mysqli::query(): Couldn't fetch mysqli in filter_warning.
```

Filter: `random` object

The `random` filter features the `random` and `random once` load balancing policies, set through the `pick[]` directive in older versions.

The `random` policy will pick a random server whenever a read-only statement is to be executed. The `random once` strategy picks a random slave server once and continues using the slave for the rest of the PHP web request. `Random once` is a default, if load balancing is not configured through a filter.

If the `random` filter is not given any arguments, it stands for random load balancing policy.

#### Example 21.275. Random load balancing with `random` filter

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      },
      "slave_1": {
        "host": "192.168.78.137",
        "port": "3306"
      }
    }
  },
  "filters": [
    "random"
  ]
}
```

Optionally, the `sticky` argument can be passed to the filter. If the parameter `sticky` is set to the string `1`, the filter follows the `random once` load balancing strategy.

#### Example 21.276. Random once load balancing with `random` filter

```
{
  "filters": {
```

```

        "random": {
            "sticky": "1"
        }
    }
}

```

Both the `random` and `roundrobin` filters support setting a priority, a weight for a server, since PECL/mysqlnd\_ms 1.4.0. If the `weight` argument is passed to the filter, it must assign a weight for all servers. Servers must be given an alias name in the `slave` respectively `master` server lists. The alias must be used to reference servers for assigning a priority with `weight`.

#### Example 21.277. Referencing error

```
[E_RECOVERABLE_ERROR] mysqli_real_connect(): (mysqlnd_ms) Unknown server 's
```

Using a wrong alias name with `weight` may result in an error similar to the shown above.

If `weight` is omitted, the default weight of all servers is one.

#### Example 21.278. Assigning a `weight` for load balancing

```

{
    "myapp": {
        "master": {
            "master1": {
                "host": "localhost",
                "socket": "\/var\/run\/mysql\/mysql.sock"
            }
        },
        "slave": {
            "slave1": {
                "host": "192.168.2.28",
                "port": 3306
            },
            "slave2": {
                "host": "192.168.2.29",
                "port": 3306
            },
            "slave3": {
                "host": "192.0.43.10",
                "port": 3306
            }
        },
        "filters": {
            "random": {
                "weights": {
                    "slave1": 8,
                    "slave2": 4,
                    "slave3": 1,
                    "master1": 1
                }
            }
        }
    }
}

```

At the average a server assigned a weight of two will be selected twice as often as a server assigned a weight of one. Different

weights can be assigned to reflect differently sized machines, to prefer co-located slaves which have a low network latency or, to configure a standby failover server. In the latter case, you may want to assign the standby server a very low weight in relation to the other servers. For example, given the configuration above `slave3` will get only some eight percent of the requests in the average. As long as `slave1` and `slave2` are running, it will be used sparsely, similar to a standby failover server. Upon failure of `slave1` and `slave2`, the usage of `slave3` increases. Please, check the notes on failover before using `weight` this way.

Valid weight values range from 1 to 65535.

Unknown arguments are ignored by the filter. No warning or error is given.

The filter expects one or more servers as input. Outputs one server. A filter sequence such as `random`, `roundrobin` may cause a warning and an error message to be set on the connection handle when executing a statement.

List of filter arguments.

Keyword	Description	Version
<code>sticky</code>	Enables or disabled random once load balancing policy. See above.	Since 1.2.0.
<code>weight</code>	Assigns a load balancing weight/priority to a server. Please, see above for a description.	Since 1.4.0.

Filter: `roundrobin` object

If using the `roundrobin` filter, the plugin iterates over the list of configured slave servers to pick a server for statement execution. If the plugin reaches the end of the list, it wraps around to the beginning of the list and picks the first configured slave server.

**Example 21.279. `roundrobin` filter**

```

{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "filters": [
      "roundrobin"
    ]
  }
}

```

Expects one or more servers as input. Outputs one server. A filter sequence such as `roundrobin`, `random` may cause a warning and an error message to be set on the connection handle when executing a statement.

List of filter arguments.

Keyword	Description	Version
<code>weight</code>	Assigns a load balancing weight/priority to a server. Please, find a description <a href="#">above</a> .	Since 1.4.0.

Filter: `user` object

The `user` replaces `mysqld_ms_set_user_pick_server` function, which was removed in 1.1.0-beta. The filter sets a callback for user-defined read/write splitting and server selection.

The plugins built-in read/write query split mechanism decisions can be overwritten in two ways. The easiest way is to prepend a query string with the SQL hints `MYSQLND_MS_MASTER_SWITCH`, `MYSQLND_MS_SLAVE_SWITCH` or `MYSQLND_MS_LAST_USED_SWITCH`. Using SQL hints one can control, for example, whether a query shall be send to the MySQL replication master server or one of the slave servers. By help of SQL hints it is not possible to pick a certain slave server for query execution.

Full control on server selection can be gained using a callback function. Use of a callback is recommended to expert users only because the callback has to cover all cases otherwise handled by the plugin.

The plugin will invoke the callback function for selecting a server from the lists of configured master and slave servers. The callback function inspects the query to run and picks a server for query execution by returning the hosts URI, as found in the master and slave list.

If the lazy connections are enabled and the callback chooses a slave server for which no connection has been established so far and establishing the connection to the slave fails, the plugin will return an error upon the next action on the failed connection, for example, when running a query. It is the responsibility of the application developer to handle the error. For example, the application can re-run the query to trigger a new server selection and callback invocation. If so, the callback must make sure to select a different slave, or check slave availability, before returning to the plugin to prevent an endless loop.

#### Example 21.280. Setting a callback

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "filters": {
      "user": {
        "callback": "pick_server"
      }
    }
  }
}
```

```

    }
  }
}

```

The callback is supposed to return a host to run the query on. The host URI is to be taken from the master and slave connection lists passed to the callback function. If callback returns a value neither found in the master nor in the slave connection lists the plugin will emit an error of the type `E_RECOVERABLE_ERROR`. The error may read like `(mysqld_ms) User filter callback has returned an unknown server. The server 'server that is not in master or slave list' can neither be found in the master list nor in the slave list.` If the application catches the error to ignore it, follow up errors may be set on the connection handle, for example, `(mysqld_ms) No connection selected by the last filter with the error code 2000 and the sqlstate HY000.` Furthermore a warning may be emitted.

Referencing a non-existing function as a callback will result in any error of the type `E_RECOVERABLE_ERROR` whenever the plugin tries to callback function. The error message may reads like: `(mysqld_ms) Specified callback (pick_server) is not a valid callback.` If the application catches the error to ignore it, follow up errors may be set on the connection handle, for example, `(mysqld_ms) Specified callback (pick_server) is not a valid callback with the error code 2000 and the sqlstate HY000.` Furthermore a warning may be emitted.

The following parameters are passed from the plugin to the callback.

Parameter	Description	Version
<code>connection</code>	URI of the currently connected database server.	Since 1.1.0.
<code>query</code>	Query string of the statement for which a server needs to be picked.	Since 1.1.0.
<code>master</code>	List of master servers to choose from. Note, that the list of master servers may not be identical to the list of configured master servers if the filter is not the first in the filter chain. Previously run filters may have reduced the master list already.	Since 1.1.0.
<code>slave</code>	List of slave servers to choose from. Note, that the list of master servers may not be identical to the list of configured master servers if the filter is not the first in the filter chain. Previously run filters may have reduced the master list already.	Since 1.1.0.
<code>last_server</code>	URI of the server of the connection used to execute the previous statement on.	Since 1.1.0.
<code>in_transaction</code>	Boolean flag indicating whether the statement is part of an open transaction. If autocommit	Since 1.1.0.

Parameter	Description	Version
	<p>mode is turned off, this will be set to <code>TRUE</code> . Otherwise it is set to <code>FALSE</code> .</p> <p>Transaction detection is based on monitoring the <code>mysqlnd</code> library call <code>set_autocommit</code>. Monitoring is not possible before PHP 5.4.0. Please, see <a href="#">connection pooling and switching</a> concepts discussion for further details.</p>	

**Example 21.281. Using a callback**

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.2.27",
        "port": "3306"
      },
      "slave_1": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "filters": {
      "user": {
        "callback": "pick_server"
      }
    }
  }
}
```

```
<?php
function pick_server($connected, $query, $masters, $slaves, $last_used_conn)
{
  static $slave_idx = 0;
  static $num_slaves = NULL;
  if (is_null($num_slaves))
    $num_slaves = count($slaves);

  /* default: fallback to the plugins build-in logic */
  $ret = NULL;

  printf("User has connected to '%s'...\n", $connected);
  printf("... deciding where to run '%s'\n", $query);

  $where = mysqlnd_ms_query_is_select($query);
  switch ($where)
  {
    case MYSQLND_MS_QUERY_USE_MASTER:
      printf("... using master\n");
      $ret = $masters[0];
      break;
    case MYSQLND_MS_QUERY_USE_SLAVE:
      /* SELECT or SQL hint for using slave */
      if (strstr($query, "FROM table_on_slave_a_only"))
      {
        /* a table which is only on the first configured slave */
        printf("... access to table available only on slave A detected\n");
        $ret = $slaves[0];
      }
    }
  }
}
```

```

    }
    else
    {
        /* round robin */
        printf("... some read-only query for a slave\n");
        $ret = $slaves[$slave_idx++ % $num_slaves];
    }
    break;
case MYSQLND_MS_QUERY_LAST_USED:
    printf("... using last used server\n");
    $ret = $last_used_connection;
    break;
}

printf("... ret = '%s'\n", $ret);
return $ret;
}

$mysqli = new mysqli("myapp", "root", "", "test");

if (!$res = $mysqli->query("SELECT 1 FROM DUAL"))
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
else
    $res->close();

if (!$res = $mysqli->query("SELECT 2 FROM DUAL"))
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
else
    $res->close();

if (!$res = $mysqli->query("SELECT * FROM table_on_slave_a_only"))
    printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
else
    $res->close();

$mysqli->close();
?>

```

The above example will output:

```

User has connected to 'myapp'...
... deciding where to run 'SELECT 1 FROM DUAL'
... some read-only query for a slave
... ret = 'tcp://192.168.2.27:3306'
User has connected to 'myapp'...
... deciding where to run 'SELECT 2 FROM DUAL'
... some read-only query for a slave
... ret = 'tcp://192.168.78.136:3306'
User has connected to 'myapp'...
... deciding where to run 'SELECT * FROM table_on_slave_a_only'
... access to table available only on slave A detected
... ret = 'tcp://192.168.2.27:3306'

```

Filter: [user\\_multi](#) object

The [user\\_multi](#) differs from the [user](#) only in one aspect. Otherwise, their syntax is identical. The [user](#) filter must pick and return exactly one node for statement execution. A filter chain usually ends with a filter that emits only one node. The filter chain shall reduce the list of candidates for statement execution down to one. This, only one node left, is the case after the [user](#) filter has been run.

The [user\\_multi](#) filter is a multi filter. It returns a list of slave and a list of master servers. This list needs further filtering to identify

exactly one node for statement execution. A multi filter is typically placed at the top of the filter chain. The `quality_of_service` filter is another example of a multi filter.

The return value of the callback set for `user_multi` must be an array with two elements. The first element holds a list of selected master servers. The second element contains a list of selected slave servers. The lists shall contain the keys of the slave and master servers as found in the slave and master lists passed to the callback. The below example returns random master and slave lists extracted from the functions input.

### Example 21.282. Returning random masters and slaves

```
<?php
function pick_server($connected, $query, $masters, $slaves, $last_used_conn)
{
    $picked_masters = array()
    foreach ($masters as $key => $value) {
        if (mt_rand(0, 2) > 1)
            $picked_masters[] = $key;
    }
    $picked_slaves = array()
    foreach ($slaves as $key => $value) {
        if (mt_rand(0, 2) > 1)
            $picked_slaves[] = $key;
    }
    return array($picked_masters, $picked_slaves);
}
?>
```

The plugin will issue an error of type `E_RECOVERABLE` if the callback fails to return a server list. The error may read `(mysqlnd_ms) User multi filter callback has not returned a list of servers to use. The callback must return an array in %s on line %d`. In case the server list is not empty but has invalid servers key/ids in it, an error of type `E_RECOVERABLE` will be thrown with an error message like `(mysqlnd_ms) User multi filter callback has returned an invalid list of servers to use. Server id is negative in %s on line %d, or similar`.

Whether an error is emitted in case of an empty slave or master list depends on the configuration. If an empty master list is returned for a write operation, it is likely that the plugin will emit a warning that may read `(mysqlnd_ms) Couldn't find the appropriate master connection. 0 masters to choose from. Something is wrong in %s on line %d`. Typically a follow up error of type `E_ERROR` will happen. In case of a read operation and an empty slave list the behavior depends on the fail over configuration. If fail over to master is enabled, no error should appear. If fail over to master is deactivated the plugin will emit a warning that may read `(mysqlnd_ms) Couldn't find the appropriate slave connection. 0 slaves to choose from. Something is wrong in %s on line %d`.

Filter: `node_groups` object

The `node_groups` filter lets you group cluster nodes and query selected groups, for example, to support data partitioning. Data partitioning can be required for manual sharding, primary copy based clusters running multiple masters, or to avoid hot spots in

update everywhere clusters that have no built-in partitioning. The filter is a multi filter which returns zero, one or multiple of its input servers. Thus, it must be followed by other filters to reduce the number of candidates down to one for statement execution.

Keyword	Description	Version
<code>user defined node group name</code>	<p>One or more node groups must be defined. A node group can have an arbitrary user defined name. The name is used in combination with a SQL hint to restrict query execution to the nodes listed for the node group. To run a query on any of the servers of a node group, the query must begin with the SQL hint <code>/*user defined node group name*/</code>. Please note, no white space is allowed around <code>user defined node group name</code>. Because <code>user defined node group name</code> is used as-is as part of a SQL hint, you should choose the name that is compliant with the SQL language.</p> <p>Each node group entry must contain a list of <code>master</code> servers. Additional <code>slave</code> servers are allowed. Failing to provide a list of <code>master</code> for a node group <code>name_of_group</code> may cause an error of type <code>E_RECOVERABLE_ERROR</code> like <code>(mysqld_ms) No masters configured in node group 'name_of_group' for 'node_groups' filter</code>.</p> <p>The list of master and slave servers must reference corresponding entries in the <code>global master</code> respectively <code>slave</code> server list. Referencing an unknown server in either of the both server lists may cause an <code>E_RECOVERABLE_ERROR</code> error like <code>(mysqld_ms) Unknown master 'server_alias_name' (section 'name_of_group') in 'node_groups' filter configuration</code>.</p> <p><b>Example 21.283. Manual partitioning</b></p> <pre> {   "myapp": {     "master": {       "master_0": {         "host": "localhost",         "socket": "\\tmp\\mysql.sock"       },     },     "slave": {       "slave_0": {         "host": "192.168.2.28",         "port": 3306       },       "slave_1": {         "host": "127.0.0.1",         "port": 3311       }     }   }, } </pre>	Since 1.5.0.

Keyword	Description	Version
	<pre> filters: {   node_groups: {     Partition_A: {       master: ["master_0"],       slave: ["slave_0"]     },     roundrobin: []   } } </pre> <p>Please note, if a filter chain generates an empty slave list and the PHP configuration directive <code>mysqlnd_ms.multi_master=0</code> is used, the plugin may emit a warning.</p>	

Filter: `quality_of_service` object

The `quality_of_service` identifies cluster nodes capable of delivering a certain quality of service. It is a multi filter which returns zero, one or multiple of its input servers. Thus, it must be followed by other filters to reduce the number of candidates down to one for statement execution.

The `quality_of_service` filter has been introduced in 1.2.0-alpha. In the 1.2 series the filters focus is on the consistency aspect of service quality. Different types of clusters offer different default data consistencies. For example, an asynchronous MySQL replication slave offers eventual consistency. The slave may not be able to deliver requested data because it has not replicated the write, it may serve stale database because its lagging behind or it may serve current information. Often, this is acceptable. In some cases higher consistency levels are needed for the application to work correct. In those cases, the `quality_of_service` can filter out cluster nodes which cannot deliver the necessary quality of service.

The `quality_of_service` filter can be replaced or created at runtime. A successful call to `mysqlnd_ms_set_qos` removes all existing `qos` filter entries from the filter list and installs a new one at the very beginning. All settings that can be made through `mysqlnd_ms_set_qos` can also be in the plugins configuration file. However, use of the function is by far the most common use case. Instead of setting session consistency and strong consistency service levels in the plugins configuration file it is recommended to define only masters and no slaves. Both service levels will force the use of masters only. Using an empty slave list shortens the configuration file, thus improving readability. The only service level for which there is a case of defining in the plugins configuration file is the combination of eventual consistency and maximum slave lag.

Keyword	Description	Version
<code>eventual</code>	<p>Request eventual consistency. Allows the use of all master and slave servers. Data returned may or may not be current.</p> <p>Eventual consistency accepts an optional <code>age</code> parameter. If <code>age</code> is given the plugin</p>	Since 1.2.0.

Keyword	Description	Version
	<p>considers only slaves for reading for which MySQL replication reports a slave lag less or equal to <code>age</code>. The replication lag is measure using <code>SHOW SLAVE STATUS</code>. If the plugin fails to fetch the replication lag, the slave tested is skipped. Implementation details and tips are given in the <a href="#">quality of service concepts section</a>.</p> <p>Please note, if a filter chain generates an empty slave list and the PHP configuration directive <code>mysqLnd_ms.multi_master=0</code> is used, the plugin may emit a warning.</p> <p><b>Example 21.284. Global limit on slave lag</b></p> <pre data-bbox="767 725 1332 1473"> {   "myapp": {     "master": {       "master_0": {         "host": "localhost"       }     },     "slave": {       "slave_0": {         "host": "192.168.2.27",         "port": "3306"       },       "slave_1": {         "host": "192.168.78.136",         "port": "3306"       }     },     "filters": {       "quality_of_service": {         "eventual_consistency": {           "age": 123         }       }     }   } } </pre>	
<a href="#">session consistency</a>	<p><b>Request session consistency</b> (read your writes). Allows use of all masters and all slaves which are in sync with the master. If no further parameters are given slaves are filtered out as there is no reliable way to test if a slave has caught up to the master or is lagging behind. Please note, if a filter chain generates an empty slave list and the PHP configuration directive <code>mysqLnd_ms.multi_master=0</code> is used, the plugin may emit a warning.</p> <p>Session consistency temporarily requested using <code>mysqLnd_ms_set_qos</code> is a valuable alternative to using <code>master_on_write</code>. <code>master_on_write</code> is likely to send more statements to the master than needed. The application may be able to continue operation</p>	<p>Since 1.1.0.</p>

Keyword	Description	Version
	at a lower consistency level after it has done some critical reads.	
<code>strong</code>	Requests strong consistency. Only masters will be used.	Since 1.2.0.

`failover` Up to and including 1.3.x: string. Since 1.4.0: object.

Failover policy. Supported policies: `disabled` (default), `master`, `loop_before_master` (Since 1.4.0).

If no failover policy is set, the plugin will not do any automatic failover (`failover=disabled`). Whenever the plugin fails to connect a server it will emit a warning and set the connections error code and message. Thereafter it is up to the application to handle the error and, for example, resend the last statement to trigger the selection of another server.

Please note, the automatic failover logic is applied when opening connections only. Once a connection has been opened no automatic attempts are made to reopen it in case of an error. If, for example, the server a connection is connected to is shut down and the user attempts to run a statement on the connection, no automatic failover will be tried. Instead, an error will be reported.

If using `failover=master` the plugin will implicitly failover to a master, if available. Please check the concepts documentation to learn about potential pitfalls and risks of using `failover=master`.

**Example 21.285. Optional master failover when failing to connect to slave (PECL/mysqld\_ms < 1.4.0)**

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "failover": "master"
  }
}
```

Since PECL/mysqld\_ms 1.4.0 the failover configuration keyword refers to an object.

**Example 21.286. New syntax since 1.4.0**

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
```

```

        "slave_0": {
            "host": "192.168.78.136",
            "port": "3306"
        },
        "failover": {"strategy": "master" }
    }
}

```

Keyword	Description	Version
<code>strategy</code>	<p>Failover policy. Possible values: <code>disabled</code> (default), <code>master</code>, <code>loop_before_master</code></p> <p>A value of <code>disabled</code> disables automatic failover.</p> <p>Setting <code>master</code> instructs the plugin to try to connect to a master in case of a slave connection error. If the master connection attempt fails, the plugin enters the failover loop and returns an error to the user.</p> <p>If using <code>loop_before_master</code> and a slave request is made, the plugin tries to connect to other slaves before failing over to a master. If multiple masters are given and multi master is enabled, the plugin also loops over the list of masters and attempts to connect before returning an error to the user.</p>	Since 1.4.0.
<code>remember_failed</code>	<p>Remember failures for the duration of a web request. Default: <code>false</code>.</p> <p>If set to <code>true</code> the plugin will remember failed hosts and skip the hosts in all future load balancing made for the duration of the current web request.</p>	Since 1.4.0. The feature is only available together with the <code>random</code> and <code>roundrobin</code> load balancing filter. Use of the setting is recommended.
<code>max_retries</code>	<p>Maximum number of connection attempts before skipping host. Default: <code>0</code> (no limit).</p> <p>The setting is used to prevent hosts from being dropped of the host list upon the first failure. If set to <code>n &gt; 0</code>, the plugin will keep the node in the node list even after a failed connection attempt. The node will not be removed immediately from the slave respectively master lists after the first connection failure but instead be tried to connect to up to <code>n</code> times in future load balancing rounds before being removed.</p>	Since 1.4.0. The feature is only available together with the <code>random</code> and <code>roundrobin</code> load balancing filter.

[lazy\\_connections](#) bool

Setting [failover](#) to any other value but [disabled](#), [master](#) or [loop\\_before\\_master](#) will not emit any warning or error.

Controls the use of lazy connections. Lazy connections are connections which are not opened before the client sends the first connection. Lazy connections are a default.

It is strongly recommended to use lazy connections. Lazy connections help to keep the number of open connections low. If you disable lazy connections and, for example, configure one MySQL replication master server and two MySQL replication slaves, the plugin will open three connections upon the first call to a connect function although the application might use the master connection only.

Lazy connections bare a risk if you make heavy use of actions which change the state of a connection. The plugin does not dispatch all state changing actions to all connections from the connection pool. The few dispatched actions are applied to already opened connections only. Lazy connections opened in the future are not affected. Only some settings are "remembered" and applied when lazy connections are opened.

#### Example 21.287. Disabling lazy connection

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "lazy_connections": 0
  }
}
```

Please, see also [server\\_charset](#) to overcome potential problems with string escaping and servers using different default charsets.

[server\\_charset](#) string

The setting has been introduced in 1.4.0. It is recommended to set it if using lazy connections.

The [server\\_charset](#) setting serves two purposes. It acts as a fallback charset to be used for string escaping done before a connection has been established and it helps to avoid escaping pitfalls in heterogeneous environments which servers using different default charsets.

String escaping takes a connections charset into account. String escaping is not possible before a connection has been opened and the connections charset is known. The use of lazy connections delays the actual opening of connections until a statement is send.

An application using lazy connections may attempt to escape a string before sending a statement. In fact, this should be a common case as the statement string may contain the string that is to be escaped. However, due to the lazy connection feature no connection has been opened yet and escaping fails. The plugin may report an error of the type `E_WARNING` and a message like `(mysqlnd_ms) string escaping doesn't work without established connection. Possible solution is to add server_charset to your configuration` to inform you of the pitfall.

Setting `server_charset` makes the plugin use the given charset for string escaping done on lazy connection handles before establishing a network connection to MySQL. Furthermore, the plugin will enforce the use of the charset when the connection is established.

Enforcing the use of the configured charset used for escaping is done to prevent tapping into the pitfall of using a different charset for escaping than used later for the connection. This has the additional benefit of removing the need to align the charset configuration of all servers used. No matter what the default charset on any of the servers is, the plugin will set the configured one as a default.

The plugin does not stop the user from changing the charset at any time using the `set_charset` call or corresponding SQL statements. Please, note that the use of SQL is not recommended as it cannot be monitored by the plugin. The user can, for example, change the charset on a lazy connection handle after escaping a string and before the actual connection is opened. The charset set by the user will be used for any subsequent escaping before the connection is established. The connection will be established using the configured charset, no matter what the server charset is or what the user has set before. Once a connection has been opened, `set_charset` is of no meaning anymore.

#### Example 21.288. String escaping on a lazy connection handle

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "lazy_connections": 1,
    "server_charset" : "utf8"
  }
}
```

```
<?php
$mysqli = new mysqli("myapp", "username", "password", "database");
$mysqli->real_escape("this will be escaped using the server_charset set
```

```
$mysqlcli->set_charset("latin1");
$mysqlcli->real_escape("this will be escaped using latin1");
/* server_charset implicitly set - utf8 connection */
$mysqlcli->query("SELECT 'This connection will be set to server_charset upon
/* latin1 used from now on */
$mysqlcli->set_charset("latin1");
?>
```

`master_on_write` bool

If set, the plugin will use the master server only after the first statement has been executed on the master. Applications can still send statements to the slaves using SQL hints to overrule the automatic decision.

The setting may help with replication lag. If an application runs an `INSERT` the plugin will, by default, use the master to execute all following statements, including `SELECT` statements. This helps to avoid problems with reads from slaves which have not replicated the `INSERT` yet.

#### Example 21.289. Master on write for consistent reads

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "master_on_write": 1
  }
}
```

Please, note the `quality_of_service` filter introduced in version 1.2.0-alpha. It gives finer control, for example, for achieving read-your-writes and, it offers additional functionality introducing `service levels`.

All `transaction stickiness` settings, including `trx_stickiness=on`, are overruled by `master_on_write=1`.

`trx_stickiness` string

Transaction stickiness policy. Supported policies: `disabled` (default), `master`.

The setting requires 5.4.0 or newer. If used with PHP older than 5.4.0, the plugin will emit a warning like `(mysqlnd_ms) trx_stickiness strategy is not supported before PHP 5.3.99`.

If no transaction stickiness policy is set or, if setting `trx_stickiness=disabled`, the plugin is not transaction aware. Thus, the plugin may load balance connections and switch connections in the middle of a transaction. The plugin is not transaction safe. SQL hints must be used avoid connection switches during a transaction.

As of PHP 5.4.0 the `mysqlnd` library allows the plugin to monitor the `autocommit` mode set by calls to the libraries `set_autocommit()` function. If setting `set_stickiness=master` and `autocommit` gets disabled by a PHP MySQL extension invoking the `mysqlnd` library internal function call `set_autocommit()`, the plugin is made aware of the begin of a transaction. Then, the plugin stops load balancing and directs all statements to the master server until `autocommit` is enabled. Thus, no SQL hints are required.

An example of a PHP MySQL API function calling the `mysqlnd` library internal function call `set_autocommit()` is `mysqli_autocommit`.

Although setting `trx_stickiness=master`, the plugin cannot be made aware of `autocommit` mode changes caused by SQL statements such as `SET AUTOCOMMIT=0` or `BEGIN`.

As of PHP 5.5.0, the `mysqlnd` library features additional C API calls to control transactions. The level of control matches the one offered by SQL statements. The `mysqli` API has been modified to use these calls. Since version 1.5.0, PECL/`mysqlnd_ms` can monitor not only `mysqli_autocommit`, but also `mysqli_begin`, `mysqli_commit` and `mysqli_rollback` to detect transaction boundaries and stop load balancing for the duration of a transaction.

#### Example 21.290. Using master to execute transactions

```
{
  "myapp": {
    "master": {
      "master_0": {
        "host": "localhost"
      }
    },
    "slave": {
      "slave_0": {
        "host": "192.168.78.136",
        "port": "3306"
      }
    },
    "trx_stickiness": "master"
  }
}
```

Since version 1.5.0 automatic and silent failover is disabled for the duration of a transaction. If the boundaries of a transaction have been properly detected, transaction stickiness is enabled and a server fails, the plugin will not attempt to fail over to the next server, if any, regardless of the failover policy configured. The user must handle the error manually. Depending on the configuration, the plugin may emit an error of type `E_WARNING` reading like `(mysqlnd_ms) Automatic failover is not permitted in the middle of a transaction`. This error may then be overwritten by follow up errors such as `(mysqlnd_ms) No connection selected by the last filter`. Those errors will be generated by the failing query function.

### Example 21.291. No automatic failover, error handling pitfall

```
<?php
/* assumption: automatic failover configured */
$mysqli = new mysqli("myapp", "username", "password", "database");

/* sets plugin internal state in_trx = 1 */
$mysqli->autocommit(false);

/* assumption: server fails */
if (!$res = $mysqli->query("SELECT 'Assume this query fails' AS _msg FROM
/* handle failure of transaction, plugin internal state is still in_trx =
printf("[%d] %s", $mysqli->errno, $mysqli->error);
/*
If using autocommit() based transaction detection it is a
MUST to call autocommit(true). Otherwise the plugin assumes
the current transaction continues and connection
changes remain forbidden.
*/
$mysqli->autocommit(true);
/* Likewise, you'll want to start a new transaction */
$mysqli->autocommit(false);
}
/* latin1 used from now on */
$mysqli->set_charset("latin1");
?>
```

If a server fails in the middle of a transaction the plugin continues to refuse to switch connections until the current transaction has been finished. Recall that the plugin monitors API calls to detect transaction boundaries. Thus, you have to, for example, enable auto commit mode to end the current transaction before the plugin continues load balancing and switches the server. Likewise, you will want to start a new transaction immediately thereafter and disable auto commit mode again.

Not handling failed queries and not ending a failed transaction using API calls may cause all following commands emit errors such as [Commands out of sync; you can't run this command now](#). Thus, it is important to handle all errors.

#### 21.9.6.6.5. Plugin configuration file (<= 1.0.x)

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### Note

The below description applies to PECL/mysqld\_ms < 1.1.0-beta. It is not valid for later versions.

The plugin is using its own configuration file. The configuration file holds information on the MySQL replication master server, the MySQL replication slave servers, the server pick (load balancing) policy, the failover strategy and the use of lazy connections.

The PHP configuration directive [mysqld\\_ms.ini\\_file](#) is used to set the plugins configuration file.

The configuration file mimics standard the [php.ini](#) format. It consists of one or more sections. Every section defines its own unit of settings. There is no global section for setting defaults.

Applications reference sections by their name. Applications use section names as the host (server) parameter to the various connect methods of the [mysqli](#), [mysql](#) and [PDO\\_MYSQL](#) extensions.

Upon connect the `mysqld` plugin compares the hostname with all section names from the plugin configuration file. If hostname and section name match, the plugin will load the sections settings.

### Example 21.292. Using section names example

```
[myapp]
master[] = localhost
slave[] = 192.168.2.27
slave[] = 192.168.2.28:3306
[localhost]
master[] = localhost:/tmp/mysql/mysql.sock
slave[] = 192.168.3.24:3305
slave[] = 192.168.3.65:3309
```

```
<?php
/* All of the following connections will be load balanced */
$mysqli = new mysqli("myapp", "username", "password", "database");
$pdo = new PDO('mysql:host=myapp;dbname=database', 'username', 'password');
$mysql = mysql_connect("myapp", "username", "password");

$mysqli = new mysqli("localhost", "username", "password", "database");
?>
```

Section names are strings. It is valid to use a section name such as `192.168.2.1`, `127.0.0.1` or `localhost`. If, for example, an application connects to `localhost` and a plugin configuration section `[localhost]` exists, the semantics of the connect operation are changed. The application will no longer only use the MySQL server running on the host `localhost` but the plugin will start to load balance MySQL queries following the rules from the `[localhost]` configuration section. This way you can load balance queries from an application without changing the applications source code.

The `master[]`, `slave[]` and `pick[]` configuration directives use a list-like syntax. Configuration directives supporting list-like syntax may appear multiple times in a configuration section. The plugin maintains the order in which entries appear when interpreting them. For example, the below example shows two `slave[]` configuration directives in the configuration section `[myapp]`. If doing round-robin load balancing for read-only queries, the plugin will send the first read-only query to the MySQL server `mysql_slave_1` because it is the first in the list. The second read-only query will be send to the MySQL server `mysql_slave_2` because it is the second in the list. Configuration directives supporting list-like syntax result are ordered from top to bottom in accordance to their appearance within a configuration section.

### Example 21.293. List-like syntax

```
[myapp]
master[] = mysql_master_server
slave[] = mysql_slave_1
slave[] = mysql_slave_2
```

Here is a short explanation of the configuration directives that can be used.

`master[]` string

URI of a MySQL replication master server. The URI follows the syntax `hostname[:port|unix_domain_socket]`.

The plugin supports using only one master server.

Setting a master server is mandatory. The plugin will report a warning upon connect if the user has failed to provide a master server for a configuration section. The warning may read (`mysqld_ms`) `Cannot find master section in config.`

	<p>Furthermore the plugin may set an error code for the connection handle such as <code>HY000/2000 (CR_UNKNOWN_ERROR)</code>. The corresponding error message depends on your language settings.</p>
<code>slave[]</code> string	<p>URI of one or more MySQL replication slave servers. The URI follows the syntax <code>hostname[:port unix_domain_socket]</code>.</p> <p>The plugin supports using one or more slave servers.</p> <p>Setting a slave server is mandatory. The plugin will report a warning upon connect if the user has failed to provide at least one slave server for a configuration section. The warning may read <code>(mysqld_ms) Cannot find slaves section in config</code>. Furthermore the plugin may set an error code for the connection handle such as <code>HY000/2000 (CR_UNKNOWN_ERROR)</code>. The corresponding error message depends on your language settings.</p>
<code>pick[]</code> string	<p>Load balancing (server picking) policy. Supported policies: <code>random</code>, <code>random_once</code> (default), <code>roundrobin</code>, <code>user</code>.</p> <p>If no load balancing policy is set, the plugin will default to <code>random_once</code>. The <code>random_once</code> policy picks a random slave server when running the first read-only statement. The slave server will be used for all read-only statements until the PHP script execution ends.</p> <p>The <code>random</code> policy will pick a random server whenever a read-only statement is to be executed.</p> <p>If using <code>roundrobin</code> the plugin iterates over the list of configured slave servers to pick a server for statement execution. If the plugin reaches the end of the list, it wraps around to the beginning of the list and picks the first configured slave server.</p> <p>Setting more than one load balancing policy for a configuration section makes only sense in conjunction with <code>user</code> and <code>mysqld_ms_set_user_pick_server</code>. If the user defined callback fails to pick a server, the plugin falls back to the second configured load balancing policy.</p>
<code>failover</code> string	<p>Failover policy. Supported policies: <code>disabled</code> (default), <code>master</code>.</p> <p>If no failover policy is set, the plugin will not do any automatic failover (<code>failover=disabled</code>). Whenever the plugin fails to connect a server it will emit a warning and set the connections error code and message. Thereafter it is up to the application to handle the error and, for example, resent the last statement to trigger the selection of another server.</p> <p>If using <code>failover=master</code> the plugin will implicitly failover to a slave, if available. Please check the concepts documentation to learn about potential pitfalls and risks of using <code>failover=master</code>.</p>
<code>lazy_connections</code> bool	<p>Controls the use of lazy connections. Lazy connections are connections which are not opened before the client sends the first connection.</p> <p>It is strongly recommended to use lazy connections. Lazy connections help to keep the number of open connections low. If you disable lazy connections and, for example, configure one</p>

MySQL replication master server and two MySQL replication slaves, the plugin will open three connections upon the first call to a connect function although the application might use the master connection only.

Lazy connections bare a risk if you make heavy use of actions which change the state of a connection. The plugin does not dispatch all state changing actions to all connections from the connection pool. The few dispatched actions are applied to already opened connections only. Lazy connections opened in the future are not affected. If, for example, the connection character set is changed using a PHP MySQL API call, the plugin will change the character set of all currently opened connection. It will not remember the character set change to apply it on lazy connections opened in the future. As a result the internal connection pool would hold connections using different character sets. This is not desired. Remember that character sets are taken into account for escaping.

`master_on_write` bool

If set, the plugin will use the master server only after the first statement has been executed on the master. Applications can still send statements to the slaves using SQL hints to overrule the automatic decision.

The setting may help with replication lag. If an application runs an `INSERT` the plugin will, by default, use the master to execute all following statements, including `SELECT` statements. This helps to avoid problems with reads from slaves which have not replicated the `INSERT` yet.

`trx_stickiness` string

Transaction stickiness policy. Supported policies: `disabled` (default), `master`.

Experimental feature.

The setting requires 5.4.0 or newer. If used with PHP older than 5.4.0, the plugin will emit a warning like `(mysqlnd_ms) trx_stickiness strategy is not supported before PHP 5.3.99`.

If no transaction stickiness policy is set or, if setting `trx_stickiness=disabled`, the plugin is not transaction aware. Thus, the plugin may load balance connections and switch connections in the middle of a transaction. The plugin is not transaction safe. SQL hints must be used avoid connection switches during a transaction.

As of PHP 5.4.0 the `mysqlnd` library allows the plugin to monitor the `autocommit` mode set by calls to the libraries `trx_autocommit()` function. If setting `trx_stickiness=master` and `autocommit` gets disabled by a PHP MySQL extension invoking the `mysqlnd` library internal function call `trx_autocommit()`, the plugin is made aware of the begin of a transaction. Then, the plugin stops load balancing and directs all statements to the master server until `autocommit` is enabled. Thus, no SQL hints are required.

An example of a PHP MySQL API function calling the `mysqlnd` library internal function call `trx_autocommit()` is `mysqli_autocommit`.

Although setting `trx_stickiness=master`, the plugin cannot be made aware of `autocommit` mode changes caused by SQL statements such as `SET AUTOCOMMIT=0`.

### 21.9.6.6. Testing

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### Note

The section applies to `mysqlnd_ms` 1.1.0 or newer, not the 1.0 series.

The PECL/`mysqlnd_ms` test suite is in the `tests/` directory of the source distribution. The test suite consists of standard phpt tests, which are described on the PHP Quality Assurance Teams website.

Running the tests requires setting up one to four MySQL servers. Some tests don't connect to MySQL at all. Others require one server for testing. Some require two distinct servers. In some cases two servers are used to emulate a replication setup. In other cases a master and a slave of an existing MySQL replication setup are required for testing. The tests will try to detect how many servers and what kind of servers are given. If the required servers are not found, the test will be skipped automatically.

Before running the tests, edit `tests/config.inc` to configure the MySQL servers to be used for testing.

The most basic configuration is as follows.

```
putenv("MYSQL_TEST_HOST=localhost");
putenv("MYSQL_TEST_PORT=3306");
putenv("MYSQL_TEST_USER=root");
putenv("MYSQL_TEST_PASSWD=");
putenv("MYSQL_TEST_DB=test");
putenv("MYSQL_TEST_ENGINE=MyISAM");
putenv("MYSQL_TEST_SOCKET=");

putenv("MYSQL_TEST_SKIP_CONNECT_FAILURE=1");
putenv("MYSQL_TEST_CONNECT_FLAGS=0");
putenv("MYSQL_TEST_EXPERIMENTAL=0");

/* replication cluster emulation */
putenv("MYSQL_TEST_EMULATED_MASTER_HOST=". getenv("MYSQL_TEST_HOST"));
putenv("MYSQL_TEST_EMULATED_SLAVE_HOST=". getenv("MYSQL_TEST_HOST"));

/* real replication cluster */
putenv("MYSQL_TEST_MASTER_HOST=". getenv("MYSQL_TEST_EMULATED_MASTER_HOST"));
putenv("MYSQL_TEST_SLAVE_HOST=". getenv("MYSQL_TEST_EMULATED_SLAVE_HOST"));
```

`MYSQL_TEST_HOST`, `MYSQL_TEST_PORT` and `MYSQL_TEST_SOCKET` define the hostname, TCP/IP port and Unix domain socket of the default database server. `MYSQL_TEST_USER` and `MYSQL_TEST_PASSWD` contain the user and password needed to connect to the database/schema configured with `MYSQL_TEST_DB`. All configured servers must have the same database user configured to give access to the test database.

Using `host`, `host:port` or `host:/path/to/socket` syntax one can set an alternate host, host and port or host and socket for any of the servers.

```
putenv("MYSQL_TEST_SLAVE_HOST=192.168.78.136:3307");
putenv("MYSQL_TEST_MASTER_HOST=myserver_hostname:/path/to/socket");
```

```
| | | | | info : Freeing memory of members
| | | | | info : scheme=unix:///tmp/mysql.sock
| | | | | >mysqlnd_error_list_pdtor
| | | | | <mysqlnd_error_list_pdtor
| | | | | <mysqlnd_conn::free_contents
| | | | | <mysqlnd_conn::connect
[...]
```

The trace log can also be used to verify correct behaviour of PECL/`mysqlnd_ms` itself, for example, to check which server has been selected for query execution and why.

Example excerpt from the debug log (plugin decision):

```
[...]
>mysqlnd_ms::query
| info : query=DROP TABLE IF EXISTS test
| >_mysqlnd_plugin_get_plugin_connection_data
| info : plugin_id=5
| <_mysqlnd_plugin_get_plugin_connection_data
| >mysqlnd_ms_pick_server_ex
| | info : conn_data=0x7fb6a7d3e5a0 *conn_data=0x7fb6a7d410d0
| | >mysqlnd_ms_select_servers_all
| | <mysqlnd_ms_select_servers_all
| | >mysqlnd_ms_choose_connection_rr
| | >mysqlnd_ms_query_is_select
[...]
```

```
| | <mysqlnd_ms_query_is_select
[...]
```

```
| | info : Init the master context
| | info : list(0x7fb6a7d3f598) has 1
| | info : Using master connection
| | >mysqlnd_ms_advanced_connect
| | >mysqlnd_conn::connect
| | | info : host=localhost user=root db=test port=3306 flags=131072 persistent=0 state=0
```

In this case the statement `DROP TABLE IF EXISTS test` has been executed. Note that the statement string is shown in the log file. You may want to take measures to restrict access to the log for security considerations.

The statement has been load balanced using round robin policy, as you can easily guess from the functions name `>mysqlnd_ms_choose_connection_rr`. It has been sent to a master server running on `host=localhost user=root db=test port=3306 flags=131072 persistent=0 state=0`.

### 21.9.6.6.8. Monitoring

Copyright 1997-2012 the PHP Documentation Group. [2906]

Plugin activity can be monitored using the `mysqlnd` trace log, `mysqlnd` statistics, `mysqlnd_ms` plugin statistics and external PHP debugging tools. Use of the trace log should be limited to debugging. It is recommended to use the plugins statistics for monitoring.

Writing a trace log is a slow operation. If using an external PHP debugging tool, please refer to the vendors manual about its performance impact and the type of information collected. In many cases, external debugging tools will provide call stacks. Often, a call stack or a trace log is more difficult to interpret than the statistics provided by the plugin.

Plugin statistics tell how often which kind of cluster node has been used (slave or master), why the node was used, if lazy connections have been used and if global transaction ID injection has been performed. The monitoring information provided enables user to verify plugin decisions and to plan their cluster resources based on usage pattern. The function `mysqlnd_ms_get_stats` is used to access the statistics. Please, see the functions description for a list of available statistics.

Statistics are collected on a per PHP process basis. Their scope is a PHP process. Depending on the PHP deployment model a process may serve one or multiple web requests. If using CGI model, a PHP process serves one web request. If using FastCGI or pre-fork web server models, a PHP process usually serves multiple web requests. The same is the case with a threaded web server. Please, note that threads running in parallel can update the statistics in parallel. Thus, if using a threaded PHP deployment model, statistics can be changed by more than one script at a time. A script cannot rely on the fact that it sees only its own changes to statistics.

**Example 21.294. Verify plugin activity in a non-threaded deployment model**

```
mysqlnd_ms.enable=1
mysqlnd_ms.collect_statistics=1
```

```
<?php
/* Load balanced following "myapp" section rules from the plugins config file (not shown) */
$mysqli = new mysqli("myapp", "username", "password", "database");
if (mysqli_connect_errno())
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

$stats_before = mysqlnd_ms_get_stats();
if ($res = $mysqli->query("SELECT 'Read request' FROM DUAL")) {
    var_dump($res->fetch_all());
}
$stats_after = mysqlnd_ms_get_stats();
if ($stats_after['use_slave'] <= $stats_before['use_slave']) {
    echo "According to the statistics the read request has not been run on a slave!";
}
?>
```

Statistics are aggregated for all plugin activities and all connections handled by the plugin. It is not possible to tell how much a certain connection handle has contributed to the overall statistics.

Utilizing PHPs [register\\_shutdown\\_function](#) function or the [auto\\_append\\_file](#) PHP configuration directive it is easily possible to dump statistics into, for example, a log file when a script finishes. Instead of using a log file it is also possible to send the statistics to an external monitoring tool for recording and display.

**Example 21.295. Recording statistics during shutdown**

```
mysqlnd_ms.enable=1
mysqlnd_ms.collect_statistics=1
error_log=/tmp/php_errors.log
```

```
<?php
function check_stats() {
    $msg = str_repeat("-", 80) . "\n";
    $msg .= var_export(mysqlnd_ms_get_stats(), true) . "\n";
    $msg .= str_repeat("-", 80) . "\n";
    error_log($msg);
}
register_shutdown_function("check_stats");
?>
```

**21.9.6.7. Predefined Constants**

Copyright 1997-2012 the PHP Documentation Group. [2906]

The constants below are defined by this extension, and will only be available when the extension has either been compiled into PHP or dynamically loaded at runtime.

*SQL hint related*

**Example 21.296. Example demonstrating the usage of [mysqLnd\\_ms](#) constants**

The [mysqLnd](#) replication and load balancing plugin ([mysqLnd\\_ms](#)) performs read/write splitting. This directs write queries to a MySQL master server, and read-only queries to the MySQL slave servers. The plugin has a built-in read/write split logic. All queries which start with [SELECT](#) are considered read-only queries, which are then sent to a MySQL slave server that is listed in the plugin configuration file. All other queries are directed to the MySQL master server that is also specified in the plugin configuration file.

User supplied SQL hints can be used to overrule automatic read/write splitting, to gain full control on the process. SQL hints are standards compliant SQL comments. The plugin will scan the beginning of a query string for an SQL comment for certain commands, which then control query redirection. Other systems involved in the query processing are unaffected by the SQL hints because other systems will ignore the SQL comments.

The plugin supports three SQL hints to direct queries to either the MySQL slave servers, the MySQL master server, or the last used MySQL server. SQL hints must be placed at the beginning of a query to be recognized by the plugin.

For better portability, it is recommended to use the string constants [MYSQLND\\_MS\\_MASTER\\_SWITCH](#) , [MYSQLND\\_MS\\_SLAVE\\_SWITCH](#) and [MYSQLND\\_MS\\_LAST\\_USED\\_SWITCH](#) instead of their literal values.

```
<?php
/* Use constants for maximum portability */
$master_query = "/*" . MYSQLND_MS_MASTER_SWITCH . "*/SELECT id FROM test";

/* Valid but less portable: using literal instead of constant */
$slave_query = "/*ms=slave*/SHOW TABLES";

printf("master_query = '%s'\n", $master_query);
printf("slave_query = '%s'\n", $slave_query);
?>
```

The above examples will output:

```
master_query = /*ms=master*/SELECT id FROM test
slave_query = /*ms=slave*/SHOW TABLES
```

[MYSQLND\\_MS\\_MASTER\\_SWITCH](#) (string) SQL hint used to send a query to the MySQL replication master server.

[MYSQLND\\_MS\\_SLAVE\\_SWITCH](#) (string) SQL hint used to send a query to one of the MySQL replication slave servers.

[MYSQLND\\_MS\\_LAST\\_USED\\_SWITCH](#) (string) SQL hint used to send a query to the last used MySQL server. The last used MySQL server can either be a master or a slave server in a MySQL replication setup.

[mysqLnd\\_ms\\_query\\_is\\_select](#) related

[MYSQLND\\_MS\\_QUERY\\_USE\\_MASTER](#) (integer) **if** [mysqLnd\\_ms\\_is\\_select](#) returns [MYSQLND\\_MS\\_QUERY\\_USE\\_MASTER](#) for a given query, the built-in read/write split mechanism recommends sending the query to a MySQL replication master server.

- `MYSQLND_MS_QUERY_USE_SLAVE` (integer) If `mysqlnd_ms_is_select` returns `MYSQLND_MS_QUERY_USE_SLAVE` for a given query, the built-in read/write split mechanism recommends sending the query to a MySQL replication slave server.
- `MYSQLND_MS_QUERY_USE_LAST_USED` (integer) If `mysqlnd_ms_is_select` returns `MYSQLND_MS_QUERY_USE_LAST_USED` for a given query, the built-in read/write split mechanism recommends sending the query to the last used server.
- `mysqlnd_ms_set_qos`, quality of service filter and service level related
- `MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL` (integer) Use to request the service level eventual consistency from the `mysqlnd_ms_set_qos`. Eventual consistency is the default quality of service when reading from an asynchronous MySQL replication slave. Data returned in this service level may or may not be stale, depending on whether the selected slaves happen to have replicated the latest changes from the MySQL replication master or not.
- `MYSQLND_MS_QOS_CONSISTENCY_SESSION` (integer) Use to request the service level session consistency from the `mysqlnd_ms_set_qos`. Session consistency is defined as read your writes. The client is guaranteed to see his latest changes.
- `MYSQLND_MS_QOS_CONSISTENCY_STRONG` (integer) Use to request the service level strong consistency from the `mysqlnd_ms_set_qos`. Strong consistency is used to ensure all clients see each others changes.
- `MYSQLND_MS_QOS_OPTION_GTID` (integer) Used as a service level option with `mysqlnd_ms_set_qos` to parameterize session consistency.
- `MYSQLND_MS_QOS_OPTION_AGE` (integer) Used as a service level option with `mysqlnd_ms_set_qos` to parameterize eventual consistency.

*Other*

The plugins version number can be obtained using `MYSQLND_MS_VERSION` or `MYSQLND_MS_VERSION_ID`. `MYSQLND_MS_VERSION` is the string representation of the numerical version number `MYSQLND_MS_VERSION_ID`, which is an integer such as 10000. Developers can calculate the version number as follows.

Version (part)	Example
Major*10000	1*10000 = 10000
Minor*100	0*100 = 0
Patch	0 = 0
<code>MYSQLND_MS_VERSION_ID</code>	10000

`MYSQLND_MS_VERSION` (string) Plugin version string, for example, "1.0.0-prototype".

`MYSQLND_MS_VERSION_ID` (integer) Plugin version number, for example, 10000.

### 21.9.6.8. MySQLnd\_ms Functions

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### 21.9.6.8.1. mysqlnd\_ms\_get\_last\_gtid

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqlnd_ms_get_last_gtid`

Returns the latest global transaction ID

## Description

```
string mysqlnd_ms_get_last_gtid(
    mixed connection);
```

Returns a global transaction identifier which belongs to a write operation no older than the last write performed by the client. It is not guaranteed that the global transaction identifier is identical to that one created for the last write transaction performed by the client.

## Parameters

*connection*

A PECL/mysqlnd\_ms connection handle to a MySQL server of the type [PDO\\_MYSQL](#), [mysqli](#) or [ext/mysql](#). The connection handle is obtained when opening a connection with a host name that matches a [mysqlnd\\_ms](#) configuration file entry using any of the above three MySQL driver extensions.

## Return Values

Returns a global transaction ID (GTID) on success. Otherwise, returns [FALSE](#).

The function [mysqlnd\\_ms\\_get\\_last\\_gtid](#) returns the GTID obtained when executing the SQL statement from the [fetch\\_last\\_gtid](#) entry of the [global\\_transaction\\_id\\_injection](#) section from the plugins configuration file.

The function may be called after the GTID has been incremented.

## Notes

### Note

[mysqlnd\\_ms\\_get\\_last\\_gtid](#) requires PHP >= 5.4.0 and PECL [mysqlnd\\_ms](#) >= 1.2.0. Internally, it is using a [mysqlnd](#) library C functionality not available with PHP 5.3.

## Examples

### Example 21.297. [mysqlnd\\_ms\\_get\\_last\\_gtid](#) example

```
<?php
/* Open mysqlnd_ms connection using mysqli, PDO_MySQL or mysql extension */
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* auto commit mode, transaction on master, GTID must be incremented */
if (!$mysqli->query("DROP TABLE IF EXISTS test"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

printf("GTID after transaction %s\n", mysqlnd_ms_get_last_gtid($mysqli));

/* auto commit mode, transaction on master, GTID must be incremented */
if (!$mysqli->query("CREATE TABLE test(id INT)"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

printf("GTID after transaction %s\n", mysqlnd_ms_get_last_gtid($mysqli));
?>
```

## See Also

[Global Transaction IDs](#)

### 21.9.6.8.2. [mysqlnd\\_ms\\_get\\_last\\_used\\_connection](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_ms\\_get\\_last\\_used\\_connection](#)

Returns an array which describes the last used connection

#### Description

```
array mysqlnd_ms_get_last_used_connection(
    mixed connection);
```

Returns an array which describes the last used connection from the plugins connection pool currently pointed to by the user connection handle. If using the plugin, a user connection handle represents a pool of database connections. It is not possible to tell from the user connection handles properties to which database server from the pool the user connection handle points.

The function can be used to debug or monitor PECL [mysqlnd\\_ms](#).

#### Parameters

*connection* A MySQL connection handle obtained from any of the connect functions of the [mysqli](#), [mysql](#) or [PDO\\_MYSQL](#) extensions.

#### Return Values

[FALSE](#) on error. Otherwise, an array which describes the connection used to execute the last statement on.

Array which describes the connection.

Property	Description	Version
<a href="#">scheme</a>	Connection scheme. Either <code>tcp://host:port</code> or <code>unix://host:socket</code> . If you want to distinguish connections from each other use a combination of <a href="#">scheme</a> and <a href="#">thread_id</a> as a unique key. Neither <a href="#">scheme</a> nor <a href="#">thread_id</a> alone are sufficient to distinguish two connections from each other. Two servers may assign the same <a href="#">thread_id</a> to two different connections. Thus, connections in the pool may have the same <a href="#">thread_id</a> . Also, do not rely on uniqueness of <a href="#">scheme</a> in a pool. Your QA engineers may use the same MySQL server instance for two distinct logical roles and add it multiple times to the pool. This hack is used, for example, in the test suite.	Since 1.1.0.
<a href="#">host</a>	Database server host used with the connection. The host is only set with TCP/IP connections. It is empty with Unix domain or Windows named pipe connections,	Since 1.1.0.
<a href="#">host_info</a>	A character string representing the server hostname and the connection type.	Since 1.1.2.
<a href="#">port</a>	Database server port used with the connection.	Since 1.1.0.
<a href="#">socket_connection</a>	Unix domain socket or Windows named pipe used with the connection. The value is empty for TCP/IP connections.	Since 1.1.2.
<a href="#">thread_id</a>	Connection thread id.	Since 1.1.0.
<a href="#">last_message</a>	Info message obtained from the MySQL C API function <code>mysql_info()</code> . Please, see <a href="#">mysqli_info</a> for a description.	Since 1.1.0.
<a href="#">errno</a>	Error code.	Since 1.1.0.
<a href="#">error</a>	Error message.	Since 1.1.0.
<a href="#">sqlstate</a>	Error SQLstate code.	Since 1.1.0.

#### Notes

**Note**

`mysqlnd_ms_get_last_used_connection` requires PHP >= 5.4.0 and PECL `mysqlnd_ms` >> 1.1.0. Internally, it is using a `mysqlnd` library C call not available with PHP 5.3.

**Examples**

The example assumes that `myapp` refers to a plugin configuration file section and represents a connection pool.

**Example 21.298. `mysqlnd_ms_get_last_used_connection` example**

```
<?php
$link = new mysqli("myapp", "user", "password", "database");
$res = $link->query("SELECT 1 FROM DUAL");
var_dump(mysqlnd_ms_get_last_used_connection($link));
?>
```

The above example will output:

```
array(10) {
  ["scheme"]=>
  string(22) "unix:///tmp/mysql.sock"
  ["host_info"]=>
  string(25) "Localhost via UNIX socket"
  ["host"]=>
  string(0) ""
  ["port"]=>
  int(3306)
  ["socket_or_pipe"]=>
  string(15) "/tmp/mysql.sock"
  ["thread_id"]=>
  int(46253)
  ["last_message"]=>
  string(0) ""
  ["errno"]=>
  int(0)
  ["error"]=>
  string(0) ""
  ["sqlstate"]=>
  string(5) "00000"
}
```

**21.9.6.8.3. `mysqlnd_ms_get_stats`**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqlnd_ms_get_stats`

Returns query distribution and connection statistics

**Description**

```
array mysqlnd_ms_get_stats();
```

Returns an array of statistics collected by the replication and load balancing plugin.

The PHP configuration setting `mysqlnd_ms.collect_statistics` controls the collection of statistics. The collection of statistics is disabled by default for performance reasons.

The scope of the statistics is the PHP process. Depending on your deployment model a PHP process may handle one or multiple requests.

Statistics are aggregated for all connections and all storage handler. It is not possible to tell how much queries originating from `mysqli`, `PDO_MySQL` or `mysql` API calls have contributed to the aggregated data values.

**Parameters**

This function has no parameters.

**Return Values**

Returns `NULL` if the PHP configuration directive `mysqlnd_ms.enable` has disabled the plugin. Otherwise, returns array of statistics.

Array of statistics

Statistic	Description	Version
<code>use_slave</code>	<p>The semantics of this statistic has changed between 1.0.1 - 1.1.0.</p> <p>The meaning for version 1.0.1 is as follows. Number of statements considered as read-only by the built-in query analyzer. Neither statements which begin with a SQL hint to force use of slave nor statements directed to a slave by an user-defined callback are included. The total number of statements sent to the slaves is <code>use_slave + use_slave_sql_hint + use_slave_callback</code>.</p> <p>PECL/mysqlnd_ms 1.1.0 introduces a new concept of chained filters. The statistics is now set by the internal load balancing filter. With version 1.1.0 the load balancing filter is always the last in the filter chain, if used. In future versions a load balancing filter may be followed by other filters causing another change in the meaning of the statistic. If, in the future, a load balancing filter is followed by another filter it is no longer guaranteed that the statement, which increments <code>use_slave</code>, will be executed on the slaves.</p> <p>The meaning for version 1.1.0 is as follows. Number of statements sent to the slaves. Statements directed to a slave by the user filter (an user-defined callback) are not included. The latter are counted by <code>use_slave_callback</code>.</p>	Since 1.0.0.
<code>use_master</code>	<p>The semantics of this statistic has changed between 1.0.1 - 1.1.0.</p> <p>The meaning for version 1.0.1 is as follows. Number of statements not considered as read-only by the built-in query analyzer. Neither statements which begin with a SQL hint to force use of master nor statements directed to a master by an user-defined callback are included. The total number of statements sent to the master is <code>use_master + use_master_sql_hint + use_master_callback</code>.</p> <p>PECL/mysqlnd_ms 1.1.0 introduces a new concept of chained filters. The statistics is now set by the internal load balancing filter. With version 1.1.0 the load balancing filter is always the last in the filter chain, if used. In future versions a load balancing filter may be followed by other filters causing another change in the meaning of the statistic. If, in the future, a load balancing filter is followed by another filter it is no longer guaranteed that the statement, which increments <code>use_master</code>, will be executed on the slaves.</p> <p>The meaning for version 1.1.0 is as follows. Number of statements sent to the masters. Statements directed to a master by the user filter (an user-defined callback) are not included. The latter are counted by <code>use_master_callback</code>.</p>	Since 1.0.0.

Statistic	Description	Version
<code>use_slave_hint</code>	Number of statements the built-in query analyzer recommends sending to a slave because they contain no SQL hint to force use of a certain server. The recommendation may be overruled in the following. It is not guaranteed whether the statement will be executed on a slave or not. This is how often the internal <code>is_select</code> function has guessed that a slave shall be used. Please, see also the user space function <code>mysqlnd_ms_query_is_select</code> .	Since 1.1.0.
<code>use_master_hint</code>	Number of statements the built-in query analyzer recommends sending to a master because they contain no SQL hint to force use of a certain server. The recommendation may be overruled in the following. It is not guaranteed whether the statement will be executed on a slave or not. This is how often the internal <code>is_select</code> function has guessed that a master shall be used. Please, see also the user space function <code>mysqlnd_ms_query_is_select</code> .	Since 1.1.0.
<code>use_slave_hint_force</code>	Number of statements sent to a slave because statement begins with the SQL hint to force use of slave.	Since 1.0.0.
<code>use_master_hint_force</code>	Number of statements sent to a master because statement begins with the SQL hint to force use of master.	Since 1.0.0.
<code>use_last_used_server</code>	Number of statements sent to server which has run the previous statement, because statement begins with the SQL hint to force use of previously used server.	Since 1.0.0.
<code>use_slave_callback</code>	Number of statements sent to a slave because an user-defined callback has chosen a slave server for statement execution.	Since 1.0.0.
<code>use_master_callback</code>	Number of statements sent to a master because an user-defined callback has chosen a master server for statement execution.	Since 1.0.0.
<code>non_lazy_connections_slave_success</code>	Number of successfully opened slave connections from configurations not using <code>lazy connections</code> . The total number of successfully opened slave connections is <code>non_lazy_connections_slave_success + lazy_connections_slave_success</code>	Since 1.0.0.
<code>non_lazy_connections_slave_failure</code>	Number of failed slave connection attempts from configurations not using <code>lazy connections</code> . The total number of failed slave connection attempts is <code>non_lazy_connections_slave_failure + lazy_connections_slave_failure</code>	Since 1.0.0.
<code>non_lazy_connections_master_success</code>	Number of successfully opened master connections from configurations not using <code>lazy connections</code> . The total number of successfully opened master connections is <code>non_lazy_connections_master_success + lazy_connections_master_success</code>	Since 1.0.0.
<code>non_lazy_connections_master_failure</code>	Number of failed master connection attempts from configurations not using <code>lazy connections</code> . The total number of failed master connection attempts is <code>non_lazy_connections_master_failure + lazy_connections_master_failure</code>	Since 1.0.0.
<code>lazy_connections_slave_success</code>	Number of successfully opened slave connections from configurations using <code>lazy connections</code> .	Since 1.0.0.
<code>lazy_connections_slave_failure</code>	Number of failed slave connection attempts from configurations using <code>lazy connections</code> .	Since 1.0.0.
<code>lazy_connections_master_success</code>	Number of successfully opened master connections from configurations using <code>lazy connections</code> .	Since 1.0.0.
<code>lazy_connections_master_failure</code>	Number of failed master connection attempts from configurations using <code>lazy connections</code> .	Since 1.0.0.

Statistic	Description	Version
<code>trx_autocommit</code>	Number of <code>autocommit</code> mode activations via API calls. This figure may be used to monitor activity related to the plugin configuration setting <code>trx_stickiness</code> . If, for example, you want to know if a certain API call invokes the <code>mysqlnd</code> library function <code>trx_autocommit()</code> , which is a requirement for <code>trx_stickiness</code> , you may call the user API function in question and check if the statistic has changed. The statistic is modified only by the plugins internal subclassed <code>trx_autocommit()</code> method.	Since 1.0.0.
<code>trx_autocommit_deact</code>	Number of <code>autocommit</code> mode deactivations via API calls.	Since 1.0.0.
<code>trx_master</code>	Number of statements redirected to the master while <code>trx_stickiness=master</code> and <code>autocommit</code> mode is disabled.	Since 1.0.0.
<code>gtid_autocommit</code>	Number of successful SQL injections in <code>autocommit</code> mode as part of the plugins client-side <code>global transaction id emulation</code> .	Since 1.2.0.
<code>gtid_autocommit_fail</code>	Number of failed SQL injections in <code>autocommit</code> mode as part of the plugins client-side <code>global transaction id emulation</code> .	Since 1.2.0.
<code>gtid_commit</code>	Number of successful SQL injections in <code>commit</code> mode as part of the plugins client-side <code>global transaction id emulation</code> .	Since 1.2.0.
<code>gtid_commit_fail</code>	Number of failed SQL injections in <code>commit</code> mode as part of the plugins client-side <code>global transaction id emulation</code> .	Since 1.2.0.
<code>gtid_implicit</code>	Number of successful SQL injections when implicit commit is detected as part of the plugins client-side <code>global transaction id emulation</code> . Implicit commit happens, for example, when <code>autocommit</code> has been turned off, a query is executed and <code>autocommit</code> is enabled again. In that case, the statement will be committed by the server and SQL to maintain is injected before the <code>autocommit</code> is re-enabled. Another sequence causing an an implicit commit is <code>begin()</code> , <code>query()</code> , <code>begin()</code> . The second call to <code>begin()</code> will implicitly commit the transaction started by the first call to <code>begin()</code> . <code>begin()</code> refers to internal library calls not actual PHP user API calls.	Since 1.2.0.
<code>gtid_implicit_fail</code>	Number of failed SQL injections when implicit commit is detected as part of the plugins client-side <code>global transaction id emulation</code> . Implicit commit happens, for example, when <code>autocommit</code> has been turned off, a query is executed and <code>autocommit</code> is enabled again. In that case, the statement will be committed by the server and SQL to maintain is injected before the <code>autocommit</code> is re-enabled.	Since 1.2.0.

## Examples

### Example 21.299. `mysqlnd_ms_get_stats` example

```
<?php
printf("mysqlnd_ms.enable = %d\n", ini_get("mysqlnd_ms.enable"));
printf("mysqlnd_ms.collect_statistics = %d\n", ini_get("mysqlnd_ms.collect_statistics"));
var_dump(mysqlnd_ms_get_stats());
?>
```

The above example will output:

```
mysqlnd_ms.enable = 1
mysqlnd_ms.collect_statistics = 1
array(26) {
  ["use_slave"]=>
    string(1) "0"
```

```

#### 21.9.6.8.4. `mysqld_ms_match_wild`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqld_ms_match_wild`

Finds whether a table name matches a wildcard pattern or not

### Description

```
bool mysqlnd_ms_match_wild(
    string table_name,
    string wildcard);
```

Finds whether a table name matches a wildcard pattern or not.

This function is not of much practical relevance with PECL [mysqlnd\\_ms](#) 1.1.0 because the plugin does not support MySQL replication table filtering yet.

### Parameters

<i>table_name</i>	The table name to check if it is matched by the wildcard.
<i>wildcard</i>	The wildcard pattern to check against the table name. The wildcard pattern supports the same placeholders as MySQL replication filters do.  MySQL replication filters can be configured by using the MySQL Server configuration options <code>--replicate-wild-do-table</code> and <code>--replicate-wild-do-db</code> . Please, consult the MySQL Reference Manual to learn more about this MySQL Server feature.  The supported placeholders are: <ul style="list-style-type: none"> <li>• <code>%</code> - zero or more literals</li> <li>• <code>%</code> - one literal</li> </ul> Placeholders can be escaped using <code>\</code> .

### Return Values

Returns `TRUE` *table\_name* is matched by *wildcard*. Otherwise, returns `FALSE`

### Examples

#### Example 21.300. [mysqlnd\\_ms\\_match\\_wild](#) example

```
<?php
var_dump(mysqlnd_ms_match_wild("schema_name.table_name", "schema%"));
var_dump(mysqlnd_ms_match_wild("abc", "_"));
var_dump(mysqlnd_ms_match_wild("table1", "table_"));
var_dump(mysqlnd_ms_match_wild("asia_customers", "%customers"));
var_dump(mysqlnd_ms_match_wild("funny%table", "funny\\%table"));
var_dump(mysqlnd_ms_match_wild("funnytable", "funny%table"));
?>
```

The above example will output:

```
bool(true)
bool(false)
bool(true)
bool(true)
bool(true)
bool(true)
bool(true)
```

#### 21.9.6.8.5. [mysqlnd\\_ms\\_query\\_is\\_select](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_ms\\_query\\_is\\_select](#)

Find whether to send the query to the master, the slave or the last used MySQL server

## Description

```
int mysqlnd_ms_query_is_select(
    string query);
```

Finds whether to send the query to the master, the slave or the last used MySQL server.

The plugin's built-in read/write split mechanism will be used to analyze the query string to make a recommendation where to send the query. The built-in read/write split mechanism is very basic and simple. The plugin will recommend sending all queries to the MySQL replication master server but those which begin with `SELECT`, or begin with a SQL hint which enforces sending the query to a slave server. Due to the basic but fast algorithm the plugin may propose to run some read-only statements such as `SHOW TABLES` on the replication master.

## Parameters

*query* Query string to test.

## Return Values

A return value of `MYSQLND_MS_QUERY_USE_MASTER` indicates that the query should be sent to the MySQL replication master server. The function returns a value of `MYSQLND_MS_QUERY_USE_SLAVE` if the query can be run on a slave because it is considered read-only. A value of `MYSQLND_MS_QUERY_USE_LAST_USED` is returned to recommend running the query on the last used server. This can either be a MySQL replication master server or a MySQL replication slave server.

If read write splitting has been disabled by setting `mysqlnd_ms.disable_rw_split`, the function will always return `MYSQLND_MS_QUERY_USE_MASTER` or `MYSQLND_MS_QUERY_USE_LAST_USED`.

## Examples

### Example 21.301. `mysqlnd_ms_query_is_select` example

```
<?php
function is_select($query)
{
    switch (mysqlnd_ms_query_is_select($query))
    {
        case MYSQLND_MS_QUERY_USE_MASTER:
            printf("%s' should be run on the master.\n", $query);
            break;
        case MYSQLND_MS_QUERY_USE_SLAVE:
            printf("%s' should be run on a slave.\n", $query);
            break;
        case MYSQLND_MS_QUERY_USE_LAST_USED:
            printf("%s' should be run on the server that has run the previous query\n", $query);
            break;
        default:
            printf("No suggestion where to run the '%s', fallback to master recommended\n", $query);
            break;
    }
}

is_select("INSERT INTO test(id) VALUES (1)");
is_select("SELECT 1 FROM DUAL");
is_select("/* . MYSQLND_MS_LAST_USED_SWITCH . */SELECT 2 FROM DUAL");
?>
```

The above example will output:

```
INSERT INTO test(id) VALUES (1) should be run on the master.
```

```
SELECT 1 FROM DUAL should be run on a slave.
/*ms=last_used*/SELECT 2 FROM DUAL should be run on the server that has run the previous query
```

Sets the quality of service needed from the cluster

### Description

```
bool mysqlnd_ms_set_qos(
    mixed connection,
    int service_level,
    int service_level_option,
    mixed option_value);
```

Sets the quality of service needed from the cluster. A database cluster delivers a certain quality of service to the user depending on its architecture. A major aspect of the quality of service is the consistency level the cluster can offer. An asynchronous MySQL replication cluster defaults to eventual consistency for slave reads: a slave may serve stale data, current data, or it may have not the requested data at all, because it is not synchronous to the master. In a MySQL replication cluster, only master accesses can give strong consistency, which promises that all clients see each others changes.

PECL/mysqlnd\_ms hides the complexity of choosing appropriate nodes to achieve a certain level of service from the cluster. The "Quality of Service" filter implements the necessary logic. The filter can either be configured in the plugins configuration file, or at runtime using [mysqlnd\\_ms\\_set\\_qos](#).

Similar results can be achieved with PECL mysqlnd\_ms < 1.2.0, if using SQL hints to force the use of a certain type of node or using the [master\\_on\\_write](#) plugin configuration option. The first requires more code and causes more work on the application side. The latter is less refined than using the quality of service filter. Settings made through the function call can be reversed, as shown in the example below. The example temporarily switches to a higher service level (session consistency, read your writes) and returns back to the clusters default after it has performed all operations that require the better service. This way, read load on the master can be minimized compared to using [master\\_on\\_write](#), which would continue using the master after the first write.

Since 1.5.0 calls will fail when done in the middle of a transaction if [transaction stickiness](#) is enabled and transaction boundaries have been detected. properly.

### Parameters

*connection*

A PECL/mysqlnd\_ms connection handle to a MySQL server of the type [PDO\\_MYSQL](#), [mysqli](#) or [ext/mysqli](#) for which a service level is to be set. The connection handle is obtained when opening a connection with a host name that matches a [mysqlnd\\_ms](#) configuration file entry using any of the above three MySQL driver extensions.

*service\_level*

The requested service level:

[MYSQLND\\_MS\\_QOS\\_CONSISTENCY\\_EVENTUAL](#) ,

`MYSQLND_MS_QOS_CONSISTENCY_SESSION` or  
`MYSQLND_MS_QOS_CONSISTENCY_STRONG` .

*service\_level\_option*

An option to parameterize the requested service level. The option can either be `MYSQLND_MS_QOS_OPTION_GTID` or `MYSQLND_MS_QOS_OPTION_AGE` .

The option `MYSQLND_MS_QOS_OPTION_GTID` can be used to refine the service level `MYSQLND_MS_QOS_CONSISTENCY_SESSION` . It must be combined with a fourth function parameter, the *option\_value*. The *option\_value* shall be a global transaction ID obtained from `mysqlnd_ms_get_last_gtid`. If set, the plugin considers both master servers and asynchronous slaves for session consistency (read your writes). Otherwise, only masters are used to achieve session consistency. A slave is considered up-to-date and checked if it has already replicated the global transaction ID from *option\_value*. Please note, searching appropriate slaves is an expensive and slow operation. Use the feature sparsely, if the master cannot handle the read load alone.

The `MYSQLND_MS_QOS_OPTION_AGE` option can be combined with the `MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL` service level, to filter out asynchronous slaves that lag more seconds behind the master than *option\_value*. If set, the plugin will only consider slaves for reading if `SHOW SLAVE STATUS` reports `Slave_IO_Running=Yes`, `Slave_SQL_Running=Yes` and `Seconds_Behind_Master <= option_value`. Please note, searching appropriate slaves is an expensive and slow operation. Use the feature sparsely in version 1.2.0. Future versions may improve the algorithm used to identify candidates. Please, see the MySQL reference manual about the precision, accuracy and limitations of the MySQL administrative command `SHOW SLAVE STATUS`.

*option\_value*

Parameter value for the service level option. See also the *service\_level\_option* parameter.

## Return Values

Returns `TRUE` if the connections service level has been switched to the requested. Otherwise, returns `FALSE`

## Notes

### Note

`mysqlnd_ms_set_qos` requires PHP  $\geq$  5.4.0 and PECL `mysqlnd_ms`  $\geq$  1.2.0. Internally, it is using a `mysqlnd` library C functionality not available with PHP 5.3.

## Examples

### Example 21.302. `mysqlnd_ms_set_qos` example

```
<?php
/* Open mysqlnd_ms connection using mysqli, PDO_MySQL or mysql extension */
$mysqli = new mysqli("myapp", "username", "password", "database");
if (!$mysqli)
    /* Of course, your error handling is nicer... */
    die(sprintf("[%d] %s\n", mysqli_connect_errno(), mysqli_connect_error()));

/* Session consistency: read your writes */
```

```
$ret = mySQLnd_ms_set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_SESSION);
if (!$ret)
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Will use master and return fresh data, client can see his last write */
if (!$res = $mysqli->query("SELECT item, price FROM orders WHERE order_id = 1"))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

/* Back to default: use of all slaves and masters permitted, stale data can happen */
if (!$mysqli->set_qos($mysqli, MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL))
    die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));
?>
```

### 21.9.6.8.7. [mysqLnd\\_ms\\_set\\_user\\_pick\\_server](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqLnd\\_ms\\_set\\_user\\_pick\\_server](#)

Sets a callback for user-defined read/write splitting

### Description

```
bool mySQLnd_ms_set_user_pick_server(
    string function);
```

Sets a callback for user-defined read/write splitting. The plugin will call the callback only if `pick[]=user` is the default rule for server picking in the relevant section of the plugins configuration file.

The plugins built-in read/write query split mechanism decisions can be overwritten in two ways. The easiest way is to prepend the query string with the SQL hints [MYSQLND\\_MS\\_MASTER\\_SWITCH](#) , [MYSQLND\\_MS\\_SLAVE\\_SWITCH](#) or [MYSQLND\\_MS\\_LAST\\_USED\\_SWITCH](#) . Using SQL hints one can control, for example, whether a query shall be send to the MySQL replication master server or one of the slave servers. By help of SQL hints it is not possible to pick a certain slave server for query execution.

Full control on server selection can be gained using a callback function. Use of a callback is recommended to expert users only because the callback has to cover all cases otherwise handled by the plugin.

The plugin will invoke the callback function for selecting a server from the lists of configured master and slave servers. The callback function inspects the query to run and picks a server for query execution by returning the hosts URI, as found in the master and slave list.

If the lazy connections are enabled and the callback chooses a slave server for which no connection has been established so far and establishing the connection to the slave fails, the plugin will return an error upon the next action on the failed connection, for example, when running a query. It is the responsibility of the application developer to handle the error. For example, the application can re-run the query to trigger a new server selection and callback invocation. If so, the callback must make sure to select a different slave, or check slave availability, before returning to the plugin to prevent an endless loop.

### Parameters

*function*                      The function to be called. Class methods may also be invoked statically using this function by passing `array($classname,`

[\\$methodname](#)) to this parameter. Additionally class methods of an object instance may be called by passing [array\(\\$objectinstance, \\$methodname\)](#) to this parameter.

## Return Values

Host to run the query on. The host URI is to be taken from the master and slave connection lists passed to the callback function. If callback returns a value neither found in the master nor in the slave connection lists the plugin will fallback to the second pick method configured via the [pick\[\]](#) setting in the plugin configuration file. If not second pick method is given, the plugin falls back to the build-in default pick method for server selection.

## Notes

### Note

[mysqlnd\\_ms\\_set\\_user\\_pick\\_server](#) is available with PECL [mysqlnd\\_ms](#) < 1.1.0. It has been replaced by the [user](#) filter. Please, check the [Change History](#) for upgrade notes.

## Examples

### Example 21.303. [mysqlnd\\_ms\\_set\\_user\\_pick\\_server](#) example

```
[myapp]
master[] = localhost
slave[] = 192.168.2.27:3306
slave[] = 192.168.78.136:3306
pick[] = user
```

```
<?php

function pick_server($connected, $query, $master, $slaves, $last_used)
{
    static $slave_idx = 0;
    static $num_slaves = NULL;
    if (is_null($num_slaves))
        $num_slaves = count($slaves);

    /* default: fallback to the plugins build-in logic */
    $ret = NULL;

    printf("User has connected to '%s'...\n", $connected);
    printf("... deciding where to run '%s'\n", $query);

    $where = mysqlnd_ms_query_is_select($query);
    switch ($where)
    {
        case MYSQLND_MS_QUERY_USE_MASTER:
            printf("... using master\n");
            $ret = $master[0];
            break;
        case MYSQLND_MS_QUERY_USE_SLAVE:
            /* SELECT or SQL hint for using slave */
            if (striestr($query, "FROM table_on_slave_a_only"))
            {
                /* a table which is only on the first configured slave */
                printf("... access to table available only on slave A detected\n");
                $ret = $slaves[0];
            }
            else
            {
                /* round robin */
                printf("... some read-only query for a slave\n");
            }
    }
}
```

```

    $ret = $slaves[$slave_idx++ % $num_slaves];
  }
  break;
case MYSQLND_MS_QUERY_LAST_USED:
  printf("... using last used server\n");
  $ret = $last_used;
  break;
}

printf("... ret = '%s'\n", $ret);
return $ret;
}

mysqld_ms_set_user_pick_server("pick_server");

$mysqli = new mysqli("myapp", "root", "root", "test");

if (!$res = $mysqli->query("SELECT 1 FROM DUAL"))
  printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
else
  $res->close();

if (!$res = $mysqli->query("SELECT 2 FROM DUAL"))
  printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
else
  $res->close();

if (!$res = $mysqli->query("SELECT * FROM table_on_slave_a_only"))
  printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
else
  $res->close();

$mysqli->close();
?>

```

The above example will output:

```

User has connected to 'myapp'...
... deciding where to run 'SELECT 1 FROM DUAL'
... some read-only query for a slave
... ret = 'tcp://192.168.2.27:3306'
User has connected to 'myapp'...
... deciding where to run 'SELECT 2 FROM DUAL'
... some read-only query for a slave
... ret = 'tcp://192.168.78.136:3306'
User has connected to 'myapp'...
... deciding where to run 'SELECT * FROM table_on_slave_a_only'
... access to table available only on slave A detected
... ret = 'tcp://192.168.2.27:3306'

```

## 21.9.6.9. Change History

Copyright 1997-2012 the PHP Documentation Group. [2906]

This change history is a high level summary of selected changes that may impact applications and/or break backwards compatibility.

See also the [CHANGES](#) file in the source distribution for a complete list of changes.

### 21.9.6.9.1. PECL/mysqlnd\_ms 1.5 series

Copyright 1997-2012 the PHP Documentation Group. [2906]

1.5.0-alpha

- Release date: 03/2013
- Motto/theme: Sharding support, improved transaction support

#### Note

This is the current development series. All features are at an early stage. Changes may happen at any time without prior notice. Please, do not use this version in production environments.

The documentation may not reflect all changes yet.

#### Bug fixes

- Fixed #60605 PHP segmentation fault when `mysqlnd_ms` is enabled.
- Setting transaction stickiness disables all load balancing, including automatic failover, for the duration of a transaction. So far connection switches could have happened in the middle of a transaction in multi-master configurations and during automatic failover although transaction monitoring had detected transaction boundaries properly.
- BC break and bug fix. SQL hints enforcing the use of a specific kind of server ( `MYSQLND_MS_MASTER_SWITCH` , `MYSQLND_MS_SLAVE_SWITCH` , `MYSQLND_MS_LAST_USED_SWITCH` ) are ignored for the duration of a transaction of transaction stickiness is enabled and transaction boundaries have been detected properly.

This is a change in behaviour. However, it is also a bug fix and a step to align behaviour. If, in previous versions, transaction stickiness, one of the above listed SQL hints and the quality of service filtering was combined it could happen that the SQL hints got ignored. In some cases the SQL hints did work, in other cases they did not. The new behaviour is more consistent. SQL hints will always be ignored for the duration of a transaction, if [transaction stickiness](#) is enabled.

Please note, transaction boundary detection continues to be based on API call monitoring. SQL commands controlling transactions are not monitored.

- BC break and bug fix. Calls to `mysqlnd_ms_set_qos` will fail when done in the middle of a transaction if [transaction stickiness](#) is enabled. Connection switches are not allowed for the duration of a transaction. Changing the quality of service likely results on a different set of servers qualifying for query execution, possibly making it necessary to switch connections. Thus, the call is not allowed in during an active transaction. The quality of server can, however, be changed in between transactions.

#### Feature changes

- Introduced the `node_group` filter. The filter lets you organize servers (master and slaves) into groups. Queries can be directed to a certain group of servers by prefixing the query statement with a SQL hint/comment that contains the groups configured name. Grouping can be used for partitioning and sharding, and also to optimize for local caching. In the case of sharding, a group name can be thought of like a shard key. All queries for a given shard key will be executed on the configured shard. Note: both the client and server must support sharding for sharding to function with `mysqlnd_ms`.
- Extended configuration file validation during PHP startup (RINIT). An `E_WARNING` level error will be thrown if the configuration file can not be read (permissions), is empty, or the file (JSON) could not be parsed. Warnings may appear in log files, which depending on how PHP is configured.

Distributions that aim to provide a pre-configured setup, including a configuration file stub, are asked to put `{ }` into the configuration file to prevent this warning about an invalid configuration file.

Further configuration file validation is done when parsing sections upon opening a connection. Please, note that there may still be situations when an invalid plugin configuration file does not lead to proper error messages but a failure to connect.

- As of PHP 5.5.0, improved support for transaction boundaries detection was added for [mysqli](#). The [mysqli](#) extension has been modified to use the new C API calls of the [mysqlnd](#) library to begin, commit, and rollback a transaction or savepoint. If [trx\\_stickiness](#) is used to enable transaction aware load balancing, the [mysqli\\_begin](#), [mysqli\\_commit](#) and [mysqli\\_rollback](#) functions will now be monitored by the plugin, to go along with the [mysqli\\_autocommit](#) function that was already supported. All SQL features to control transactions are also available through the improved [mysqli](#) transaction control related functions. This means that it is not required to issue SQL statements instead of using API calls. Applications using the appropriate API calls can be load balanced by PECL/[mysqlnd\\_ms](#) in a completely transaction-aware way.

Please note, [PDO\\_MYSQL](#) has not been updated yet to utilize the new [mysqlnd](#) API calls. Thus, transaction boundary detection with [PDO\\_MYSQL](#) continues to be limited to the monitoring by passing in `PDO::ATTR_AUTOCOMMIT` to `PDO::setAttribute`.

- Introduced `trx_stickiness=on`. This [trx\\_stickiness](#) option differs from `trx_stickiness=master` as it tries to execute a read-only transaction on a slave, if quality of service (consistency level) allows the use of a slave. Read-only transactions were introduced in MySQL 5.6, and they offer performance gains.
- Query cache support is considered beta if used with the [mysqli](#) API. It should work fine with primary copy based clusters. For all other APIs, this feature continues to be called experimental.
- The code examples in the [mysqlnd\\_ms](#) source were updated.

#### 21.9.6.9.2. PECL/[mysqlnd\\_ms](#) 1.4 series

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

##### 1.4.2-stable

- Release date: 08/2012
- Motto/theme: Tweaking based on user feedback

##### 1.4.1-beta

- Release date: 08/2012
- Motto/theme: Tweaking based on user feedback

##### Bug fixes

- Fixed build with PHP 5.5

##### 1.4.0-alpha

- Release date: 07/2012
- Motto/theme: Tweaking based on user feedback

##### Feature changes

- BC break: Renamed plugin configuration setting `ini_file` to `config_file`. In early versions the plugin configuration file used ini style. Back then the configuration setting was named accordingly. It has now been renamed to reflect the newer file format and to distinguish it from PHP's own ini file (configuration directives file).

- Introduced new default charset setting [server\\_charset](#) to allow proper escaping before a connection is opened. This is most useful when using lazy connections, which are a default.
- Introduced [wait\\_for\\_gtid\\_timeout](#) setting to throttle slave reads that need session consistency. If global transaction identifier are used and the service level is set to session consistency, the plugin tries to find up-to-date slaves. The slave status check is done by a SQL statement. If nothing else is set, the slave status is checked only one can the search for more up-to-date slaves continues immediately thereafter. Setting [wait\\_for\\_gtid\\_timeout](#) instructs the plugin to poll a slaves status for [wait\\_for\\_gtid\\_timeout](#) seconds if the first execution of the SQL statement has shown that the slave is not up-to-date yet. The poll will be done once per second. This way, the plugin will wait for slaves to catch up and throttle the client.
- New failover strategy [loop\\_before\\_master](#). By default the plugin does no failover. It is possible to enable automatic failover if a connection attempt fails. Upto version 1.3 only [master](#) strategy existed to failover to a master if a slave connection fails. [loop\\_before\\_master](#) is similar but tries all other slaves before attempting to connect to the master if a slave connection fails.

The number of attempts can be limited using the [max\\_retries](#) option. Failed hosts can be remembered and skipped in load balancing for the rest of the web request. [max\\_retries](#) and [remember\\_failed](#) are considered experimental although decent stability is given. Syntax and semantics may change in the future without prior notice.

### 21.9.6.9.3. PECL/mysqLnd\_ms 1.3 series

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

#### 1.3.2-stable

- Release date: 04/2012
- Motto/theme: see 1.3.0-alpha

#### Bug fixes

- Fixed problem with multi-master where although in a transaction the queries to the master weren't sticky and were spread all over the masters (RR). Still not sticky for Random. [Random\\_once](#) is not affected.

#### 1.3.1-beta

- Release date: 04/2012
- Motto/theme: see 1.3.0-alpha

#### Bug fixes

- Fixed problem with building together with QC.

#### 1.3.0-alpha

- Release date: 04/2012
- Motto/theme: Query caching through quality-of-service concept

The 1.3 series aims to improve the performance of applications and the overall load of an asynchronous MySQL cluster, for example, a MySQL cluster using MySQL Replication. This is done by transparently replacing a slave access with a local cache access, if the application allows it by setting an appropriate quality of service flag. When using MySQL replication a slave can serve stale data. An application using MySQL replication must continue to work correctly with stale data. Given that the application is know to work correctly with stale data, the slave access can transparently be replace with a local cache access.

[PECL/mysqlnd\\_qc](#) serves as a cache backend. PECL/mysqlnd\_qc supports use of various storage locations, among others main memory, [APC](#) and [MEMCACHE](#).

#### Feature changes

- Added cache option to quality-of-service (QoS) filter.
  - New configure option `enable-mysqlnd-ms-cache-support`
  - New constant `MYSQLND_MS_HAVE_CACHE_SUPPORT`.
  - New constant `MYSQLND_MS_QOS_OPTION_CACHE` to be used with `mysqlnd_ms_set_qos`.
- Support for built-in global transaction identifier feature of MySQL 5.6.5-m8 or newer.

#### 21.9.6.9.4. PECL/mysqlnd\_ms 1.2 series

Copyright 1997-2012 the PHP Documentation Group. [2906]

##### 1.2.1-beta

- Release date: 01/2012
- Motto/theme: see 1.2.0-alpha

Minor test changes.

##### 1.2.0-alpha

- Release date: 11/2011
- Motto/theme: Global Transaction ID injection and quality-of-service concept

In version 1.2 the focus continues to be on supporting MySQL database clusters with asynchronous replication. The plugin tries to make using the cluster introducing a quality-of-service filter which applications can use to define what service quality they need from the cluster. Service levels provided are eventual consistency with optional maximum age/slave slag, session consistency and strong consistency.

Additionally the plugin can do client-side global transaction id injection to make manual master failover easier.

#### Feature changes

- Introduced quality-of-service (QoS) filter. Service levels provided by QoS filter:
  - eventual consistency, optional option slave lag
  - session consistency, optional option GTID
  - strong consistency
- Added the `mysqlnd_ms_set_qos` function to set the required connection quality at runtime. The new constants related to `mysqlnd_ms_set_qos` are:
  - `MYSQLND_MS_QOS_CONSISTENCY_STRONG`
  - `MYSQLND_MS_QOS_CONSISTENCY_SESSION`
  - `MYSQLND_MS_QOS_CONSISTENCY_EVENTUAL`
  - `MYSQLND_MS_QOS_OPTION_GTID`
  - `MYSQLND_MS_QOS_OPTION_AGE`

- Added client-side global transaction id injection (GTID).
- New statistics related to GTID:
  - `gtid_autocommit_injections_success`
  - `gtid_autocommit_injections_failure`
  - `gtid_commit_injections_success`
  - `gtid_commit_injections_failure`
  - `gtid_implicit_commit_injections_success`
  - `gtid_implicit_commit_injections_failure`
- Added `mysqlnd_ms_get_last_gtid` to fetch the last global transaction id.
- Enabled support for multi master without slaves.

#### 21.9.6.9.5. PECL/mysqlnd\_ms 1.1 series

Copyright 1997-2012 the PHP Documentation Group. [2906]

1.1.0

- Release date: 09/2011
- Motto/theme: Cover replication basics with production quality

The 1.1 and 1.0 series expose a similar feature set. Internally, the 1.1 series has been refactored to plan for future feature additions. A new configuration file format has been introduced, and limitations have been lifted. And the code quality and quality assurance has been improved.

Feature changes

- Added the (chainable) [filter concept](#):
  - BC break: `mysqlnd_ms_set_user_pick_server` has been removed. The [http://svn.php.net/viewvc/pecl/mysqlnd\\_ms/trunk/user](http://svn.php.net/viewvc/pecl/mysqlnd_ms/trunk/user) filter has been introduced to replace it. The filter offers similar functionality, but see below for an explanation of the differences.
- New powerful JSON based configuration syntax.
- [Lazy connections improved](#): security relevant, and state changing commands are covered.
- Support for (native) prepared statements.
- New statistics: `use_master_guess`, `use_slave_guess`.
  - BC break: Semantics of statistics changed for `use_slave`, `use_master`. Future changes are likely. Please see, `mysqlnd_ms_get_stats`.
- List of broadcasted messages extended by `ssl_set`.
- Library calls now monitored to remember settings for lazy connections: `change_user`, `select_db`, `set_charset`, `set_autocommit`.
- Introduced `mysqlnd_ms.disable_rw_split`. The configuration setting allows using the load balancing and lazy connection functionality independently of read write splitting.

Bug fixes

- Fixed PECL #22724 - Server switching (`mysqlnd_ms_query_is_select()` case sensitive)

- Fixed PECL #22784 - Using `mysql_connect` and `mysql_select_db` did not work
- Fixed PECL #59982 - Unusable extension with `--enable-mysqlnd-ms-table-filter`. Use of the option is NOT supported. You must not use it. Added note to m4.
- Fixed Bug #60119 - `host="localhost"` lost in `mysqlnd_ms_get_last_used_connection()`

The `mysqlnd_ms_set_user_pick_server` function was removed, and replaced in favor of a new `user` filter. You can no longer set a callback function using `mysqlnd_ms_set_user_pick_server` at runtime, but instead have to configure it in the plugins configuration file. The `user` filter will pass the same arguments to the callback as before. Therefore, you can continue to use the same procedural function as a `callback.callback`. It is no longer possible to use static class methods, or class methods of an object instance, as a callback. Doing so will cause the function executing a statement handled by the plugin to emit an `E_RECOVERABLE_ERROR` level error, which might look like: `"(mysqlnd_ms) Specified callback (picker) is not a valid callback."` Note: this may halt your application.

#### 21.9.6.9.6. PECL/mysqlnd\_ms 1.0 series

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

1.0.1-alpha

- Release date: 04/2011
- Motto/theme: bug fix release

1.0.0-alpha

- Release date: 04/2011
- Motto/theme: Cover replication basics to test user feedback

The first release of practical use. It features basic automatic read-write splitting, SQL hints to overrule automatic redirection, load balancing of slave requests, lazy connections, and optional, automatic use of the master after the first write.

The public feature set is close to that of the 1.1 release.

1.0.0-pre-alpha

- Release date: 09/2010
- Motto/theme: Proof of concept

Initial check-in. Essentially a demo of the [mysqlnd](#) plugin API.

#### 21.9.7. Mysqlnd query result cache plugin ([mysqlnd\\_qc](#))

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The `mysqlnd` query result cache plugin adds easy to use client-side query caching to all PHP MySQL extensions using [mysqlnd](#).

As of version PHP 5.3.3 the MySQL native driver for PHP ([mysqlnd](#)) features an internal plugin C API. C plugins, such as the query cache plugin, can extend the functionality of [mysqlnd](#).

`mysqlnd` plugins such as the query cache plugin operate transparent from a user perspective. The cache plugin supports all PHP applications and all PHP MySQL extensions ([mysqli](#), [mysql](#), [PDO\\_MYSQL](#)). It does not change existing APIs.

No significant application changes are required to cache a query. The cache has two operation modes. It will either cache all queries (not recommended) or only those queries marked with a certain SQL hint (recommended).

### 21.9.7.1. Key Features

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

- Transparent and therefore easy to use
  - supports all PHP MySQL extensions
  - no API changes
  - very little application changes required
- Flexible invalidation strategy
  - Time-to-Live (TTL)
  - user-defined
- Storage with different scope and life-span
  - Default (Hash, process memory)
  - [APC](#)
  - MEMCACHE
  - sqlite
  - user-defined
- Built-in slam defense to prevent cache stampeding.

### 21.9.7.2. Limitations

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The current 1.0.1 release of PECL `mysqlnd_qc` does not support PHP 5.4. Version 1.1.0-alpha lifts this limitation.

Prepared statements and unbuffered queries are fully supported. Thus, the plugin is capable of caching all statements issued with `mysqli` or `PDO_MySQL`, which are the only two PHP MySQL APIs to offer prepared statement support.

### 21.9.7.3. On the name

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The shortcut `mysqlnd_qc` stands for `mysqlnd query cache plugin`. The name was chosen for a quick-and-dirty proof-of-concept. In the beginning the developers did not expect to continue using the code base. Sometimes PECL/`mysqlnd_qc` has also been called `client-side query result set cache`.

### 21.9.7.4. Quickstart and Examples

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The `mysqlnd` query cache plugin is easy to use. This quickstart will demo typical use-cases, and provide practical advice on getting started.

It is strongly recommended to read the reference sections in addition to the quickstart. It is safe to begin with the quickstart. However, before using the plugin in mission critical environments we urge you to read additionally the background information from the reference sections.

Most of the examples use the [mysqli](#) extension because it is the most feature complete PHP MySQL extension. However, the plugin can be used with any PHP MySQL extension that is using the [mysqlnd](#) library.

#### 21.9.7.4.1. Architecture and Concepts

Copyright 1997-2012 the PHP Documentation Group. [2906]

The query cache plugin is implemented as a PHP extension. It is written in C and operates under the hood of PHP. During the startup of the PHP interpreter, it gets registered as a [mysqlnd](#) plugin to replace selected [mysqlnd](#) C methods. Hereby, it can change the behaviour of any PHP MySQL extension ([mysqli](#), [PDO\\_MYSQL](#), [mysql](#)) compiled to use the [mysqlnd](#) library without changing the extensions API. This makes the plugin compatible with each and every PHP MySQL application. Because existing APIs are not changed, it is almost transparent to use. Please, see the [mysqlnd plugin API description](#) for a discussion of the advantages of the plugin architecture and a comparison with proxy based solutions.

##### *Transparent to use*

At PHP run time PECL/[mysqlnd\\_qc](#) can proxy queries send from PHP ([mysqlnd](#)) to the MySQL server. It then inspects the statement string to find whether it shall cache its results. If so, result set is cached using a storage handler and further executions of the statement are served from the cache for a user-defined period. The Time to Live (TTL) of the cache entry can either be set globally or on a per statement basis.

A statement is either cached if the plugin is instructed to cache all statements globally using a or, if the query string starts with the SQL hint (`/*qc=on*/`). The plugin is capable of caching any query issued by calling appropriate API calls of any of the existing PHP MySQL extensions.

##### *Flexible storage: various storage handler*

Various storage handler are supported to offer different scopes for cache entries. Different scopes allow for different degrees in sharing cache entries among clients.

- [default](#) (built-in): process memory, scope: process, one or more web requests depending on PHP deployment model used
- [APC](#): shared memory, scope: single server, multiple web requests
- [SQLite](#): memory or file, scope: single server, multiple web requests
- [MEMCACHE](#): main memory, scope: single or multiple server, multiple web requests
- [user](#) (built-in): user-defined - any, scope: user-defined - any

Support for the [APC](#), [SQLite](#) and [MEMCACHE](#) storage handler has to be enabled at compile time. The [default](#) and [user](#) handler are built-in. It is possible to switch between compiled-in storage handlers on a per query basis at run time. However, it is recommended to pick one storage handler and use it for all cache entries.

##### *Built-in slam defense to avoid overloading*

To avoid overload situations the cache plugin has a built-in slam defense mechanism. If a popular cache entries expires many clients using the cache entries will try to refresh the cache entry. For the duration of the refresh many clients may access the database server concurrently. In the worst case, the database server becomes overloaded and it takes more and more time to refresh the cache entry, which in turn lets more and more clients try to refresh the cache entry. To prevent this from happening the plugin has a slam defense mechanism. If slam defense is enabled and the plugin detects an expired cache entry it extends the life time of the cache entry before it refreshes the cache entry. This way other concurrent accesses to the expired cache entry are still served from the cache for a certain time. The other concurrent accesses do not trigger a concurrent refresh. Ideally, the cache entry gets

refreshed by the client which extended the cache entries lifespan before other clients try to refresh the cache and potentially cause an overload situation.

#### *Unique approach to caching*

PECL/mysqlnd\_qc has a unique approach to caching result sets that is superior to application based cache solutions. Application based solutions first fetch a result set into PHP variables. Then, the PHP variables are serialized for storage in a persistent cache, and then unserialized when fetching. The mysqlnd query cache stores the raw wire protocol data sent from MySQL to PHP in its cache and replays it, if still valid, on a cache hit. This way, it saves an extra serialization step for a cache put that all application based solutions have to do. It can store the raw wire protocol data in the cache without having to serialize into a PHP variable first and deserializing the PHP variable for storing in the cache again.

### 21.9.7.4.2. Setup

Copyright 1997-2012 the PHP Documentation Group. [2906]

The plugin is implemented as a PHP extension. See also the [installation instructions](#) to install the PECL/mysqlnd\_qc extension.

Compile or configure the PHP MySQL extension (`mysqli`, `PDO_MYSQL`, `mysql`) that you plan to use with support for the `mysqlnd` library. PECL/mysqlnd\_qc is a plugin for the `mysqlnd` library. To use the plugin with any of the existing PHP MySQL extensions (APIs), the extension has to use the `mysqlnd` library.

Then, load the extension into PHP and activate the plugin in the PHP configuration file using the PHP configuration directive named `mysqlnd_qc.enable_qc`.

#### **Example 21.304. Enabling the plugin (php.ini)**

```
mysqlnd_qc.enable_qc=1
```

### 21.9.7.4.3. Caching queries

Copyright 1997-2012 the PHP Documentation Group. [2906]

There are four ways to trigger caching of a query.

- Use of SQL hints on a per query basis
- User supplied callbacks to decide on a per query basis, for example, using `mysqlnd_qc_is_select`
- `mysqlnd_set_cache_condition` for rule based automatic per query decisions
- `mysqlnd_qc.cache_by_default = 1` to cache all queries blindly

Use of SQL hints and `mysqlnd_qc.cache_by_default = 1` are explained below. Please, refer to the function reference on `mysqlnd_qc_is_select` for a description of using a callback and, `mysqlnd_qc_set_cache_condition` on how to set rules for automatic caching.

A SQL hint is a SQL standards compliant comment. As a SQL comment it is ignored by the database. A statement is considered eligible for caching if it either begins with the SQL hint enabling caching or it is a `SELECT` statement.

An individual query which shall be cached must begin with the SQL hint `/*qc=on*/`. It is recommended to use the PHP constant `MYSQLND_QC_ENABLE_SWITCH` instead of using the string value.

- not eligible for caching and not cached: `INSERT INTO test(id) VALUES (1)`

- not eligible for caching and not cached: `SHOW ENGINES`
- eligible for caching but uncached: `SELECT id FROM test`
- eligible for caching and cached: `/*qc=on*/SELECT id FROM test`

The examples `SELECT` statement string is prefixed with the `MYSQLND_QC_ENABLE_SWITCH` SQL hint to enable caching of the statement. The SQL hint must be given at the very beginning of the statement string to enable caching.

**Example 21.305. Using the `MYSQLND_QC_ENABLE_SWITCH` SQL hint**

```
mysqlnd_qc.enable_qc=1

<?php
/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2)");

/* Will be cached because of the SQL hint */
$start = microtime(true);
$res    = $mysqli->query("/* . MYSQLND_QC_ENABLE_SWITCH . */" . "SELECT id FROM test WHERE id = 1");

var_dump($res->fetch_assoc());
$res->free();

printf("Total time uncached query: %.6fs\n", microtime(true) - $start);

/* Cache hit */
$start = microtime(true);
$res    = $mysqli->query("/* . MYSQLND_QC_ENABLE_SWITCH . */" . "SELECT id FROM test WHERE id = 1");

var_dump($res->fetch_assoc());
$res->free();

printf("Total time cached query: %.6fs\n", microtime(true) - $start);
?>
```

The above examples will output something similar to:

```
array(1) {
  ["id"]=>
  string(1) "1"
}
Total time uncached query: 0.000740s
array(1) {
  ["id"]=>
  string(1) "1"
}
Total time cached query: 0.000098s
```

If nothing else is configured, as it is the case in the quickstart example, the plugin will use the built-in `default` storage handler. The `default` storage handler uses process memory to hold a cache entry. Depending on the PHP deployment model, a PHP process may serve one or more web requests. Please, consult the web server manual for details. Details make no difference for the examples given in the quickstart.

The query cache plugin will cache all queries regardless if the query string begins with the SQL hint which enables caching or not, if the PHP configuration directive `mysqlnd_qc.cache_by_default` is

set to 1. The setting `mysqlnd_qc.cache_by_default` is evaluated by the core of the query cache plugins. Neither the built-in nor user-defined storage handler can overrule the setting.

The SQL hint `/*qc=off*/` can be used to disable caching of individual queries if `mysqlnd_qc.cache_by_default = 1`. It is recommended to use the PHP constant `MYSQLND_QC_DISABLE_SWITCH` instead of using the string value.

**Example 21.306. Using the `MYSQLND_QC_DISABLE_SWITCH` SQL hint**

```
mysqlnd_qc.enable_qc=1
mysqlnd_qc.cache_by_default=1
```

```
<?php
/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2)");

/* Will be cached although no SQL hint is present because of mysqlnd_qc.cache_by_default = 1*/
$res = $mysqli->query("SELECT id FROM test WHERE id = 1");
var_dump($res->fetch_assoc());
$res->free();

$mysqli->query("DELETE FROM test WHERE id = 1");

/* Cache hit - no automatic invalidation and still valid! */
$res = $mysqli->query("SELECT id FROM test WHERE id = 1");
var_dump($res->fetch_assoc());
$res->free();

/* Cache miss - query must not be cached because of the SQL hint */
$res = $mysqli->query("/*" . MYSQLND_QC_DISABLE_SWITCH . "*/SELECT id FROM test WHERE id = 1");
var_dump($res->fetch_assoc());
$res->free();
?>
```

The above examples will output:

```
array(1) {
  ["id"]=>
  string(1) "1"
}
array(1) {
  ["id"]=>
  string(1) "1"
}
NULL
```

PECL/`mysqlnd_qc` forbids caching of statements for which at least one column from the statements result set shows no table name in its meta data by default. This is usually the case for columns originating from SQL functions such as `NOW()` or `LAST_INSERT_ID()`. The policy aims to prevent pitfalls if caching by default is used.

**Example 21.307. Example showing which type of statements are not cached**

```
mysqlnd_qc.enable_qc=1
mysqlnd_qc.cache_by_default=1
```

```

<?php
/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1)");

for ($i = 0; $i < 3; $i++) {

    $start = microtime(true);

    /* Note: statement will not be cached because of NOW() use */
    $res = $mysqli->query("SELECT id, NOW() AS _time FROM test");
    $row = $res->fetch_assoc();

    /* dump results */
    var_dump($row);

    printf("Total time: %.6fs\n", microtime(true) - $start);

    /* pause one second */
    sleep(1);
}
?>

```

The above examples will output something similar to:

```

array(2) {
  ["id"]=>
  string(1) "1"
  ["_time"]=>
  string(19) "2012-01-11 15:43:10"
}
Total time: 0.000540s
array(2) {
  ["id"]=>
  string(1) "1"
  ["_time"]=>
  string(19) "2012-01-11 15:43:11"
}
Total time: 0.000555s
array(2) {
  ["id"]=>
  string(1) "1"
  ["_time"]=>
  string(19) "2012-01-11 15:43:12"
}
Total time: 0.000549s

```

It is possible to enable caching for all statements including those which has columns in their result set for which MySQL reports no table, such as the statement from the example. Set [mysqlnd\\_qc.cache\\_no\\_table = 1](#) to enable caching of such statements. Please, note the difference in the measured times for the above and below examples.

**Example 21.308. Enabling caching for all statements using the [mysqlnd\\_qc.cache\\_no\\_table](#) ini setting**

```

mysqlnd_qc.enable_qc=1
mysqlnd_qc.cache_by_default=1
mysqlnd_qc.cache_no_table=1

```

```
<?php
/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1)");

for ($i = 0; $i < 3; $i++) {

    $start = microtime(true);

    /* Note: statement will not be cached because of NOW() use */
    $res = $mysqli->query("SELECT id, NOW() AS _time FROM test");
    $row = $res->fetch_assoc();

    /* dump results */
    var_dump($row);

    printf("Total time: %.6fs\n", microtime(true) - $start);

    /* pause one second */
    sleep(1);
}
?>
```

The above examples will output something similar to:

```
array(2) {
  ["id"]=>
  string(1) "1"
  ["_time"]=>
  string(19) "2012-01-11 15:47:45"
}
Total time: 0.000546s
array(2) {
  ["id"]=>
  string(1) "1"
  ["_time"]=>
  string(19) "2012-01-11 15:47:45"
}
Total time: 0.000187s
array(2) {
  ["id"]=>
  string(1) "1"
  ["_time"]=>
  string(19) "2012-01-11 15:47:45"
}
Total time: 0.000167s
```

#### Note

Although `mysqlnd_qc.cache_no_table = 1` has been created for use with `mysqlnd_qc.cache_by_default = 1` it is bound it. The plugin will evaluate the `mysqlnd_qc.cache_no_table` whenever a query is to be cached, no matter whether caching has been enabled using a SQL hint or any other measure.

#### 21.9.7.4.4. Setting the TTL

Copyright 1997-2012 the PHP Documentation Group. [2906]

The default invalidation strategy of the query cache plugin is Time to Live (TTL). The built-in storage handlers will use the default TTL defined by the PHP configuration value `mysqlnd_qc.ttl` unless

the query string contains a hint for setting a different `TTL`. The `TTL` is specified in seconds. By default cache entries expire after 30 seconds

The example sets `mysqlnd_qc.ttl=3` to cache statements for three seconds by default. Every second it updates a database table record to hold the current time and executes a `SELECT` statement to fetch the record from the database. The `SELECT` statement is cached for three seconds because it is prefixed with the SQL hint enabling caching. The output verifies that the query results are taken from the cache for the duration of three seconds before they are refreshed.

### Example 21.309. Setting the TTL with the `mysqlnd_qc.ttl` ini setting

```
mysqlnd_qc.enable_qc=1
mysqlnd_qc.ttl=3
```

```
<?php
/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id VARCHAR(255))");

for ($i = 0; $i < 7; $i++) {

    /* update DB row */
    if (!$mysqli->query("DELETE FROM test") ||
        !$mysqli->query("INSERT INTO test(id) VALUES (NOW())"))
        /* Of course, a real-life script should do better error handling */
        die(sprintf("[%d] %s\n", $mysqli->errno, $mysqli->error));

    /* select latest row but cache results */
    $query = "/*" . MYSQLND_QC_ENABLE_SWITCH . "*/";
    $query .= "SELECT id AS _time FROM test";
    if (!$res = $mysqli->query($query) ||
        !($row = $res->fetch_assoc()))
    {
        printf("[%d] %s\n", $mysqli->errno, $mysqli->error);
    }
    $res->free();
    printf("Wall time %s - DB row time %s\n", date("H:i:s"), $row['_time']);

    /* pause one second */
    sleep(1);
}
?>
```

The above examples will output something similar to:

```
Wall time 14:55:59 - DB row time 2012-01-11 14:55:59
Wall time 14:56:00 - DB row time 2012-01-11 14:55:59
Wall time 14:56:01 - DB row time 2012-01-11 14:55:59
Wall time 14:56:02 - DB row time 2012-01-11 14:56:02
Wall time 14:56:03 - DB row time 2012-01-11 14:56:02
Wall time 14:56:04 - DB row time 2012-01-11 14:56:02
Wall time 14:56:05 - DB row time 2012-01-11 14:56:05
```

As can be seen from the example, any `TTL` based cache can serve stale data. Cache entries are not automatically invalidated, if underlying data changes. Applications using the default `TTL` invalidation strategy must be able to work correctly with stale data.

A user-defined cache storage handler can implement any invalidation strategy to work around this limitation.

The default `TTL` can be overruled using the SQL hint `/*qc_tt=seconds*/`. The SQL hint must be appear immediately after the SQL hint which enables caching. It is recommended to use the PHP constant `MYSQLND_QC_TTL_SWITCH` instead of using the string value.

### Example 21.310. Setting TTL with SQL hints

```
<?php
$start = microtime(true);

/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2)");

printf("Default TTL\t: %d seconds\n", ini_get("mysqlnd_qc.ttl"));

/* Will be cached for 2 seconds */
$sql = sprintf("/*s*//*s%d*/SELECT id FROM test WHERE id = 1", MYSQLND_QC_ENABLE_SWITCH, MYSQLND_QC_TTL_S);
$res = $mysqli->query($sql);

var_dump($res->fetch_assoc());
$res->free();

$mysqli->query("DELETE FROM test WHERE id = 1");
sleep(1);

/* Cache hit - no automatic invalidation and still valid! */
$res = $mysqli->query($sql);
var_dump($res->fetch_assoc());
$res->free();

sleep(2);

/* Cache miss - cache entry has expired */
$res = $mysqli->query($sql);
var_dump($res->fetch_assoc());
$res->free();

printf("Script runtime\t: %d seconds\n", microtime(true) - $start);
?>
```

The above examples will output something similar to:

```
Default TTL      : 30 seconds
array(1) {
  ["id"]=>
    string(1) "1"
}
array(1) {
  ["id"]=>
    string(1) "1"
}
NULL
Script runtime   : 3 seconds
```

#### 21.9.7.4.5. Pattern based caching

Copyright 1997-2012 the PHP Documentation Group. [2906]

An application has three options for telling PECL/`mysqlnd_qc` whether a particular statement shall be used. The most basic approach is to cache all statements by setting `mysqlnd_qc.cache_by_default = 1`. This approach is often of little practical value. But it enables

users to make a quick estimation about the maximum performance gains from caching. An application designed to use a cache may be able to prefix selected statements with the appropriate SQL hints. However, altering an applications source code may not always be possible or desired, for example, to avoid problems with software updates. Therefore, PECL/mysqlnd\_qc allows setting a callback which decides if a query is to be cached.

The callback is installed with the `mysqlnd_qc_set_is_select` function. The callback is given the statement string of every statement inspected by the plugin. Then, the callback can decide whether to cache the function. The callback is supposed to return `FALSE` if the statement shall not be cached. A return value of `TRUE` makes the plugin try to add the statement into the cache. The cache entry will be given the default TTL ( `mysqlnd_qc.ttl`). If the callback returns a numerical value it is used as the TTL instead of the global default.

### Example 21.311. Setting a callback with `mysqlnd_qc_set_is_select`

```
mysqlnd_qc.enable_qc=1
mysqlnd_qc.collect_statistics=1
```

```
<?php
/* callback which decides if query is cached */
function is_select($query) {
    static $patterns = array(
        /* true - use default from mysqlnd_qc.ttl */
        "@SELECT\s+.*\s+FROM\s+test@ismU" => true,
        /* 3 - use TTL = 3 seconds */
        "@SELECT\s+.*\s+FROM\s+news@ismU" => 3
    );

    /* check if query does match pattern */
    foreach ($patterns as $pattern => $ttl) {
        if (preg_match($pattern, $query)) {
            printf("is_select(%45s): cache\n", $query);
            return $ttl;
        }
    }
    printf("is_select(%45s): do not cache\n", $query);
    return false;
}
/* install callback */
mysqlnd_qc_set_is_select("is_select");

/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)");

/* cache put */
$mysqli->query("SELECT id FROM test WHERE id = 1");
/* cache hit */
$mysqli->query("SELECT id FROM test WHERE id = 1");
/* cache put */
$mysqli->query("SELECT * FROM test");

$stats = mysqlnd_qc_get_core_stats();
printf("Cache put: %d\n", $stats['cache_put']);
printf("Cache hit: %d\n", $stats['cache_hit']);
?>
```

The above examples will output something similar to:

```
is_select(          DROP TABLE IF EXISTS test): do not cache
```

```
is_select(          CREATE TABLE test(id INT)): do not cache
is_select(    INSERT INTO test(id) VALUES (1), (2), (3)): do not cache
is_select(          SELECT id FROM test WHERE id = 1): cache
is_select(          SELECT id FROM test WHERE id = 1): cache
is_select(          SELECT * FROM test): cache
Cache put: 2
Cache hit: 1
```

The examples callback tests if a statement string matches a pattern. If this is the case, it either returns `TRUE` to cache the statement using the global default TTL or an alternative TTL.

To minimize application changes the callback can put into and registered in an auto prepend file.

#### 21.9.7.4.6. Slam defense

Copyright 1997-2012 the PHP Documentation Group. [2906]

A badly designed cache can do more harm than good. In the worst case a cache can increase database server load instead of minimizing it. An overload situation can occur if a highly shared cache entry expires (cache stampeding).

Cache entries are shared and reused to a different degree depending on the storage used. The default storage handler stores cache entries in process memory. Thus, a cache entry can be reused for the life-span of a process. Other PHP processes cannot access it. If Memcache is used, a cache entry can be shared among multiple PHP processes and even among multiple machines, depending on the set up being used.

If a highly shared cache entry stored, for example, in Memcache expires, many clients gets a cache miss. Many client requests can no longer be served from the cache but try to run the underlying query on the database server. Until the cache entry is refreshed, more and more clients contact the database server. In the worst case, a total lost of service is the result.

The overload can be avoided using a storage handler which limits the reuse of cache entries to few clients. Then, at the average, its likely that only a limited number of clients will try to refresh a cache entry concurrently.

Additionally, the built-in slam defense mechanism can and should be used. If slam defense is activated an expired cache entry is given an extended life time. The first client getting a cache miss for the expired cache entry tries to refresh the cache entry within the extended life time. All other clients requesting the cache entry are temporarily served from the cache although the original `TTL` of the cache entry has expired. The other clients will not experience a cache miss before the extended life time is over.

#### Example 21.312. Enabling the slam defense mechanism

```
mysqlnd_qc.slam_defense=1
mysqlnd_qc.slam_defense_ttl=1
```

The slam defense mechanism is enabled with the PHP configuration directive `mysqlnd_qc.slam_defense`. The extended life time of a cache entry is set with `mysqlnd_qc.slam_defense_ttl`.

The function `mysqlnd_qc_get_core_stats` returns an array of statistics. The statistics `slam_stale_refresh` and `slam_stale_hit` are incremented if slam defense takes place.

It is not possible to give a one-fits-all recommendation on the slam defense configuration. Users are advised to monitor and test their setup and derive settings accordingly.

### 21.9.7.4.7. Finding cache candidates

Copyright 1997-2012 the PHP Documentation Group. [2906]

A statement should be considered for caching if it is executed often and has a long run time. Cache candidates are found by creating a list of statements sorted by the product of the number of executions multiplied by the statements run time. The function `mysqlnd_qc_get_query_trace_log` returns a query log which help with the task.

Collecting a query trace is a slow operation. Thus, it is disabled by default. The PHP configuration directive `mysqlnd_qc.collect_query_trace` is used to enable it. The functions trace contains one entry for every query issued before the function is called.

#### Example 21.313. Collecting a query trace

```
mysqlnd_qc.enable_qc=1
mysqlnd_qc.collect_query_trace=1
```

```
<?php
/* connect to MySQL */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");

/* dummy queries to fill the query trace */
for ($i = 0; $i < 2; $i++) {
    $res = $mysqli->query("SELECT 1 AS _one FROM DUAL");
    $res->free();
}

/* dump trace */
var_dump(mysqlnd_qc_get_query_trace_log());
?>
```

The above examples will output:

```
array(2) {
  [0]=>
  array(8) {
    ["query"]=>
    string(26) "SELECT 1 AS _one FROM DUAL"
    ["origin"]=>
    string(102) "#0 qc.php(7): mysqli->query('SELECT 1 AS _on...')
#1 {main}"
    ["run_time"]=>
    int(0)
    ["store_time"]=>
    int(25)
    ["eligible_for_caching"]=>
    bool(false)
    ["no_table"]=>
    bool(false)
    ["was_added"]=>
    bool(false)
    ["was_already_in_cache"]=>
    bool(false)
  }
  [1]=>
  array(8) {
    ["query"]=>
    string(26) "SELECT 1 AS _one FROM DUAL"
    ["origin"]=>
    string(102) "#0 qc.php(7): mysqli->query('SELECT 1 AS _on...')
#1 {main}"
```

```

["run_time"]=>
int(0)
["store_time"]=>
int(8)
["eligible_for_caching"]=>
bool(false)
["no_table"]=>
bool(false)
["was_added"]=>
bool(false)
["was_already_in_cache"]=>
bool(false)
}
}

```

Assorted information is given in the trace. Among them timings and the origin of the query call. The origin property holds a code backtrace to identify the source of the query. The depth of the backtrace can be limited with the PHP configuration directive `mysqlnd_qc.query_trace_bt_depth`. The default depth is 3.

**Example 21.314. Setting the backtrace depth with the `mysqlnd_qc.query_trace_bt_depth` ini setting**

```

mysqlnd_qc.enable_qc=1
mysqlnd_qc.collect_query_trace=1

```

```

<?php
/* connect to MySQL */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)");

/* dummy queries to fill the query trace */
for ($i = 0; $i < 3; $i++) {
    $res = $mysqli->query("SELECT id FROM test WHERE id = " . $mysqli->real_escape_string($i));
    $res->free();
}

$trace = mysqlnd_qc_get_query_trace_log();
$summary = array();
foreach ($trace as $entry) {
    if (!isset($summary[$entry['query']])) {
        $summary[$entry['query']] = array(
            "executions" => 1,
            "time"       => $entry['run_time'] + $entry['store_time'],
        );
    } else {
        $summary[$entry['query']]['executions']++;
        $summary[$entry['query']]['time'] += $entry['run_time'] + $entry['store_time'];
    }
}

foreach ($summary as $query => $details) {
    printf("%45s: %5dms (%dx)\n",
        $query, $details['time'], $details['executions']);
}
?>

```

The above examples will output something similar to:

```

        DROP TABLE IF EXISTS test:      0ms (1x)
        CREATE TABLE test(id INT):      0ms (1x)
INSERT INTO test(id) VALUES (1), (2), (3): 0ms (1x)
        SELECT id FROM test WHERE id = 0: 25ms (1x)
        SELECT id FROM test WHERE id = 1: 10ms (1x)
        SELECT id FROM test WHERE id = 2:  9ms (1x)

```

#### 21.9.7.4.8. Measuring cache efficiency

Copyright 1997-2012 the PHP Documentation Group. [2906]

PECL/`mysqlnd_qc` offers three ways to measure the cache efficiency. The function `mysqlnd_qc_get_normalized_query_trace_log` returns statistics aggregated by the normalized query string, `mysqlnd_qc_get_cache_info` gives storage handler specific information which includes a list of all cached items, depending on the storage handler. Additionally, the core of PECL/`mysqlnd_qc` collects high-level summary statistics aggregated per PHP process. The high-level statistics are returned by `mysqlnd_qc_get_core_stats`.

The functions `mysqlnd_qc_get_normalized_query_trace_log` and `mysqlnd_qc_get_core_stats` will not collect data unless data collection has been enabled through their corresponding PHP configuration directives. Data collection is disabled by default for performance considerations. It is configurable with the `mysqlnd_qc.time_statistics` option, which determines if timing information should be collected. Collection of time statistics is enabled by default but only performed if data collection as such has been enabled. Recording time statistics causes extra system calls. In most cases, the benefit of the monitoring outweighs any potential performance penalty of the additional system calls.

**Example 21.315. Collecting statistics data with the `mysqlnd_qc.time_statistics` ini setting**

```

mysqlnd_qc.enable_qc=1
mysqlnd_qc.collect_statistics=1

```

```

<?php
/* connect to MySQL */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)");

/* dummy queries */
for ($i = 1; $i <= 4; $i++) {
    $query = sprintf("/*%s*/SELECT id FROM test WHERE id = %d", MYSQLND_QC_ENABLE_SWITCH, $i % 2);
    $res    = $mysqli->query($query);

    $res->free();
}

var_dump(mysqlnd_qc_get_core_stats());
?>

```

The above examples will output something similar to:

```

array(26) {
  ["cache_hit"]=>
  string(1) "2"
  ["cache_miss"]=>
  string(1) "2"
  ["cache_put"]=>

```

```

string(1) "2"
["query_should_cache"]=>
string(1) "4"
["query_should_not_cache"]=>
string(1) "3"
["query_not_cached"]=>
string(1) "3"
["query_could_cache"]=>
string(1) "4"

For a quick overview, call `mysqlnd_qc_get_core_stats`. It delivers cache usage, cache timing and traffic related statistics. Values are aggregated on a per process basis for all queries issued by any PHP MySQL API call.

Some storage handler, such as the default handler, can report cache entries, statistics related to the entries and meta data for the underlying query through the `mysqlnd_qc_get_cache_info` function. Please note, that the information returned depends on the storage handler. Values are aggregated on a per process basis.

#### Example 21.316. Example `mysqlnd_qc_get_cache_info` usage

```
mysqlnd_qc.enable_qc=1
```

```
<?php
/* connect to MySQL */
```

```

$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)");

/* dummy queries to fill the query trace */
for ($i = 1; $i <= 4; $i++) {
    $query = sprintf("/*%s*/SELECT id FROM test WHERE id = %d", MYSQLND_QC_ENABLE_SWITCH, $i % 2);
    $res = $mysqli->query($query);

    $res->free();
}

var_dump(mysqlnd_qc_get_cache_info());
?>

```

The above examples will output something similar to:

```

  }
}
}
}
}

```

It is possible to further break down the granularity of statistics to the level of the normalized statement string. The normalized statement string is the statements string with all parameters replaced with question marks. For example, the two statements `SELECT id FROM test WHERE id = 0` and

`SELECT id FROM test WHERE id = 1` are normalized into `SELECT id FROM test WHERE id = ?`. Their both statistics are aggregated into one entry for `SELECT id FROM test WHERE id = ?`.

**Example 21.317. Example `mysqld_qc_get_normalized_query_trace_log` usage**

```
mysqld_qc.enable_qc=1
mysqld_qc.collect_normalized_query_trace=1
```

```
<?php
/* connect to MySQL */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)");

/* dummy queries to fill the query trace */
for ($i = 1; $i <= 4; $i++) {
    $query = sprintf("/*%s*/SELECT id FROM test WHERE id = %d", MYSQLND_QC_ENABLE_SWITCH, $i % 2);
    $res = $mysqli->query($query);

    $res->free();
}

var_dump(mysqld_qc_get_normalized_query_trace_log());
?>
```

The above examples will output something similar to:

The source distribution of PECL/mysqlnd\_qc contains a directory [web/](#) in which web based monitoring scripts can be found which give an example how to write a cache monitor. Please, follow the instructions given in the source.

Since PECL/mysqlnd\_qc 1.1.0 it is possible to write statistics into a log file. Please, see [mysqlnd\\_qc.collect\\_statistics\\_log\\_file](#).

#### 21.9.7.4.9. Beyond TTL: user-defined storage

Copyright 1997-2012 the PHP Documentation Group. [2906]

The query cache plugin supports the use of user-defined storage handler. User-defined storage handler can use arbitrarily complex invalidation algorithms and support arbitrary storage media.

All user-defined storage handlers have to provide a certain interface. The functions of the user-defined storage handler will be called by the core of the cache plugin. The necessary interface consists of seven public functions. Both procedural and object oriented user-defined storage handler must implement the same set of functions.

**Example 21.318. Using a user-defined storage handler**

```

<?php
/* Enable default caching of all statements */
ini_set("mysqld_qc.cache_by_default", 1);

/* Procedural user defined storage handler functions */

$__cache = array();

function get_hash($host_info, $port, $user, $db, $query) {
    global $__cache;
    printf("\t%s(%d)\n", __FUNCTION__, func_num_args());

    return md5(sprintf("%s%s%s%s", $host_info, $port, $user, $db, $query));
}

function find_query_in_cache($key) {
    global $__cache;
    printf("\t%s(%d)\n", __FUNCTION__, func_num_args());

    if (isset($__cache[$key])) {
        $tmp = $__cache[$key];
        if ($tmp["valid_until"] < time()) {
            unset($__cache[$key]);
            $ret = NULL;
        } else {
            $ret = $__cache[$key]["data"];
        }
    } else {
        $ret = NULL;
    }

    return $ret;
}

function return_to_cache($key) {
    /*
     * Called on cache hit after cached data has been processed,
     * may be used for reference counting
     */
    printf("\t%s(%d)\n", __FUNCTION__, func_num_args());
}

function add_query_to_cache_if_not_exists($key, $data, $ttl, $run_time, $store_time, $row_count) {
    global $__cache;
    printf("\t%s(%d)\n", __FUNCTION__, func_num_args());

    $__cache[$key] = array(
        "data" => $data,
        "row_count" => $row_count,
        "valid_until" => time() + $ttl,
        "hits" => 0,
        "run_time" => $run_time,
        "store_time" => $store_time,
        "cached_run_times" => array(),
        "cached_store_times" => array(),
    );

    return TRUE;
}

function query_is_select($query) {
    printf("\t%s('%s'):", __FUNCTION__, $query);

    $ret = FALSE;
    if (strstr($query, "SELECT") !== FALSE) {
        /* cache for 5 seconds */
        $ret = 5;
    }
}

```

```
printf("%s\n", (FALSE === $ret) ? "FALSE" : $ret);
return $ret;
}

function update_query_run_time_stats($key, $run_time, $store_time) {
    global $__cache;
    printf("\t%s(%d)\n", __FUNCTION__, func_num_args());

    if (isset($__cache[$key])) {
        $__cache[$key]['hits']++;
        $__cache[$key]['cached_run_times'][] = $run_time;
        $__cache[$key]['cached_store_times'][] = $store_time;
    }
}

function get_stats($key = NULL) {
    global $__cache;
    printf("\t%s(%d)\n", __FUNCTION__, func_num_args());

    if ($key && isset($__cache[$key])) {
        $stats = $__cache[$key];
    } else {
        $stats = array();
        foreach ($__cache as $key => $details) {
            $stats[$key] = array(
                'hits' => $details['hits'],
                'bytes' => strlen($details['data']),
                'uncached_run_time' => $details['run_time'],
                'cached_run_time' => (count($details['cached_run_times']))
                    ? array_sum($details['cached_run_times']) / count($details['cached_run_times'])
                    : 0,
            );
        }
    }

    return $stats;
}

function clear_cache() {
    global $__cache;
    printf("\t%s(%d)\n", __FUNCTION__, func_num_args());

    $__cache = array();
    return TRUE;
}

/* Install procedural user-defined storage handler */
if (!mysqlnd_qc_set_user_handlers("get_hash", "find_query_in_cache",
    "return_to_cache", "add_query_to_cache_if_not_exists",
    "query_is_select", "update_query_run_time_stats", "get_stats", "clear_cache")) {

    printf("Failed to install user-defined storage handler\n");
}

/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2)");

printf("\nCache put/cache miss\n");

$res = $mysqli->query("SELECT id FROM test WHERE id = 1");
var_dump($res->fetch_assoc());
$res->free();

/* Delete record to verify we get our data from the cache */
$mysqli->query("DELETE FROM test WHERE id = 1");

printf("\nCache hit\n");
```

```

$res = $mysqli->query("SELECT id FROM test WHERE id = 1");
var_dump($res->fetch_assoc());
$res->free();

printf("\nDisplay cache statistics\n");
var_dump(mysqlnd_qc_get_cache_info());

printf("\nFlushing cache, cache put/cache miss");
var_dump(mysqlnd_qc_clear_cache());

$res = $mysqli->query("SELECT id FROM test WHERE id = 1");
var_dump($res->fetch_assoc());
$res->free();
?>

```

The above examples will output something similar to:

```

query_is_select('DROP TABLE IF EXISTS test'): FALSE
query_is_select('CREATE TABLE test(id INT)'): FALSE

## 21.9.7.5. Installing/Configuring

Copyright 1997-2012 the PHP Documentation Group. [2906]

### 21.9.7.5.1. Requirements

Copyright 1997-2012 the PHP Documentation Group. [2906]

PHP 5.3.3 or a newer version of PHP.

PECL/`mysqlnd_qc` is a `mysqlnd` plugin. It plugs into the `mysqlnd` library. To use you this plugin with a PHP MySQL extension, the extension (`mysqli`, `mysql`, or `PDO_MYSQL`) must enable the `mysqlnd` library.

For using the `APC` storage handler with PECL/`mysqlnd_qc` 1.0 `APC 3.1.3p1-beta` or newer. PECL/`mysqlnd_qc` 1.2 has been tested with `APC 3.1.13-beta`. The `APC` storage handler cannot be used with a shared build. You cannot use the PHP configuration directive `extension` to load the `APC` and PECL/`mysqlnd_qc` extensions if PECL/`mysqlnd_qc` will use `APC` as a storage handler. For using the `APC` storage handler, you have to statically compile PHP with `APC` and PECL/`mysqlnd_qc` support into PHP.

For using `MEMCACHE` storage handler: Use `libmemcache 0.38` or newer. PECL/`mysqlnd_qc` 1.2 has been tested with `libmemcache 1.4.0`.

For using `sqlite` storage handler: Use the `sqlite3` extension that bundled with PHP.

### 21.9.7.5.2. Installation

Copyright 1997-2012 the PHP Documentation Group. [2906]

This `PECL` extension is not bundled with PHP.

Information for installing this `PECL` extension may be found in the manual chapter titled [Installation of PECL extensions](#). Additional information such as new releases, downloads, source files, maintainer information, and a `CHANGELOG`, can be located here: [http://pecl.php.net/package/mysqlnd\\_qc](http://pecl.php.net/package/mysqlnd_qc)

A `DLL` for this `PECL` extension is currently unavailable. See also the [building on Windows](#) section.

### 21.9.7.5.3. Runtime Configuration

Copyright 1997-2012 the PHP Documentation Group. [2906]

The behaviour of these functions is affected by settings in `php.ini`.

**Table 21.75. `mysqlnd_qc` Configure Options**

Name	Default	Changeable	Changelog
<code>mysqlnd_qc.enable_qc</code>	1	PHP_INI_SYSTEM	
<code>mysqlnd_qc.ttl</code>	30	PHP_INI_ALL	
<code>mysqlnd_qc.cache_by_default</code>	0	PHP_INI_ALL	
<code>mysqlnd_qc.cache_no_table</code>	0	PHP_INI_ALL	
<code>mysqlnd_qc.use_request_time</code>	0	PHP_INI_ALL	
<code>mysqlnd_qc.time_statistics</code>	1	PHP_INI_ALL	

Name	Default	Changeable	Changelog
<code>mysqlnd_qc.collect_statistics</code>	0	PHP_INI_ALL	
<code>mysqlnd_qc.collect_statistics_log_file</code>	<code>mysqlnd_qc.stats</code>	PHP_INI_SYSTEM	
<code>mysqlnd_qc.collect_query_trace</code>	0	PHP_INI_SYSTEM	
<code>mysqlnd_qc.query_trace_bt_depth</code>	8	PHP_INI_SYSTEM	
<code>mysqlnd_qc.collect_normalized_query_trace</code>	0	PHP_INI_SYSTEM	
<code>mysqlnd_qc.ignore_sql_comments</code>	1	PHP_INI_ALL	
<code>mysqlnd_qc.slam_defense</code>	0	PHP_INI_SYSTEM	
<code>mysqlnd_qc.slam_defense_ttl</code>	30	PHP_INI_SYSTEM	
<code>mysqlnd_qc.std_data_copy</code>	0	PHP_INI_SYSTEM	
<code>mysqlnd_qc.apc_prefix</code>	<code>qc_</code>	PHP_INI_ALL	
<code>mysqlnd_qc.memc_server</code>	127.0.0.1	PHP_INI_ALL	
<code>mysqlnd_qc.memc_port</code>	11211	PHP_INI_ALL	
<code>mysqlnd_qc.sqlite_data_file</code>	memory:	PHP_INI_ALL	

Here's a short explanation of the configuration directives.

`mysqlnd_qc.enable_qc` integer Enables or disables the plugin. If disabled the extension will not plug into `mysqlnd` to proxy internal `mysqlnd` C API calls.

`mysqlnd_qc.ttl` integer Default Time-to-Live (TTL) for cache entries in seconds.

`mysqlnd_qc.cache_by_default` integer Cache all queries regardless if they begin with the SQL hint that enables caching of a query or not. Storage handler cannot overrule the setting. It is evaluated by the core of the plugin.

`mysqlnd_qc.cache_no_table` integer Whether to cache queries with no table name in any of columns meta data of their result set, for example, `SELECT SLEEP(1)`, `SELECT NOW()`, `SELECT SUBSTRING()`.

`mysqlnd_qc.use_request_time` integer Use PHP global request time to avoid `gettimeofday()` system calls? If using `APC` storage handler it should be set to the value of `apc.use_request_time`, if not warnings will be generated.

`mysqlnd_qc.time_statistics` integer Collect run time and store time statistics using `gettimeofday()` system call? Data will be collected only if you also set `mysqlnd_qc.collect_statistics = 1`,

`mysqlnd_qc.collect_statistics_log_file` integer Collect statistics for `mysqlnd_qc_get_core_stats`? Does not influence storage handler statistics! Handler statistics can be an integral part of the handler internal storage format. Therefore, collection of some handler statistics cannot be disabled.

`mysqlnd_qc.collect_statistics_log_file` integer If `mysqlnd_qc.collect_statistics` and `mysqlnd_qc.collect_statistics_log_file` are set, the plugin will dump statistics into the specified log file at every 10th web request during PHP request shutdown. The log file needs to be writable by the web server user.

Since 1.1.0.

`mysqlnd_qc.collect_query_trace` integer Collect query back traces?

`mysqlnd_qc.query_trace_bt_depth` integer Maximum depth/level of a query code backtrace.

<code>mysqlnd_qc.ignore_sql_comments</code> integer	Whether to remove SQL comments from a query string before hashing it to generate a cache key. Disable if you do not want two statements such as <code>SELECT /*my_source_ip=123*/ id FROM test</code> and <code>SELECT /*my_source_ip=456*/ id FROM test</code> to refer to the same cache entry.  Since 1.1.0.
<code>mysqlnd_qc.slam_defense</code> integer	Activates handler based slam defense (cache stampeding protection) if available. Supported by <code>Default</code> and <code>APC</code> storage handler
<code>mysqlnd_qc.slam_defense_ttl</code> integer	TTL for stale cache entries which are served while another client updates the entries. Supported by <code>APC</code> storage handler.
<code>mysqlnd_qc.collect_normalized_queries</code> integer	Collect aggregated normalized query traces? The setting has no effect by default. You compile the extension using the define <code>NORM_QUERY_TRACE_LOG</code> to make use of the setting.
<code>mysqlnd_qc.std_data_copy</code> integer	Default storage handler: copy cached wire data? EXPERIMENTAL – use default setting!
<code>mysqlnd_qc.apc_prefix</code> string	The <code>APC</code> storage handler stores data in the <code>APC</code> user cache. The setting sets a prefix to be used for cache entries.
<code>mysqlnd_qc.memc_server</code> string	<code>MEMCACHE</code> storage handler: memcache server host.
<code>mysqlnd_qc.memc_port</code> integer	<code>MEMCACHE</code> storage handler: memcached server port.
<code>mysqlnd_qc.sqlite_data_file</code> string	<code>sqlite</code> storage handler: data file. Any setting but <code>:memory:</code> may be of little practical value.

### 21.9.7.6. Predefined Constants

Copyright 1997-2012 the PHP Documentation Group. [2906]

The constants below are defined by this extension, and will only be available when the extension has either been compiled into PHP or dynamically loaded at runtime.

*SQL hint related*

#### Example 21.319. Using SQL hint constants

The query cache is controlled by SQL hints. SQL hints are used to enable and disable caching. SQL hints can be used to set the `TTL` of a query.

The SQL hints recognized by the query cache can be manually changed at compile time. This makes it possible to use `mysqlnd_qc` in environments in which the default SQL hints are already taken and interpreted by other systems. Therefore it is recommended to use the SQL hint string constants instead of manually adding the default SQL hints to the query string.

```
<?php
/* Use constants for maximum portability */
$query = "/*" . MYSQLND_QC_ENABLE_SWITCH . "*/SELECT id FROM test";

/* Valid but less portable: default TTL */
$query = "/*qc=on*/SELECT id FROM test";

/* Valid but less portable: per statement TTL */
$query = "/*qc=on/*qc_ttl=5*/SELECT id FROM test";

printf("MYSQLND_QC_ENABLE_SWITCH: %s\n", MYSQLND_QC_ENABLE_SWITCH);
printf("MYSQLND_QC_DISABLE_SWITCH: %s\n", MYSQLND_QC_DISABLE_SWITCH);
```

```
printf("MYSQLND_QC_TTL_SWITCH: %s\n", MYSQLND_QC_TTL_SWITCH);
?>
```

The above examples will output:

```
MYSQLND_QC_ENABLE_SWITCH: qc=on
MYSQLND_QC_DISABLE_SWITCH: qc=off
MYSQLND_QC_TTL_SWITCH: qc_ttl=
```

`MYSQLND_QC_ENABLE_SWITCH` SQL hint used to enable caching of a query.  
(string)

`MYSQLND_QC_DISABLE_SWITCH` SQL hint used to disable caching of a query if  
(string) `mysqLnd_qc.cache_by_default = 1`.

`MYSQLND_QC_TTL_SWITCH` SQL hint used to set the TTL of a result set.  
(string)

`MYSQLND_QC_SERVER_ID_SWITCH` This SQL hint should not be used in general.  
(string)

It is needed by [PECL/mysqLnd\\_ms](#) to group cache entries for one statement but originating from different physical connections. If the hint is used connection settings such as user, hostname and charset are not considered for generating a cache key of a query. Instead the given value and the query string are used as input to the hashing function that generates the key.

`PECL/mysqLnd_ms` may, if instructed, cache results from MySQL Replication slaves. Because it can hold many connections to the slave the cache key shall not be formed from the user, hostname or other settings that may vary for the various slave connections. Instead, `PECL/mysqLnd_ms` provides an identifier which refers to the group of slave connections that shall be enabled to share cache entries no matter which physical slave connection was to generate the cache entry.

Use of this feature outside of `PECL/mysqLnd_ms` is not recommended.

*[mysqLnd\\_qc\\_set\\_cache\\_condition](#) related*

### Example 21.320. Example `mysqLnd_qc_set_cache_condition` usage

The function `mysqLnd_qc_set_cache_condition` allows setting conditions for automatic caching of statements which don't begin with the SQL hints necessary to manually enable caching.

```
<?php
/* Cache all accesses to tables with the name "new%" in schema/database "db_example" for 1 second */
if (!mysqLnd_qc_set_cache_condition(MYSQLND_QC_CONDITION_META_SCHEMA_PATTERN, "db_example.new%", 1)) {
    die("Failed to set cache condition!");
}

$mysqli = new mysqli("host", "user", "password", "db_example", "port");
/* cached although no SQL hint given */
$mysqli->query("SELECT id, title FROM news");

$pdo_mysql = new PDO("mysql:host=host;dbname=db_example;port=port", "user", "password");
/* not cached: no SQL hint, no pattern match */
$pdo_mysql->query("SELECT id, title FROM latest_news");
/* cached: TTL 1 second, pattern match */
```

```
$pdo_mysql->query("SELECT id, title FROM news");
?>
```

`MYSQLND_QC_CONDITION_META` Used as a parameter of `mysqlnd_qc_set_cache_condition` to set conditions for schema based automatic caching.

(int)

*Other*

The plugin version number can be obtained using either `MYSQLND_QC_VERSION`, which is the string representation of the numerical version number, or `MYSQLND_QC_VERSION_ID`, which is an integer such as 10000. Developers can calculate the version number as follows.

Version (part)	Example
Major*10000	1*10000 = 10000
Minor*100	0*100 = 0
Patch	0 = 0
<code>MYSQLND_QC_VERSION_ID</code>	10000

`MYSQLND_QC_VERSION` (string) Plugin version string, for example, "1.0.0-prototype".

`MYSQLND_QC_VERSION_ID` (int) Plugin version number, for example, 10000.

### 21.9.7.7. `mysqlnd_qc` Functions

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### 21.9.7.7.1. `mysqlnd_qc_clear_cache`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqlnd_qc_clear_cache`

Flush all cache contents

#### Description

```
bool mysqlnd_qc_clear_cache();
```

Flush all cache contents.

Flushing the cache is a storage handler responsibility. All built-in storage handler but the `memcache` storage handler support flushing the cache. The `memcache` storage handler cannot flush its cache contents.

User-defined storage handler may or may not support the operation.

#### Parameters

This function has no parameters.

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

A return value of `FALSE` indicates that flushing all cache contents has failed or the operation is not supported by the active storage handler. Applications must not expect that calling the function will always flush the cache.

#### 21.9.7.7.2. `mysqlnd_qc_get_available_handlers`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_qc\\_get\\_available\\_handlers](#)

Returns a list of available storage handler

### Description

```
array mysqlnd_qc_get_available_handlers();
```

Which storage are available depends on the compile time configuration of the query cache plugin. The [default](#) storage handler is always available. All other storage handler must be enabled explicitly when building the extension.

### Parameters

This function has no parameters.

### Return Values

Returns an array of available built-in storage handler. For each storage handler the version number and version string is given.

### Examples

#### Example 21.321. [mysqlnd\\_qc\\_get\\_available\\_handlers](#) example

```
<?php
var_dump(mysqlnd_qc_get_available_handlers());
?>
```

The above examples will output:

```
array(5) {
  ["default"]=>
  array(2) {
    ["version"]=>
    string(5) "1.0.0"
    ["version_number"]=>
    int(100000)
  }
  ["user"]=>
  array(2) {
    ["version"]=>
    string(5) "1.0.0"
    ["version_number"]=>
    int(100000)
  }
  ["APC"]=>
  array(2) {
    ["version"]=>
    string(5) "1.0.0"
    ["version_number"]=>
    int(100000)
  }
  ["MEMCACHE"]=>
  array(2) {
    ["version"]=>
    string(5) "1.0.0"
    ["version_number"]=>
    int(100000)
  }
  ["sqlite"]=>
  array(2) {
    ["version"]=>
    string(5) "1.0.0"
    ["version_number"]=>
    int(100000)
  }
}
```

```
}
}
```

**See Also**[Installation](#)[mysqlnd\\_qc\\_set\\_storage\\_handler](#)**21.9.7.7.3. mysqlnd\_qc\_get\_cache\_info**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_qc\\_get\\_cache\\_info](#)

Returns information on the current handler, the number of cache entries and cache entries, if available

**Description**

```
array mysqlnd_qc_get_cache_info();
```

**Parameters**

This function has no parameters.

**Return Values**

Returns information on the current handler, the number of cache entries and cache entries, if available. If and what data will be returned for the cache entries is subject to the active storage handler. Storage handler are free to return any data. Storage handler are recommended to return at least the data provided by the default handler, if technically possible.

The scope of the information is the PHP process. Depending on the PHP deployment model a process may serve one or more web requests.

Values are aggregated for all cache activities on a per storage handler basis. It is not possible to tell how much queries originating from `mysqli`, `PDO_MySQL` or `mysql`.API calls have contributed to the aggregated data values. Use [mysqlnd\\_qc\\_get\\_core\\_stats](#) to get timing data aggregated for all storage handlers.

Array of cache information

<code>handler</code> string	The active storage handler. All storage handler. Since 1.0.0.
<code>handler_version</code> string	The version of the active storage handler. All storage handler. Since 1.0.0.
<code>num_entries</code> int	The number of cache entries. The value depends on the storage handler in use.  The default, APC and SQLite storage handler provide the actual number of cache entries.  The MEMCACHE storage handler always returns 0. MEMCACHE does not support counting the number of cache entries.  If a user defined handler is used, the number of entries of the <code>data</code> property is reported.

Since 1.0.0.

`data` array

The version of the active storage handler.

Additional storage handler dependent data on the cache entries. Storage handler are requested to provide similar and comparable information. A user defined storage handler is free to return any data.

Since 1.0.0.

The following information is provided by the default storage handler for the `data` property.

The `data` property holds a hash. The hash is indexed by the internal cache entry identifier of the storage handler. The cache entry identifier is human-readable and contains the query string leading to the cache entry. Please, see also the example below. The following data is given for every cache entry.

`statistics` array

Statistics of the cache entry.

Since 1.0.0.

Property	Description	Version
<code>rows</code>	Number of rows of the cached result set.	Since 1.0.0.
<code>storage_size</code>	The size of the cached result set in bytes. This is the size of the payload. The value is not suited for calculating the total memory consumption of all cache entries including the administrative overhead of the cache entries.	Since 1.0.0.
<code>cache_hits</code>	How often the cached entry has been returned.	Since 1.0.0.
<code>runtime</code>	Run time of the statement to which the cache entry belongs. This is the run time of the uncached statement. It is the time between sending the statement to MySQL receiving a reply from MySQL. Run time saved by using the query cache plugin can be calculated like this: <code>cache_hits</code>	Since 1.0.0.

Property	Description	Version
	<code>* ((run_time - avg_run_time) + (store_time - avg_store_time)).</code>	
<code>store_time</code>	Store time of the statements result set to which the cache entry belongs. This is the time it took to fetch and store the results of the uncached statement.	Since 1.0.0.
<code>min_run_time</code>	Minimum run time of the cached statement. How long it took to find the statement in the cache.	Since 1.0.0.
<code>min_store_time</code>	Minimum store time of the cached statement. The time taken for fetching the cached result set from the storage medium and decoding	Since 1.0.0.
<code>avg_run_time</code>	Average run time of the cached statement.	Since 1.0.0.
<code>avg_store_time</code>	Average store time of the cached statement.	Since 1.0.0.
<code>max_run_time</code>	Average run time of the cached statement.	Since 1.0.0.
<code>max_store_time</code>	Average store time of the cached statement.	Since 1.0.0.
<code>validity</code>	Timestamp when the cache entry expires.	Since 1.1.0.

`metadata` array

Metadata of the cache entry. This is the metadata provided by MySQL together with the result set of the statement in question. Different versions of the MySQL server may return different metadata. Unlike with some of the PHP MySQL extensions no attempt is made to hide MySQL server version dependencies and version details from the caller. Please, refer to the MySQL C API documentation that belongs to the MySQL server in use for further details.

The metadata list contains one entry for every column.

Since 1.0.0.

Property	Description	Version
<code>name</code>	The field name. Depending on the MySQL version this may be the fields alias name.	Since 1.0.0.
<code>org_name</code>	The field name.	Since 1.0.0.
<code>table</code>	The table name. If an alias name was used for the table, this usually holds the alias name.	Since 1.0.0.
<code>org_table</code>	The table name.	Since 1.0.0.
<code>db</code>	The database/schema name.	Since 1.0.0.
<code>max_length</code>	The maximum width of the field. Details may vary by MySQL server version.	Since 1.0.0.
<code>length</code>	The width of the field. Details may vary by MySQL server version.	Since 1.0.0.
<code>type</code>	The data type of the field. Details may vary by the MySQL server in use. This is the MySQL C API type constants value. It is recommended to use type constants provided by the <code>mysqli</code> extension to test for its meaning. You should not test for certain type values by comparing with certain numbers.	Since 1.0.0.

The APC storage handler returns the same information for the `data` property but no `metadata`. The `metadata` of a cache entry is set to `NULL`.

The MEMCACHE storage handler does not fill the `data` property. Statistics are not available on a per cache entry basis with the MEMCACHE storage handler.

A user defined storage handler is free to provide any data.

## Examples

### Example 21.322. `mysqld_qc_get_cache_info` example

The example shows the output from the built-in default storage handler. Other storage handler may report different data.

```
<?php
/* Populate the cache, e.g. using mysqli */
$mysqli = new mysqli("host", "user", "password", "schema");
$mysqli->query("/*" . MYSQLND_QC_ENABLE_SWITCH . "*/SELECT id FROM test");

/* Display cache information */
var_dump(mysqld_qc_get_cache_info());
?>
```

The above examples will output:

```
array(4) {
  ["num_entries"]=>
  int(1)
  ["handler"]=>
  string(7) "default"
  ["handler_version"]=>
  string(5) "1.0.0"
  ["data"]=>
  array(1) {
    ["Localhost via UNIX socket 3306 user schema/*qc=on*/SELECT id FROM test"]=>
    array(2) {
      ["statistics"]=>
      array(11) {
        ["rows"]=>
        int(6)
        ["stored_size"]=>
        int(101)
        ["cache_hits"]=>
        int(0)
        ["run_time"]=>
        int(471)
        ["store_time"]=>
        int(27)
        ["min_run_time"]=>
        int(0)
        ["max_run_time"]=>
        int(0)
        ["min_store_time"]=>
        int(0)
        ["max_store_time"]=>
        int(0)
        ["avg_run_time"]=>
        int(0)
        ["avg_store_time"]=>
        int(0)
      }
      ["metadata"]=>
      array(1) {
        [0]=>
        array(8) {
          ["name"]=>
          string(2) "id"
          ["orig_name"]=>
          string(2) "id"
          ["table"]=>
          string(4) "test"
          ["orig_table"]=>
          string(4) "test"
          ["db"]=>
          string(4) "schema"
          ["max_length"]=>
          int(1)
        }
      }
    }
  }
}
```

Statistic	Description	Version
<code>cache_miss</code>	<p>Statement is considered cacheable...</p> <ul style="list-style-type: none"> <li>• ... and has been added to the cache</li> <li>• ... but the <code>PHP</code> configuration directive setting of <code>mysqlnd_qc.cache_no_table = 1</code> has prevented caching.</li> <li>• ... but an unbuffered result set is requested.</li> <li>• ... but a buffered result set was empty.</li> </ul>	Since 1.0.0.
<code>cache_put</code>	<p>Statement is considered cacheable and has been added to the cache. Take care when calculating derived statistics. Storage handler with a storage life time beyond process scope may report <code>cache_put = 0</code> together with <code>cache_hit &gt; 0</code>, if another process has filled the cache. You may want to use <code>num_entries</code> from <code>mysqlnd_qc_get_cache_info</code> if the handler supports it ( <code>default</code>, <code>APC</code>).</p>	Since 1.0.0.
<code>query_should_cache</code>	<p>Statement is considered cacheable based on query string analysis. The statement may or may not be added to the cache. See also <code>cache_put</code>.</p>	Since 1.0.0.
<code>query_should_not_cache</code>	<p>Statement is considered not cacheable based on query string analysis.</p>	Since 1.0.0.
<code>query_not_cached</code>	<p>Statement is considered not cacheable or it is considered cacheable but the storage handler has not returned a hash key for it.</p>	Since 1.0.0.
<code>query_could_cache</code>	<p>Statement is considered cacheable...</p> <ul style="list-style-type: none"> <li>• ... and statement has been run without errors</li> <li>• ... and meta data shows at least one column in the result set</li> </ul> <p>The statement may or may not be in the cache already. It may or</p>	Since 1.0.0.

Statistic	Description	Version
	may not be added to the cache later on.	
<code>query_found_in_cache</code>	Statement is considered cacheable and we have found it in the cache but we have not replayed the cached data yet and we have not send the result set to the client yet. This is not considered a cache hit because the client might not fetch the result or the cached data may be faulty.	Since 1.0.0.
<code>query_uncached_other</code>	Statement is considered cacheable and it may or may not be in the cache already but either replaying cached data has failed, no result set is available or some other error has happened.	
<code>query_uncached_no_table</code>	Statement has not been cached because the result set has at least one column which has no table name in its meta data. An example of such a query is <code>SELECT SLEEP(1)</code> . To cache those statements you have to change default value of the PHP configuration directive <code>mysqld_qc.cache_no_table</code> and set <code>mysqld_qc.cache_no_table = 1</code> . Often, it is not desired to cache such statements.	Since 1.0.0.
<code>query_uncached_use_result</code>	Statement would have been cached if a buffered result set had been used. The situation is also considered as a cache miss and <code>cache_miss</code> will be incremented as well.	Since 1.0.0.
<code>query_aggr_run_time_cache</code>	Aggregated run time (ms) of all cached queries. Cached queries are those which have incremented <code>cache_hit</code> .	Since 1.0.0.
<code>query_aggr_run_time_cache</code>	Aggregated run time (ms) of all uncached queries that have been put into the cache. See also <code>cache_put</code> .	Since 1.0.0.
<code>query_aggr_run_time_total</code>	Aggregated run time (ms) of all uncached and cached queries that have been inspected and executed by the query cache.	Since 1.0.0.
<code>query_aggr_store_time_cache</code>	Aggregated store time (ms) of all cached queries. Cached	Since 1.0.0.

Statistic	Description	Version
	queries are those which have incremented <code>cache_hit</code> .	
<code>query_aggr_store_time_cache</code>	Aggregated store time (ms) of all uncached queries that have been put into the cache. See also <code>cache_put</code> .	Since 1.0.0.
<code>query_aggr_store_time_total</code>	Aggregated store time (ms) of all uncached and cached queries that have been inspected and executed by the query cache.	Since 1.0.0.
<code>receive_bytes_recorded</code>	Recorded incoming network traffic (bytes) send from MySQL to PHP. The traffic may or may not have been added to the cache. The traffic is the total for all queries regardless if cached or not.	Since 1.0.0.
<code>receive_bytes_replayed</code>	Network traffic replayed during cache. This is the total amount of incoming traffic saved because of the usage of the query cache plugin.	Since 1.0.0.
<code>send_bytes_recorded</code>	Recorded outgoing network traffic (bytes) send from MySQL to PHP. The traffic may or may not have been added to the cache. The traffic is the total for all queries regardless if cached or not.	Since 1.0.0.
<code>send_bytes_replayed</code>	Network traffic replayed during cache. This is the total amount of outgoing traffic saved because of the usage of the query cache plugin.	Since 1.0.0.
<code>slam_stale_refresh</code>	Number of cache misses which triggered serving stale data until the client causing the cache miss has refreshed the cache entry.	Since 1.0.0.
<code>slam_stale_hit</code>	Number of cache hits while a stale cache entry gets refreshed.	Since 1.0.0.

## Examples

### Example 21.323. `mysqlnd_qc_get_core_stats` example

```
<?php
/* Enable collection of statistics - default: disabled */
ini_set("mysqlnd_qc.collect_statistics", 1);

/* Enable collection of all timing related statistics -
default: enabled but overruled by mysqlnd_qc.collect_statistics = 0 */
ini_set("mysqlnd_qc.collect_time_statistics", 1);

/* Populate the cache, e.g. using mysqli */
$mysqli = new mysqli('host', 'user', 'password', 'schema');
```

```

/* Cache miss and cache put */
$mysqlcli->query("/*qc=on*/SELECT id FROM test");
/* Cache hit */
$mysqlcli->query("/*qc=on*/SELECT id FROM test");

/* Display core statistics */
var_dump(mysqld_qc_get_core_stats());
?>

```

The above examples will output:

```

array(26) {
  ["cache_hit"]=>
  string(1) "1"
  ["cache_miss"]=>
  string(1) "1"
  ["cache_put"]=>
  string(1) "1"

**21.9.7.7.5. mysqlnd\_qc\_get\_normalized\_query\_trace\_log**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_qc\\_get\\_normalized\\_query\\_trace\\_log](#)

Returns a normalized query trace log for each query inspected by the query cache

**Description**

```
array mysqlnd_qc_get_normalized_query_trace_log();
```

Returns a normalized query trace log for each query inspected by the query cache. The collection of the trace log is disabled by default. To collect the trace log you have to set the PHP configuration directive `mysqlnd_qc.collect_normalized_query_trace` to `1`

Entries in the trace log are grouped by the normalized query statement. The normalized query statement is the query statement with all statement parameter values being replaced with a question mark. For example, the two statements `SELECT id FROM test WHERE id = 1` and `SELECT id FROM test WHERE id = 2` are normalized as `SELECT id FROM test WHERE id = ?`. Whenever a statement is inspected by the query cache which matches the normalized statement pattern, its statistics are grouped by the normalized statement string.

**Parameters**

This function has no parameters.

**Return Values**

An array of query log. Every list entry contains the normalized query string and further detail information.

Key	Description
<code>query</code>	Normalized statement string.
<code>occurrences</code>	How many statements have matched the normalized statement string in addition to the one which has created the log entry. The value is zero if a statement has been normalized, its normalized representation has been added to the log but no further queries inspected by PECL/mysqlnd_qc have the same normalized statement string.
<code>eligible_for_cache</code>	Whether the statement could be cached. An statement eligible for caching has not necessarily been cached. It not possible to tell for sure if or how many cached statement have contributed to the aggregated normalized statement log entry. However, comparing the minimum and average run time one can make an educated guess.
<code>avg_run_time</code>	The average run time of all queries contributing to the query log entry. The run time is the time between sending the query statement to MySQL and receiving an answer from MySQL.
<code>avg_store_time</code>	The average store time of all queries contributing to the query log entry. The store time is the time needed to fetch a statements result set from the server to the client and, storing it on the client.
<code>min_run_time</code>	The minimum run time of all queries contributing to the query log entry.
<code>min_store_time</code>	The minimum store time of all queries contributing to the query log entry.
<code>max_run_time</code>	The maximum run time of all queries contributing to the query log entry.
<code>max_store_time</code>	The maximum store time of all queries contributing to the query log entry.

## Examples

### Example 21.324. [mysqlnd\\_qc\\_get\\_normalized\\_query\\_trace\\_log](#) example

```
mysqlnd_qc.collect_normalized_query_trace=1
```

```
<?php
/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2)");

/* not cached */
$res = $mysqli->query("SELECT id FROM test WHERE id = 1");
var_dump($res->fetch_assoc());
$res->free();

/* cache put */
$res = $mysqli->query("/*" . MYSQLND_QC_ENABLE_SWITCH . "*/" . "SELECT id FROM test WHERE id = 2");
var_dump($res->fetch_assoc());
$res->free();

/* cache hit */
$res = $mysqli->query("/*" . MYSQLND_QC_ENABLE_SWITCH . "*/" . "SELECT id FROM test WHERE id = 2");
var_dump($res->fetch_assoc());
$res->free();

var_dump(mysqlnd_qc_get_normalized_query_trace_log());
?>
```

The above examples will output:

```

### 21.9.7.7.6. `mysqlnd_qc_get_query_trace_log`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqlnd_qc_get_query_trace_log`

Returns a backtrace for each query inspected by the query cache

#### Description

```
array mysqlnd_qc_get_query_trace_log();
```

Returns a backtrace for each query inspected by the query cache. The collection of the backtrace is disabled by default. To collect the backtrace you have to set the PHP configuration directive `mysqlnd_qc.collect_query_trace` to `1`

The maximum depth of the backtrace is limited to the depth set with the PHP configuration directive `mysqlnd_qc.query_trace_bt_depth`.

#### Parameters

This function has no parameters.

#### Return Values

An array of query backtrace. Every list entry contains the query string, a backtrace and further detail information.

Key	Description
<code>query</code>	Query string.
<code>origin</code>	Code backtrace.
<code>run_time</code>	Query run time in milliseconds. The collection of all times and the necessary <code>gettimeofday</code> system calls can be disabled by setting the PHP configuration directive <code>mysqlnd_qc.time_statistics</code> to <code>0</code>
<code>store_time</code>	Query result set store time in milliseconds. The collection of all times and the necessary <code>gettimeofday</code> system calls can be disabled by setting the PHP configuration directive <code>mysqlnd_qc.time_statistics</code> to <code>0</code>
<code>eligible_for_cache</code>	<code>TRUE</code> if query is cacheable otherwise <code>FALSE</code> .
<code>no_table_name</code>	<code>TRUE</code> if the query has generated a result set and at least one column from the result set has no table name set in its metadata. This is usually the case with queries which one probably do not want to cache such as <code>SELECT SLEEP(1)</code> . By default any such query will not be added to the cache. See also PHP configuration directive <code>mysqlnd_qc.cache_no_table</code> .
<code>was_added</code>	<code>TRUE</code> if the query result has been put into the cache, otherwise <code>FALSE</code> .
<code>was_already_in_cache</code>	<code>TRUE</code> if the query result would have been added to the cache if it was not already in the cache (cache hit). Otherwise <code>FALSE</code> .

#### Examples

##### Example 21.325. `mysqlnd_qc_get_query_trace_log` example

```
mysqlnd_qc.collect_query_trace=1
```

```
<?php
/* Connect, create and populate test table */
```

```

$mysqli = new mysqli("host", "user", "password", "schema", "port", "socket");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2)");

/* not cached */
$res = $mysqli->query("SELECT id FROM test WHERE id = 1");
var_dump($res->fetch_assoc());
$res->free();

/* cache put */
$res = $mysqli->query("/* . MYSQLND_QC_ENABLE_SWITCH . */" . "SELECT id FROM test WHERE id = 2");
var_dump($res->fetch_assoc());
$res->free();

/* cache hit */
$res = $mysqli->query("/* . MYSQLND_QC_ENABLE_SWITCH . */" . "SELECT id FROM test WHERE id = 2");
var_dump($res->fetch_assoc());
$res->free();

var_dump(mysqlnd_qc_get_query_trace_log());
?>

```

The above examples will output:

```

array(1) {
  ["id"]=>
  string(1) "1"
}

#### 21.9.7.7.7. [mysqlnd\\_qc\\_set\\_cache\\_condition](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_qc\\_set\\_cache\\_condition](#)

Set conditions for automatic caching

### Description

```
bool mysqlnd_qc_set_cache_condition(
    int condition_type,
    mixed condition,
    mixed condition_option);
```

Sets a condition for automatic caching of statements which do not contain the necessary SQL hints to enable caching of them.

### Parameters

*condition\_type*

Type of the condition. The only allowed value is `MYSQLND_QC_CONDITION_META_SCHEMA_PATTERN`.

*condition*

Parameter for the condition set with `condition_type`. Parameter type and structure depend on `condition_type`

If `condition_type` equals `MYSQLND_QC_CONDITION_META_SCHEMA_PATTERN` `condition` must be a string. The string sets a pattern. Statements are cached if table and database meta data entry of their result sets match the pattern. The pattern is checked for a match with the `db` and `org_table` meta data entries provided by the underlying MySQL client server library. Please, check the MySQL Reference manual for details about the two entries. The `db` and `org_table` values are concatenated with a dot (.) before matched against `condition`. Pattern matching supports the wildcards `%` and `_`. The wildcard `%` will

match one or many arbitrary characters. `_` will match one arbitrary character. The escape symbol is backslash.

`condition_option`

Option for `condition`. Type and structure depend on `condition_type`.

If `condition_type` equals `MYSQLND_QC_CONDITION_META_SCHEMA_PATTERN` `condition_options` is the TTL to be used.

## Examples

### Example 21.326. `mysqlnd_qc_set_cache_condition` example

```
<?php
/* Cache all accesses to tables with the name "new%" in schema/database "db_example" for 1 second */
if (!mysqlnd_qc_set_cache_condition(MYSQLND_QC_CONDITION_META_SCHEMA_PATTERN, "db_example.new%", 1)) {
    die("Failed to set cache condition!");
}

$mysqli = new mysqli("host", "user", "password", "db_example", "port");
/* cached although no SQL hint given */
$mysqli->query("SELECT id, title FROM news");

$pdo_mysql = new PDO("mysql:host=host;dbname=db_example;port=port", "user", "password");
/* not cached: no SQL hint, no pattern match */
$pdo_mysql->query("SELECT id, title FROM latest_news");
/* cached: TTL 1 second, pattern match */
$pdo_mysql->query("SELECT id, title FROM news");
?>
```

## Return Values

Returns TRUE on success or FALSE on FAILURE.

## See Also

[Quickstart: pattern based caching](#)

### 21.9.7.7.8. `mysqlnd_qc_set_is_select`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqlnd_qc_set_is_select`

Installs a callback which decides whether a statement is cached

## Description

```
mixed mysqlnd_qc_set_is_select(
    string callback);
```

Installs a callback which decides whether a statement is cached.

There are several ways of hinting PECL/`mysqlnd_qc` to cache a query. By default, PECL/`mysqlnd_qc` attempts to cache a if caching of all statements is enabled or the query string begins with a certain SQL hint. The plugin internally calls a function named `is_select()` to find out. This internal function can be replaced with a user-defined callback. Then, the user-defined callback is responsible to decide whether the plugin attempts to cache a statement. Because the internal function is replaced with the callback, the callback gains full control. The callback is free to ignore the configuration setting `mysqlnd_qc.cache_by_default` and SQL hints.

The callback is invoked for every statement inspected by the plugin. It is given the statements string as a parameter. The callback returns `FALSE` if the statement shall not be cached. It returns `TRUE` to

make the plugin attempt to cache the statements result set, if any. A so-created cache entry is given the default TTL set with the PHP configuration directive `mysqlnd_qc.ttl`. If a different TTL shall be used, the callback returns a numeric value to be used as the TTL.

The internal `is_select` function is part of the internal cache storage handler interface. Thus, a user-defined storage handler offers the same capabilities.

### Parameters

This function has no parameters.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 21.327. `mysqlnd_qc_set_is_select` example

```
<?php
/* callback which decides if query is cached */
function is_select($query) {
    static $patterns = array(
        /* true - use default from mysqlnd_qc.ttl */
        "@SELECT\s+.*\s+FROM\s+test@ismU" => true,
        /* 3 - use TTL = 3 seconds */
        "@SELECT\s+.*\s+FROM\s+news@ismU" => 3
    );
    /* check if query does match pattern */
    foreach ($patterns as $pattern => $ttl) {
        if (preg_match($pattern, $query)) {
            printf("is_select(%45s): cache\n", $query);
            return $ttl;
        }
    }
    printf("is_select(%45s): do not cache\n", $query);
    return false;
}
mysqlnd_qc_set_is_select("is_select");

/* Connect, create and populate test table */
$mysqli = new mysqli("host", "user", "password", "schema");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1), (2), (3)");

/* cache put */
$mysqli->query("SELECT id FROM test WHERE id = 1");
/* cache hit */
$mysqli->query("SELECT id FROM test WHERE id = 1");
/* cache put */
$mysqli->query("SELECT * FROM test");
?>
```

The above examples will output:

```
is_select(                DROP TABLE IF EXISTS test): do not cache
is_select(                CREATE TABLE test(id INT)): do not cache
is_select(    INSERT INTO test(id) VALUES (1), (2), (3)): do not cache
is_select(                SELECT id FROM test WHERE id = 1): cache
is_select(                SELECT id FROM test WHERE id = 1): cache
is_select(                SELECT * FROM test): cache
```

### 21.9.7.7.9. [mysqlnd\\_qc\\_set\\_storage\\_handler](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_qc\\_set\\_storage\\_handler](#)

Change current storage handler

#### Description

```
bool mysqlnd_qc_set_storage_handler(
    string handler);
```

Sets the storage handler used by the query cache. A list of available storage handler can be obtained from [mysqlnd\\_qc\\_get\\_available\\_handlers](#). Which storage are available depends on the compile time configuration of the query cache plugin. The `default` storage handler is always available. All other storage handler must be enabled explicitly when building the extension.

#### Parameters

*handler* Handler can be of type string representing the name of a built-in storage handler or an object of type [mysqlnd\\_qc\\_handler\\_default](#). The names of the built-in storage handler are `default`, `APC`, `MEMCACHE`, `sqlite`.

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

If changing the storage handler fails a catchable fatal error will be thrown. The query cache cannot operate if the previous storage handler has been shutdown but no new storage handler has been installed.

#### Examples

##### Example 21.328. [mysqlnd\\_qc\\_set\\_storage\\_handler](#) example

The example shows the output from the built-in default storage handler. Other storage handler may report different data.

```
<?php
var_dump(mysqlnd_qc_set_storage_handler("memcache"));

if (true === mysqlnd_qc_set_storage_handler("default"))
    printf("Default storage handler activated");

/* Catchable fatal error */
var_dump(mysqlnd_qc_set_storage_handler("unknown"));
?>
```

The above examples will output:

```
bool(true)
Default storage handler activated
Catchable fatal error: mysqlnd_qc_set_storage_handler(): Unknown handler 'unknown' in (file) on line (1
```

**See Also**[Installation](#)[mysqlnd\\_qc\\_get\\_available\\_handlers](#)**21.9.7.7.10. mysqlnd\_qc\_set\_user\_handlers**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_qc\\_set\\_user\\_handlers](#)

Sets the callback functions for a user-defined procedural storage handler

**Description**

```
bool mysqlnd_qc_set_user_handlers(  
    string get_hash,  
    string find_query_in_cache,  
    string return_to_cache,  
    string add_query_to_cache_if_not_exists,  
    string query_is_select,  
    string update_query_run_time_stats,  
    string get_stats,  
    string clear_cache);
```

Sets the callback functions for a user-defined procedural storage handler.

**Parameters**

<a href="#">get_hash</a>	Name of the user function implementing the storage handler <a href="#">get_hash</a> functionality.
<a href="#">find_query_in_cache</a>	Name of the user function implementing the storage handler <a href="#">find_in_cache</a> functionality.
<a href="#">return_to_cache</a>	Name of the user function implementing the storage handler <a href="#">return_to_cache</a> functionality.
<a href="#">add_query_to_cache_if_not_exists</a>	Name of the user function implementing the storage handler <a href="#">add_query_to_cache_if_not_exists</a> functionality.
<a href="#">query_is_select</a>	Name of the user function implementing the storage handler <a href="#">query_is_select</a> functionality.
<a href="#">update_query_run_time_stats</a>	Name of the user function implementing the storage handler <a href="#">update_query_run_time_stats</a> functionality.
<a href="#">get_stats</a>	Name of the user function implementing the storage handler <a href="#">get_stats</a> functionality.
<a href="#">clear_cache</a>	Name of the user function implementing the storage handler <a href="#">clear_cache</a> functionality.

**Return Values**

Returns TRUE on success or FALSE on FAILURE.

**See Also**[Procedural user-defined storage handler example](#)**21.9.7.8. Change History**

Copyright 1997-2012 the PHP Documentation Group. [2906]

This change history is a high level summary of selected changes that may impact applications and/or break backwards compatibility.

See also the [CHANGES](#) file in the source distribution for a complete list of changes.

#### 21.9.7.8.1. PECL/mysqlnd\_qc 1.2 series

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

1.2.0 - alpha

- Release date: 03/2013
- Motto/theme: PHP 5.5 compatibility

Feature changes

- Update build for PHP 5.5 (Credits: Remi Collet)
- APC storage handler update
  - Fix build for APC 3.1.13-beta and trunk
- Introduced [MYSQLND\\_QC\\_VERSION](#) and [MYSQLND\\_QC\\_VERSION\\_ID](#).

#### 21.9.7.8.2. PECL/mysqlnd\_qc 1.1 series

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

1.1.0 - stable

- Release date: 04/2012
- Motto/theme: PHP 5.4 compatibility, schema pattern based caching and mysqlnd\_ms support

1.1.0 - beta

- Release date: 04/2012
- Motto/theme: PHP 5.4 compatibility, schema pattern based caching and mysqlnd\_ms support

1.1.0 - alpha

- Release date: 04/2012
- Motto/theme: PHP 5.4 compatibility, schema pattern based caching and mysqlnd\_ms support

Feature changes

- APC storage handler update
  - Fix build for APC 3.1.9+
  - Note: Use of the APC storage handler is currently not recommended due to stability issues of APC itself.
- New PHP configuration directives
  - [mysqlnd\\_qc.collect\\_statistics\\_log\\_file](#). Aggregated cache statistics log file written after every 10th request served by the PHP process.
  - [mysqlnd\\_qc.ignore\\_sql\\_comments](#). Control whether SQL comments are ignored for cache key hash generation.

- New constants and SQL hints
  - [MYSQLND\\_QC\\_SERVER\\_ID\\_SWITCH](#) allows grouping of cache entries from different physical connections. This is needed by PECL/mysqlnd\_ms.
  - [MYSQLND\\_QC\\_CONDITION\\_META\\_SCHEMA\\_PATTERN](#) to be used with [mysqlnd\\_qc\\_set\\_cache\\_condition](#).
- New function [mysqlnd\\_qc\\_set\\_cache\\_condition](#) for built-in schema pattern based caching. Likely to support a wider range of conditions in the future.
- Report [valid\\_until](#) timestamp for cache entries of the default handler through [mysqlnd\\_qc\\_get\\_cache\\_info](#).
- Include charset number for cache entry hashing. This should prevent serving result sets which have the wrong charset.  
  
API change: [get\\_hash\\_key](#) expects new "charsetnr" (int) parameter after "port".
- API change: changing [is\\_select\(\)](#) signature from bool [is\\_select\(\)](#) to mixed [is\\_select\(\)](#). Mixed can be either boolean or array(long ttl, string server\_id). This is needed by PECL/mysqlnd\_ms.

#### Other

- Support acting as a cache backend for [PECL/mysqlnd\\_ms](#) 1.3.0-beta or later to transparently replace MySQL Replication slave reads with cache accesses, if the user explicitly allows.

#### Bug fixes

- Fixed Bug #59959 (config.m4, wrong library - 64bit memcached handler builds) (Credits: Remi Collet)

### 21.9.7.8.3. PECL/mysqlnd\_qc 1.0 series

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

#### 1.0.1-stable

- Release date: 12/2010
- Motto/theme: Prepared statement support

Added support for Prepared statements and unbuffered queries.

#### 1.0.0-beta

- Release date: 07/2010
- Motto/theme: TTL-based cache with various storage options (Memcache, APC, SQLite, user-defined)

Initial public release of the transparent TTL-based query result cache. Flexible storage of cached results. Various storage media supported.

### 21.9.8. Mysqlnd user handler plugin ([mysqlnd\\_uh](#))

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The mysqlnd user handler plugin ([mysqlnd\\_uh](#)) allows users to set hooks for most internal calls of the MySQL native driver for PHP ([mysqlnd](#)). Mysqlnd and its plugins, including PECL/mysqlnd\_uh, operate on a layer beneath the PHP MySQL extensions. A mysqlnd plugin can be considered as a proxy between the PHP MySQL extensions and the MySQL server as part of the PHP executable on

the client-side. Because the plugins operates on their own layer below the PHP MySQL extensions, they can monitor and change application actions without requiring application changes. If the PHP MySQL extensions (`mysqli`, `mysql`, `PDO_MYSQL`) are compiled to use `mysqlnd` this can be used for:

- Monitoring
  - Queries executed by any of the PHP MySQL extensions
  - Prepared statements executing by any of the PHP MySQL extensions
- Auditing
  - Detection of database usage
  - SQL injection protection using black and white lists
- Assorted
  - Load Balancing connections

The MySQL native driver for PHP (`mysqlnd`) features an internal plugin C API. C plugins, such as the `mysqlnd` user handler plugin, can extend the functionality of `mysqlnd`. PECL/`mysqlnd_uh` makes parts of the internal plugin C API available to the PHP user for plugin development with PHP.

#### Status

The `mysqlnd` user handler plugin is in alpha status. Take appropriate care before using it in production environments.

### 21.9.8.1. Security considerations

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

PECL/`mysqlnd_uh` gives users access to MySQL user names, MySQL password used by any of the PHP MySQL extensions to connect to MySQL. It allows monitoring of all queries and prepared statements exposing the statement string to the user. Therefore, the extension should be installed with care. The `PHP_INI_SYSTEM` configuration setting `mysqlnd_uh.enable` can be used to prevent users from hooking `mysqlnd` calls.

Code obfuscators and similar technologies are not suitable to prevent monitoring of `mysqlnd` library activities if PECL/`mysqlnd_uh` is made available and the user can install a proxy, for example, using [auto\\_prepend\\_file](#).

### 21.9.8.2. Documentation note

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

Many of the `mysqlnd_uh` functions are briefly described because the `mysqli` extension is a thin abstraction layer on top of the MySQL C API that the `mysqlnd` library provides. Therefore, the corresponding `mysqli` documentation (along with the MySQL reference manual) can be consulted to receive more information about a particular function.

### 21.9.8.3. On the name

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The shortcut `mysqlnd_uh` stands for `mysqlnd user handler`, and has been the name since early development.

### 21.9.8.4. Quickstart and Examples

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The `mysqlnd` user handler plugin can be understood as a client-side proxy for all PHP MySQL extensions (`mysqli`, `mysql`, `PDO_MYSQL`), if they are compiled to use the `mysqlnd` library. The extensions use the `mysqlnd` library internally, at the C level, to communicate with the MySQL server. PECL/`mysqlnd_uh` allows it to hook many `mysqlnd` calls. Therefore, most activities of the PHP MySQL extensions can be monitored.

Because monitoring happens at the level of the library, at a layer below the application, it is possible to monitor applications without changing them.

On the C level, the `mysqlnd` library is structured in modules or classes. The extension hooks almost all methods of the `mysqlnd` internal `connection` class and exposes them through the user space class `MysqlndUhConnection`. Some few methods of the `mysqlnd` internal `statement` class are made available to the PHP user with the class `MysqlndUhPreparedStatement`. By subclassing the classes `MysqlndUhConnection` and `MysqlndUhPreparedStatement` users get access to `mysqlnd` internal function calls.

**Note**

The internal `mysqlnd` function calls are not designed to be exposed to the PHP user. Manipulating their activities may cause PHP to crash or leak memory. Often, this is not considered a bug. Please, keep in mind that you are accessing C library functions through PHP which are expected to take certain actions, which you may not be able to emulate in user space. Therefore, it is strongly recommended to always call the parent method implementation when subclassing `MysqlndUhConnection` or `MysqlndUhPreparedStatement`. To prevent the worst case, the extension performs some sanity checks. Please, see also the [Mysqlnd\\_uh Configure Options](#).

#### 21.9.8.4.1. Setup

Copyright 1997-2012 the PHP Documentation Group. [2906]

The plugin is implemented as a PHP extension. See the [installation instructions](#) to install the [PECL/mysqlnd\\_uh](#) extension. Then, load the extension into PHP and activate the plugin in the PHP configuration file using the PHP configuration directive named `mysqlnd_uh.enable`. The below example shows the default settings of the extension.

**Example 21.329. Enabling the plugin (php.ini)**

```
mysqlnd_uh.enable=1
mysqlnd_uh.report_wrong_types=1
```

#### 21.9.8.4.2. How it works

Copyright 1997-2012 the PHP Documentation Group. [2906]

This describes the background and inner workings of the `mysqlnd_uh` extension.

Two classes are provided by the extension: `MysqlndUhConnection` and `MysqlndUhPreparedStatement`. `MysqlndUhConnection` lets you access almost all methods of the `mysqlnd` internal `connection` class. The latter exposes some selected methods of the `mysqlnd` internal `statement` class. For example, `MysqlndUhConnection::connect` maps to the `mysqlnd` library C function `mysqlnd_conn__connect`.

As a `mysqlnd` plugin, the `PECL/mysqlnd_uh` extension replaces `mysqlnd` library C functions with its own functions. Whenever a PHP MySQL extension compiled to use `mysqlnd` calls a `mysqlnd` function, the functions installed by the plugin are executed instead of the original `mysqlnd` ones. For example, `mysqli_connect` invokes `mysqlnd_conn__connect`, so the `connect` function installed by `PECL/`

`mysqlnd_uh` will be called. The functions installed by PECL/`mysqlnd_uh` are the methods of the built-in classes.

The built-in PHP classes and their methods do nothing but call their `mysqlnd` C library counterparts, to behave exactly like the original `mysqlnd` function they replace. The code below illustrates in pseudo-code what the extension does.

**Example 21.330. Pseudo-code: what a built-in class does**

```
class MySQLndUhConnection {
    public function connect(($conn, $host, $user, $passwd, $db, $port, $socket, $mysql_flags) {
        MYSQLND* c_mysqlnd_connection = convert_from_php_to_c($conn);
        ...
        return call_c_function(mysqlnd_conn_connect(c_mysqlnd_connection, ...));
    }
}
```

The built-in classes behave like a transparent proxy. It is possible for you to replace the proxy with your own. This is done by subclassing `MySQLndUhConnection` or `MySQLndUhPreparedStatement` to extend the functionality of the proxy, followed by registering a new proxy object. Proxy objects are installed by `mysqlnd_uh_set_connection_proxy` and `mysqlnd_uh_set_statement_proxy`.

**Example 21.331. Installing a proxy**

```
<?php
class proxy extends MySQLndUhConnection {
    public function connect($res, $host, $user, $passwd, $db, $port, $socket, $mysql_flags) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::connect($res, $host, $user, $passwd, $db, $port, $socket, $mysql_flags);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
?>
```

The above example will output:

```
proxy::connect(array (
  0 => NULL,
  1 => 'localhost',
  2 => 'root',
  3 => '',
  4 => 'test',
  5 => 3306,
  6 => NULL,
  7 => 131072,
))
proxy::connect returns true
```

**21.9.8.4.3. Installing a proxy**

Copyright 1997-2012 the PHP Documentation Group. [2906]

The extension provides two built-in classes: `MySQLndUhConnection` and `MySQLndUhPreparedStatement`. The classes are used for hooking `mysqlnd` library calls. Their methods correspond to `mysqlnd` internal functions. By default they act like a transparent proxy and do

nothing but call their `mysqlnd` counterparts. By subclassing the classes you can install your own proxy to monitor `mysqlnd`.

See also the [How it works](#) guide to learn about the inner workings of this extension.

Connection proxies are objects of the type `MySqlndUhConnection`. Connection proxy objects are installed by `mysqlnd_uh_set_connection_proxy`. If you install the built-in class `MySqlndUhConnection` as a proxy, nothing happens. It behaves like a transparent proxy.

#### Example 21.332. Proxy registration, `mysqlnd_uh.enable=1`

```
<?php
mysqlnd_uh_set_connection_proxy(new MySqlndUhConnection());
$mysqli = new mysqli("localhost", "root", "", "test");
?>
```

The `PHP_INI_SYSTEM` configuration setting `mysqlnd_uh.enable` controls whether a proxy may be set. If disabled, the extension will throw errors of type `E_WARNING`

#### Example 21.333. Proxy installation disabled

```
mysqlnd_uh.enable=0
```

```
<?php
mysqlnd_uh_set_connection_proxy(new MySqlndUhConnection());
$mysqli = new mysqli("localhost", "root", "", "test");
?>
```

The above example will output:

```
PHP Warning: MySqlndUhConnection::__construct(): (MySqlnd User Handler) The plugin has been disabled by set
PHP Warning: mysqlnd_uh_set_connection_proxy(): (MySqlnd User Handler) The plugin has been disabled by set
```

To monitor `mysqlnd`, you have to write your own proxy object subclassing `MySqlndUhConnection`. Please, see the function reference for a the list of methods that can be subclassed. Alternatively, you can use reflection to inspect the built-in `MySqlndUhConnection`.

Create a new class `proxy`. Derive it from the built-in class `MySqlndUhConnection`. Replace the `MySqlndUhConnection::connect` method. Print out the host parameter value passed to the method. Make sure that you call the parent implementation of the `connect` method. Failing to do so may give unexpected and undesired results, including memory leaks and crashes.

Register your proxy and open three connections using the PHP MySQL extensions `mysqli`, `mysql`, `PDO_MYSQL`. If the extensions have been compiled to use the `mysqlnd` library, the `proxy::connect` method will be called three times, once for each connection opened.

#### Example 21.334. Connection proxy

```
<?php
class proxy extends MySqlndUhConnection {
    public function connect($res, $host, $user, $passwd, $db, $port, $socket, $mysql_flags) {
        printf("Connection opened to '%s'\n", $host);
        /* Always call the parent implementation! */
        return parent::connect($res, $host, $user, $passwd, $db, $port, $socket, $mysql_flags);
    }
}
```

```

    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysql = mysql_connect("localhost", "root", "");
$pdo = new PDO("mysql:host=localhost;dbname=test", "root", "");
?>

```

The above example will output:

```

Connection opened to 'localhost'
Connection opened to 'localhost'
Connection opened to 'localhost'

```

The use of prepared statement proxies follows the same pattern: create a proxy object of the type `MysqlndUhPreparedStatement` and install the proxy using `mysqlnd_uh_set_statement_proxy`.

#### Example 21.335. Prepared statement proxy

```

<?php
class stmt_proxy extends MysqlndUhPreparedStatement {
    public function prepare($res, $query) {
        printf("%s(%s)\n", __METHOD__, $query);
        return parent::prepare($res, $query);
    }
}
mysqlnd_uh_set_statement_proxy(new stmt_proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$stmt = $mysqli->prepare("SELECT 'mysqlnd hacking made easy' AS _msg FROM DUAL");
?>

```

The above example will output:

```

stmt_proxy::prepare(SELECT 'mysqlnd hacking made easy' AS _msg FROM DUAL)

```

#### 21.9.8.4.4. Basic query monitoring

Copyright 1997-2012 the PHP Documentation Group. [2906]

Basic monitoring of a query statement is easy with PECL/mysqlnd\_uh. Combined with `debug_print_backtrace` it can become a powerful tool, for example, to find the origin of certain statement. This may be desired when searching for slow queries but also after database refactoring to find code still accessing deprecated databases or tables. The latter may be a complicated matter to do otherwise, especially if the application uses auto-generated queries.

#### Example 21.336. Basic Monitoring

```

<?php
class conn_proxy extends MysqlndUhConnection {
    public function query($res, $query) {
        debug_print_backtrace();
        return parent::query($res, $query);
    }
}

```

```
class stmt_proxy extends MysqlndUhPreparedStatement {
    public function prepare($res, $query) {
        debug_print_backtrace();
        return parent::prepare($res, $query);
    }
}
mysqlnd_uh_set_connection_proxy(new conn_proxy());
mysqlnd_uh_set_statement_proxy(new stmt_proxy());

printf("Proxies installed...\n");
$pdo = new PDO("mysql:host=localhost;dbname=test", "root", "");
var_dump($pdo->query("SELECT 1 AS _one FROM DUAL")->fetchAll(PDO::FETCH_ASSOC));

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->prepare("SELECT 1 AS _two FROM DUAL");
?>
```

The above example will output:

```
#0 conn_proxy->query(Resource id #19, SELECT 1 AS _one FROM DUAL)
#1 PDO->query(SELECT 1 AS _one FROM DUAL) called at [example.php:19]
array(1) {
    [0]=>
    array(1) {
        ["_one"]=>
        string(1) "1"
    }
}
#0 stmt_proxy->prepare(Resource id #753, SELECT 1 AS _two FROM DUAL)
#1 mysqli->prepare(SELECT 1 AS _two FROM DUAL) called at [example.php:22]
```

For basic query monitoring you should install a connection and a prepared statement proxy. The connection proxy should subclass `MysqlndUhConnection::query`. All database queries not using native prepared statements will call this method. In the example the `query` function is invoked by a PDO call. By default, `PDO_MySQL` is using prepared statement emulation.

All native prepared statements are prepared with the `prepare` method of `mysqlnd` exported through `MysqlndUhPreparedStatement::prepare`. Subclass `MysqlndUhPreparedStatement` and overwrite `prepare` for native prepared statement monitoring.

### 21.9.8.5. Installing/Configuring

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### 21.9.8.5.1. Requirements

Copyright 1997-2012 the PHP Documentation Group. [2906]

[PHP 5.3.3](#) or later. It is recommended to use [PHP 5.4.0](#) or later to get access to the latest `mysqlnd` features.

The `mysqlnd_uh` user handler plugin supports all PHP applications and all available PHP MySQL extensions (`mysqli`, `mysql`, `PDO_MYSQL`). The PHP MySQL extension must be configured to use `mysqlnd` in order to be able to use the `mysqlnd_uh` plugin for `mysqlnd`.

The alpha versions makes use of some `mysqli` features. You must enable `mysqli` to compile the plugin. This requirement may be removed in the future. Note, that this requirement does not restrict you to use the plugin only with `mysqli`. You can use the plugin to monitor `mysql`, `mysqli` and `PDO_MYSQL`.

#### 21.9.8.5.2. Installation

Copyright 1997-2012 the PHP Documentation Group. [2906]

Information for installing this PECL extension may be found in the manual chapter titled [Installation of PECL extensions](#). Additional information such as new releases, downloads, source files, maintainer information, and a CHANGELOG, can be located here: <http://pecl.php.net/package/mysqlnd-uh>

PECL/`mysqlnd_uh` is currently not available on Windows. The source code of the extension makes use of `C99` constructs not allowed with PHP Windows builds.

### 21.9.8.5.3. Runtime Configuration

Copyright 1997-2012 the PHP Documentation Group. [2906]

The behaviour of these functions is affected by settings in `php.ini`.

**Table 21.76. MySQLnd\_uh Configure Options**

Name	Default	Changeable	Changelog
<code>mysqlnd_uh.enable</code>	1	PHP_INI_SYSTEM	
<code>mysqlnd_uh.report_wrong1_types</code>		PHP_INI_ALL	

Here's a short explanation of the configuration directives.

`mysqlnd_uh.enable` integer Enables or disables the plugin. If set to disabled, the extension will not allow users to plug into `mysqlnd` to hook `mysqlnd` calls.

`mysqlnd_uh.report_wrong_types` integer Whether to report wrong return value types of user hooks as `E_WARNING` level errors. This is recommended for detecting errors.

### 21.9.8.5.4. Resource Types

Copyright 1997-2012 the PHP Documentation Group. [2906]

This extension has no resource types defined.

### 21.9.8.6. Predefined Constants

Copyright 1997-2012 the PHP Documentation Group. [2906]

The constants below are defined by this extension, and will only be available when the extension has either been compiled into PHP or dynamically loaded at runtime.

Most of the constants refer to details of the MySQL Client Server Protocol. Please, refer to the MySQL reference manual to learn about their meaning. To avoid content duplication, only short descriptions are given.

`MySQLndUhConnection::simpleCommand` related

The following constants can be used to detect what command is to be send through `MySQLndUhConnection::simpleCommand`.

`MYSQLND_UH_MYSQLND_COM_SLEEP` MySQL Client Server protocol command: COM\_SLEEP.  
(integer)

`MYSQLND_UH_MYSQLND_COM_QUIT` MySQL Client Server protocol command: COM\_QUIT.  
(integer)

`MYSQLND_UH_MYSQLND_COM_INIT_DB` MySQL Client Server protocol command: COM\_INIT\_DB.  
(integer)

`MYSQLND_UH_MYSQLND_COM_QUERY` MySQL Client Server protocol command: COM\_QUERY.  
(integer)

`MYSQLND_UH_MYSQLND_COM_FIELD_LIST` MySQL Client Server protocol command: COM\_FIELD\_LIST.  
(integer)

`MYSQLND_UH_MYSQLND_COM_CREATE_DB` MySQL Client Server protocol command: COM\_CREATE\_DB.  
(integer)

`MYSQLND_UH_MYSQLND_COM_DROP_DB` MySQL Client Server protocol command: COM\_DROP\_DB.  
(integer)

`MYSQLND_UH_MYSQLND_COM_REFRESH` MySQL Client Server protocol command: COM\_REFRESH.  
(integer)

`MYSQLND_UH_MYSQLND_COM_SHUTDOWN` MySQL Client Server protocol command: COM\_SHUTDOWN.  
(integer)

`MYSQLND_UH_MYSQLND_COM_STATISTICS` MySQL Client Server protocol command: COM\_STATISTICS.  
(integer)

`MYSQLND_UH_MYSQLND_COM_PROCESS_INFO` MySQL Client Server protocol command: COM\_PROCESS\_INFO.  
(integer)

`MYSQLND_UH_MYSQLND_COM_CONNECT` MySQL Client Server protocol command: COM\_CONNECT.  
(integer)

`MYSQLND_UH_MYSQLND_COM_PROCESS_KILL` MySQL Client Server protocol command: COM\_PROCESS\_KILL.  
(integer)

`MYSQLND_UH_MYSQLND_COM_DEBUG` MySQL Client Server protocol command: COM\_DEBUG.  
(integer)

`MYSQLND_UH_MYSQLND_COM_PING` MySQL Client Server protocol command: COM\_PING.  
(integer)

`MYSQLND_UH_MYSQLND_COM_TIME` MySQL Client Server protocol command: COM\_TIME.  
(integer)

`MYSQLND_UH_MYSQLND_COM_DELAYED_INSERT` MySQL Client Server protocol command:  
(integer) COM\_DELAYED\_INSERT.

`MYSQLND_UH_MYSQLND_COM_CHANGE_USER` MySQL Client Server protocol command: COM\_CHANGE\_USER.  
(integer)

`MYSQLND_UH_MYSQLND_COM_BINLOG_DUMP` MySQL Client Server protocol command: COM\_BINLOG\_DUMP.  
(integer)

`MYSQLND_UH_MYSQLND_COM_TABLE_DUMP` MySQL Client Server protocol command: COM\_TABLE\_DUMP.  
(integer)

`MYSQLND_UH_MYSQLND_COM_CONNECT_OUT` MySQL Client Server protocol command: COM\_CONNECT\_OUT.  
(integer)

`MYSQLND_UH_MYSQLND_COM_REGISTER_SLAVED` MySQL Client Server protocol command:  
(integer) COM\_REGISTER\_SLAVED.

`MYSQLND_UH_MYSQLND_COM_STMT_PREPARE` MySQL Client Server protocol command: COM\_STMT\_PREPARE.  
(integer)

`MYSQLND_UH_MYSQLND_COM_STMT_EXECUTE` MySQL Client Server protocol command: COM\_STMT\_EXECUTE.  
(integer)

`MYSQLND_UH_MYSQLND_COM_STMT_SEND_LONG_DATA` MySQL Client Server protocol command:  
(integer) COM\_STMT\_SEND\_LONG\_DATA.

`MYSQLND_UH_MYSQLND_COM_STMT_CLOSE` MySQL Client Server protocol command: COM\_STMT\_CLOSE.  
(integer)

`MYSQLND_UH_MYSQLND_COM_STMT_RESET` MySQL Client Server protocol command: COM\_STMT\_RESET.  
(integer)

`MYSQLND_UH_MYSQLND_COM_SET_OPTION` MySQL Client Server protocol command: COM\_SET\_OPTION.  
(integer)

`MYSQLND_UH_MYSQLND_COM_STMT_FETCH` MySQL Client Server protocol command: COM\_STMT\_FETCH.  
(integer)

`MYSQLND_UH_MYSQLND_COM_DAEMON` MySQL Client Server protocol command: COM\_DAEMON.  
(integer)

`MYSQLND_UH_MYSQLND_COM_END` MySQL Client Server protocol command: COM\_END.  
(integer)

The following constants can be used to analyze the `ok_packet` argument of `MySQLndUhConnection::simpleCommand`.

`MYSQLND_UH_MYSQLND_PROT_GREETING` MySQL Client Server protocol packet: greeting.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_AUTH` MySQL Client Server protocol packet: authentication.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_OK` MySQL Client Server protocol packet: OK.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_EOF` MySQL Client Server protocol packet: EOF.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_CMD` MySQL Client Server protocol packet: command.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_RS_HEADER` MySQL Client Server protocol packet: result set header.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_RS_FIELD` MySQL Client Server protocol packet: resultset field.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_ROW` MySQL Client Server protocol packet: row.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_STATS` MySQL Client Server protocol packet: stats.  
(integer)

`MYSQLND_UH_MYSQLND_PREPARE` MySQL Client Server protocol packet: prepare response.  
(integer)

`MYSQLND_UH_MYSQLND_CHG_USER` MySQL Client Server protocol packet: change user response.  
(integer)

`MYSQLND_UH_MYSQLND_PROT_LAST` No practical meaning. Last entry marker of internal C data structure list.  
(integer)

`MySQLndUhConnection::close` *related*

The following constants can be used to detect why a connection has been closed through `MySQLndUhConnection::close()`.

`MYSQLND_UH_MYSQLND_CLOSE_USER` User has called `mysqlnd` to close the connection.  
(integer)

`MYSQLND_UH_MYSQLND_CLOSE_IMPLICIT` Implicitly closed, for example, during garbage connection.  
(integer)

`MYSQLND_UH_MYSQLND_CLOSE_ID` Connection error.  
(integer)

`MYSQLND_UH_MYSQLND_CLOSE_ID` No practical meaning. Last entry marker of internal C data structure  
(integer) list.

*MySQLndUhConnection::setServerOption()* related

The following constants can be used to detect which option is set through `MySQLndUhConnection::setServerOption()`.

`MYSQLND_UH_SERVER_OPTION_M` Option: enables multi statement support.  
(integer)

`MYSQLND_UH_SERVER_OPTION_M` Option: disables multi statement support.  
(integer)

*MySQLndUhConnection::setClientOption* related

The following constants can be used to detect which option is set through `MySQLndUhConnection::setClientOption`.

`MYSQLND_UH_MYSQLND_OPTION` Option: connection timeout.  
(integer)

`MYSQLND_UH_MYSQLND_OPTION` Option: whether the MySQL compressed protocol is to be used.  
(integer)

`MYSQLND_UH_MYSQLND_OPTION` Option: named pipe to use for connection (Windows).  
(integer)

`MYSQLND_UH_MYSQLND_OPTION` Option: init command to execute upon connect.  
(integer)

`MYSQLND_UH_MYSQLND_READ_DE` Option: MySQL server default file to read upon connect.  
(integer)

`MYSQLND_UH_MYSQLND_READ_DE` Option: MySQL server default file group to read upon connect.  
(integer)

`MYSQLND_UH_MYSQLND_SET_CHA` Option: charset description files directory.  
(integer)

`MYSQLND_UH_MYSQLND_SET_CHA` Option: charset name.  
(integer)

`MYSQLND_UH_MYSQLND_OPT_LO` Option: Whether to allow `LOAD DATA LOCAL INFILE` use.  
(integer)

`MYSQLND_UH_MYSQLND_OPT_PR` Option: supported protocol version.  
(integer)

`MYSQLND_UH_MYSQLND_SHARED` Option: shared memory base name for shared memory connections.  
(integer)

`MYSQLND_UH_MYSQLND_OPT_RE` Option: connection read timeout.  
(integer)

`MYSQLND_UH_MYSQLND_OPT_W` Option: connection write timeout.  
(integer)

`MYSQLND_UH_MYSQLND_OPT_U` Option: unbuffered result sets.  
(integer)

- `MYSQLND_UH_MYSQLND_OPT_USE_EMBEDDED_SERVER` Embedded server related.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_USE_EMBEDDED_SERVER_BIND` Embedded server related.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_GUEST_CONNECTION` TODO  
(integer)
- `MYSQLND_UH_MYSQLND_SET_CLIENT_IP` TODO  
(integer)
- `MYSQLND_UH_MYSQLND_SECURE_FILE` TODO  
(integer)
- `MYSQLND_UH_MYSQLND_REPORT_TRUNCATION` Option: Whether to report data truncation.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_RECONNECT` Option: Whether to reconnect automatically.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_SSL_VERIFY_SERVER_CERT` Option: TODO  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_NETWORK_BUFFER_SIZE_COMMANDS` Option: mysqlnd network buffer size for commands.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_NETWORK_BUFFER_SIZE_READING` Option: mysqlnd network buffer size for reading from the server.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_SSL_KEY` Option: SSL key.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_SSL_CERTIFICATE` Option: SSL certificate.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_SSL_CA` Option: SSL CA.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_SSL_PATH_TO_CA` Option: Path to SSL CA.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_SSL_CIPHER` Option: SSL cipher.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_SSL_PASSPHRASE` Option: SSL passphrase.  
(integer)
- `MYSQLND_UH_SERVER_OPTION_PLUGIN_DIRECTORY` Option: server plugin directory.  
(integer)
- `MYSQLND_UH_SERVER_OPTION_DEFAULT_AUTHENTICATION_METHOD` Option: default authentication method.  
(integer)
- `MYSQLND_UH_SERVER_OPTION_SECURE_CLIENT_IP` TODO  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_MAXIMUM_ALLOWED_PACKET_SIZE` Option: maximum allowed packet size. Available as of PHP 5.4.0.  
(integer)
- `MYSQLND_UH_MYSQLND_OPT_AUTOMATICALLY_LOAD_EXTENSION` Option: TODO. Available as of PHP 5.4.0.  
(integer)

`MYSQLND_UH_MYSQLND_OPT_INT_INTEGER` (integer) Option: `make mysqLnd` return integer and float columns as long even when using the MySQL Client Server text protocol. Only available with a custom build of `mysqLnd`.

*Other*

The plugins version number can be obtained using `MYSQLND_UH_VERSION` or `MYSQLND_UH_VERSION_ID`. `MYSQLND_UH_VERSION` is the string representation of the numerical version number `MYSQLND_UH_VERSION_ID`, which is an integer such as 10000. Developers can calculate the version number as follows.

Version (part)	Example
Major*10000	1*10000 = 10000
Minor*100	0*100 = 0
Patch	0 = 0
<code>MYSQLND_UH_VERSION_ID</code>	10000

`MYSQLND_UH_VERSION` (string) Plugin version string, for example, "1.0.0-alpha".

`MYSQLND_UH_VERSION_ID` (integer) Plugin version number, for example, 10000.

### 21.9.8.7. The `MysqLndUhConnection` class (`MysqLndUhConnection`)

Copyright 1997-2012 the PHP Documentation Group. [2906]

```
MysqLndUhConnection {
MysqLndUhConnection

    Methods

    public bool MysqLndUhConnection::changeUser(
        mysqLnd_connection connection,
        string user,

### 21.9.8.7.1. `MysqlndUhConnection::changeUser`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::changeUser`

Changes the user of the specified mysqlnd database connection

#### Description

```

public bool MysqlndUhConnection::changeUser(
    mysqlnd_connection connection,
    string user,
    string password,
    string database,
    bool silent,
    int passwd_len);

```

Changes the user of the specified mysqlnd database connection

#### Parameters

<i>connection</i>	Mysqlnd connection handle. Do not modify!
<i>user</i>	The MySQL user name.
<i>password</i>	The MySQL password.
<i>database</i>	The MySQL database to change to.
<i>silent</i>	Controls if mysqlnd is allowed to emit errors or not.
<i>passwd_len</i>	Length of the MySQL password.

#### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

#### Examples

##### Example 21.337. `MysqlndUhConnection::changeUser` example

```

<?php
class proxy extends MysqlndUhConnection {
    /* Hook mysqlnd's connection::change_user call */
    public function changeUser($res, $user, $passwd, $db, $silent, $passwd_len) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::changeUser($res, $user, $passwd, $db, $silent, $passwd_len);
    }
}

```

```
printf("%s returns %s\n", __METHOD__, var_export($ret, true));
return $ret;
}
}
/* Install proxy/hooks to be used with all future mysqlnd connection */
mysqlnd_uh_set_connection_proxy(new proxy());

/* Create mysqli connection which is using the mysqlnd library */
$mysqli = new mysqli("localhost", "root", "", "test");

/* Example of a user API call which triggers the hooked mysqlnd call */
var_dump($mysqli->change_user("root", "bar", "test"));
?>
```

The above example will output:

```
proxy::changeUser(array (
  0 => NULL,
  1 => 'root',
  2 => 'bar',
  3 => 'test',
  4 => false,
  5 => 3,
))
proxy::changeUser returns false
bool(false)
```

### 21.9.8.7.2. `MysqlndUhConnection::charsetName`

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

- [MysqlndUhConnection::charsetName](#)

Returns the default character set for the database connection

#### Description

```
public string MysqlndUhConnection::charsetName(
    mysqlnd_connection connection);
```

Returns the default character set for the database connection.

#### Parameters

*connection* Mysqlnd connection handle. Do not modify!

#### Return Values

The default character set.

#### Examples

##### Example 21.338. `MysqlndUhConnection::charsetName` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function charsetName($res) {
```

```

printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
$ret = parent::charsetName($res);
printf("%s returns %s\n", __METHOD__, var_export($ret, true));
return $ret;
}
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump(mysqli_character_set_name($mysqli));
?>

```

The above example will output:

```

proxy::charsetName(array (
  0 => NULL,
))
proxy::charsetName returns 'latin1'
string(6) "latin1"

```

### See Also

#### 21.9.8.7.3. `MysqlndUhConnection::close`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::close`

Closes a previously opened database connection

### Description

```

public bool MysqlndUhConnection::close(
    mysqlnd_connection connection,
    int close_type);

```

Closes a previously opened database connection.

### Note

Failing to call the parent implementation may cause memory leaks or crash PHP. This is not considered a bug. Please, keep in mind that the `mysqlnd` library functions have never been designed to be exposed to the user space.

### Parameters

*connection*

The connection to be closed. Do not modify!

*close\_type*

Why the connection is to be closed. The value of *close\_type* is one of `MYSQLND_UH_MYSQLND_CLOSE_EXPLICIT`, `MYSQLND_UH_MYSQLND_CLOSE_IMPLICIT`, `MYSQLND_UH_MYSQLND_CLOSE_DISCONNECTED` or `MYSQLND_UH_MYSQLND_CLOSE_LAST`. The latter should never be seen, unless the default behaviour of the `mysqlnd` library has been changed by a plugin.

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

## Examples

### Example 21.339. [MysqlndUhConnection::close](#) example

```
<?php
function close_type_to_string($close_type) {
    $mapping = array(
        MYSQLND_UH_MYSQLND_CLOSE_DISCONNECTED => "MYSQLND_UH_MYSQLND_CLOSE_DISCONNECTED",
        MYSQLND_UH_MYSQLND_CLOSE_EXPLICIT => "MYSQLND_UH_MYSQLND_CLOSE_EXPLICIT",
        MYSQLND_UH_MYSQLND_CLOSE_IMPLICIT => "MYSQLND_UH_MYSQLND_CLOSE_IMPLICIT",
        MYSQLND_UH_MYSQLND_CLOSE_LAST => "MYSQLND_UH_MYSQLND_CLOSE_IMPLICIT"
    );
    return (isset($mapping[$close_type])) ? $mapping[$close_type] : 'unknown';
}

class proxy extends MysqlndUhConnection {
    public function close($res, $close_type) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        printf("close_type = %s\n", close_type_to_string($close_type));
        /* WARNING: you must call the parent */
        $ret = parent::close($res, $close_type);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->close();
?>
```

The above example will output:

```
proxy::close(array (
    0 => NULL,
    1 => 0,
))
close_type = MYSQLND_UH_MYSQLND_CLOSE_EXPLICIT
proxy::close returns true
```

## See Also

### 21.9.8.7.4. [MysqlndUhConnection::connect](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::connect](#)

Open a new connection to the MySQL server

## Description

```
public bool MysqlndUhConnection::connect(
    mysqlnd_connection connection,
    string host,
    string use",
    string password,
    string database,
    int port,
    string socket,
```

```
int mysql_flags);
```

Open a new connection to the MySQL server.

### Parameters

<code>connection</code>	Mysqlnd connection handle. Do not modify!
<code>host</code>	Can be either a host name or an IP address. Passing the <code>NULL</code> value or the string "localhost" to this parameter, the local host is assumed. When possible, pipes will be used instead of the TCP/IP protocol.
<code>user</code>	The MySQL user name.
<code>password</code>	If not provided or <code>NULL</code> , the MySQL server will attempt to authenticate the user against those user records which have no password only. This allows one username to be used with different permissions (depending on if a password as provided or not).
<code>database</code>	If provided will specify the default database to be used when performing queries.
<code>port</code>	Specifies the port number to attempt to connect to the MySQL server.
<code>socket</code>	Specifies the socket or named pipe that should be used. If <code>NULL</code> , mysqlnd will default to <code>/tmp/mysql.sock</code> .
<code>mysql_flags</code>	Connection options.

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

#### Example 21.340. `MysqlndUhConnection::connect` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function connect($res, $host, $user, $passwd, $db, $port, $socket, $mysql_flags) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::connect($res, $host, $user, $passwd, $db, $port, $socket, $mysql_flags);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
?>
```

The above example will output:

```
proxy::connect(array (
    0 => NULL,
    1 => 'localhost',
    2 => 'root',
    3 => '',
    4 => 'test',
    5 => 3306,
    6 => NULL,
```

```
7 => 131072,
))
proxy::connect returns true
```

#### 21.9.8.7.5. `mysqlnd_uh_connection::__construct`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqlnd_uh_connection::__construct`

The `__construct` purpose

### Description

```
public MysqlndUhConnection::__construct();
```

### Warning

This function is currently not documented; only its argument list is available.

### Parameters

This function has no parameters.

### Return Values

#### 21.9.8.7.6. `mysqlnd_uh_connection::endPSession`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqlnd_uh_connection::endPSession`

End a persistent connection

### Description

```
public bool MysqlndUhConnection::endPSession(
    mysqlnd_connection connection);
```

End a persistent connection

### Warning

This function is currently not documented; only its argument list is available.

### Parameters

`connection` Mysqlnd connection handle. Do not modify!

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

**Example 21.341. [MySQLndUhConnection::endPSession](#) example**

```
<?php
class proxy extends MySQLndUhConnection {
    public function endPSession($conn) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::endPSession($conn);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("p:localhost", "root", "", "test");
$mysqli->close();
?>
```

The above example will output:

```
proxy::endPSession(array (
    0 => NULL,
))
proxy::endPSession returns true
```

**See Also**

[mysqlnd\\_uh\\_set\\_connection\\_proxy](#)

**21.9.8.7.7. [MySQLndUhConnection::escapeString](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MySQLndUhConnection::escapeString](#)

Escapes special characters in a string for use in an SQL statement, taking into account the current charset of the connection

**Description**

```
public string MySQLndUhConnection::escapeString(
    mysqlnd_connection connection,
    string escape_string);
```

Escapes special characters in a string for use in an SQL statement, taking into account the current charset of the connection.

**Parameters**

[MYSQLND\\_UH\\_RES\\_MYSQLND\\_NAME](#) MySQLnd connection handle. Do not modify!

[escape\\_string](#) The string to be escaped.

**Return Values**

The escaped string.

**Examples**

**Example 21.342. [MySQLndUhConnection::escapeString](#) example**

```
<?php
```

```
class proxy extends MysqlndUhConnection {
    public function escapeString($res, $string) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::escapeString($res, $string);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->set_charset("latin1");
$mysqli->real_escape_string("test0'test");
?>
```

The above example will output:

```
proxy::escapeString(array (
    0 => NULL,
    1 => 'test0'test',
))
proxy::escapeString returns 'test0\\\'test'
```

### 21.9.8.7.8. [MysqlndUhConnection::getAffectedRows](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getAffectedRows](#)

Gets the number of affected rows in a previous MySQL operation

#### Description

```
public int MysqlndUhConnection::getAffectedRows(
    mysqlnd_connection connection);
```

Gets the number of affected rows in a previous MySQL operation.

#### Parameters

*connection* Mysqlnd connection handle. Do not modify!

#### Return Values

Number of affected rows.

#### Examples

#### Example 21.343. [MysqlndUhConnection::getAffectedRows](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function getAffectedRows($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getAffectedRows($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
    }
}
```

```

    return $ret;
}
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT)");
$mysqli->query("INSERT INTO test(id) VALUES (1)");
var_dump($mysqli->affected_rows);
?>

```

The above example will output:

```

proxy::getAffectedRows(array (
  0 => NULL,
))
proxy::getAffectedRows returns 1
int(1)

```

#### 21.9.8.7.9. `MysqlndUhConnection::getErrorNumber`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getErrorNumber](#)

Returns the error code for the most recent function call

### Description

```

public int MysqlndUhConnection::getErrorNumber(
    mysqlnd_connection connection);

```

Returns the error code for the most recent function call.

### Parameters

*connection* Mysqlnd connection handle. Do not modify!

### Return Values

Error code for the most recent function call.

### Examples

`MysqlndUhConnection::getErrorNumber` is not only executed after the invocation of a user space API call which maps directly to it but also called internally.

#### Example 21.344. `MysqlndUhConnection::getErrorNumber` example

```

<?php
class proxy extends MysqlndUhConnection {
    public function getErrorNumber($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getErrorNumber($res);
    }
}

```

```

    printf("%s returns %s\n", __METHOD__, var_export($ret, true));
    return $ret;
}
}
mysqlnd_uh_set_connection_proxy(new proxy());

printf("connect...\n");
$mysqli = new mysqli("localhost", "root", "", "test");
printf("query...\n");
$mysqli->query("PLEASE_LET_THIS_BE_INVALID_SQL");
printf("errno...\n");
var_dump($mysqli->errno);
printf("close...\n");
$mysqli->close();
?>

```

The above example will output:

```

connect...
proxy::getLineNumber(array (
    0 => NULL,
))
proxy::getLineNumber returns 0
query...
errno...
proxy::getLineNumber(array (
    0 => NULL,
))
proxy::getLineNumber returns 1064

- [MysqlndUhConnection::getFieldCount](#)

Returns the number of columns for the most recent query

#### Description

```
public int MysqlndUhConnection::getFieldCount(
    mysqlnd_connection connection);
```

Returns the number of columns for the most recent query.

## Parameters

[connection](#) Mysqlnd connection handle. Do not modify!

## Return Values

Number of columns.

## Examples

[MysqlndUhConnection::getFieldCount](#) is not only executed after the invocation of a user space API call which maps directly to it but also called internally.

### Example 21.346. [MysqlndUhConnection::getFieldCount](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function getFieldCount($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getFieldCount($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->query("WILL_I_EVER_LEARN_SQL?");
var_dump($mysqli->field_count);
$mysqli->query("SELECT 1, 2, 3 FROM DUAL");
var_dump($mysqli->field_count);
?>
```

The above example will output:

```
proxy::getFieldCount(array (
    0 => NULL,
))
proxy::getFieldCount returns 0
int(0)
proxy::getFieldCount(array (
    0 => NULL,
))
proxy::getFieldCount returns 3
proxy::getFieldCount(array (
    0 => NULL,
))
proxy::getFieldCount returns 3
int(3)
```

### 21.9.8.7.12. [MysqlndUhConnection::getHostInformation](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getHostInformation](#)

Returns a string representing the type of connection used

## Description

```
public string MysqlndUhConnection::getHostInformation(
    mysqlnd_connection connection);
```

Returns a string representing the type of connection used.

## Parameters

*connection* Mysqlnd connection handle. Do not modify!

## Return Values

Connection description.

## Examples

### Example 21.347. [MysqlndUhConnection::getHostInformation](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function getHostInformation($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getHostInformation($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->host_info);
?>
```

The above example will output:

```
proxy::getHostInformation(array (
    0 => NULL,
))
proxy::getHostInformation returns 'Localhost via UNIX socket'
string(25) "Localhost via UNIX socket"
```

### 21.9.8.7.13. [MysqlndUhConnection::getLastInsertId](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getLastInsertId](#)

Returns the auto generated id used in the last query.

## Description

```
public int MysqlndUhConnection::getLastInsertId(
    mysqlnd_connection connection);
```

Returns the auto generated id used in the last query.

## Parameters

[connection](#) Mysqlnd connection handle. Do not modify!

## Return Values

Last insert id.

## Examples

### Example 21.348. [MysqlndUhConnection::getLastInsertId](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function getLastInsertId($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getLastInsertId($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->query("DROP TABLE IF EXISTS test");
$mysqli->query("CREATE TABLE test(id INT AUTO_INCREMENT PRIMARY KEY, col VARCHAR(255))");
$mysqli->query("INSERT INTO test(col) VALUES ('a')");
var_dump($mysqli->insert_id);
?>
```

The above example will output:

```
proxy::getLastInsertId(array (
    0 => NULL,
))
proxy::getLastInsertId returns 1
int(1)
```

### 21.9.8.7.14. [MysqlndUhConnection::getLastMessage](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getLastMessage](#)

Retrieves information about the most recently executed query

## Description

```
public void MysqlndUhConnection::getLastMessage(
    mysqlnd_connection connection);
```

Retrieves information about the most recently executed query.

## Parameters

[connection](#) Mysqlnd connection handle. Do not modify!

## Return Values

Last message. Trying to return a string longer than 511 bytes will cause an error of the type [E\\_WARNING](#) and result in the string being truncated.

## Examples

### Example 21.349. [MysqlndUhConnection::getLastMessage](#) example

```

<?php
class proxy extends MysqlndUhConnection {
    public function getLastMessage($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getLastMessage($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->info);
$mysqli->query("DROP TABLE IF EXISTS test");
var_dump($mysqli->info);
?>

```

The above example will output:

```

proxy::getLastMessage(array (
    0 => NULL,
))
proxy::getLastMessage returns ''
string(0) ""
proxy::getLastMessage(array (
    0 => NULL,
))
proxy::getLastMessage returns ''
string(0) ""

```

### 21.9.8.7.15. [MysqlndUhConnection::getProtocolInformation](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getProtocolInformation](#)

Returns the version of the MySQL protocol used

## Description

```

public string MysqlndUhConnection::getProtocolInformation(
    mysqlnd_connection connection);

```

Returns the version of the MySQL protocol used.

## Parameters

[connection](#) MySQLnd connection handle. Do not modify!

## Return Values

The protocol version.

## Examples

### Example 21.350. `MysqlndUhConnection::getProtocolInformation` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function getProtocolInformation($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getProtocolInformation($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->protocol_version);
?>
```

The above example will output:

```
proxy::getProtocolInformation(array (
  0 => NULL,
))
proxy::getProtocolInformation returns 10
int(10)
```

### 21.9.8.7.16. `MysqlndUhConnection::getServerInformation`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::getServerInformation`

Returns the version of the MySQL server

## Description

```
public string MysqlndUhConnection::getServerInformation(
    mysqlnd_connection connection);
```

Returns the version of the MySQL server.

## Parameters

*connection* MySQLnd connection handle. Do not modify!

## Return Values

The server version.

## Examples

**Example 21.351. [MySQLndUhConnection::getServerInformation](#) example**

```
<?php
class proxy extends MySQLndUhConnection {
    public function getServerInformation($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getServerInformation($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->server_info);
?>
```

The above example will output:

```
proxy::getServerInformation(array (
    0 => NULL,
))
proxy::getServerInformation returns '5.1.45-debug-log'
string(16) "5.1.45-debug-log"
```

**21.9.8.7.17. [MySQLndUhConnection::getServerStatistics](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MySQLndUhConnection::getServerStatistics](#)

Gets the current system status

**Description**

```
public string MySQLndUhConnection::getServerStatistics(
    mysqlnd_connection connection);
```

Gets the current system status.

**Parameters**

*connection* MySQLnd connection handle. Do not modify!

**Return Values**

The system status message.

**Examples**

**Example 21.352. [MySQLndUhConnection::getServerStatistics](#) example**

```
<?php
class proxy extends MySQLndUhConnection {
    public function getServerStatistics($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
```

```

    $ret = parent::getServerStatistics($res);
    printf("%s returns %s\n", __METHOD__, var_export($ret, true));
    return $ret;
}
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump(mysqli_stat($mysqli));
?>

```

The above example will output:

```

proxy::getServerStatistics(array (
    0 => NULL,
))
proxy::getServerStatistics returns 'Uptime: 2059995 Threads: 1 Questions: 126157 Slow queries: 0 Opens: 1
string(140) "Uptime: 2059995 Threads: 1 Questions: 126157 Slow queries: 0 Opens: 6377 Flush tables: 1

```

### 21.9.8.7.18. `MySQLndUhConnection::getServerVersion`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MySQLndUhConnection::getServerVersion`

Returns the version of the MySQL server as an integer

#### Description

```

public int MySQLndUhConnection::getServerVersion(
    mysqlnd_connection connection);

```

Returns the version of the MySQL server as an integer.

#### Parameters

*connection* MySQLnd connection handle. Do not modify!

#### Return Values

The MySQL version.

#### Examples

##### Example 21.353. `MySQLndUhConnection::getServerVersion` example

```

<?php
class proxy extends MySQLndUhConnection {
    public function getServerVersion($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getServerVersion($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

```

```
$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->server_version);
?>
```

The above example will output:

```
proxy::getServerVersion(array (
  0 => NULL,
))
proxy::getServerVersion returns 50145
int(50145)
```

### 21.9.8.7.19. [MySQLndUhConnection::getSqlstate](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MySQLndUhConnection::getSqlstate](#)

Returns the SQLSTATE error from previous MySQL operation

#### Description

```
public string MySQLndUhConnection::getSqlstate(
    mysqlnd_connection connection);
```

Returns the SQLSTATE error from previous MySQL operation.

#### Parameters

*connection* MySQLnd connection handle. Do not modify!

#### Return Values

The SQLSTATE code.

#### Examples

##### Example 21.354. [MySQLndUhConnection::getSqlstate](#) example

```
<?php
class proxy extends MySQLndUhConnection {
    public function getSqlstate($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getSqlstate($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->sqlstate);
$mysqli->query("AN_INVALID_REQUEST_TO_PROVOKE_AN_ERROR");
var_dump($mysqli->sqlstate);
?>
```

The above example will output:

```
proxy::getSqlstate(array (
  0 => NULL,
))
proxy::getSqlstate returns '00000'
string(5) "00000"
proxy::getSqlstate(array (
  0 => NULL,
))
proxy::getSqlstate returns '42000'
string(5) "42000"
```

### See Also

#### 21.9.8.7.20. [MysqlndUhConnection::getStatistics](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getStatistics](#)

Returns statistics about the client connection.

### Description

```
public array MysqlndUhConnection::getStatistics(
    mysqlnd_connection connection);
```

Returns statistics about the client connection.

### Warning

This function is currently not documented; only its argument list is available.

### Parameters

*connection* Mysqlnd connection handle. Do not modify!

### Return Values

Connection statistics collected by mysqlnd.

### Examples

#### Example 21.355. [MysqlndUhConnection::getStatistics](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function getStatistics($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getStatistics($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->get_connection_stats());
?>
```

The above example will output:

```
proxy::getStatistics(array (
  0 => NULL,
))
proxy::getStatistics returns array (

**21.9.8.7.21. MySQLndUhConnection::getThreadId**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getThreadId](#)

Returns the thread ID for the current connection

### Description

```
public int MysqlndUhConnection::getThreadId(
    mysqlnd_connection connection);
```

Returns the thread ID for the current connection.

### Parameters

*connection* Mysqlnd connection handle. Do not modify!

### Return Values

Connection thread id.

### Examples

#### Example 21.356. [MysqlndUhConnection::getThreadId](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function getThreadId($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getThreadId($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->thread_id);
?>
```

The above example will output:

```
proxy::getThreadId(array (
    0 => NULL,
))
proxy::getThreadId returns 27646
int(27646)
```

#### 21.9.8.7.22. [MysqlndUhConnection::getWarningCount](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::getWarningCount](#)

Returns the number of warnings from the last query for the given link

## Description

```
public int MysqlndUhConnection::getWarningCount(
    mysqlnd_connection connection);
```

Returns the number of warnings from the last query for the given link.

## Parameters

[connection](#) Mysqlnd connection handle. Do not modify!

## Return Values

Number of warnings.

## Examples

### Example 21.357. [MysqlndUhConnection::getWarningCount](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function getWarningCount($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::getWarningCount($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
var_dump($mysqli->warning_count);
?>
```

The above example will output:

```
proxy::getWarningCount(array (
    0 => NULL,
))
proxy::getWarningCount returns 0
int(0)
```

### 21.9.8.7.23. [MysqlndUhConnection::init](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::init](#)

Initialize mysqlnd connection

## Description

```
public bool MysqlndUhConnection::init(
    mysqlnd_connection connection);
```

Initialize mysqlnd connection. This is an mysqlnd internal call to initialize the connection object.

**Note**

Failing to call the parent implementation may cause memory leaks or crash PHP. This is not considered a bug. Please, keep in mind that the [mysqlnd](#) library functions have never been designed to be exposed to the user space.

**Parameters**

[connection](#) Mysqlnd connection handle. Do not modify!

**Return Values**

Returns [TRUE](#) on success. Otherwise, returns [FALSE](#)

**Examples****Example 21.358. [MysqlndUhConnection::init](#) example**

```
<?php
class proxy extends MysqlndUhConnection {
    public function init($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::init($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
?>
```

The above example will output:

```
proxy::init(array (
    0 => NULL,
))
proxy::init returns true
```

**See Also**

**21.9.8.7.24. [MysqlndUhConnection::killConnection](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::killConnection](#)

Asks the server to kill a MySQL thread

**Description**

```
public bool MysqlndUhConnection::killConnection(
    mysqlnd_connection connection,
    int pid);
```

Asks the server to kill a MySQL thread.

**Parameters**

`connection` Mysqlnd connection handle. Do not modify!

`pid` Thread Id of the connection to be killed.

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

#### Example 21.359. `MysqlndUhConnection::kill` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function killConnection($res, $pid) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::killConnection($res, $pid);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->kill($mysqli->thread_id);
?>
```

The above example will output:

```
proxy::killConnection(array (
    0 => NULL,
    1 => 27650,
))
proxy::killConnection returns true
```

#### 21.9.8.7.25. `MysqlndUhConnection::listFields`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::listFields`

List MySQL table fields

### Description

```
public array MysqlndUhConnection::listFields(
    mysqlnd_connection connection,
    string table,
    string achtung_wild);
```

List MySQL table fields.

### Warning

This function is currently not documented; only its argument list is available.

## Parameters

<i>connection</i>	Mysqlnd connection handle. Do not modify!
<i>table</i>	The name of the table that's being queried.
<i>pattern</i>	Name pattern.

## Return Values

## Examples

### Example 21.360. `MysqlndUhConnection::listFields` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function listFields($res, $table, $pattern) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::listFields($res, $table, $pattern);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysql = mysql_connect("localhost", "root", "");
mysql_select_db("test", $mysql);
mysql_query("DROP TABLE IF EXISTS test_a", $mysql);
mysql_query("CREATE TABLE test_a(id INT, coll VARCHAR(255))", $mysql);
$res = mysql_list_fields("test", "test_a", $mysql);
printf("num_rows = %d\n", mysql_num_rows($res));
while ($row = mysql_fetch_assoc($res))
    var_dump($row);
?>
```

The above example will output:

```
proxy::listFields(array (
  0 => NULL,
  1 => 'test_a',
  2 => '',
))
proxy::listFields returns NULL
num_rows = 0
```

### 21.9.8.7.26. `MysqlndUhConnection::listMethod`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::listMethod](#)

Wrapper for assorted list commands

## Description

```
public void MysqlndUhConnection::listMethod(
```

```
mysqlnd_connection connection,
string query,
string achtung_wild,
string par1);
```

Wrapper for assorted list commands.

### Warning

This function is currently not documented; only its argument list is available.

### Parameters

<code>connection</code>	Mysqlnd connection handle. Do not modify!
<code>query</code>	SHOW command to be executed.
<code>achtung_wild</code>	
<code>par1</code>	

### Return Values

### Return Values

TODO

### Examples

#### Example 21.361. `MysqlndUhConnection::listMethod` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function listMethod($res, $query, $pattern, $par1) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::listMethod($res, $query, $pattern, $par1);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysql = mysql_connect("localhost", "root", "");
$res = mysql_list_dbs($mysql);
printf("num_rows = %d\n", mysql_num_rows($res));
while ($row = mysql_fetch_assoc($res))
    var_dump($row);
?>
```

The above example will output:

```
proxy::listMethod(array (
    0 => NULL,
    1 => 'SHOW DATABASES',
    2 => '',
    3 => '',
))
proxy::listMethod returns NULL
num_rows = 6
array(1) {
    ["Database"]=>
    string(18) "information_schema"
```

```
}
array(1) {

#### 21.9.8.7.27. `MysqlndUhConnection::moreResults`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::moreResults`

Check if there are any more query results from a multi query

### Description

```
public bool MysqlndUhConnection::moreResults(
    mysqlnd_connection connection);
```

Check if there are any more query results from a multi query.

### Parameters

*connection* Mysqlnd connection handle. Do not modify!

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

#### Example 21.362. `MysqlndUhConnection::moreResults` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function moreResults($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::moreResults($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());
```

```

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->multi_query("SELECT 1 AS _one; SELECT 2 AS _two");
do {
    $res = $mysqli->store_result();
    var_dump($res->fetch_assoc());
    printf("%s\n", str_repeat("-", 40));
} while ($mysqli->more_results() && $mysqli->next_result());
?>

```

The above example will output:

```

array(1) {
    ["_one"]=>
        string(1) "1"
}
-----
proxy::moreResults(array (
    0 => NULL,
))
proxy::moreResults returns true
proxy::moreResults(array (
    0 => NULL,
))
proxy::moreResults returns true
array(1) {
    ["_two"]=>
        string(1) "2"
}
-----
proxy::moreResults(array (
    0 => NULL,
))
proxy::moreResults returns false

```

#### 21.9.8.7.28. `MysqlndUhConnection::nextResult`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::nextResult](#)

Prepare next result from `multi_query`

### Description

```

public bool MysqlndUhConnection::nextResult(
    mysqlnd_connection connection);

```

Prepare next result from `multi_query`.

### Parameters

*connection* Mysqlnd connection handle. Do not modify!

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

**Example 21.363. [MySQLndUhConnection::nextResult](#) example**

```
<?php
class proxy extends MySQLndUhConnection {
    public function nextResult($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::nextResult($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->multi_query("SELECT 1 AS _one; SELECT 2 AS _two");
do {
    $res = $mysqli->store_result();
    var_dump($res->fetch_assoc());
    printf("%s\n", str_repeat("-", 40));
} while ($mysqli->more_results() && $mysqli->next_result());
?>
```

The above example will output:

```
array(1) {
    ["_one"]=>
    string(1) "1"
}
-----
proxy::nextResult(array (
    0 => NULL,
))
proxy::nextResult returns true
array(1) {
    ["_two"]=>
    string(1) "2"
}
-----
```

**21.9.8.7.29. [MySQLndUhConnection::ping](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MySQLndUhConnection::ping](#)

Pings a server connection, or tries to reconnect if the connection has gone down

**Description**

```
public bool MySQLndUhConnection::ping(
    mysqlnd_connection connection);
```

Pings a server connection, or tries to reconnect if the connection has gone down.

**Parameters**

*connection* MySQLnd connection handle. Do not modify!

## Return Values

Returns [TRUE](#) on success. Otherwise, returns [FALSE](#)

## Examples

### Example 21.364. [MysqlndUhConnection::ping](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function ping($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::ping($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->ping();
?>
```

The above example will output:

```
proxy::ping(array (
  0 => NULL,
))
proxy::ping returns true
```

### 21.9.8.7.30. [MysqlndUhConnection::query](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::query](#)

Performs a query on the database

## Description

```
public bool MysqlndUhConnection::query(
    mysqlnd_connection connection,
    string query);
```

Performs a query on the database (COM\_QUERY).

## Parameters

*connection* MySQLnd connection handle. Do not modify!

*query* The query string.

## Return Values

Returns [TRUE](#) on success. Otherwise, returns [FALSE](#)

## Examples

### Example 21.365. [MysqlndUhConnection::query](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function query($res, $query) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $query = "SELECT 'How about query rewriting?'";
        $ret = parent::query($res, $query);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$res = $mysqli->query("SELECT 'Welcome mysqlnd_uh!' FROM DUAL");
var_dump($res->fetch_assoc());
?>
```

The above example will output:

```
proxy::query(array (
    0 => NULL,
    1 => 'SELECT \'Welcome mysqlnd_uh!\' FROM DUAL',
))
proxy::query returns true
array(1) {
    ["How about query rewriting?"]=>
    string(26) "How about query rewriting?"
}
```

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::queryReadResultsetHeader](#)

Read a result set header

## Description

```
public bool MysqlndUhConnection::queryReadResultsetHeader(
    mysqlnd_connection connection,
    mysqlnd_statement mysqlnd_stmt);
```

Read a result set header.

## Parameters

*connection*

Mysqlnd connection handle. Do not modify!

*mysqlnd\_stmt*

Mysqlnd statement handle. Do not modify! Set to [NULL](#) , if function is not used in the context of a prepared statement.

## Return Values

Returns [TRUE](#) on success. Otherwise, returns [FALSE](#)

## Examples

### Example 21.366. [MySQLndUhConnection::queryReadResultsetHeader](#) example

```
<?php
class proxy extends MySQLndUhConnection {
    public function queryReadResultsetHeader($res, $stmt) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::queryReadResultsetHeader($res, $stmt);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$res = $mysqli->query("SELECT 'Welcome mysqlnd_uh!' FROM DUAL");
var_dump($res->fetch_assoc());
?>
```

The above example will output:

```
proxy::queryReadResultsetHeader(array (
  0 => NULL,
  1 => NULL,
))
proxy::queryReadResultsetHeader returns true
array(1) {
  ["Welcome mysqlnd_uh!"]=>
    string(19) "Welcome mysqlnd_uh!"
}
```

### 21.9.8.7.32. [MySQLndUhConnection::reapQuery](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MySQLndUhConnection::reapQuery](#)

Get result from async query

## Description

```
public bool MySQLndUhConnection::reapQuery(
    mysqlnd_connection connection);
```

Get result from async query.

## Parameters

*connection*

MySQLnd connection handle. Do not modify!

## Return Values

Returns **TRUE** on success. Otherwise, returns **FALSE**

## Examples

### Example 21.367. MysqlndUhConnection::reapQuery example

```
<?php
class proxy extends MysqlndUhConnection {
    public function reapQuery($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::reapQuery($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$conn1 = new mysqli("localhost", "root", "", "test");
$conn2 = new mysqli("localhost", "root", "", "test");

$conn1->query("SELECT 1 as 'one', SLEEP(1) AS _sleep FROM DUAL", MYSQLI_ASYNC | MYSQLI_USE_RESULT);
$conn2->query("SELECT 1.1 as 'one dot one' FROM DUAL", MYSQLI_ASYNC | MYSQLI_USE_RESULT);

$links = array(
    $conn1->thread_id => array('link' => $conn1, 'processed' => false),
    $conn2->thread_id => array('link' => $conn2, 'processed' => false)
);

$saved_errors = array();
do {
    $poll_links = $poll_errors = $poll_reject = array();
    foreach ($links as $thread_id => $link) {
        if (!$link['processed']) {
            $poll_links[] = $link['link'];
            $poll_errors[] = $link['link'];
            $poll_reject[] = $link['link'];
        }
    }
    if (0 == count($poll_links))
        break;

    if (0 == ($num_ready = mysqli_poll($poll_links, $poll_errors, $poll_reject, 0, 200000)))
        continue;

    if (!empty($poll_errors)) {
        die(var_dump($poll_errors));
    }

    foreach ($poll_links as $link) {
        $thread_id = mysqli_thread_id($link);
        $links[$thread_id]['processed'] = true;

        if (is_object($res = mysqli_reap_async_query($link))) {
            // result set object
            while ($row = mysqli_fetch_assoc($res)) {
                // eat up all results
                var_dump($row);
            }
            mysqli_free_result($res);
        } else {
            // either there is no result (no SELECT) or there is an error
            if (mysqli_errno($link) > 0) {
                $saved_errors[$thread_id] = mysqli_errno($link);
                printf("%s' caused %d\n", $links[$thread_id]['query'],    mysqli_errno($link));
            }
        }
    }
} while (true);
?>
```

The above example will output:

```
proxy::reapQuery(array (
  0 => NULL,
))
proxy::reapQuery returns true
array(1) {
  ["one dot one"]=>
  string(3) "1.1"
}
proxy::reapQuery(array (
  0 => NULL,
))
proxy::reapQuery returns true
array(2) {
  ["one"]=>
  string(1) "1"
  ["_sleep"]=>
  string(1) "0"
}
```

### 21.9.8.7.33. `MySQLndUhConnection::refreshServer`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MySQLndUhConnection::refreshServer`

Flush or reset tables and caches

#### Description

```
public bool MySQLndUhConnection::refreshServer(
    mysqlnd_connection connection,
    int options);
```

Flush or reset tables and caches.

#### Warning

This function is currently not documented; only its argument list is available.

#### Parameters

*connection* MySQLnd connection handle. Do not modify!

*options* What to refresh.

#### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

#### Examples

##### Example 21.368. `MySQLndUhConnection::refreshServer` example

```
<?php
```

```

class proxy extends MysqlndUhConnection {
    public function refreshServer($res, $option) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::refreshServer($res, $option);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());
$mysqli = new mysqli("localhost", "root", "", "test");
mysqli_refresh($mysqli, 1);
?>

```

The above example will output:

```

proxy::refreshServer(array (
    0 => NULL,
    1 => 1,
))
proxy::refreshServer returns false

```

Sends a close command to MySQL

### Description

```
public bool MysqlndUhConnection::sendClose(
    mysqlnd_connection connection);
```

Sends a close command to MySQL.

### Parameters

*connection* MySQLnd connection handle. Do not modify!

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

#### Example 21.371. `MysqlndUhConnection::sendClose` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function sendClose($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::sendClose($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());
$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->close();
?>
```

The above example will output:

```

proxy::sendClose(array (
    0 => NULL,
))
proxy::sendClose returns true
proxy::sendClose(array (
    0 => NULL,
))
proxy::sendClose returns true

```

### 21.9.8.7.39. `MysqlndUhConnection::setAutocommit`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::setAutocommit`

Turns on or off auto-committing database modifications

#### Description

```
public bool MysqlndUhConnection::setAutocommit(
    mysqlnd_connection connection,
    int mode);
```

Turns on or off auto-committing database modifications

#### Parameters

<code>connection</code>	Mysqlnd connection handle. Do not modify!
<code>mode</code>	Whether to turn on auto-commit or not.

#### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

#### Examples

##### Example 21.374. `MysqlndUhConnection::setAutocommit` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function setAutocommit($res, $mode) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::setAutocommit($res, $mode);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());
$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->autocommit(false);
$mysqli->autocommit(true);
?>
```

The above example will output:

```
proxy::setAutocommit(array (
    0 => NULL,
    1 => 0,
))
proxy::setAutocommit returns true
proxy::setAutocommit(array (
    0 => NULL,
    1 => 1,
))
proxy::setAutocommit returns true
```

- [MySQLndUhConnection::setCharset](#)

Sets the default client character set

#### Description

```
public bool MySQLndUhConnection::setCharset(
    mysqlnd_connection connection,
    string charset);
```

Sets the default client character set.

#### Parameters

<i>connection</i>	MySQLnd connection handle. Do not modify!
<i>charset</i>	The charset to be set as default.

#### Return Values

Returns [TRUE](#) on success. Otherwise, returns [FALSE](#)

#### Examples

##### Example 21.375. [MySQLndUhConnection::setCharset](#) example

```
<?php
class proxy extends MySQLndUhConnection {
    public function setCharset($res, $charset) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::setCharset($res, $charset);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());
$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->set_charset("latin1");
?>
```

The above example will output:

```
proxy::setCharset(array (
    0 => NULL,
    1 => 'latin1',
))
proxy::setCharset returns true
```

        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        printf("Option '%s' set\n", server_option_to_string($option));
        $ret = parent::setServerOption($res, $option);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}

mysqlnd_uh_set_connection_proxy(new proxy());
$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->multi_query("SELECT 1; SELECT 2");
?>
```

The above example will output:

```
proxy::setServerOption(array (
    0 => NULL,
    1 => 0,
))
Option 'MYSQLND_UH_SERVER_OPTION_MULTI_STATEMENTS_ON' set
proxy::setServerOption returns true
```

### 21.9.8.7.43. `MySQLndUhConnection::shutdownServer`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MySQLndUhConnection::shutdownServer`

The `shutdownServer` purpose

#### Description

```
public void MySQLndUhConnection::shutdownServer(
    string MYSQLND_UH_RES_MYSQLND_NAME,
    string "level");
```

#### Warning

This function is currently not documented; only its argument list is available.

#### Parameters

`MYSQLND_UH_RES_MYSQLND_NAME`

`"level"`

#### Return Values

### 21.9.8.7.44. `MySQLndUhConnection::simpleCommand`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MySQLndUhConnection::simpleCommand`

Sends a basic `COM_*` command

#### Description

```
public bool MySQLndUhConnection::simpleCommand(
    mysqlnd_connection connection,
    int command,
    string arg,
    int ok_packet,
    bool silent,
    bool ignore_upsert_status);
```

Sends a basic `COM_*` command to MySQL.

#### Parameters

<code>connection</code>	MySQLnd connection handle. Do not modify!
<code>command</code>	The COM command to be send.
<code>arg</code>	Optional COM command arguments.
<code>ok_packet</code>	The OK packet type.
<code>silent</code>	Whether mysqlnd may emit errors.
<code>ignore_upsert_status</code>	Whether to ignore <code>UPDATE/INSERT</code> status.

#### Return Values

Returns **TRUE** on success. Otherwise, returns **FALSE**

## Examples

### Example 21.378. MysqLndUhConnection::simpleCommand example

```
<?php
function server_cmd_2_string($command) {
    $mapping = array(
        MYSQLND_UH_MYSQLND_COM_SLEEP => "MYSQLND_UH_MYSQLND_COM_SLEEP",

#### 21.9.8.7.45. [MysqlndUhConnection::simpleCommandHandleResponse](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::simpleCommandHandleResponse](#)

Process a response for a basic COM\_\* command send to the client

### Description

```

public bool MysqlndUhConnection::simpleCommandHandleResponse(
    mysqlnd_connection connection,
    int ok_packet,
    bool silent,
    int command,
    bool ignore_upsert_status);

```

Process a response for a basic COM\_\* command send to the client.

### Parameters

<i>connection</i>	Mysqlnd connection handle. Do not modify!
<i>ok_packet</i>	The OK packet type.
<i>silent</i>	Whether mysqlnd may emit errors.
<i>command</i>	The COM command to process results from.

*ignore\_upsert\_status* Whether to ignore UPDATE/INSERT status.

## Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

## Examples

### 21.9.8.7.46. `MysqlndUhConnection::sslSet`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::sslSet`

Used for establishing secure connections using SSL

### Description

```
public bool MysqlndUhConnection::sslSet(
    mysqlnd_connection connection,
    string key,
    string cert,
    string ca,
    string capath,
    string cipher);
```

Used for establishing secure connections using SSL.

### Parameters

<i>connection</i>	Mysqlnd connection handle. Do not modify!
<i>key</i>	The path name to the key file.
<i>cert</i>	The path name to the certificate file.
<i>ca</i>	The path name to the certificate authority file.
<i>capath</i>	The pathname to a directory that contains trusted SSL CA certificates in PEM format.
<i>cipher</i>	A list of allowable ciphers to use for SSL encryption.

### Return Values

Returns [TRUE](#) on success. Otherwise, returns [FALSE](#)

## Examples

### Example 21.380. [MysqlndUhConnection::sslSet](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function sslSet($conn, $key, $cert, $ca, $capath, $cipher) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::sslSet($conn, $key, $cert, $ca, $capath, $cipher);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());
$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->ssl_set("key", "cert", "ca", "capath", "cipher");
?>
```

The above example will output:

```
proxy::sslSet(array (
  0 => NULL,
  1 => 'key',
  2 => 'cert',
  3 => 'ca',
  4 => 'capath',
  5 => 'cipher',
))
proxy::sslSet returns true
```

### 21.9.8.7.47. [MysqlndUhConnection::stmtInit](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::stmtInit](#)

Initializes a statement and returns a resource for use with `mysqli_statement::prepare`

## Description

```
public resource MysqlndUhConnection::stmtInit(
    mysqlnd_connection connection);
```

Initializes a statement and returns a resource for use with `mysqli_statement::prepare`.

## Parameters

*connection* Mysqlnd connection handle. Do not modify!

## Return Values

Resource of type [Mysqlnd Prepared Statement \(internal only - you must not modify it!\)](#). The documentation may also refer to such resources using the alias name [mysqlnd\\_prepared\\_statement](#).

## Examples

### Example 21.381. `MysqlndUhConnection::stmtInit` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function stmtInit($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        var_dump($res);
        $ret = parent::stmtInit($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        var_dump($ret);
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());
$mysqli = new mysqli("localhost", "root", "", "test");
$stmt = $mysqli->prepare("SELECT 1 AS _one FROM DUAL");
$stmt->execute();
$one = NULL;
$stmt->bind_result($one);
$stmt->fetch();
var_dump($one);
?>
```

The above example will output:

```
proxy::stmtInit(array (
    0 => NULL,
))
resource(19) of type (Mysqlnd Connection)
proxy::stmtInit returns NULL
resource(246) of type (Mysqlnd Prepared Statement (internal only - you must not modify it!))
int(1)
```

### 21.9.8.7.48. `MysqlndUhConnection::storeResult`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::storeResult`

Transfers a result set from the last query

## Description

```
public resource MysqlndUhConnection::storeResult(
    mysqlnd_connection connection);
```

Transfers a result set from the last query.

## Parameters

*connection* Mysqlnd connection handle. Do not modify!

## Return Values

Resource of type `Mysqlnd Resultset (internal only - you must not modify it!)`. The documentation may also refer to such resources using the alias name `mysqlnd_resultset`.

## Examples

### Example 21.382. [MysqlndUhConnection::storeResult](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function storeResult($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::storeResult($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        var_dump($ret);
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$res = $mysqli->query("SELECT 'Also called buffered result' AS _msg FROM DUAL");
var_dump($res->fetch_assoc());

$mysqli->real_query("SELECT 'Good morning!' AS _msg FROM DUAL");
$res = $mysqli->store_result();
var_dump($res->fetch_assoc());
?>
```

The above example will output:

```
proxy::storeResult(array (
    0 => NULL,
))
proxy::storeResult returns NULL
resource(475) of type (Mysqlnd Resultset (internal only - you must not modify it!))
array(1) {
    ["_msg"]=>
        string(27) "Also called buffered result"
}
proxy::storeResult(array (
    0 => NULL,
))
proxy::storeResult returns NULL
resource(730) of type (Mysqlnd Resultset (internal only - you must not modify it!))
array(1) {
    ["_msg"]=>
        string(13) "Good morning!"
}
```

### 21.9.8.7.49. [MysqlndUhConnection::txCommit](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::txCommit](#)

Commits the current transaction

### Description

```
public bool MysqlndUhConnection::txCommit(
```

```
mysqlnd_connection connection);
```

Commits the current transaction.

### Parameters

`connection` Mysqlnd connection handle. Do not modify!

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

#### Example 21.383. `MysqlndUhConnection::txCommit` example

```
<?php
class proxy extends MysqlndUhConnection {
    public function txCommit($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::txCommit($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->commit();
?>
```

The above example will output:

```
proxy::txCommit(array (
    0 => NULL,
))
proxy::txCommit returns true
```

#### 21.9.8.7.50. `MysqlndUhConnection::txRollback`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhConnection::txRollback`

Rolls back current transaction

### Description

```
public bool MysqlndUhConnection::txRollback(
    mysqlnd_connection connection);
```

Rolls back current transaction.

### Parameters

`connection` Mysqlnd connection handle. Do not modify!

## Return Values

Returns [TRUE](#) on success. Otherwise, returns [FALSE](#)

## Examples

### Example 21.384. [MysqlndUhConnection::txRollback](#) example

```
<?php
class proxy extends MysqlndUhConnection {
    public function txRollback($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::txRollback($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->rollback();
?>
```

The above example will output:

```
proxy::txRollback(array (
    0 => NULL,
))
proxy::txRollback returns true
```

### 21.9.8.7.51. [MysqlndUhConnection::useResult](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [MysqlndUhConnection::useResult](#)

Initiate a result set retrieval

## Description

```
public resource MysqlndUhConnection::useResult(
    mysqlnd_connection connection);
```

Initiate a result set retrieval.

## Parameters

*connection* Mysqlnd connection handle. Do not modify!

## Return Values

Resource of type [Mysqlnd Resultset](#) (*internal only - you must not modify it!*). The documentation may also refer to such resources using the alias name [mysqlnd\\_resultset](#).

## Examples

**Example 21.385. [MysqlndUhConnection::useResult](#) example**

```
<?php
class proxy extends MysqlndUhConnection {
    public function useResult($res) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::useResult($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        var_dump($ret);
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->real_query("SELECT 'Good morning!' AS _msg FROM DUAL");
$res = $mysqli->use_result();
var_dump($res->fetch_assoc());
?>
```

The above example will output:

```
proxy::useResult(array (
    0 => NULL,
))
proxy::useResult returns NULL
resource(425) of type (Mysqlnd Resultset (internal only - you must not modify it!))
array(1) {
    ["_msg"]=>
        string(13) "Good morning!"
}
```

MysqlndUhPreparedStatement {
MysqlndUhPreparedStatement

    Methods

    public MysqlndUhPreparedStatement::__construct();

    public bool MysqlndUhPreparedStatement::execute(
        mysqlnd_prepared_statement statement);

    public bool MysqlndUhPreparedStatement::prepare(
        mysqlnd_prepared_statement statement,
        string query);
}
```

**21.9.8.8.1. [MysqlndUhPreparedStatement::\\_\\_construct](#)**

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhpStatement::__construct`

The `__construct` purpose

### Description

```
public MysqlndUhpStatement::__construct();
```

### Warning

This function is currently not documented; only its argument list is available.

### Parameters

This function has no parameters.

### Return Values

## 21.9.8.8.2. `MysqlndUhpStatement::execute`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhpStatement::execute`

Executes a prepared Query

### Description

```
public bool MysqlndUhpStatement::execute(
    mysqlnd_prepared_statement statement);
```

Executes a prepared Query.

### Parameters

*statement*

Mysqlnd prepared statement handle. Do not modify! Resource of type `Mysqlnd Prepared Statement (internal only - you must not modify it!)`.

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

#### Example 21.386. `MysqlndUhpStatement::execute` example

```
<?php
class stmt_proxy extends MysqlndUhpStatement {
    public function execute($res) {
        printf("%s(", __METHOD__);
        var_dump($res);
        printf(")\n");
        $ret = parent::execute($res);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        var_dump($ret);
        return $ret;
    }
}
mysqlnd_uh_set_statement_proxy(new stmt_proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
```

```
$stmt = $mysqli->prepare("SELECT 'Labskaus' AS _msg FROM DUAL");
$stmt->execute();
$msg = NULL;
$stmt->bind_result($msg);
$stmt->fetch();
var_dump($msg);
?>
```

The above example will output:

```
stmt_proxy::execute(resource(256) of type (Mysqlnd Prepared Statement (internal only - you must not modify
)
)
stmt_proxy::execute returns true
bool(true)
string(8) "Labskaus"
```

### 21.9.8.8.3. `MysqlndUhPreparedStatement::prepare`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `MysqlndUhPreparedStatement::prepare`

Prepare an SQL statement for execution

#### Description

```
public bool MysqlndUhPreparedStatement::prepare(
    mysqlnd_prepared_statement statement,
    string query);
```

Prepare an SQL statement for execution.

#### Parameters

<i>statement</i>	Mysqlnd prepared statement handle. Do not modify! Resource of type <code>Mysqlnd Prepared Statement (internal only - you must not modify it!)</code> .
<i>query</i>	The query to be prepared.

#### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

#### Examples

##### Example 21.387. `MysqlndUhPreparedStatement::prepare` example

```
<?php
class stmt_proxy extends MysqlndUhPreparedStatement {
    public function prepare($res, $query) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $query = "SELECT 'No more you-know-what-I-mean for lunch, please' AS _msg FROM DUAL";
        $ret = parent::prepare($res, $query);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        var_dump($ret);
    }
}
```

```

    return $ret;
}
}
mysqlnd_uh_set_statement_proxy(new stmt_proxy());

$mysqli = new mysqli("localhost", "root", "", "test");
$stmt = $mysqli->prepare("SELECT 'Labskaus' AS _msg FROM DUAL");
$stmt->execute();
$msg = NULL;
$stmt->bind_result($msg);
$stmt->fetch();
var_dump($msg);
?>

```

The above example will output:

```

stmt_proxy::prepare(array (
  0 => NULL,
  1 => 'SELECT \'Labskaus\' AS _msg FROM DUAL',
))
stmt_proxy::prepare returns true
bool(true)
string(46) "No more you-know-what-I-mean for lunch, please"

```

## 21.9.8.9. Mysqlnd\_uh Functions

Copyright 1997-2012 the PHP Documentation Group. [2906]

### 21.9.8.9.1. [mysqlnd\\_uh\\_convert\\_to\\_mysqlnd](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_uh\\_convert\\_to\\_mysqlnd](#)

Converts a MySQL connection handle into a mysqlnd connection handle

#### Description

```

resource mysqlnd_uh_convert_to_mysqlnd(
    mysqli mysql_connection);

```

Converts a MySQL connection handle into a mysqlnd connection handle. After conversion you can execute mysqlnd library calls on the connection handle. This can be used to access mysqlnd functionality not made available through user space API calls.

The function can be disabled with [mysqlnd\\_uh.enable](#). If [mysqlnd\\_uh.enable](#) is set to [FALSE](#) the function will not install the proxy and always return [TRUE](#). Additionally, an error of the type [E\\_WARNING](#) may be emitted. The error message may read like [PHP Warning: mysqlnd\\_uh\\_convert\\_to\\_mysqlnd\(\): \(Mysqlnd User Handler\) The plugin has been disabled by setting the configuration parameter mysqlnd\\_uh.enable = false. You are not allowed to call this function \[...\]](#).

#### Parameters

*MySQL connection handle* A MySQL connection handle of type [mysql](#), [mysqli](#) or [PDO\\_MySQL](#).

## Return Values

A mysqlnd connection handle.

## Changelog

Version	Description
5.4.0	The <code>mysql_connection</code> parameter can now be of type <code>mysql</code> , <code>PDO_MySQL</code> , or <code>mysqli</code> . Before, only the <code>mysqli</code> type was allowed.

## Examples

### Example 21.388. [mysqlnd\\_uh\\_convert\\_to\\_mysqlnd](#) example

```
<?php
/* PDO user API gives no access to connection thread id */
$mysql_connection = new PDO("mysql:host=localhost;dbname=test", "root", "");

/* Convert PDO MySQL handle to mysqlnd handle */
$mysqlnd = mysqlnd_uh_convert_to_mysqlnd($mysql_connection);

/* Create Proxy to call mysqlnd connection class methods */
$obj = new MySQLndUHConnection();
/* Call mysqlnd_conn::get_thread_id */
var_dump($obj->getThreadId($mysqlnd));

/* Use SQL to fetch connection thread id */
var_dump($mysql_connection->query("SELECT CONNECTION_ID()")->fetchAll());
?>
```

The above example will output:

```
int(27054)
array(1) {
  [0]=>
  array(2) {
    ["CONNECTION_ID()"]=>
    string(5) "27054"
    [0]=>
    string(5) "27054"
  }
}
```

## See Also

### 21.9.8.9.2. [mysqlnd\\_uh\\_set\\_connection\\_proxy](#)

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_uh\\_set\\_connection\\_proxy](#)

Installs a proxy for mysqlnd connections

## Description

```
bool mysqlnd_uh_set_connection_proxy(
    MySQLndUHConnection connection_proxy,
    mysqli mysqli_connection);
```

Installs a proxy object to hook mysqlnd's connection objects methods. Once installed, the proxy will be used for all MySQL connections opened with `mysqli`, `mysql` or `PDO_MYSQL`, assuming that the listed extensions are compiled to use the `mysqlnd` library.

The function can be disabled with `mysqlnd_uh.enable`. If `mysqlnd_uh.enable` is set to `FALSE` the function will not install the proxy and always return `TRUE`. Additionally, an error of the type `E_WARNING` may be emitted. The error message may read like `PHP Warning: mysqlnd_uh_set_connection_proxy(): (Mysqlnd User Handler) The plugin has been disabled by setting the configuration parameter mysqlnd_uh.enable = false. The proxy has not been installed [...]`.

### Parameters

<code>connection_proxy</code>	A proxy object of type <code>MysqlndUhConnection</code> .
<code>mysqli_connection</code>	Object of type <code>mysqli</code> . If given, the proxy will be set for this particular connection only.

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

### Examples

#### Example 21.389. `mysqlnd_uh_set_connection_proxy` example

```
<?php
$mysqli = new mysqli("localhost", "root", "", "test");
$mysqli->query("SELECT 'No proxy installed, yet'");

class proxy extends MysqlndUhConnection {
    public function query($res, $query) {
        printf("%s(%s)\n", __METHOD__, var_export(func_get_args(), true));
        $ret = parent::query($res, $query);
        printf("%s returns %s\n", __METHOD__, var_export($ret, true));
        return $ret;
    }
}
mysqlnd_uh_set_connection_proxy(new proxy());

$mysqli->query("SELECT 'mysqlnd rocks!'");

$mysql = mysql_connect("localhost", "root", "", "test");
mysql_query("SELECT 'Ahoy Andrey!'", $mysql);

$pdo = new PDO("mysql:host=localhost;dbname=test", "root", "");
$pdo->query("SELECT 'Moin Johannes!'");
?>
```

The above example will output:

```
proxy::query(array (
  0 => NULL,
  1 => 'SELECT \'mysqlnd rocks!\'',
))
proxy::query returns true
proxy::query(array (
  0 => NULL,
  1 => 'SELECT \'Ahoy Andrey!\'',
))
proxy::query returns true
proxy::query(array (
  0 => NULL,
  1 => 'SELECT \'Moin Johannes!\'',
```

```
))  
proxy::query returns true
```

#### 21.9.8.9.3. `mysqlnd_uh_set_statement_proxy`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_uh\\_set\\_statement\\_proxy](#)

Installs a proxy for mysqlnd statements

### Description

```
bool mysqlnd_uh_set_statement_proxy(  
    MysqlndUhStatement statement_proxy);
```

Installs a proxy for mysqlnd statements. The proxy object will be used for all mysqlnd prepared statement objects, regardless which PHP MySQL extension ([mysqli](#), [mysql](#), [PDO\\_MYSQL](#)) has created them as long as the extension is compiled to use the [mysqlnd](#) library.

The function can be disabled with [mysqlnd\\_uh.enable](#). If [mysqlnd\\_uh.enable](#) is set to `FALSE` the function will not install the proxy and always return `TRUE`. Additionally, an error of the type `E_WARNING` may be emitted. The error message may read like `PHP Warning: mysqlnd_uh_set_statement_proxy(): (Mysqlnd User Handler) The plugin has been disabled by setting the configuration parameter mysqlnd_uh.enable = false. The proxy has not been installed [...]`.

### Parameters

*statement\_proxy*                      The mysqlnd statement proxy object of type `MysqlndUhStatement`

### Return Values

Returns `TRUE` on success. Otherwise, returns `FALSE`

#### 21.9.8.10. Change History

Copyright 1997-2012 the PHP Documentation Group. [2906]

The Change History lists major changes users need to be aware of if upgrading from one version to another. It is a high level summary of selected changes that may impact applications or might even break backwards compatibility. See also the [CHANGES](#) file contained in the source for additional changelog information. The commit history is also available.

##### 21.9.8.10.1. PECL/mysqlnd\_uh 1.0 series

Copyright 1997-2012 the PHP Documentation Group. [2906]

1.0.1-alpha

- Release date: TBD
- Motto/theme: bug fix release

#### Feature changes

- Support of PHP 5.4.0 or later.
- BC break: `MysqlndUhConnection::changeUser` requires additional `passwd_len` parameter.
- BC break: `MYSQLND_UH_VERSION_STR` renamed to `MYSQLND_UH_VERSION`.  
`MYSQLND_UH_VERSION` renamed to `MYSQLND_UH_VERSION_ID`.
- BC break: `mysqlnd_uh.enabled` configuration setting renamed to `mysqlnd_uh.enable`.

#### 1.0.0-alpha

- Release date: 08/2010
- Motto/theme: Initial release

## 21.9.9. Mysqlnd connection multiplexing plugin ([mysqlnd\\_mux](#))

Copyright 1997-2012 the PHP Documentation Group. [2906]

The `mysqlnd` multiplexing plugin ([mysqlnd\\_mux](#)) multiplexes MySQL connections established by all PHP MySQL extensions that use the MySQL native driver ([mysqlnd](#)) for PHP.

The MySQL native driver for PHP features an internal C API for plugins, such as the connection multiplexing plugin, which can extend the functionality of `mysqlnd`. See the [mysqlnd](#) for additional details about its benefits over the MySQL Client Library `libmysqlclient`.

`mysqlnd` plugins like [mysqlnd\\_mux](#) operate, for the most part, transparently from a user perspective. The connection multiplexing plugin supports all PHP applications, and all MySQL PHP extensions. It does not change existing APIs. Therefore, it can easily be used with existing PHP applications.

### Note

This is a proof-of-concept. All features are at an early stage. Not all kinds of queries are handled by the plugin yet. Thus, it cannot be used in a drop-in fashion at the moment.

Please, do not use this version in production environments.

### 21.9.9.1. Key Features

Copyright 1997-2012 the PHP Documentation Group. [2906]

The key features of `mysqlnd_mux` are as follows:

- Transparent and therefore easy to use:
  - Supports all of the PHP MySQL extensions.
  - Little to no application changes are required, dependent on the required usage scenario.
- Reduces server load and connection establishment latency:
  - Opens less connections to the MySQL server.
  - Less connections to MySQL mean less work for the MySQL server. In a client-server environment scaling the server is often more difficult than scaling the client. Multiplexing helps with horizontal scale-out (scale-by-client).

- Pooling saves connection time.
- Multiplexed connection: multiple user handles share the same network connection. Once opened, a network connection is cached and shared among multiple user handles. There is a 1:n relationship between internal network connection and user connection handles.
- Persistent connection: a network connection is kept open at the end of the web request, if the PHP deployment model allows. Thus, subsequently web requests can reuse a previously opened connection. Like other resources, network connections are bound to the scope of a process. Thus, they can be reused for all web requests served by a process.

### 21.9.9.2. Limitations

Copyright 1997-2012 the PHP Documentation Group. [2906]

The proof-of-concept does not support unbuffered queries, prepared statements, and asynchronous queries.

The connection pool is using a combination of the transport method and hostname as keys. As a consequence, two connections to the same host using the same transport method (TCP/IP, Unix socket, Windows named pipe) will be linked to the same pooled connection even if username and password differ. Be aware of the possible security implications.

The proof-of-concept is transaction agnostic. It does not about SQL transactions.

#### Note

Applications must be aware of the consequences of connection sharing connections.

### 21.9.9.3. About the name `mysqlnd_mux`

Copyright 1997-2012 the PHP Documentation Group. [2906]

The shortcut `mysqlnd_mux` stands for `mysqlnd connection multiplexing plugin`.

### 21.9.9.4. Concepts

Copyright 1997-2012 the PHP Documentation Group. [2906]

This explains the architecture and related concepts for this plugin. Reading and understanding these concepts is required to successfully use this plugin.

#### 21.9.9.4.1. Architecture

Copyright 1997-2012 the PHP Documentation Group. [2906]

The `mysqlnd` connection multiplexing plugin is implemented as a PHP extension. It is written in C and operates under the hood of PHP. During the startup of the PHP interpreter, in the module initialization phase of the PHP engine, it gets registered as a `mysqlnd` plugin to replace specific `mysqlnd` C methods.

The `mysqlnd` library uses PHP streams to communicate with the MySQL server. PHP streams are accessed by the `mysqlnd` library through its net module. The `mysqlnd` connection multiplexing plugin proxies methods of the `mysqlnd` library net module to control opening and closing of network streams.

Upon opening a user connection to MySQL using the appropriate connection functions of either `mysqli`, `PDO_MYSQL` or `ext/mysqli`, the plugin will search its connection pool for an open network connection. If the pool contains a network connection to the host specified by the connect function using the transport method requested (TCP/IP, Unix domain socket, Windows named pipe), the pooled connection is

linked to the user handle. Otherwise, a new network connection is opened, put into the pool and associated with the user connection handle. This way, multiple user handles can be linked to the same network connection.

#### 21.9.9.4.2. Connection pool

Copyright 1997-2012 the PHP Documentation Group. [2906]

The plugins connection pool is created when PHP initializes its modules (`MINIT`) and free'd when PHP shuts down the modules (`MSHUTDOWN`). This is the same as for persistent MySQL connections.

Depending on the deployment model, the pool is used for the duration of one or multiple web requests. Network connections are bound to the lifespan of an operating system level process. If the PHP process serves multiple web requests as it is the case for Fast-CGI or threaded web server deployments, then the pooled connections can be reused over multiple connections. Because multiplexing means sharing connections, it can even happen with a threaded deployment that two threads or two distinct web requests are linked to one pooled network connections.

A pooled connection is explicitly closed once the last reference to it is released. An implicit close happens when PHP shuts down its modules.

#### 21.9.9.4.3. Sharing connections

Copyright 1997-2012 the PHP Documentation Group. [2906]

The PHP mysqlnd connection multiplexing plugin changes the relationship between a users connection handle and the underlying MySQL connection. Without the plugin, every MySQL connection belongs to exactly one user connection at a time. The multiplexing plugin changes. A MySQL connection is shared among multiple user handles. There no one-to-one relation if using the plugin.

Sharing pooled connections has an impact on the connection state. State changing operations from multiple user handles pointing to one MySQL connection are not isolated from each other. If, for example, a session variable is set through one user connection handle, the session variable becomes visible to all other user handles that reference the same underlying MySQL connection.

This is similar in concept to connection state related phenomena described for the PHP mysqlnd replication and load balancing plugin. Please, check the [PECL/mysqlnd\\_ms documentation](#) for more details on the state of a connection.

The proof-of-concept takes no measures to isolate multiplexed connections from each other.

#### 21.9.9.5. Installing/Configuring

Copyright 1997-2012 the PHP Documentation Group. [2906]

##### 21.9.9.5.1. Requirements

Copyright 1997-2012 the PHP Documentation Group. [2906]

[PHP 5.5.0](#) or newer. Some advanced functionality requires [PHP 5.5.0](#) or newer.

The [mysqlnd\\_mux](#) replication and load balancing plugin supports all PHP applications and all available PHP MySQL extensions ([mysqli](#), [mysql](#), [PDO\\_MYSQL](#)). The PHP MySQL extension must be configured to use [mysqlnd](#) in order to be able to use the [mysqlnd\\_mux](#) plugin for [mysqlnd](#).

##### 21.9.9.5.2. Installation

Copyright 1997-2012 the PHP Documentation Group. [2906]

Information for installing this PECL extension may be found in the manual chapter titled [Installation of PECL extensions](#). Additional information such as new releases, downloads, source files, maintainer information, and a CHANGELOG, can be located here: [http://pecl.php.net/package/mysqlnd\\_mux](http://pecl.php.net/package/mysqlnd_mux)

### 21.9.9.5.3. Runtime Configuration

Copyright 1997-2012 the PHP Documentation Group. [2906]

The behaviour of these functions is affected by settings in `php.ini`.

**Table 21.77. Mysqlnd\_mux Configure Options**

Name	Default	Changeable	Changelog
<code>mysqlnd_mux.enable</code>	0	PHP_INI_SYSTEM	

Here's a short explanation of the configuration directives.

`mysqlnd_mux.enable` integer Enables or disables the plugin. If disabled, the extension will not plug into `mysqlnd` to proxy internal `mysqlnd` C API calls.

### 21.9.9.6. Predefined Constants

Copyright 1997-2012 the PHP Documentation Group. [2906]

The constants below are defined by this extension, and will only be available when the extension has either been compiled into PHP or dynamically loaded at runtime.

*Other*

The plugins version number can be obtained using `MYSQLND_MUX_VERSION` or `MYSQLND_MUX_VERSION_ID`. `MYSQLND_MUX_VERSION` is the string representation of the numerical version number `MYSQLND_MUX_VERSION_ID`, which is an integer such as 10000. Developers can calculate the version number as follows.

Version (part)	Example
Major*10000	1*10000 = 10000
Minor*100	0*100 = 0
Patch	0 = 0
<code>MYSQLND_MUX_VERSION_ID</code>	10000

`MYSQLND_MUX_VERSION` (string) Plugin version string, for example, "1.0.0-prototype".

`MYSQLND_MUX_VERSION_ID` (integer) Plugin version number, for example, 10000.

### 21.9.9.7. Change History

Copyright 1997-2012 the PHP Documentation Group. [2906]

This change history is a high level summary of selected changes that may impact applications and/or break backwards compatibility.

See also the `CHANGES` file in the source distribution for a complete list of changes.

#### 21.9.9.7.1. PECL/mysqlnd\_mux 1.0 series

Copyright 1997-2012 the PHP Documentation Group. [2906]

1.0.0-pre-alpha

- Release date: no package released, initial check-in 09/2012

- Motto/theme: Proof of concept

Initial check-in. Essentially a demo of the [mysqlnd](#) plugin API.

**Note**

This is the current development series. All features are at an early stage. Changes may happen at any time without prior notice. Please, do not use this version in production environments.

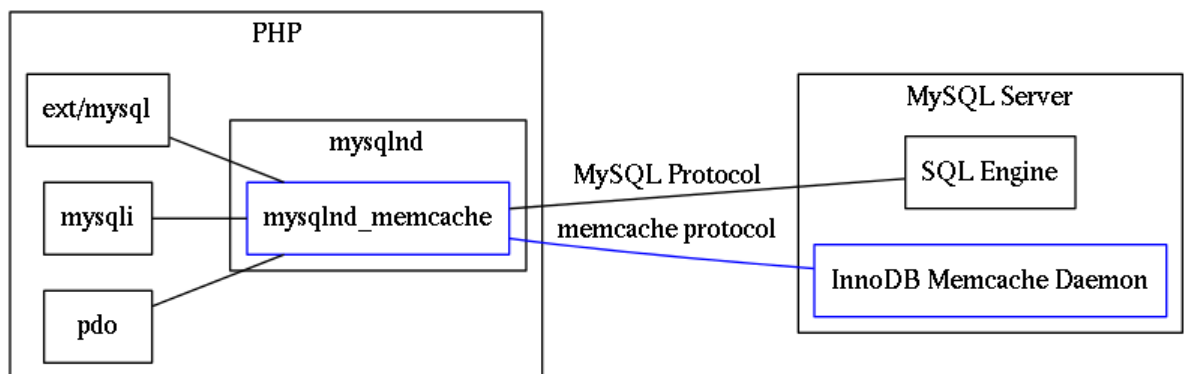

The documentation may not reflect all changes yet.

## 21.9.10. Mysqlnd Memcache plugin ([mysqlnd\\_memcache](#))

Copyright 1997-2012 the PHP Documentation Group. [2906]

The [mysqlnd memcache plugin](#) ([mysqlnd\\_memcache](#)) is an PHP extension for transparently translating SQL into requests for the MySQL InnoDB Memcached Daemon Plugin (server plugin). It includes experimental support for the MySQL Cluster Memcached Daemon. The server plugin provides access to data stored inside MySQL InnoDB (respectively MySQL Cluster NDB) tables using the Memcache protocol. This PHP extension, which supports all PHP MySQL extensions that use [mysqlnd](#), will identify tables exported in this way and will translate specific SELECT queries into Memcache requests.

**Figure 21.92. [mysqlnd\\_memcache](#) data flow**

**Note**

This plugin depends on the MySQL InnoDB Memcached Daemon Plugin. It is not provided to be used with a stand-alone Memcached. For a generic query cache using Memcached look at the [mysqlnd query cache plugin](#). For direct Memcache access look at the [memcache](#) and [memcached](#) extensions.

The MySQL native driver for PHP is a C library that ships together with PHP as of PHP 5.3.0. It serves as a drop-in replacement for the MySQL Client Library (libmysqlclient). Using [mysqlnd](#) has several advantages: no extra downloads are required because it's bundled with PHP, it's under the PHP license, there is lower memory consumption in certain cases, and it contains new functionality such as asynchronous queries.

The [mysqlnd\\_mmemcache](#) operates, for the most part, transparently from a user perspective. The [mysqlnd memcache plugin](#) supports all PHP applications, and all MySQL PHP extensions. It does not change existing APIs. Therefore, it can easily be used with existing PHP applications.

The MySQL Memcache plugins add key-value style access method for data stored in InnoDB resp. NDB (MySQL Cluster) SQL tables through the Memcache protocol. This type of key-value access is often faster than using SQL.

### 21.9.10.1. Key Features

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The key features of PECL/[mysqLnd\\_memcache](#) are as follows.

- Possible performance benefits
  - Client-side: light-weight protocol.
  - Server-side: no SQL parsing, direct access to the storage.
- Please, run your own benchmarks! Actual performance results are highly dependent on setup and hardware used.

### 21.9.10.2. Limitations

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The initial version is not binary safe. Due to the way the MySQL Memcache plugins works there are restrictions related to separators.

Prepared statements and asynchronous queries are not supported. Result set meta data support is limited.

The mapping information for tables accessible via Memcache is not cached in the plugin between requests but fetched from the MySQL server each time a MySQL connection is associated with a Memcache connection. See [mysqLnd\\_memcache\\_set](#) for details.

### 21.9.10.3. On the name

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The shortcut [mysqLnd\\_memcache](#) stands for [mysqLnd memcache plugin](#). Memcache refers to support of the MySQL Memcache plugins for InnoDB and NDB (MySQL Cluster). The plugin is not related to the Memcached cache server.

### 21.9.10.4. Quickstart and Examples

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The [mysqLnd memcache](#) plugin is easy to use. This quickstart will demo typical use-cases, and provide practical advice on getting started.

It is strongly recommended to read the reference sections in addition to the quickstart. The quickstart tries to avoid discussing theoretical concepts and limitations. Instead, it will link to the reference sections. It is safe to begin with the quickstart. However, before using the plugin in mission critical environments we urge you to read additionally the background information from the reference sections.

#### 21.9.10.4.1. Setup

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

The plugin is implemented as a PHP extension. See also the [installation instructions](#) to install this extension.

Compile or configure the PHP MySQL extension (API) ([mysqli](#), [PDO\\_MYSQL](#), [mysql](#)). That extension must use the [mysqLnd](#) library as because [mysqLnd\\_memcache](#) is a plugin for the [mysqLnd](#) library. For additional information, refer to the [mysqLnd\\_memcache installation instructions](#).

Then, load this extension into PHP and activate the plugin in the PHP configuration file using the PHP configuration directive named [mysqLnd\\_memcache.enable](#).

### Example 21.390. Enabling the plugin (php.ini)

```
; On Windows the filename is php_mysqlnd_memcache.dll
; Load the extension
extension=mysqlnd_memcache.so
; Enable it
mysqlnd_memcache.enable=1
```

Follow the instructions given in the [MySQL Reference Manual on installing the Memcache plugins](#) for the MySQL server. Activate the plugins and configure Memcache access for SQL tables.

The examples in this quickguide assume that the following table exists, and that Memcache is configured with access to it.

### Example 21.391. SQL table used for the Quickstart

```
CREATE TABLE test(
  id CHAR(16),
  f1 VARCHAR(255),
  f2 VARCHAR(255),
  f3 VARCHAR(255),
  flags INT NOT NULL,
  cas_column INT,
  expire_time_column INT,
  PRIMARY KEY(id)
) ENGINE=InnoDB;

INSERT INTO test (id, f1, f2, f3) VALUES (1, 'Hello', 'World', '');
INSERT INTO test (id, f1, f2, f3) VALUES (2, 'Lady', 'and', 'the tramp');

INSERT INTO innodb_memcache.containers(
  name, db_schema, db_table, key_columns, value_columns,
  flags, cas_column, expire_time_column, unique_idx_name_on_key)
VALUES (
  'plugin_test', 'test', 'test', 'id', 'f1,f2,f3',
  'flags', 'cas_column', 'expire_time_column', 'PRIMARY KEY');
```

## 21.9.10.4.2. Usage

[Copyright 1997-2012 the PHP Documentation Group. \[2906\]](#)

After associating a MySQL connection with a Memcache connection using [mysqlnd\\_memcache\\_set](#) the plugin attempts to transparently replace SQL [SELECT](#) statements by a memcache access. For that purpose the plugin monitors all SQL statements executed and tries to match the statement string against [MYSQLND\\_MEMCACHE\\_DEFAULT\\_REGEXP](#). In case of a match, the mysqlnd memcache plugin checks whether the [SELECT](#) is accessing only columns of a mapped table and the [WHERE](#) clause is limited to a single key lookup.

In case of the example SQL table, the plugin will use the Memcache interface of the MySQL server to fetch results for a SQL query like [SELECT f1, f2, f3 WHERE id = n](#).

### Example 21.392. Basic example.

```
<?php
$mysqli = new mysqli("host", "user", "passwd", "database");
$memc = new Memcached();
$memc->addServer("host", 11211);
mysqlnd_memcache_set($mysqli, $memc);

/*
  This is a query which queries table test using id as key in the WHERE part
```

```
and is accessing fields f1, f2 and f3. Therefore, mysqlnd_memcache
will intercept it and route it via memcache.
*/
$result = $mysqli->query("SELECT f1, f2, f3 FROM test WHERE id = 1");
while ($row = $result->fetch_row()) {
    print_r($row);
}

/*
This is a query which queries table test but using f1 in the WHERE clause.
Therefore, mysqlnd_memcache can't intercept it. This will be executed
using the MySQL protocol
*/
$mysqli->query("SELECT id FROM test WHERE f1 = 'Lady'");
while ($row = $result->fetch_row()) {
    print_r($row);
}
?>
```

The above example will output:

```
array(
  [f1] => Hello
  [f2] => World
  [f3] => !
)
array(
  [id] => 2
)
```

### 21.9.10.5. Installing/Configuring

Copyright 1997-2012 the PHP Documentation Group. [2906]

#### 21.9.10.5.1. Requirements

Copyright 1997-2012 the PHP Documentation Group. [2906]

PHP: this extension requires PHP 5.4+, version PHP 5.4.4 or newer. The required PHP extensions are [PCRE](#) (enabled by default), and the [memcached](#) extension version 2.0.x.

The `mysqlnd_memcache` Memcache plugin supports all PHP applications and all available PHP MySQL extensions ([mysqli](#), [mysql](#), [PDO\\_MYSQL](#)). The PHP MySQL extension must be configured with [mysqlnd](#) support.

For accessing [InnoDB](#) tables, this PHP extension requires [MySQL Server 5.6.6](#) or newer with the InnoDB Memcache Daemon Plugin enabled.

For accessing [MySQL Cluster NDB](#) tables, this PHP extension requires [MySQL Cluster 7.2](#) or newer with the NDB Memcache API nodes enabled.

#### 21.9.10.5.2. Installation

Copyright 1997-2012 the PHP Documentation Group. [2906]

This [PECL](#) extension is not bundled with PHP.

Information for installing this PECL extension may be found in the manual chapter titled [Installation of PECL extensions](#). Additional information such as new releases, downloads, source files, maintainer information, and a CHANGELOG, can be located here: [http://pecl.php.net/package/mysqlnd\\_memcache](http://pecl.php.net/package/mysqlnd_memcache)

A DLL for this PECL extension is currently unavailable. See also the [building on Windows](#) section.

### 21.9.10.5.3. Runtime Configuration

Copyright 1997-2012 the PHP Documentation Group. [2906]

The behaviour of these functions is affected by settings in `php.ini`.

**Table 21.78. MySQLnd\_memcache Configure Options**

Name	Default	Changeable	Changelog
<code>mysqlnd_memcache.enable</code>		PHP_INI_SYSTEM	Available since 1.0.0

Here's a short explanation of the configuration directives.

`mysqlnd_memcache.enable` integer Enables or disables the plugin. If disabled, the extension will not plug into `mysqlnd` to proxy internal `mysqlnd` C API calls.

#### Note

This option is mainly used by developers to build this extension statically into PHP. General users are encouraged to build this extension as a shared object, and to unload it completely when it is not needed.

### 21.9.10.6. Predefined Constants

Copyright 1997-2012 the PHP Documentation Group. [2906]

The constants below are defined by this extension, and will only be available when the extension has either been compiled into PHP or dynamically loaded at runtime.

#### MySQL Memcache Plugin related

`MYSQLND_MEMCACHE_DEFAULT_FILTER` Default regular expression (PCRE style) used for matching `SELECT` statements that will be mapped into a MySQL Memcache Plugin access point, if possible.

It is also possible to use `mysqlnd_memcache_set`, but the default approach is using this regular expression for pattern matching.

#### Assorted

The version number of this plugin can be obtained by using `MYSQLND_MEMCACHE_VERSION` or `MYSQLND_MEMCACHE_VERSION_ID`. `MYSQLND_MEMCACHE_VERSION` is the string representation of the numerical version number `MYSQLND_MEMCACHE_VERSION_ID`, which is an integer such as 10000. Developers can calculate the version number as follows.

Version (part)	Example
Major*10000	1*10000 = 10000
Minor*100	0*100 = 0
Patch	0 = 0
<code>MYSQLND_MEMCACHE_VERSION_ID</code>	10000

`MYSQLND_MEMCACHE_VERSION` Plugin version string, for example, "1.0.0-alpha". (string)

`MYSQLND_MEMCACHE_VERSION_ID` Plugin version number, for example, 10000. (integer)

## 21.9.10.7. Mysqlnd\_memcache Functions

Copyright 1997-2012 the PHP Documentation Group. [2906]

### 21.9.10.7.1. `mysqlnd_memcache_get_config`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- `mysqlnd_memcache_get_config`

Returns information about the plugin configuration

#### Description

```
array mysqlnd_memcache_get_config(
    mixed connection);
```

This function returns an array of all `mysqlnd_memcache` related configuration information that is attached to the MySQL connection. This includes MySQL, the Memcache object provided via `mysqlnd_memcache_set`, and the table mapping configuration that was automatically collected from the MySQL Server.

#### Parameters

*connection*

A handle to a MySQL Server using one of the MySQL API extensions for PHP, which are `PDO_MYSQL`, `mysqli` or `ext/mysql`.

#### Return Values

An array of `mysqlnd_memcache` configuration information on success, otherwise `FALSE`.

The returned array has these elements:

**Table 21.79.** `mysqlnd_memcache_get_config` array structure

Array Key	Description
<code>memcached</code>	Instance of Memcached associated to this MySQL connection by <code>mysqlnd_memcache_set</code> . You can use this to change settings of the memcache connection, or directly by querying the server on this connection.
<code>pattern</code>	The PCRE regular expression used to match the SQL query sent to the server. Queries matching this pattern will be further analyzed to decide whether the query can be intercepted and sent via the memcache interface or whether the query is sent using the general MySQL protocol to the server. The pattern is either the default pattern ( <code>MYSQLND_MEMCACHE_DEFAULT_REGEXP</code> ) or it is set via <code>mysqlnd_memcache_set</code> .
<code>mappings</code>	An associative array with a list of all configured containers as they were discovered by this plugin. The key for these elements is the name of the container in the MySQL configuration. The value is described below. The contents of this field is created by querying the MySQL Server during association to MySQL and a memcache connection using <code>mysqlnd_memcache_set</code> .
<code>mapping_query</code>	An SQL query used during <code>mysqlnd_memcache_set</code> to identify the

Array Key	Description
	available containers and mappings. The result of that query is provided in the mappings element.

**Table 21.80. Mapping entry structure**

Array Key	Description
prefix	A prefix used while accessing data via memcache. With the MySQL InnoDB Memcache Daemon plugin, this usually begins with @@ and ends with a configurable separator. This prefix is placed in front of the key value while using the memcache protocol.
schema_name	Name of the schema (database) which contains the table being accessed.
table_name	Name of the table which contains the data accessible via memcache protocol.
id_field_name	Name of the database field (column) with the id used as key when accessing the table via memcache. Often this is the database field having a primary key.
separator	<p>The separator used to split the different field values. This is needed as memcache only provides access to a single value while MySQL can map multiple columns to this value.</p> <div style="display: flex; align-items: center;"> <div style="margin-right: 10px;"></div> <div> <p><b>Note</b></p> <p>The separator, which can be set in the MySQL Server configuration, should not be part of any value retrieved via memcache because proper mapping can't be guaranteed.</p> </div> </div>
fields	An array with the name of all fields available for this mapping.

## Examples

### Example 21.393. `mysqld_memcache_get_config` example

```
<?php
$mysqli = new mysqli("host", "user", "passwd", "database");
$memc = new Memcached();
$memc->addServer("host", 11211);
mysqld_memcache_set($mysqli, $memc);

var_dump(mysqld_memcache_get_config($mysqli));
?>
```

The above example will output:

```
array(4) {
  ["memcached"]=>
```

```

object(Memcached)#2 (0) {
}
["pattern"]=>
string(125) "/^\s*SELECT\s*(.+?)\s*FROM\s*`?([a-z0-9_]+)`?\s*WHERE\s*`?([a-z0-9_]+)`?\s*=\s*(?(['"])[^
["mappings"]=>
array(1) {
  ["mymem_test"]=>
  array(6) {
    ["prefix"]=>
    string(13) "@@mymem_test."
    ["schema_name"]=>
    string(4) "test"
    ["table_name"]=>
    string(10) "mymem_test"
    ["id_field_name"]=>
    string(2) "id"
    ["separator"]=>
    string(1) "|"
    ["fields"]=>
    array(3) {
      [0]=>
      string(2) "f1"
      [1]=>
      string(2) "f2"
      [2]=>
      string(2) "f3"
    }
  }
}
["mapping_query"]=>
string(209) "      SELECT c.name,
              CONCAT('@@', c.name, (SELECT value FROM innodb_memcache.config_options WHERE name
              c.db_schema,
              c.db_table,
              c.key_columns,
              c.value_columns,
              (SELECT value FROM innodb_memcache.config_options WHERE name = 'separator') AS s
              FROM innodb_memcache.containers c"
}

```

## See Also

[mysqlnd\\_memcache\\_set](#)

### 21.9.10.7.2. `mysqlnd_memcache_set`

Copyright 1997-2012 the PHP Documentation Group. [2906]

- [mysqlnd\\_memcache\\_set](#)

Associate a MySQL connection with a Memcache connection

## Description

```

bool mysqlnd_memcache_set(
    mixed mysql_connection,
    Memcached memcache_connection,
    string pattern,
    callback callback);

```

Associate *mysql\_connection* with *memcache\_connection* using *pattern* as a PCRE regular expression, and *callback* as a notification callback or to unset the association of *mysql\_connection*.

While associating a MySQL connection with a Memcache connection, this function will query the MySQL Server for its configuration. It will automatically detect whether the server is configured to use the InnoDB Memcache Daemon Plugin or MySQL Cluster NDB Memcache support. It will also query

the server to automatically identify exported tables and other configuration options. The results of this automatic configuration can be retrieved using `mysqlnd_memcache_get_config`.

## Parameters

<code>mysql_connection</code>	A handle to a MySQL Server using one of the MySQL API extensions for PHP, which are <code>PDO_MYSQL</code> , <code>mysqli</code> or <code>ext/mysql</code> .
<code>memcache_connection</code>	A <code>Memcached</code> instance with a connection to the MySQL Memcache Daemon plugin. If this parameter is omitted, then <code>mysql_connection</code> will be unassociated from any memcache connection. And if a previous association exists, then it will be replaced.
<code>pattern</code>	A regular expression in <code>Perl Compatible Regular Expression</code> syntax used to identify potential Memcache-queries. The query should have three sub patterns. The first subpattern contains the requested field list, the second the name of the ID column from the query and the third the requested value. If this parameter is omitted or is set to <code>NULL</code> , then a default pattern will be used.
<code>callback</code>	A callback which will be used whenever a query is being sent to MySQL. The callback will receive a single boolean parameter telling if a query was sent via Memcache.

## Return Values

`TRUE` if the association or disassociation is successful, otherwise `FALSE` if there is an error.

## Examples

**Example 21.394.** `mysqlnd_memcache_set` example with `var_dump` as a simple debugging callback.

```
<?php
$mysqli = new mysqli("host", "user", "passwd", "database");
$memc = new Memcached();
$memc->addServer("host", 11211);
mysqlnd_memcache_set($mysqli, $memc, NULL, 'var_dump');

/* This query will be intercepted and executed via Memcache protocol */
echo "Sending query for id via Memcache: ";
$mysqli->query("SELECT f1, f2, f3 FROM test WHERE id = 1");

/* f1 is not configured as valid key field, this won't be sent via Memcache */
echo "Sending query for f1 via Memcache: ";
$mysqli->query("SELECT id FROM test WHERE f1 = 1");

mysqlnd_memcache_set($mysqli);

/* Now the regular MySQL protocol will be used */
echo "var_dump won't be invoked: ";
$mysqli->query("SELECT f1, f2, f3 WHERE id = 1");

?>
```

The above example will output:

```
Sending query for id via Memcache: bool(true)
Sending query for f1 via Memcache: bool(false)
var_dump won't be invoked:
```

---

**See Also**[mysqlnd\\_memcache\\_get\\_config](#)

### 21.9.10.8. Change History

Copyright 1997-2012 the PHP Documentation Group. [2906]

This change history is a high level summary of selected changes that may impact applications and/or break backwards compatibility.

See also the [CHANGES](#) file in the source distribution for a complete list of changes.

#### 21.9.10.8.1. PECL/mysqlnd\_memcache 1.0 series

Copyright 1997-2012 the PHP Documentation Group. [2906]

1.0.0-alpha

- Release date: TBD
- Motto/theme: Basic mapping of SQL SELECT to a MySQL Memcache plugin access.

The initial release does map basic SQL SELECT statements to a MySQL Memcache plugin access. This bares potential performance benefits as the direct key-value access to MySQL storage using the Memcache protocol is usually faster than using SQL access.

### 21.9.11. Connector/PHP

This documentation, and other publications, sometimes uses the term [Connector/PHP](#). This term refers to the full set of MySQL related functionality in PHP, which includes the three APIs that are described above, along with the [mysqlnd](#) core library and all of its plugins.

### 21.9.12. Common Problems with MySQL and PHP

- [Error: Maximum Execution Time Exceeded](#): This is a PHP limit; go into the [php.ini](#) file and set the maximum execution time up from 30 seconds to something higher, as needed. It is also not a bad idea to double the RAM allowed per script to 16MB instead of 8MB.
- [Fatal error: Call to unsupported or undefined function mysql\\_connect\(\) in ...](#): This means that your PHP version isn't compiled with MySQL support. You can either compile a dynamic MySQL module and load it into PHP or recompile PHP with built-in MySQL support. This process is described in detail in the PHP manual.
- [Error: Undefined reference to 'uncompress'](#): This means that the client library is compiled with support for a compressed client/server protocol. The fix is to add `-lz` last when linking with `-lmysqlclient`.
- [Error: Client does not support authentication protocol](#): This is most often encountered when trying to use the older [mysql](#) extension with MySQL 4.1.1 and later. Possible solutions are: downgrade to MySQL 4.0; switch to PHP 5 and the newer [mysqli](#) extension; or configure the MySQL server with the [old\\_passwords](#) [517] system variable set to 1. (See [Section C.5.2.4](#), "Client does not support authentication protocol", for more information.)

### 21.9.13. Enabling Both [mysql](#) and [mysqli](#) in PHP

If you're experiencing problems with enabling both the [mysql](#) and the [mysqli](#) extension when building PHP on Linux yourself, you should try the following procedure.

1. Configure PHP like this:

```
./configure --with-mysqli=/usr/bin/mysql_config --with-mysql=/usr
```

2. Edit the `Makefile` and search for a line that starts with `EXTRA_LIBS`. It might look like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl
-lxml2 -lz -lm -lxml2 -lz -lm -lmysqlclient -lz -lcrypt -lnsl -lm
-lxml2 -lz -lm -lcrypt -lxml2 -lz -lm -lcrypt
```

Remove all duplicates, so that the line looks like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl
-lxml2
```

3. Build and install PHP:

```
make
make install
```

## 21.10. MySQL Perl API

The Perl `DBI` module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI with MySQL, install the following:

1. The `DBI` module.
2. The `DBD::mysql` module. This is the DataBase Driver (DBD) module for Perl.
3. Optionally, the DBD module for any other type of database server you want to access.

Perl DBI is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

These sections contain information about using Perl with MySQL and writing MySQL applications in Perl:

- For installation instructions for Perl DBI support, see [Section 2.13, “Perl Installation Notes”](#).
- For an example of reading options from option files, see [Section 5.6.4, “Using Client Programs in a Multiple-Server Environment”](#).
- For secure coding tips, see [Section 6.1.1, “Security Guidelines”](#).
- For debugging tips, see [Section 22.4.1.4, “Debugging mysqld under gdb”](#).
- For some Perl-specific environment variables, see [Section 2.12, “Environment Variables”](#).
- For considerations for running on Mac OS X, see [Section 2.4.5, “Using the Bundled MySQL on Mac OS X Server”](#).
- For ways to quote string literals, see [Section 9.1.1, “String Literals”](#).

DBI information is available at the command line, online, or in printed form:

- Once you have the `DBI` and `DBD::mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

```
shell> perldoc DBI
shell> perldoc DBI:FAQ
shell> perldoc DBD:mysql
```

You can also use `pod2man`, `pod2html`, and so on to translate this information into other formats.

- For online information about Perl DBI, visit the DBI Web site, <http://dbi.perl.org/>. That site hosts a general DBI mailing list. Oracle Corporation hosts a list specifically about `DBD::mysql`; see [Section 1.6.1, “MySQL Mailing Lists”](#).
- For printed information, the official DBI book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI Web site, <http://dbi.perl.org/>.

For information that focuses specifically on using DBI with MySQL, see *MySQL and Perl for the Web* (Paul DuBois, New Riders, 2001). This book's Web site is <http://www.kitebird.com/mysql-perl/>.

## 21.11. MySQL Python API

`MySQLdb` is a third-party driver that provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at <http://sourceforge.net/projects/mysql-python/>.

The new MySQL Connector/Python component provides an interface to the same Python API, and is built into the MySQL Server and supported by Oracle. See [Section 21.6, “MySQL Connector/Python”](#) for details on the Connector, as well as coding guidelines for Python applications and sample Python code.

## 21.12. MySQL Ruby APIs

Two APIs are available for Ruby programmers developing MySQL applications:

- The MySQL/Ruby API is based on the `libmysqlclient` API library. For information on installing and using the MySQL/Ruby API, see [Section 21.12.1, “The MySQL/Ruby API”](#).
- The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver). For information on installing and using the Ruby/MySQL API, see [Section 21.12.2, “The Ruby/MySQL API”](#).

For background and syntax information about the Ruby language, see [Ruby Programming Language](#).

### 21.12.1. The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through `libmysqlclient`.

For information on installing the module, and the functions exposed, see [MySQL/Ruby](#).

### 21.12.2. The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol.

For information on installing the module, and the functions exposed, see [Ruby/MySQL](#).

## 21.13. MySQL Tcl API

`MySQLtcl` is a simple API for accessing a MySQL database server from the [Tcl programming language](#). It can be found at <http://www.xdobry.de/mysqltcl/>.

## 21.14. MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the [Eiffel programming language](#), written by Michael Ravits. It can be found at <http://efsa.sourceforge.net/archive/ravits/mysql.htm>.

## 22.1. MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. To track or contribute to MySQL development, follow the instructions in [Section 2.9.3, “Installing MySQL from a Development Source Tree”](#). If you are interested in MySQL internals, you should also subscribe to our `internals` mailing list. This list has relatively low traffic. For details on how to subscribe, please see [Section 1.6.1, “MySQL Mailing Lists”](#). Many MySQL developers at Oracle Corporation are on the `internals` list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

### 22.1.1. MySQL Threads

The MySQL server creates the following threads:

- Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.
- Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

For information about tuning the parameters that control thread resources, see [Section 8.11.5.1, “How MySQL Uses Threads for Client Connections”](#).

- On a master replication server, connections from slave servers are handled like client connections: There is one thread per connected slave.

- On a slave replication server, an I/O thread is started to connect to the master server and read updates from it. An SQL thread is started to apply updates read from the master. These two threads run independently and can be started and stopped independently.
- A signal thread handles all signals. This thread also normally handles alarms and calls `process_alarm()` to force timeouts on connections that have been idle too long.
- If InnoDB is used, there will be additional read and write threads by default. The number of these are controlled by the `innodb_read_io_threads` [1743] and `innodb_write_io_threads` [1754] parameters. See Section 14.2.6, “InnoDB Startup Options and System Variables”.
- If `mysqld` is compiled with `-DUSE_ALARM_THREAD`, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with `sigwait()` or if you want to use the `thr_alarm()` code in your application without a dedicated signal handling thread.
- If the server is started with the `--flush_time=val` [482] option, a dedicated thread is created to flush all tables every `val` seconds.
- Each table for which `INSERT DELAYED` statements are issued gets its own thread. See Section 13.2.5.2, “INSERT DELAYED Syntax”.
- If the event scheduler is active, there is one thread for the scheduler, and a thread for each event currently running. See Section 18.4.1, “Event Scheduler Overview”.

`mysqladmin processlist` only shows the connection, `INSERT DELAYED`, replication, and event threads.

## 22.1.2. The MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix.

You can also write your own test cases. For information about the MySQL Test Framework, including system requirements, see the manual available at <http://dev.mysql.com/doc/mysqctest/2.0/en/>.

The current set of test cases doesn't test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, operating system or library issues, and is quite thorough in testing replication. Our goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system because this ensures that all future MySQL releases work well with your applications.

The test system consists of a test language interpreter (`mysqctest`), a Perl script to run all tests (`mysql-test-run.pl`), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type `make test` from the source root directory, or change location to the `mysql-test` directory and type `./mysql-test-run.pl`. If you have installed a binary distribution, change location to the `mysql-test` directory under the installation root directory (for example, `/usr/local/mysql/mysql-test`), and run `./mysql-test-run.pl`. All tests should succeed. If any do not, feel free to try to find out why and report the problem if it indicates a bug in MySQL. See Section 1.7, “How to Report Bugs or Problems”.

If one test fails, you should run `mysql-test-run.pl` with the `--force` option to check whether any other tests fail.

If you have a copy of `mysqld` running on the machine where you want to run the test suite, you do not have to stop it, as long as it is not using ports 9306 or 9307. If either of those ports is taken, you should set the `MTR_BUILD_THREAD` environment variable to an appropriate value, and the test suite will use a different set of ports for master, slave, and NDB). For example:

```
shell> export MTR_BUILD_THREAD=31
shell> ./mysql-test-run.pl [options] [test_name]
```

In the `mysql-test` directory, you can run an individual test case with `./mysql-test-run.pl test_name`.

If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL [internals](#) mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#).

## 22.2. The MySQL Plugin API

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The API is generic and does not specify what plugins can do. The components supported by this interface include, but are not limited to, storage engines, full-text parser plugins, and server extensions.

For example, full-text parser plugins can be used to replace or augment the built-in full-text parser. A plugin can parse text into words using rules that differ from those used by the built-in parser. This can be useful if you need to parse text with characteristics different from those expected by the built-in parser.

The plugin interface is more general than the older user-defined function (UDF) interface.

The plugin interface uses the `plugin` table in the `mysql` database to record information about plugins that have been installed permanently with the `INSTALL PLUGIN` statement. This table is created as part of the MySQL installation process. Plugins can also be installed for a single server invocation with the `--plugin-load` option. Plugins installed this way are not recorded in the `plugin` table. See [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

MySQL 5.6 supports an API for client plugins in addition to that for server plugins. This is used, for example, by authentication plugins where a server-side plugin and a client-side plugin cooperate to enable clients to connect to the server through a variety of authentication methods.

### Additional Resources

The book *MySQL 5.1 Plugin Development* by Sergei Golubchik and Andrew Hutchings provides a wealth of detail about the plugin API. Despite the fact that the book's title refers to MySQL Server 5.1, most of the information in it applies to later versions as well.

#### 22.2.1. Plugin API Characteristics

The server plugin API has these characteristics:

- All plugins have several things in common.

Each plugin has a name that it can be referred to in SQL statements, as well as other metadata such as an author and a description that provide other information. This information can be examined in the `INFORMATION_SCHEMA.PLUGINS` table or using the `SHOW PLUGINS` statement.

- The plugin framework is extendable to accommodate different kinds of plugins.

Although some aspects of the plugin API are common to all types of plugins, the API also permits type-specific interface elements so that different types of plugins can be created. A plugin with one purpose can have an interface most appropriate to its own requirements and not the requirements of some other plugin type.

Interfaces for several types of plugins exist, such as storage engines, full-text parser, and `INFORMATION_SCHEMA` tables. Others can be added.

- Plugins can expose information to users.

A plugin can implement system and status variables that are available through the `SHOW VARIABLES` and `SHOW STATUS` statements.

- The plugin API includes versioning information.

The version information included in the plugin API enables a plugin library and each plugin that it contains to be self-identifying with respect to the API version that was used to build the library. If the

API changes over time, the version numbers will change, but a server can examine a given plugin library's version information to determine whether it supports the plugins in the library.

There are two types of version numbers. The first is the version for the general plugin framework itself. Each plugin library includes this kind of version number. The second type of version applies to individual plugins. Each specific type of plugin has a version for its interface, so each plugin in a library has a type-specific version number. For example, a library containing a full-text parser plugin has a general plugin API version number, and the plugin has a version number specific to the full-text plugin interface.

- The plugin API implements security restrictions.

A plugin library must be installed in a specific dedicated directory for which the location is controlled by the server and cannot be changed at runtime. Also, the library must contain specific symbols that identify it as a plugin library. The server will not load something as a plugin if it was not built as a plugin.

- Plugins have access to server services.

The services interface exposes server functionality that plugins can access using ordinary function calls. For details, see [Section 22.2.5, “MySQL Services for Plugins”](#).

In some respects, the server plugin API is similar to the older user-defined function (UDF) API that it supersedes, but the plugin API has several advantages over the older interface. For example, UDFs had no versioning information. Also, the newer plugin interface eliminates the security issues of the older UDF interface. The older interface for writing nonplugin UDFs permitted libraries to be loaded from any directory searched by the system's dynamic linker, and the symbols that identified the UDF library were relatively nonspecific.

The client plugin API has similar architectural characteristics, but client plugins have no direct access to the server the way server plugins do.

## 22.2.2. Plugin API Components

The server plugin implementation comprises several components.

SQL statements:

- `INSTALL PLUGIN` registers a plugin in the `mysql.plugin` table and loads the plugin code.
- `UNINSTALL PLUGIN` unregisters a plugin from the `mysql.plugin` table and unloads the plugin code.
- The `WITH PARSER` clause for full-text index creation associates a full-text parser plugin with a given `FULLTEXT` index.
- `SHOW PLUGINS` displays information about server plugins.

Command-line options and system variables:

- The `--plugin-load` [\[435\]](#) option enables plugins to be loaded at server startup time.
- The `plugin_dir` [\[525\]](#) system variable indicates the location of the directory where all plugins must be installed. The value of this variable can be specified at server startup with a `--plugin_dir=path` [\[525\]](#) option. `mysql_config --plugindir` displays the default plugin directory path name.

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

Plugin-related tables:

- The `INFORMATION_SCHEMA.PLUGINS` table contains plugin information.
- The `mysql.plugin` table lists each plugin that was installed with `INSTALL PLUGIN` and is required for plugin use. For new MySQL installations, this table is created during the installation process.

The client plugin implementation is simpler:

- For the `mysql_options()` C API function, the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options enable client programs to load authentication plugins.
- There are C API functions that enable management of client plugins.

To examine how MySQL implements plugins, consult the following source files in a MySQL source distribution:

- In the `include/mysql` directory, `plugin.h` exposes the public plugin API. This file should be examined by anyone who wants to write a plugin library. `plugin_XXX.h` files provide additional information that pertains to specific types of plugins. `client_plugin.h` contains information specific to client plugins.
- In the `sql` directory, `sql_plugin.h` and `sql_plugin.cc` comprise the internal plugin implementation. `sql_acl.cc` is where the server uses authentication plugins. These files need not be consulted by plugin developers. They may be of interest for those who want to know more about how the server handles plugins.
- In the `sql-common` directory, `client_plugin.h` implements the C API client plugin functions, and `client.c` implements client authentication support. These files need not be consulted by plugin developers. They may be of interest for those who want to know more about how the server handles plugins.

### 22.2.3. Types of Plugins

The plugin API enables creation of plugins that implement several capabilities:

- Storage engines
- Full-text parsers
- Daemons
- `INFORMATION_SCHEMA` tables
- Semisynchronous replication
- Auditing
- Authentication

The following sections provide an overview of these plugin types.

#### 22.2.3.1. Storage Engine Plugins

The pluggable storage engine architecture used by MySQL Server enables storage engines to be written as plugins and loaded into and unloaded from a running server. For a description of this architecture, see [Section 14.12, “Overview of MySQL Storage Engine Architecture”](#).

For information on how to use the plugin API to write storage engines, see [MySQL Internals: Writing a Custom Storage Engine](#).

#### 22.2.3.2. Full-Text Parser Plugins

MySQL has a built-in parser that it uses by default for full-text operations (parsing text to be indexed, or parsing a query string to determine the terms to be used for a search). For full-text processing,

“parsing” means extracting words from text or a query string based on rules that define which character sequences make up a word and where word boundaries lie.

When parsing for indexing purposes, the parser passes each word to the server, which adds it to a full-text index. When parsing a query string, the parser passes each word to the server, which accumulates the words for use in a search.

The parsing properties of the built-in full-text parser are described in [Section 12.9, “Full-Text Search Functions”](#). These properties include rules for determining how to extract words from text. The parser is influenced by certain system variables such as `ft_min_word_len` [484] and `ft_max_word_len` [484] that cause words shorter or longer to be excluded, and by the stopword list that identifies common words to be ignored.

The plugin API enables you to provide a full-text parser of your own so that you have control over the basic duties of a parser. A parser plugin can operate in either of two roles:

- The plugin can replace the built-in parser. In this role, the plugin reads the input to be parsed, splits it up into words, and passes the words to the server (either for indexing or for word accumulation).

One reason to use a parser this way is that you need to use different rules from those of the built-in parser for determining how to split up input into words. For example, the built-in parser considers the text “case-sensitive” to consist of two words “case” and “sensitive,” whereas an application might need to treat the text as a single word.

- The plugin can act in conjunction with the built-in parser by serving as a front end for it. In this role, the plugin extracts text from the input and passes the text to the parser, which splits up the text into words using its normal parsing rules. In particular, this parsing will be affected by the `ft_XXX` system variables and the stopword list.

One reason to use a parser this way is that you need to index content such as PDF documents, XML documents, or `.doc` files. The built-in parser is not intended for those types of input but a plugin can pull out the text from these input sources and pass it to the built-in parser.

It is also possible for a parser plugin to operate in both roles. That is, it could extract text from nonplaintext input (the front end role), and also parse the text into words (thus replacing the built-in parser).

A full-text plugin is associated with full-text indexes on a per-index basis. That is, when you install a parser plugin initially, that does not cause it to be used for any full-text operations. It simply becomes available. For example, a full-text parser plugin becomes available to be named in a `WITH PARSE` clause when creating individual `FULLTEXT` indexes. To create such an index at table-creation time, do this:

```
CREATE TABLE t
(
  doc CHAR(255),
  FULLTEXT INDEX (doc) WITH PARSE my_parser
) ENGINE=MyISAM;
```

Or you can add the index after the table has been created:

```
ALTER TABLE t ADD FULLTEXT INDEX (doc) WITH PARSE my_parser;
```

The only SQL change for associating the parser with the index is the `WITH PARSE` clause. Searches are specified as before, with no changes needed for queries.

When you associate a parser plugin with a `FULLTEXT` index, the plugin is required for using the index. If the parser plugin is dropped, any index associated with it becomes unusable. Any attempt to use it a table for which a plugin is not available results in an error, although `DROP TABLE` is still possible.

For more information about full-text plugins, see [Section 22.2.4.4, “Writing Full-Text Parser Plugins”](#).

### 22.2.3.3. Daemon Plugins

A daemon plugin is a simple type of plugin used for code that should be run by the server but that does not communicate with it. MySQL distributions include an example daemon plugin that writes periodic heartbeat messages to a file.

For more information about daemon plugins, see [Section 22.2.4.5, “Writing Daemon Plugins”](#).

#### 22.2.3.4. **INFORMATION\_SCHEMA** Plugins

**INFORMATION\_SCHEMA** plugins enable the creation of tables containing server metadata that are exposed to users through the **INFORMATION\_SCHEMA** database. For example, **InnoDB** uses **INFORMATION\_SCHEMA** plugins to provide tables that contain information about current transactions and locks.

For more information about **INFORMATION\_SCHEMA** plugins, see [Section 22.2.4.6, “Writing INFORMATION\\_SCHEMA Plugins”](#).

#### 22.2.3.5. **Semisynchronous Replication** Plugins

MySQL replication is asynchronous by default. With semisynchronous replication, a commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction. Semisynchronous replication is implemented through complementary master and client plugins. See [Section 16.3.8, “Semisynchronous Replication”](#).

For more information about semisynchronous replication plugins, see [Section 22.2.4.7, “Writing Semisynchronous Replication Plugins”](#).

#### 22.2.3.6. **Audit** Plugins

In MySQL 5.6, the server provides a pluggable audit interface that enables information about server operations to be reported to interested parties. Currently, audit notification occurs for these operations (although the interface is general and the server could be modified to report others):

- Write a message to the general query log (if the log is enabled)
- Write a message to the error log
- Send a query result to a client

Audit plugins may register with the audit interface to receive notification about server operations. When an auditable event occurs within the server, the server determines whether notification is needed. For each registered audit plugin, the server checks the event against those event classes in which the plugin is interested and passes the event to the plugin if there is a match.

This interface enables audit plugins to receive notifications only about operations in event classes they consider significant and to ignore others. The interface provides for categorization of operations into event classes and further division into event subclasses within each class.

When an audit plugin is notified of an auditable event, it receives a pointer to the current THD structure and a pointer to a structure that contains information about the event. The plugin can examine the event and perform whatever auditing actions are appropriate. For example, the plugin can see what statement produced a result set or was logged, the number of rows in a result, who the current user was for an operation, or the error code for failed operations.

For more information about audit plugins, see [Section 22.2.4.8, “Writing Audit Plugins”](#).

#### 22.2.3.7. **Authentication** Plugins

MySQL 5.6 supports pluggable authentication. Authentication plugins exist on both the server and client sides. Plugins on the server side implement authentication methods for use by clients when they connect to the server. A plugin on the client side communicates with a server-side plugin to provide the authentication information that it requires. A client-side plugin may interact with the user, performing

tasks such as soliciting a password or other authentication credentials to be sent to the server. See [Section 6.3.7, “Pluggable Authentication”](#).

Pluggable authentication also enables proxy user capability, in which one user takes the identity of another user. A server-side authentication plugin can return to the server the name of the user whose identity the connecting user should have. See [Section 6.3.8, “Proxy Users”](#).

For more information about authentication plugins, see [Section 22.2.4.9, “Writing Authentication Plugins”](#).

### 22.2.3.8. Password-Validation Plugins

As of MySQL 5.6.6, the server provides an interface for writing plugins that test passwords. Such a plugin implements two capabilities:

- Rejection of too-weak passwords in statements that assign passwords (such as `CREATE USER`, `GRANT`, and `SET PASSWORD` statements), and passwords given as arguments to the `PASSWORD( )` [1263] and `OLD_PASSWORD( )` [1263] functions.
- Assessing the strength of potential passwords for the `VALIDATE_PASSWORD_STRENGTH( )` [1265] SQL function.

For information about writing this type of plugin, see [Section 22.2.4.10, “Writing Password-Validation Plugins”](#).

## 22.2.4. Writing Plugins

To create a plugin library, you must provide the required descriptor information that indicates what plugins the library file contains, and write the interface functions for each plugin.

Every server plugin must have a general descriptor that provides information to the plugin API, and a type-specific descriptor that provides information about the plugin interface for a given type of plugin. The structure of the general descriptor is the same for all plugin types. The structure of the type-specific descriptor varies among plugin types and is determined by the requirements of what the plugin needs to do. The server plugin interface also enables plugins to expose status and system variables. These variables become visible through the `SHOW STATUS` and `SHOW VARIABLES` statements and the corresponding `INFORMATION_SCHEMA` tables.

For client-side plugins, the architecture is a bit different. Each plugin must have a descriptor, but there is no division into separate general and type-specific descriptors. Instead, the descriptor begins with a fixed set of members common to all client plugin types, and the common members are followed by any additional members required to implement the specific plugin type.

You can write plugins in C or C++ (or another language that can use C calling conventions). Plugins are loaded and unloaded dynamically, so your operating system must support dynamic loading and you must have compiled the calling application dynamically (not statically). For server plugins, this means that `mysqld` must be compiled dynamically.

A server plugin contains code that becomes part of the running server, so when you write the plugin, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to plugins originally written for older servers. For information about these constraints, see [Section 2.9.4, “MySQL Source-Configuration Options”](#), and [Section 2.9.5, “Dealing with Problems Compiling MySQL”](#).

Client plugin writers should avoid dependencies on what symbols the calling application has because you cannot be sure what applications will use the plugin.

### 22.2.4.1. Overview of Plugin Writing

The following procedure provides an overview of the steps needed to create a plugin library. The next sections provide additional details on setting plugin data structures and writing specific types of plugins.

1. In the plugin source file, include the header files that the plugin library needs. The `plugin.h` file is required, and the library might require other files as well. For example:

```
#include <stdlib.h>
#include <ctype.h>
#include <mysql/plugin.h>
```

2. Set up the descriptor information for the plugin library file. For server plugins, write the library descriptor, which must contain the general plugin descriptor for each server plugin in the file. For more information, see [Section 22.2.4.2.1, “Server Plugin Library and Plugin Descriptors”](#). In addition, set up the type-specific descriptor for each server plugin in the library. Each plugin's general descriptor points to its type-specific descriptor.

For client plugins, write the client descriptor. For more information, see [Section 22.2.4.2.3, “Client Plugin Descriptors”](#).

3. Write the plugin interface functions for each plugin. For example, each plugin's general plugin descriptor points to the initialization and deinitialization functions that the server should invoke when it loads and unloads the plugin. The plugin's type-specific description may also point to interface functions.
4. For server plugins, set up the status and system variables, if there are any.
5. Compile the plugin library as a shared library and install it in the plugin directory. For more information, see [Section 22.2.4.3, “Compiling and Installing Plugin Libraries”](#).
6. For server plugins, register the plugin with the server. For more information, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).
7. Test the plugin to verify that it works properly.

### 22.2.4.2. Plugin Data Structures

A plugin library file includes descriptor information to indicate what plugins it contains.

If the plugin library contains any server plugins, it must include the following descriptor information:

- A library descriptor indicates the general server plugin API version number used by the library and contains a general plugin descriptor for each server plugin in the library. To provide the framework for this descriptor, invoke two macros from the `plugin.h` header file:

```
mysql_declare_plugin(name)
... one or more server plugin descriptors here ...
mysql_declare_plugin_end;
```

The macros expand to provide a declaration for the API version automatically. You must provide the plugin descriptors.

- Within the library descriptor, each general server plugin is described by a `st_mysql_plugin` structure. This plugin descriptor structure contains information that is common to every type of server plugin: A value that indicates the plugin type; the plugin name, author, description, and license type; pointers to the initialization and deinitialization functions that the server invokes when it loads and unloads the plugin, and pointers to any status or system variables the plugin implements.
- Each general server plugin descriptor within the library descriptor also contains a pointer to a type-specific plugin descriptor. The structure of the type-specific descriptors varies from one plugin type to another because each type of plugin can have its own API. A type-specific plugin descriptor contains a type-specific API version number and pointers to the functions that are needed to implement that plugin type. For example, a full-text parser plugin has initialization and deinitialization functions, and a main parsing function. The server invokes these functions when it uses the plugin to parse text.

The plugin library also contains the interface functions that are referenced by the general and type-specific descriptors for each plugin in the library.

If the plugin library contains a client plugin, it must include a descriptor for the plugin. The descriptor begins with a fixed set of members common to all client plugins, followed by any members specific to the plugin type. To provide the descriptor framework, invoke two macros from the `client_plugin.h` header file:

```
mysql_declare_client_plugin(plugin_type)
... members common to all client plugins ...
... type-specific extra members ...
mysql_end_client_plugin;
```

The plugin library also contains any interface functions referenced by the client descriptor.

The `mysql_declare_plugin()` and `mysql_declare_client_plugin()` macros differ somewhat in how they can be invoked, which has implications for the contents of plugin libraries. The following guidelines summarize the rules:

- `mysql_declare_plugin()` and `mysql_declare_client_plugin()` can both be used in the same source file, which means that a plugin library can contain both server and client plugins. However, each of `mysql_declare_plugin()` and `mysql_declare_client_plugin()` can be used at most once.
- `mysql_declare_plugin()` permits multiple server plugin declarations, so a plugin library can contain multiple server plugins.
- `mysql_declare_client_plugin()` permits only a single client plugin declaration. To create multiple client plugins, separate plugin libraries must be used.

When a client program looks for a client plugin that is in a plugin library and not built into `libmysqlclient`, it looks for a file with a basename that is the same as the plugin name. For example, if a program needs to use a client authentication plugin named `auth_xxx` on a system that uses `.so` as the library suffix, it looks in the file named `auth_xxx.so`. (On Mac OS X, the program looks first for `auth_xxx.dylib`, then for `auth_xxx.so`.) For this reason, if a plugin library contains a client plugin, the library must have the same basename as that plugin.

The same is not true for a library that contains server plugins. The `--plugin-load` [435] option and the `INSTALL PLUGIN` statement provide the library file name explicitly, so there need be no explicit relationship between the library name and the name of any server plugins it contains.

#### 22.2.4.2.1. Server Plugin Library and Plugin Descriptors

Every plugin library that contains server plugins must include a library descriptor that contains the general plugin descriptor for each server plugin in the file. This section discusses how to write the library and general descriptors for server plugins.

The library descriptor must define two symbols:

- `_mysql_plugin_interface_version` specifies the version number of the general plugin framework. This is given by the `MYSQL_PLUGIN_INTERFACE_VERSION` symbol, which is defined in the `plugin.h` file.
- `_mysql_plugin_declarations` defines an array of plugin declarations, terminated by a declaration with all members set to 0. Each declaration is an instance of the `st_mysql_plugin` structure (also defined in `plugin.h`). There must be one of these for each server plugin in the library.

If the server does not find those two symbols in a library, it does not accept it as a legal plugin library and rejects it with an error. This prevents use of a library for plugin purposes unless it was built specifically as a plugin library.

The conventional way to define the two required symbols is by using the `mysql_declare_plugin()` and `mysql_declare_plugin_end` macros from the `plugin.h` file:

```
mysql_declare_plugin(name)
... one or more server plugin descriptors here ...
```

```
mysql_declare_plugin_end;
```

Each server plugin must have a general descriptor that provides information to the server plugin API. The general descriptor has the same structure for all plugin types. The `st_mysql_plugin` structure in the `plugin.h` file defines this descriptor:

```
struct st_mysql_plugin
{
    int type; /* the plugin type (a MYSQL_XXX_PLUGIN value) */
    void *info; /* pointer to type-specific plugin descriptor */
    const char *name; /* plugin name */
    const char *author; /* plugin author (for I_S.PLUGINS) */
    const char *descr; /* general descriptive text (for I_S.PLUGINS) */
    int license; /* the plugin license (PLUGIN_LICENSE_XXX) */
    int (*init)(void *); /* the function to invoke when plugin is loaded */
    int (*deinit)(void *); /* the function to invoke when plugin is unloaded */
    unsigned int version; /* plugin version (for I_S.PLUGINS) */
    struct st_mysql_show_var *status_vars;
    struct st_mysql_sys_var **system_vars;
    void * __reserved1; /* reserved for dependency checking */
    unsigned long flags; /* flags for plugin */
};
```

The `st_mysql_plugin` descriptor structure members are used as follows. `char *` members should be specified as null-terminated strings.

- `type`: The plugin type. This must be one of the plugin-type values from `plugin.h`:

```
/*
 * The allowable types of plugins
 */
#define MYSQL_UDF_PLUGIN 0 /* User-defined function */
#define MYSQL_STORAGE_ENGINE_PLUGIN 1 /* Storage Engine */
#define MYSQL_FTPARSER_PLUGIN 2 /* Full-text parser plugin */
#define MYSQL_DAEMON_PLUGIN 3 /* The daemon/raw plugin type */
#define MYSQL_INFORMATION_SCHEMA_PLUGIN 4 /* The I_S plugin type */
#define MYSQL_AUDIT_PLUGIN 5 /* The Audit plugin type */
#define MYSQL_REPLICATION_PLUGIN 6 /* The replication plugin type */
#define MYSQL_AUTHENTICATION_PLUGIN 7 /* The authentication plugin type */
...
```

For example, for a full-text parser plugin, the `type` value is `MYSQL_FTPARSER_PLUGIN`.

- `info`: A pointer to the type-specific descriptor for the plugin. This descriptor's structure depends on the particular type of plugin, unlike that of the general plugin descriptor structure. For version-control purposes, the first member of the type-specific descriptor for every plugin type is expected to be the interface version for the type. This enables the server to check the type-specific version for every plugin no matter its type. Following the version number, the descriptor includes any other members needed, such as callback functions and other information needed by the server to invoke the plugin properly. Later sections on writing particular types of server plugins describe the structure of their type-specific descriptors.
- `name`: A string that gives the plugin name. This is the name that will be listed in the `mysql.plugin` table and by which you refer to the plugin in SQL statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`, or with the `--plugin-load` [435] option. The name is also visible in the `INFORMATION_SCHEMA.PLUGINS` table or the output from `SHOW PLUGINS`.

The plugin name should not begin with the name of any server option. If it does, the server will fail to initialize it. For example, the server has a `--socket` [442] option, so you should not use a plugin name such as `socket`, `socket_plugin`, and so forth.

- `author`: A string naming the plugin author. This can be whatever you like.
- `desc`: A string that provides a general description of the plugin. This can be whatever you like.
- `license`: The plugin license type. The value can be one of `PLUGIN_LICENSE_PROPRIETARY`, `PLUGIN_LICENSE_GPL`, or `PLUGIN_LICENSE_BSD`.

- `init`: A once-only initialization function, or `NULL` if there is no such function. The server executes this function when it loads the plugin, which happens for `INSTALL PLUGIN` or, for plugins listed in the `mysql.plugin` table, at server startup. The function takes one argument that points to the internal structure used to identify the plugin. It returns zero for success and nonzero for failure.
- `deinit`: A once-only deinitialization function, or `NULL` if there is no such function. The server executes this function when it unloads the plugin, which happens for `UNINSTALL PLUGIN` or, for plugins listed in the `mysql.plugin` table, at server shutdown. The function takes one argument that points to the internal structure used to identify the plugin. It returns zero for success and nonzero for failure.
- `version`: The plugin version number. When the plugin is installed, this value can be retrieved from the `INFORMATION_SCHEMA.PLUGINS` table. The value includes major and minor numbers. If you write the value as a hex constant, the format is `0xMMNN`, where `MM` and `NN` are the major and minor numbers, respectively. For example, `0x0302` represents version 3.2.

- `status_vars`: A pointer to a structure for status variables associated with the plugin, or `NULL` if there are no such variables. When the plugin is installed, these variables are displayed in the output of the `SHOW STATUS` statement.

The `status_vars` member, if not `NULL`, points to an array of `st_mysql_show_var` structures that describe status variables. See [Section 22.2.4.2.2, “Server Plugin Status and System Variables”](#).

- `system_vars`: A pointer to a structure for system variables associated with the plugin, or `NULL` if there are no such variables. These options and system variables can be used to help initialize variables within the plugin.

The `system_vars` member, if not `NULL`, points to an array of `st_mysql_sys_var` structures that describe system variables. See [Section 22.2.4.2.2, “Server Plugin Status and System Variables”](#).

- `__reserved1`: A placeholder for the future. Currently, it should be set to `NULL`.
- `flags`: Plugin flags. Individual bits correspond to different flags. The value should be set to the OR of the applicable flags. These flags are available:

```
#define PLUGIN_OPT_NO_INSTALL 1UL /* Not dynamically loadable */
#define PLUGIN_OPT_NO_UNINSTALL 2UL /* Not dynamically unloadable */
```

`PLUGIN_OPT_NO_INSTALL` indicates that the plugin cannot be loaded at runtime with the `INSTALL PLUGIN` statement. This is appropriate for plugins that must be loaded at server startup with the `--plugin-load [435]` option. `PLUGIN_OPT_NO_UNINSTALL` indicates that the plugin cannot be unloaded at runtime with the `UNINSTALL PLUGIN` statement.

This member was added in MySQL 5.6.3.

The server invokes the `init` and `deinit` functions in the general plugin descriptor only when loading and unloading the plugin. They have nothing to do with use of the plugin such as happens when an SQL statement causes the plugin to be invoked.

For example, the descriptor information for a library that contains a single full-text parser plugin named `simple_parser` looks like this:

```
mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN,          /* type */
    &simple_parser_descriptor,       /* descriptor */
    "simple_parser",                 /* name */
    "Oracle Corporation",          /* author */
    "Simple Full-Text Parser",     /* description */
    PLUGIN_LICENSE_GPL,            /* plugin license */
    simple_parser_plugin_init,     /* init function (when loaded) */
    simple_parser_plugin_deinit,   /* deinit function (when unloaded) */
    0x0001,                         /* version */
    simple_status,                  /* status variables */
}
```

```

simple_system_variables, /* system variables */
NULL,
0
}
mysql_declare_plugin_end;

```

For a full-text parser plugin, the type must be `MYSQL_FTPARSER_PLUGIN`. This is the value that identifies the plugin as being legal for use in a `WITH PARSER` clause when creating a `FULLTEXT` index. (No other plugin type is legal for this clause.)

`plugin.h` defines the `mysql_declare_plugin()` and `mysql_declare_plugin_end` macros like this:

```

#ifndef MYSQL_DYNAMIC_PLUGIN
#define __MYSQL_DECLARE_PLUGIN(NAME, VERSION, PSIZE, DECLS) \
MYSQL_PLUGIN_EXPORT int VERSION= MYSQL_PLUGIN_INTERFACE_VERSION; \
MYSQL_PLUGIN_EXPORT int PSIZE= sizeof(struct st_mysql_plugin); \
MYSQL_PLUGIN_EXPORT struct st_mysql_plugin DECLS[]= {
#else
#define __MYSQL_DECLARE_PLUGIN(NAME, VERSION, PSIZE, DECLS) \
MYSQL_PLUGIN_EXPORT int _mysql_plugin_interface_version= MYSQL_PLUGIN_INTERFACE_VERSION; \
MYSQL_PLUGIN_EXPORT int _mysql_sizeof_struct_st_plugin= sizeof(struct st_mysql_plugin); \
MYSQL_PLUGIN_EXPORT struct st_mysql_plugin _mysql_plugin_declarations[]= {
#endif

#define mysql_declare_plugin(NAME) \
__MYSQL_DECLARE_PLUGIN(NAME, \
    builtin_ ## NAME ## _plugin_interface_version, \
    builtin_ ## NAME ## _sizeof_struct_st_plugin, \
    builtin_ ## NAME ## _plugin)

#define mysql_declare_plugin_end ,{0,0,0,0,0,0,0,0,0,0,0,0}

```

#### Note

Those declarations define the `_mysql_plugin_interface_version` symbol only if the `MYSQL_DYNAMIC_PLUGIN` symbol is defined. This means that `-DMYSQL_DYNAMIC_PLUGIN` must be provided as part of the compilation command to build the plugin as a shared library.

When the macros are used as just shown, they expand to the following code, which defines both of the required symbols (`_mysql_plugin_interface_version` and `_mysql_plugin_declarations`):

```

int _mysql_plugin_interface_version= MYSQL_PLUGIN_INTERFACE_VERSION;
int _mysql_sizeof_struct_st_plugin= sizeof(struct st_mysql_plugin);
struct st_mysql_plugin _mysql_plugin_declarations[]= {
{
    MYSQL_FTPARSER_PLUGIN, /* type */
    &simple_parser_descriptor, /* descriptor */
    "simple_parser", /* name */
    "Oracle Corporation", /* author */
    "Simple Full-Text Parser", /* description */
    PLUGIN_LICENSE_GPL, /* plugin license */
    simple_parser_plugin_init, /* init function (when loaded) */
    simple_parser_plugin_deinit, /* deinit function (when unloaded) */
    0x0001, /* version */
    simple_status, /* status variables */
    simple_system_variables, /* system variables */
    NULL,
    0
}
, {0,0,0,0,0,0,0,0,0,0,0,0}
};

```

The preceding example declares a single plugin in the general descriptor, but it is possible to declare multiple plugins. List the declarations one after the other between `mysql_declare_plugin()` and `mysql_declare_plugin_end`, separated by commas.

MySQL server plugins can be written in C or C++ (or another language that can use C calling conventions). If you write a C++ plugin, one C++ feature that you should not use is nonconstant variables to initialize global structures. Members of structures such as the `st_mysql_plugin` structure should be initialized only with constant variables. The `simple_parser` descriptor shown earlier is permissible in a C++ plugin because it satisfies that requirement:

```
mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN,      /* type */
    &simple_parser_descriptor,   /* descriptor */
    "simple_parser",             /* name */
    "Oracle Corporation",       /* author */
    "Simple Full-Text Parser",  /* description */
    PLUGIN_LICENSE_GPL,        /* plugin license */
    simple_parser_plugin_init,  /* init function (when loaded) */
    simple_parser_plugin_deinit, /* deinit function (when unloaded) */
    0x0001,                     /* version */
    simple_status,              /* status variables */
    simple_system_variables,    /* system variables */
    NULL,
    0
}
mysql_declare_plugin_end;
```

Here is another valid way to write the general descriptor. It uses constant variables to indicate the plugin name, author, and description:

```
const char *simple_parser_name = "simple_parser";
const char *simple_parser_author = "Oracle Corporation";
const char *simple_parser_description = "Simple Full-Text Parser";

mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN,      /* type */
    &simple_parser_descriptor,   /* descriptor */
    simple_parser_name,         /* name */
    simple_parser_author,       /* author */
    simple_parser_description,  /* description */
    PLUGIN_LICENSE_GPL,        /* plugin license */
    simple_parser_plugin_init,  /* init function (when loaded) */
    simple_parser_plugin_deinit, /* deinit function (when unloaded) */
    0x0001,                     /* version */
    simple_status,              /* status variables */
    simple_system_variables,    /* system variables */
    NULL,
    0
}
mysql_declare_plugin_end;
```

However, the following general descriptor is invalid. It uses structure members to indicate the plugin name, author, and description, but structures are not considered constant initializers in C++:

```
typedef struct
{
    const char *name;
    const char *author;
    const char *description;
} plugin_info;

plugin_info parser_info = {
    "simple_parser",
    "Oracle Corporation",
    "Simple Full-Text Parser"
};

mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN,      /* type */
    &simple_parser_descriptor,   /* descriptor */
    parser_info.name,           /* name */
    parser_info.author,         /* author */

```

```

parser_info.description, /* description */
PLUGIN_LICENSE_GPL, /* plugin license */
simple_parser_plugin_init, /* init function (when loaded) */
simple_parser_plugin_deinit, /* deinit function (when unloaded) */
0x0001, /* version */
simple_status, /* status variables */
simple_system_variables, /* system variables */
NULL,
0
}
mysql_declare_plugin_end;

```

### 22.2.4.2.2. Server Plugin Status and System Variables

The server plugin interface enables plugins to expose status and system variables using the `status_vars` and `system_vars` members of the general plugin descriptor.

The `status_vars` member of the general plugin descriptor, if not 0, points to an array of `st_mysql_show_var` structures, each of which describes one status variable, followed by a structure with all members set to 0. The `st_mysql_show_var` structure has this definition:

```

struct st_mysql_show_var {
    const char *name;
    char *value;
    enum enum_mysql_show_type type;
};

```

When the plugin is installed, the plugin name and the `name` value are joined with an underscore to form the name displayed by `SHOW STATUS`.

The following table shows the permissible status variable `type` values and what the corresponding variable should be.

**Table 22.1. Server Plugin Status Variable Types**

Variable Type	Meaning
<code>SHOW_BOOL</code>	Pointer to a boolean variable
<code>SHOW_INT</code>	Pointer to an integer variable
<code>SHOW_LONG</code>	Pointer to a long integer variable
<code>SHOW_LONGLONG</code>	Pointer to a longlong integer variable
<code>SHOW_CHAR</code>	A string
<code>SHOW_CHAR_PTR</code>	Pointer to a string
<code>SHOW_ARRAY</code>	Pointer to another <code>st_mysql_show_var</code> array
<code>SHOW_FUNC</code>	Pointer to a function
<code>SHOW_DOUBLE</code>	Pointer to a double

For the `SHOW_FUNC` type, the function is called and fills in its `out` parameter, which then provides information about the variable to be displayed. The function has this signature:

```

#define SHOW_VAR_FUNC_BUFF_SIZE 1024

typedef int (*mysql_show_var_func) (void *thd,
                                   struct st_mysql_show_var *out,
                                   char *buf);

```

The `system_vars` member, if not 0, points to an array of `st_mysql_sys_var` structures, each of which describes one system variable (which can also be set from the command-line or configuration file), followed by a structure with all members set to 0. The `st_mysql_sys_var` structure is defined as follows:

```

struct st_mysql_sys_var {
    int flags;
    const char *name, *comment;
};

```

```
int (*check)(THD*, struct st_mysql_sys_var *, void*, st_mysql_value*);
void (*update)(THD*, struct st_mysql_sys_var *, void*, const void*);
};
```

Additional fields are append as required depending upon the flags.

For convenience, a number of macros are defined that make creating new system variables within a plugin much simpler.

Throughout the macros, the following fields are available:

- **name**: An unquoted identifier for the system variable.
- **varname**: The identifier for the static variable. Where not available, it is the same as the **name** field.
- **opt**: Additional use flags for the system variable. The following table shows the permissible flags.

**Table 22.2. Server Plugin System Variable Flags**

Flag Value	Description
<code>PLUGIN_VAR_READONLY</code>	The system variable is read only
<code>PLUGIN_VAR_NOSYSVAR</code>	The system variable is not user visible at runtime
<code>PLUGIN_VAR_NOCMDOPT</code>	The system variable is not configurable from the command line
<code>PLUGIN_VAR_NOCMDARG</code>	No argument is required at the command line (typically used for boolean variables)
<code>PLUGIN_VAR_RQCMDARG</code>	An argument is required at the command line (this is the default)
<code>PLUGIN_VAR_OPCMDARG</code>	An argument is optional at the command line
<code>PLUGIN_VAR_MEMALLOC</code>	Used for string variables; indicates that memory is to be allocated for storage of the string

- **comment**: A descriptive comment to be displayed in the server help message. `NULL` if this variable is to be hidden.
- **check**: The check function, `NULL` for default.
- **update**: The update function, `NULL` for default.
- **default**: The variable default value.
- **minimum**: The variable minimum value.
- **maximum**: The variable maximum value.
- **blocksize**: The variable block size. When the value is set, it is rounded to the nearest multiple of **blocksize**.

A system variable may be accessed either by using the static variable directly or by using the `SYSVAR()` accessor macro. The `SYSVAR()` macro is provided for completeness. Usually it should be used only when the code cannot directly access the underlying variable.

For example:

```
static int my_foo;
static MYSQL_SYSVAR_INT(foo_var, my_foo,
                        PLUGIN_VAR_RQCMDARG, "foo comment",
                        NULL, NULL, 0, 0, INT_MAX, 0);
...
SYSVAR(foo_var)= value;
value= SYSVAR(foo_var);
my_foo= value;
value= my_foo;
```

Session variables may be accessed only through the `THDVAR()` accessor macro. For example:

```
static MYSQL_THDVAR_BOOL(some_flag,
                        PLUGIN_VAR_NOCMDARG, "flag comment",
                        NULL, NULL, FALSE);
...
if (THDVAR(thd, some_flag))
{
    do_something();
    THDVAR(thd, some_flag)= FALSE;
}
```

All global and session system variables must be published to `mysqld` before use. This is done by constructing a `NULL`-terminated array of the variables and linking to it in the plugin public interface. For example:

```
static struct st_mysql_sys_var *my_plugin_vars[] = {
    MYSQL_SYSVAR(foo_var),
    MYSQL_SYSVAR(some_flag),
    NULL
};
mysql_declare_plugin(fooplug)
{
    MYSQL_..._PLUGIN,
    &plugin_data,
    "fooplug",
    "foo author",
    "This does foo!",
    PLUGIN_LICENSE_GPL,
    foo_init,
    foo_fini,
    0x0001,
    NULL,
    my_plugin_vars,
    NULL,
    0
}
mysql_declare_plugin_end;
```

The following convenience macros enable you to declare different types of system variables:

- Boolean system variables of type `my_bool`, which is a 1-byte boolean. (0 = FALSE, 1 = TRUE)

```
MYSQL_THDVAR_BOOL(name, opt, comment, check, update, default)
MYSQL_SYSVAR_BOOL(name, varname, opt, comment, check, update, default)
```

- String system variables of type `char*`, which is a pointer to a null-terminated string.

```
MYSQL_THDVAR_STR(name, opt, comment, check, update, default)
MYSQL_SYSVAR_STR(name, varname, opt, comment, check, update, default)
```

- Integer system variables, of which there are several varieties.

- An `int` system variable, which is typically a 4-byte signed word.

```
MYSQL_THDVAR_INT(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_INT(name, varname, opt, comment, check, update, default,
                 minimum, maximum, blocksize)
```

- An `unsigned int` system variable, which is typically a 4-byte unsigned word.

```
MYSQL_THDVAR_UINT(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_UINT(name, varname, opt, comment, check, update, default,
                  minimum, maximum, blocksize)
```

- A `long` system variable, which is typically either a 4- or 8-byte signed word.

```
MYSQL_THDVAR_LONG(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_LONG(name, varname, opt, comment, check, update, default,
                  minimum, maximum, blocksize)
```

- An `unsigned long` system variable, which is typically either a 4- or 8-byte unsigned word.

```
MYSQL_THDVAR_ULONG(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_ULONG(name, varname, opt, comment, check, update, default,
                    minimum, maximum, blocksize)
```

- A `long long` system variable, which is typically an 8-byte signed word.

```
MYSQL_THDVAR_LONGLONG(name, opt, comment, check, update,
                      default, minimum, maximum, blocksize)
MYSQL_SYSVAR_LONGLONG(name, varname, opt, comment, check, update,
                      default, minimum, maximum, blocksize)
```

- An `unsigned long long` system variable, which is typically an 8-byte unsigned word.

```
MYSQL_THDVAR_ULONGLONG(name, opt, comment, check, update,
                       default, minimum, maximum, blocksize)
MYSQL_SYSVAR_ULONGLONG(name, varname, opt, comment, check, update,
                       default, minimum, maximum, blocksize)
```

- An `unsigned long` system variable, which is typically either a 4- or 8-byte unsigned word. The range of possible values is an ordinal of the number of elements in the `typelib`, starting from 0.

```
MYSQL_THDVAR_ENUM(name, opt, comment, check, update, default, typelib)
MYSQL_SYSVAR_ENUM(name, varname, opt, comment, check, update,
                  default, typelib)
```

- An `unsigned long long` system variable, which is typically an 8-byte unsigned word. Each bit represents an element in the `typelib`.

```
MYSQL_THDVAR_SET(name, opt, comment, check, update, default, typelib)
MYSQL_SYSVAR_SET(name, varname, opt, comment, check, update,
                 default, typelib)
```

Internally, all mutable and plugin system variables are stored in a `HASH` structure.

Display of the server command-line help text is handled by compiling a `DYNAMIC_ARRAY` of all variables relevant to command-line options, sorting them, and then iterating through them to display each option.

When a command-line option has been handled, it is then removed from the `argv` by the `handle_option()` function (`my_getopt.c`); in effect, it is consumed.

The server processes command-line options during the plugin installation process, immediately after the plugin has been successfully loaded but before the plugin initialization function has been called

Plugins loaded at runtime do not benefit from any configuration options and must have usable defaults. Once they are installed, they are loaded at `mysqld` initialization time and configuration options can be set at the command line or within `my.cnf`.

Plugins should consider the `thd` parameter to be read only.

### 22.2.4.2.3. Client Plugin Descriptors

Each client plugin must have a descriptor that provides information to the client plugin API. The descriptor structure begins with a fixed set of members common to all client plugins, followed by any members specific to the plugin type.

The `st_mysql_client_plugin` structure in the `client_plugin.h` file defines a “generic” descriptor that contains the common members:

```
struct st_mysql_client_plugin
{
    int type;
    unsigned int interface_version;
    const char *name;
    const char *author;
    const char *desc;
```

```

unsigned int version[3];
const char *license;
void *mysql_api;
int (*init)(char *, size_t, int, va_list);
int (*deinit)();
int (*options)(const char *option, const void *);
};

```

The common `st_mysql_client_plugin` descriptor structure members are used as follows. `char *` members should be specified as null-terminated strings.

- `type`: The plugin type. This must be one of the plugin-type values from `client_plugin.h`, such as `MYSQL_CLIENT_AUTHENTICATION_PLUGIN`.
- `interface_version`: The plugin interface version. For example, this is `MYSQL_CLIENT_AUTHENTICATION_PLUGIN_INTERFACE_VERSION` for an authentication plugin.
- `name`: A string that gives the plugin name. This is the name by which you refer to the plugin when you call `mysql_options()` with the `MYSQL_DEFAULT_AUTH` option or specify the `--default-auth` option to a MySQL client program.
- `author`: A string naming the plugin author. This can be whatever you like.
- `desc`: A string that provides a general description of the plugin. This can be whatever you like.
- `version`: The plugin version as an array of three integers indicating the major, minor, and teeny versions. For example, `{1, 2, 3}` indicates version 1.2.3.
- `license`: A string that specifies the license type.
- `mysql_api`: For internal use. Specify it as `NULL` in the plugin descriptor.
- `init`: A once-only initialization function, or `NULL` if there is no such function. The client library executes this function when it loads the plugin. The function returns zero for success and nonzero for failure.

The `init` function uses its first two arguments to return an error message if an error occurs. The first argument is a pointer to a `char` buffer, and the second argument indicates the buffer length. Any message returned by the `init` function must be null-terminated, so the maximum message length is the buffer length minus one. The next arguments are passed to `mysql_load_plugin()`. The first indicates how many more arguments there are (0 if none), followed by any remaining arguments.

- `deinit`: A once-only deinitialization function, or `NULL` if there is no such function. The client library executes this function when it unloads the plugin. The function takes no arguments. It returns zero for success and nonzero for failure.
- `options`: A function for handling options passed to the plugin, or `NULL` if there is no such function. The function takes two arguments representing the option name and a pointer to its value.

For a given client plugin type, the common descriptor members may be followed by additional members necessary to implement plugins of that type. For example, the `st_mysql_client_plugin_AUTHENTICATION` structure for authentication plugins has a function at the end that the client library calls to perform authentication.

To declare a plugin, use the `mysql_declare_client_plugin()` and `mysql_end_client_plugin` macros:

```

mysql_declare_client_plugin(plugin_type)
... members common to all client plugins ...
... type-specific extra members ...
mysql_end_client_plugin;

```

Do not specify the `type` or `interface_version` member explicitly. The `mysql_declare_client_plugin()` macro uses the `plugin_type` argument to generate their values automatically. For example, declare an authentication client plugin like this:

```
mysql_declare_client_plugin(AUTHENTICATION)
    "my_auth_plugin",
    "Author Name",
    "My Client Authentication Plugin",
    {1,0,0},
    "GPL",
    NULL,
    my_auth_init,
    my_auth_deinit,
    my_auth_options,
    my_auth_main
mysql_end_client_plugin;
```

This declaration uses the `AUTHENTICATION` argument to set the `type` and `interface_version` members to `MYSQL_CLIENT_AUTHENTICATION_PLUGIN` and `MYSQL_CLIENT_AUTHENTICATION_PLUGIN_INTERFACE_VERSION`.

Depending on the plugin type, the descriptor may have other members following the common members. For example, for an authentication plugin, there is a function (`my_auth_main()` in the descriptor just shown) that handles communication with the server. See [Section 22.2.4.9, “Writing Authentication Plugins”](#).

Normally, a client program that supports the use of authentication plugins causes a plugin to be loaded by calling `mysql_options()` to set the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options:

```
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";

/* ... process command-line options ... */

mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept `--plugin-dir` and `--default-auth` options that enable users to override the default values.

Should a client program require lower-level plugin management, the client library contains functions that take an `st_mysql_client_plugin` argument. See [Section 21.8.13, “C API Client Plugin Functions”](#).

### 22.2.4.3. Compiling and Installing Plugin Libraries

After your plugin is written, you must compile it and install it. The procedure for compiling shared objects varies from system to system. If you build your library using `CMake`, it should be able to generate the correct compilation commands for your system. If the library is named `somepluglib`, you should end up with a shared object file that has a name something like `somepluglib.so`. (The file name might have a different suffix on your system.)

To use `CMake`, you'll need to set up the configuration files to enable the plugin to be compiled and installed. Use the plugin examples under the `plugin` directory of a MySQL source distribution as a guide.

Create `CMakeLists.txt`, which should look something like this:

```
MYSQL_ADD_PLUGIN(somepluglib somepluglib.c
    MODULE_ONLY MODULE_OUTPUT_NAME "somepluglib")
```

When `CMake` generates the `Makefile`, it should take care of passing to the compilation command the `-DMYSQL_DYNAMIC_PLUGIN` flag, and passing to the linker the `-lmysqservices` flag, which is needed to link in any functions from services provided through the plugin services interface. See [Section 22.2.5, “MySQL Services for Plugins”](#).

Run `CMake`, then run `make`:

```
shell> cmake .
```

```
shell> make
```

If you need to specify configuration options to CMake, see [Section 2.9.4, “MySQL Source-Configuration Options”](#), for a list. For example, you might want to specify `CMAKE_INSTALL_PREFIX [132]` to indicate the MySQL base directory under which the plugin should be installed. You can see what value to use for this option with `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'basedir';
+-----+-----+
| Variable_name | Value                |
+-----+-----+
| base          | /usr/local/mysql    |
+-----+-----+
```

The location of the plugin directory where you should install the library is given by the `plugin_dir [525]` system variable. For example:

```
mysql> SHOW VARIABLES LIKE 'plugin_dir';
+-----+-----+
| Variable_name | Value                |
+-----+-----+
| plugin_dir    | /usr/local/mysql/lib/mysql/plugin |
+-----+-----+
```

To install the plugin library, use `make`:

```
shell> make install
```

Verify that `make install` installed the plugin library in the proper directory. After installing it, make sure that the library permissions permit it to be executed by the server.

#### 22.2.4.4. Writing Full-Text Parser Plugins

A full-text parser server plugin can be used to replace or modify the built-in full-text parser. This section describes how to write a full-text parser plugin named `simple_parser`. This plugin performs parsing based on simpler rules than those used by the MySQL built-in full-text parser: Words are nonempty runs of whitespace characters.

The instructions use the source code in the `plugin/fulltext` directory of MySQL source distributions, so change location into that directory. The following procedure describes how the plugin library is created:

1. To write a full-text parser plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed.

```
#include <mysql/plugin.h>
```

`plugin.h` defines the `MYSQL_FTPARSER_PLUGIN` server plugin type and the data structures needed to declare the plugin.

2. Set up the library descriptor for the plugin library file.

This descriptor contains the general plugin descriptor for the server plugin. For a full-text parser plugin, the type must be `MYSQL_FTPARSER_PLUGIN`. This is the value that identifies the plugin as being legal for use in a `WITH PARSER` clause when creating a `FULLTEXT` index. (No other plugin type is legal for this clause.)

For example, the library descriptor for a library that contains a single full-text parser plugin named `simple_parser` looks like this:

```
mysql_declare_plugin(ftexample)
{
  MYSQL_FTPARSER_PLUGIN,      /* type                */
  &simple_parser_descriptor,   /* descriptor          */
  "simple_parser",             /* name                */
  "Oracle Corporation",      /* author              */
}
```

```

"Simple Full-Text Parser", /* description */
PLUGIN_LICENSE_GPL, /* plugin license */
simple_parser_plugin_init, /* init function (when loaded) */
simple_parser_plugin_deinit, /* deinit function (when unloaded) */
0x0001, /* version */
simple_status, /* status variables */
simple_system_variables, /* system variables */
NULL,
0
}
mysql_declare_plugin_end;

```

The `name` member (`simple_parser`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

For more information, see [Section 22.2.4.2.1, “Server Plugin Library and Plugin Descriptors”](#).

### 3. Set up the type-specific plugin descriptor.

Each general plugin descriptor in the library descriptor points to a type-specific descriptor. For a full-text parser plugin, the type-specific descriptor is an instance of the `st_mysql_ftparser` structure in the `plugin.h` file:

```

struct st_mysql_ftparser
{
    int interface_version;
    int (*parse)(MYSQL_FTPARSER_PARAM *param);
    int (*init)(MYSQL_FTPARSER_PARAM *param);
    int (*deinit)(MYSQL_FTPARSER_PARAM *param);
};

```

As shown by the structure definition, the descriptor has an interface version number and contains pointers to three functions. The version is specified using a symbol of the form `MYSQL_xxx_INTERFACE_VERSION` (such as `MYSQL_FTPARSER_INTERFACE_VERSION` for full-text parser plugins). The `init` and `deinit` members should point to a function or be set to 0 if the function is not needed. The `parse` member must point to the function that performs the parsing.

In the `simple_parser` declaration, that descriptor is indicated by `&simple_parser_descriptor`. The descriptor specifies the version number for the full-text plugin interface (as given by `MYSQL_FTPARSER_INTERFACE_VERSION`), and the plugin's parsing, initialization, and deinitialization functions:

```

static struct st_mysql_ftparser simple_parser_descriptor=
{
    MYSQL_FTPARSER_INTERFACE_VERSION, /* interface version */
    simple_parser_parse, /* parsing function */
    simple_parser_init, /* parser init function */
    simple_parser_deinit /* parser deinit function */
};

```

A full-text parser plugin is used in two different contexts, indexing and searching. In both contexts, the server calls the initialization and deinitialization functions at the beginning and end of processing each SQL statement that causes the plugin to be invoked. However, during statement processing, the server calls the main parsing function in context-specific fashion:

- For indexing, the server calls the parser for each column value to be indexed.
- For searching, the server calls the parser to parse the search string. The parser might also be called for rows processed by the statement. In natural language mode, there is no need for the server to call the parser. For boolean mode phrase searches or natural language searches with query expansion, the parser is used to parse column values for information that is not in the index. Also, if a boolean mode search is done for a column that has no `FULLTEXT` index, the built-in parser will be called. (Plugins are associated with specific indexes. If there is no index, no plugin is used.)

The plugin declaration in the general plugin descriptor has `init` and `deinit` members that point initialization and deinitialization functions, and so does the type-specific plugin descriptor to which it points. However, these pairs of functions have different purposes and are invoked for different reasons:

- For the plugin declaration in the general plugin descriptor, the initialization and deinitialization functions are invoked when the plugin is loaded and unloaded.
- For the type-specific plugin descriptor, the initialization and deinitialization functions are invoked per SQL statement for which the plugin is used.

Each interface function named in the plugin descriptor should return zero for success or nonzero for failure, and each of them receives an argument that points to a `MYSQL_FTPARSER_PARAM` structure containing the parsing context. The structure has this definition:

```
typedef struct st_mysql_ftparser_param
{
    int (*mysql_parse)(struct st_mysql_ftparser_param *,
                      char *doc, int doc_len);
    int (*mysql_add_word)(struct st_mysql_ftparser_param *,
                          char *word, int word_len,
                          MYSQL_FTPARSER_BOOLEAN_INFO *boolean_info);
    void *ftparser_state;
    void *mysql_ftparam;
    struct charset_info_st *cs;
    char *doc;
    int length;
    int flags;
    enum enum_ftparser_mode mode;
} MYSQL_FTPARSER_PARAM;
```

The structure members are used as follows:

- `mysql_parse`: A pointer to a callback function that invokes the server's built-in parser. Use this callback when the plugin acts as a front end to the built-in parser. That is, when the plugin parsing function is called, it should process the input to extract the text and pass the text to the `mysql_parse` callback.

The first parameter for this callback function should be the `param` value itself:

```
param->mysql_parse(param, ...);
```

A front end plugin can extract text and pass it all at once to the built-in parser, or it can extract and pass text to the built-in parser a piece at a time. However, in this case, the built-in parser treats the pieces of text as though there are implicit word breaks between them.

- `mysql_add_word`: A pointer to a callback function that adds a word to a full-text index or to the list of search terms. Use this callback when the parser plugin replaces the built-in parser. That is, when the plugin parsing function is called, it should parse the input into words and invoke the `mysql_add_word` callback for each word.

The first parameter for this callback function should be the `param` value itself:

```
param->mysql_add_word(param, ...);
```

- `ftparser_state`: This is a generic pointer. The plugin can set it to point to information to be used internally for its own purposes.
- `mysql_ftparam`: This is set by the server. It is passed as the first argument to the `mysql_parse` or `mysql_add_word` callback.
- `cs`: A pointer to information about the character set of the text, or 0 if no information is available.

- `doc`: A pointer to the text to be parsed.
- `length`: The length of the text to be parsed, in bytes.
- `flags`: Parser flags. This is zero if there are no special flags. Currently, the only nonzero flag is `MYSQL_FTFLAGS_NEED_COPY`, which means that `mysql_add_word()` must save a copy of the word (that is, it cannot use a pointer to the word because the word is in a buffer that will be overwritten.) This member was added in MySQL 5.1.12.

This flag might be set or reset by MySQL before calling the parser plugin, by the parser plugin itself, or by the `mysql_parse()` function.

- `mode`: The parsing mode. This value will be one of the following constants:
  - `MYSQL_FTPARSER_SIMPLE_MODE`: Parse in fast and simple mode, which is used for indexing and for natural language queries. The parser should pass to the server only those words that should be indexed. If the parser uses length limits or a stopword list to determine which words to ignore, it should not pass such words to the server.
  - `MYSQL_FTPARSER_WITH_STOPWORDS`: Parse in stopword mode. This is used in boolean searches for phrase matching. The parser should pass all words to the server, even stopwords or words that are outside any normal length limits.
  - `MYSQL_FTPARSER_FULL_BOOLEAN_INFO`: Parse in boolean mode. This is used for parsing boolean query strings. The parser should recognize not only words but also boolean-mode operators and pass them to the server as tokens using the `mysql_add_word` callback. To tell the server what kind of token is being passed, the plugin needs to fill in a `MYSQL_FTPARSER_BOOLEAN_INFO` structure and pass a pointer to it.

If the parser is called in boolean mode, the `param->mode` value will be `MYSQL_FTPARSER_FULL_BOOLEAN_INFO`. The `MYSQL_FTPARSER_BOOLEAN_INFO` structure that the parser uses for passing token information to the server looks like this:

```
typedef struct st_mysql_ftparser_boolean_info
{
    enum enum_ft_token_type type;
    int yesno;
    int weight_adjust;
    bool wasign;
    bool trunc;
    /* These are parser state and must be removed. */
    byte prev;
    byte *quot;
} MYSQL_FTPARSER_BOOLEAN_INFO;
```

The parser should fill in the structure members as follows:

- `type`: The token type. The following table shows the permissible types.

**Table 22.3. Full-Text Parser Token Types**

Token Value	Meaning
<code>FT_TOKEN_EOF</code>	End of data
<code>FT_TOKEN_WORD</code>	A regular word
<code>FT_TOKEN_LEFT_PAREN</code>	The beginning of a group or subexpression
<code>FT_TOKEN_RIGHT_PAREN</code>	The end of a group or subexpression
<code>FT_TOKEN_STOPWORD</code>	A stopword

- `yesno`: Whether the word must be present for a match to occur. 0 means that the word is optional but increases the match relevance if it is present. Values larger than 0 mean that the word must be present. Values smaller than 0 mean that the word must not be present.
- `weight_adjust`: A weighting factor that determines how much a match for the word counts. It can be used to increase or decrease the word's importance in relevance calculations. A value of zero indicates no weight adjustment. Values greater than or less than zero mean higher or lower weight, respectively. The examples at [Section 12.9.2, "Boolean Full-Text Searches"](#), that use the `<` and `>` operators illustrate how weighting works.
- `wasign`: The sign of the weighting factor. A negative value acts like the `~` boolean-search operator, which causes the word's contribution to the relevance to be negative.
- `trunc`: Whether matching should be done as if the boolean-mode `*` truncation operator had been given.

Plugins should not use the `prev` and `quot` members of the `MYSQL_FTPARSER_BOOLEAN_INFO` structure.

#### 4. Set up the plugin interface functions.

The general plugin descriptor in the library descriptor names the initialization and deinitialization functions that the server should invoke when it loads and unloads the plugin. For `simple_parser`, these functions do nothing but return zero to indicate that they succeeded:

```
static int simple_parser_plugin_init(void *arg __attribute__((unused)))
{
    return(0);
}

static int simple_parser_plugin_deinit(void *arg __attribute__((unused)))
{
    return(0);
}
```

Because those functions do not actually do anything, you could omit them and specify 0 for each of them in the plugin declaration.

The type-specific plugin descriptor for `simple_parser` names the initialization, deinitialization, and parsing functions that the server invokes when the plugin is used. For `simple_parser`, the initialization and deinitialization functions do nothing:

```
static int simple_parser_init(MYSQL_FTPARSER_PARAM *param
                             __attribute__((unused)))
{
    return(0);
}

static int simple_parser_deinit(MYSQL_FTPARSER_PARAM *param
                                __attribute__((unused)))
{
    return(0);
}
```

Here too, because those functions do nothing, you could omit them and specify 0 for each of them in the plugin descriptor.

The main parsing function, `simple_parser_parse()`, acts as a replacement for the built-in full-text parser, so it needs to split text into words and pass each word to the server. The parsing function's first argument is a pointer to a structure that contains the parsing context. This structure has a `doc` member that points to the text to be parsed, and a `length` member that indicates how long the text is. The simple parsing done by the plugin considers nonempty runs of whitespace characters to be words, so it identifies words like this:

```
static int simple_parser_parse(MYSQL_FTPARSER_PARAM *param)
{
    char *end, *start, *docend= param->doc + param->length;

    for (end= start= param->doc;; end++)
    {
        if (end == docend)
        {
            if (end > start)
                add_word(param, start, end - start);
            break;
        }
        else if (isspace(*end))
        {
            if (end > start)
                add_word(param, start, end - start);
            start= end + 1;
        }
    }
    return(0);
}
```

As the parser finds each word, it invokes a function `add_word()` to pass the word to the server. `add_word()` is a helper function only; it is not part of the plugin interface. The parser passes the parsing context pointer to `add_word()`, as well as a pointer to the word and a length value:

```
static void add_word(MYSQL_FTPARSER_PARAM *param, char *word, size_t len)
{
    MYSQL_FTPARSER_BOOLEAN_INFO bool_info=
        { FT_TOKEN_WORD, 0, 0, 0, 0, ' ', 0 };

    param->mysql_add_word(param, word, len, &bool_info);
}
```

For boolean-mode parsing, `add_word()` fills in the members of the `bool_info` structure as described earlier in the discussion of the `st_mysql_ftparser_boolean_info` structure.

5. Set up the status variables. For the `simple_parser` plugin, the following status variable array sets up one status variable with a value that is static text, and another with a value that is stored in a long integer variable:

```
long number_of_calls= 0;

struct st_mysql_show_var simple_status[]=
{
    {"static", (char *)"just a static text", SHOW_CHAR},
    {"called", (char *)&number_of_calls, SHOW_LONG},
    {0,0,0}
};
```

When the plugin is installed, the plugin name and the `name` value are joined with an underscore to form the name displayed by `SHOW STATUS`. For the array just shown, the resulting status variable names are `simple_parser_static` and `simple_parser_called`. This convention means that you can easily display the variables for a plugin using its name:

```
mysql> SHOW STATUS LIKE 'simple_parser%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| simple_parser_static | just a static text |
| simple_parser_called | 0 |
+-----+-----+
```

6. To compile and install a plugin library object file, use the instructions in [Section 22.2.4.3, "Compiling and Installing Plugin Libraries"](#). To use the library file, it must be installed in the plugin directory (the directory named by the `plugin_dir` [525] system variable). For the `simple_parser` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary

distributions. The build process produces a shared object library with a name of `mypluglib.so` (the suffix might differ depending on your platform).

- To use the plugin, register it with the server. For example, to register the plugin at runtime, use this statement (changing the suffix as necessary):

```
mysql> INSTALL PLUGIN simple_parser SONAME 'mypluglib.so';
```

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

- To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement.
- Test the plugin to verify that it works properly.

Create a table that contains a string column and associate the parser plugin with a `FULLTEXT` index on the column:

```
mysql> CREATE TABLE t (c VARCHAR(255),
-> FULLTEXT (c) WITH PARSER simple_parser
-> ) ENGINE=MyISAM;
Query OK, 0 rows affected (0.01 sec)
```

Insert some text into the table and try some searches. These should verify that the parser plugin treats all nonwhitespace characters as word characters:

```
mysql> INSERT INTO t VALUES
-> ('latin1_general_cs is a case-sensitive collation'),
-> ('I\'d like a case of oranges'),
-> ('this is sensitive information'),
-> ('another row'),
-> ('yet another row');
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT c FROM t;
+-----+
| c |
+-----+
| latin1_general_cs is a case-sensitive collation |
| I'd like a case of oranges |
| this is sensitive information |
| another row |
| yet another row |
+-----+
5 rows in set (0.00 sec)
```

```
mysql> SELECT MATCH(c) AGAINST('case') FROM t;
+-----+
| MATCH(c) AGAINST('case') |
+-----+
| 0 |
| 1.2968142032623 |
| 0 |
| 0 |
| 0 |
+-----+
5 rows in set (0.00 sec)
```

```
mysql> SELECT MATCH(c) AGAINST('sensitive') FROM t;
+-----+
| MATCH(c) AGAINST('sensitive') |
+-----+
| 0 |
| 0 |
| 1.3253291845322 |
| 0 |
| 0 |
+-----+
```

```

+-----+
5 rows in set (0.01 sec)

mysql> SELECT MATCH(c) AGAINST('case-sensitive') FROM t;
+-----+
| MATCH(c) AGAINST('case-sensitive') |
+-----+
|                                     |
|                                     |
|                                     |
|                                     |
|                                     |
+-----+
5 rows in set (0.01 sec)

mysql> SELECT MATCH(c) AGAINST('I\'d') FROM t;
+-----+
| MATCH(c) AGAINST('I\'d') |
+-----+
|                             |
|                             |
|                             |
|                             |
|                             |
+-----+
5 rows in set (0.01 sec)

```

Note how neither “case” nor “insensitive” match “case-insensitive” the way that they would for the built-in parser.

### 22.2.4.5. Writing Daemon Plugins

A daemon plugin is a simple type of plugin used for code that should be run by the server but that does not communicate with it. This section describes how to write a daemon server plugin, using the example plugin found in the `plugin/daemon_example` directory of MySQL source distributions. That directory contains the `daemon_example.cc` source file for a daemon plugin named `daemon_example` that writes a heartbeat string at regular intervals to a file named `mysql-heartbeat.log` in the data directory.

To write a daemon plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed.

```
#include <mysql/plugin.h>
```

`plugin.h` defines the `MYSQL_DAEMON_PLUGIN` server plugin type and the data structures needed to declare the plugin.

The `daemon_example.cc` file sets up the library descriptor as follows. The library descriptor includes a single general server plugin descriptor.

```

mysql_declare_plugin(daemon_example)
{
    MYSQL_DAEMON_PLUGIN,
    &daemon_example_plugin,
    "daemon_example",
    "Brian Aker",
    "Daemon example, creates a heartbeat beat file in mysql-heartbeat.log",
    PLUGIN_LICENSE_GPL,
    daemon_example_plugin_init, /* Plugin Init */
    daemon_example_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    NULL, /* status variables */
    NULL, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;

```

The `name` member (`daemon_example`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The second member of the plugin descriptor, `daemon_example_plugin`, points to the type-specific daemon plugin descriptor. This structure consists only of the type-specific API version number:

```
struct st_mysql_daemon daemon_example_plugin=
{ MYSQL_DAEMON_INTERFACE_VERSION  };
```

The type-specific structure has no interface functions. There is no communication between the server and the plugin, except that the server calls the initialization and deinitialization functions from the general plugin descriptor to start and stop the plugin:

- `daemon_example_plugin_init()` opens the heartbeat file and spawns a thread that wakes up periodically and writes the next message to the file.
- `daemon_example_plugin_deinit()` closes the file and performs other cleanup.

To compile and install a plugin library object file, use the instructions in [Section 22.2.4.3, “Compiling and Installing Plugin Libraries”](#). To use the library file, it must be installed in the plugin directory (the directory named by the `plugin_dir` [525] system variable). For the `daemon_example` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `libdaemon_example.so` (the suffix might differ depending on your platform).

To use the plugin, register it with the server. For example, to register the plugin at runtime, use this statement (change the suffix as necessary):

```
mysql> INSTALL PLUGIN daemon_example SONAME 'libdaemon_example.so';
```

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement.

While the plugin is loaded, it writes a heartbeat string at regular intervals to a file named `mysql-heartbeat.log` in the data directory. This file grows without limit, so after you have satisfied yourself that the plugin operates correctly, unload it:

```
mysql> UNINSTALL PLUGIN daemon_example;
```

## 22.2.4.6. Writing `INFORMATION_SCHEMA` Plugins

This section describes how to write an `INFORMATION_SCHEMA` table server plugin. For example code that implements such plugins, see the `sql/sql_show.cc` file of a MySQL source distribution. You can also look at the example plugins found in the InnoDB source. See the `handler/i_s.cc` and `handler/ha_innodb.cc` files within the InnoDB source tree (in the `storage/innobase` directory).

To write an `INFORMATION_SCHEMA` table plugin, include the following header files in the plugin source file. Other MySQL or general header files might also be needed.

```
#include <sql_class.h>
#include <table.h>
```

These header files are located in the `sql` directory of MySQL source distributions. They contain C++ structures, so the source file for an `INFORMATION_SCHEMA` plugin must be compiled as C++ (not C) code.

The source file for the example plugin developed here is named `simple_i_s_table.cc`. It creates a simple `INFORMATION_SCHEMA` table named `SIMPLE_I_S_TABLE` that has two columns named `NAME` and `VALUE`. The general descriptor for a plugin library that implements the table looks like this:

```
mysql_declare_plugin(simple_i_s_library)
{
    MYSQL_INFORMATION_SCHEMA_PLUGIN,
    &simple_table_info,           /* type-specific descriptor */
    "SIMPLE_I_S_TABLE",         /* table name */
    "Author Name",             /* author */
    "Simple INFORMATION_SCHEMA table", /* description */
    PLUGIN_LICENSE_GPL,        /* license type */
    simple_table_init,         /* init function */
    NULL,
    0x0100,                    /* version = 1.0 */
    NULL,                      /* no status variables */
    NULL,                      /* no system variables */
    NULL,                      /* no reserved information */
    0                           /* no flags */
}
mysql_declare_plugin_end;
```

The `name` member (`SIMPLE_I_S_TABLE`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The `simple_table_info` member of the general descriptor points to the type-specific descriptor, which consists only of the type-specific API version number:

```
static struct st_mysql_information_schema simple_table_info =
{ MYSQL_INFORMATION_SCHEMA_INTERFACE_VERSION };
```

The general descriptor points to the initialization and deinitialization functions:

- The initialization function provides information about the table structure and a function that populates the table.
- The deinitialization function performs any required cleanup. If no cleanup is needed, this descriptor member can be `NULL` (as in the example shown).

The initialization function should return 0 for success, 1 if an error occurs. The function receives a generic pointer, which it should interpret as a pointer to the table structure:

```
static int table_init(void *ptr)
{
    ST_SCHEMA_TABLE *schema_table= (ST_SCHEMA_TABLE*)ptr;

    schema_table->fields_info= simple_table_fields;
    schema_table->fill_table= simple_fill_table;
    return 0;
}
```

The function should set these two members of the table structure:

- `fields_info`: An array of `ST_FIELD_INFO` structures that contain information about each column.
- `fill_table`: A function that populates the table.

The array pointed to by `fields_info` should contain one element per column of the `INFORMATION_SCHEMA` plus a terminating element. The following `simple_table_fields` array for the example plugin indicates that `SIMPLE_I_S_TABLE` has two columns. `NAME` is string-valued with a length of 10 and `VALUE` is integer-valued with a display width of 20. The last structure marks the end of the array.

```
static ST_FIELD_INFO simple_table_fields[]=
{
    {"NAME", 10, MYSQL_TYPE_STRING, 0, 0 0, 0},
    {"VALUE", 6, MYSQL_TYPE_LONG, 0, MY_I_S_UNSIGNED, 0, 0},
    {0, 0, MYSQL_TYPE_NULL, 0, 0, 0, 0}
};
```

For more information about the column information structure, see the definition of `ST_FIELD_INFO` in the `table.h` header file. The permissible `MYSQL_TYPE_XXX` type values are those used in the C API; see [Section 21.8.4, “C API Data Structures”](#).

The `fill_table` member should be set to a function that populates the table and returns 0 for success, 1 if an error occurs. For the example plugin, the `simple_fill_table()` function looks like this:

```
static int simple_fill_table(THD *thd, TABLE_LIST *tables, Item *cond)
{
    TABLE *table= tables->table;

    table->field[0]->store("Name 1", 6, system_charset_info);
    table->field[1]->store(1);
    if (schema_table_store_record(thd, table))
        return 1;
    table->field[0]->store("Name 2", 6, system_charset_info);
    table->field[1]->store(2);
    if (schema_table_store_record(thd, table))
        return 1;
    return 0;
}
```

For each row of the `INFORMATION_SCHEMA` table, this function initializes each column, then calls `schema_table_store_record()` to install the row. The `store()` method arguments depend on the type of value to be stored. For column 0 (`NAME`, a string), `store()` takes a pointer to a string, its length, and information about the character set of the string:

```
store(const char *to, uint length, CHARSET_INFO *cs);
```

For column 1 (`VALUE`, an integer), `store()` takes the value and a flag indicating whether it is unsigned:

```
store(longlong nr, bool unsigned_value);
```

For other examples of how to populate `INFORMATION_SCHEMA` tables, search for instances of `schema_table_store_record()` in `sql_show.cc`.

To compile and install a plugin library object file, see the instructions in [Section 22.2.4.3, “Compiling and Installing Plugin Libraries”](#). To use the library file, it must be installed in the plugin directory (the directory named by the `plugin_dir` [525] system variable).

To test the plugin, install it:

```
mysql> INSTALL PLUGIN SIMPLE_I_S_TABLE SONAME 'simple_i_s_table.so';
```

Verify that the table is present:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_NAME = 'SIMPLE_I_S_TABLE';
+-----+
| TABLE_NAME |
+-----+
| SIMPLE_I_S_TABLE |
+-----+
```

Try to select from it:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SIMPLE_I_S_TABLE;
+-----+-----+
| NAME | VALUE |
+-----+-----+
| Name 1 | 1 |
| Name 2 | 2 |
+-----+-----+
```

Uninstall it:

```
mysql> UNINSTALL PLUGIN SIMPLE_I_S_TABLE;
```

### 22.2.4.7. Writing Semisynchronous Replication Plugins

This section describes how to write semisynchronous replication server plugins, using the example plugins found in the `plugin/semisync` directory of MySQL source distributions. That directory contains the source files for master and slave plugins named `rpl_semi_sync_master` and `rpl_semi_sync_slave`. The information here covers only how to set up the plugin framework. For details about how the plugins implement replication functions, see the source.

To write a semisynchronous replication plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed.

```
#include <mysql/plugin.h>
```

`plugin.h` defines the `MYSQL_REPLICATION_PLUGIN` server plugin type and the data structures needed to declare the plugin.

For the master side, `semisync_master_plugin.cc` contains this general descriptor for a plugin named `rpl_semi_sync_master`:

```
mysql_declare_plugin(semi_sync_master)
{
    MYSQL_REPLICATION_PLUGIN,
    &semi_sync_master_plugin,
    "rpl_semi_sync_master",
    "He Zhenxing",
    "Semi-synchronous replication master",
    PLUGIN_LICENSE_GPL,
    semi_sync_master_plugin_init, /* Plugin Init */
    semi_sync_master_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    semi_sync_master_status_vars, /* status variables */
    semi_sync_master_system_vars, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;
```

For the slave side, `semisync_slave_plugin.cc` contains this general descriptor for a plugin named `rpl_semi_sync_slave`:

```
mysql_declare_plugin(semi_sync_slave)
{
    MYSQL_REPLICATION_PLUGIN,
    &semi_sync_slave_plugin,
    "rpl_semi_sync_slave",
    "He Zhenxing",
    "Semi-synchronous replication slave",
    PLUGIN_LICENSE_GPL,
    semi_sync_slave_plugin_init, /* Plugin Init */
    semi_sync_slave_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    semi_sync_slave_status_vars, /* status variables */
    semi_sync_slave_system_vars, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;
```

For both the master and slave plugins, the general descriptor has pointers to the type-specific descriptor, the initialization and deinitialization functions, and to the status and system variables implemented by the plugin. For information about variable setup, see [Section 22.2.4.2.2, “Server Plugin Status and System Variables”](#). The following remarks discuss the type-specific descriptor and the initialization and deinitialization functions for the master plugin but apply similarly to the slave plugin.

The `semi_sync_master_plugin` member of the master general descriptor points to the type-specific descriptor, which consists only of the type-specific API version number:

```
struct Mysql_replication semi_sync_master_plugin= {
    MYSQL_REPLICATION_INTERFACE_VERSION
};
```

The initialization and deinitialization function declarations look like this:

```
static int semi_sync_master_plugin_init(void *p);
static int semi_sync_master_plugin_deinit(void *p);
```

The initialization function uses the pointer to register transaction and binary logging “observers” with the server. After successful initialization, the server takes care of invoking the observers at the appropriate times. (For details on the observers, see the source files.) The deinitialization function cleans up by deregistering the observers. Each function returns 0 for success or 1 if an error occurs.

To compile and install a plugin library object file, use the instructions in [Section 22.2.4.3, “Compiling and Installing Plugin Libraries”](#). To use the library files, they must be installed in the plugin directory (the directory named by the `plugin_dir` [525] system variable). For the `rpl_semi_sync_master` and `rpl_semi_sync_slave` plugins, they are compiled and installed when you build MySQL from source. They are also included in binary distributions. The build process produces shared object libraries with names of `semisync_master.so` and `semisync_slave.so` (the suffix might differ depending on your platform).

### 22.2.4.8. Writing Audit Plugins

This section describes how to write an audit server plugin, using the example plugin found in the `plugin/audit_null` directory of MySQL source distributions. The `audit_null.c` source file in that directory implements a simple example audit plugin named `NULL_AUDIT`.

Within the server, the pluggable audit interface is implemented in the `sql_audit.h` and `sql_audit.cc` files in the `sql` directory of MySQL source distributions. Additionally, several places in the server are modified to call the audit interface when an auditable event occurs, so that registered audit plugins can be notified about the event if necessary. To see where such calls occur, look for invocations of functions with names of the form `mysql_audit_xxx()`. Audit notification occurs for server operations such as these:

- Writing a message to the general query log (if the log is enabled)
- Writing a message to the error log
- Sending a query result to a client
- Client connect and disconnect events

To write an audit plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed.

```
#include <mysql/plugin_audit.h>
```

`plugin_audit.h` includes `plugin.h`, so you need not include the latter file explicitly. `plugin.h` defines the `MYSQL_AUDIT_PLUGIN` server plugin type and the data structures needed to declare the plugin. `plugin_audit.h` defines data structures specific to audit plugins.

An audit plugin, like any MySQL server plugin, has a general plugin descriptor (see [Section 22.2.4.2.1, “Server Plugin Library and Plugin Descriptors”](#)). In `audit_null.c`, the general descriptor looks like this:

```
mysql_declare_plugin(audit_null)
{
    MYSQL_AUDIT_PLUGIN,          /* type */
    &audit_null_descriptor,      /* descriptor */
    "NULL_AUDIT",               /* name */
    "Oracle Corp",              /* author */
    "Simple NULL Audit",        /* description */
};
```

```

PLUGIN_LICENSE_GPL,
audit_null_plugin_init,      /* init function (when loaded) */
audit_null_plugin_deinit,   /* deinit function (when unloaded) */
0x0003,                      /* version */
simple_status,               /* status variables */
NULL,                       /* system variables */
NULL,
0,
}
mysql_declare_plugin_end;

```

The `name` member (`NULL_AUDIT`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

The general descriptor also refers to `simple_status`, a structure that exposes several status variables to the `SHOW STATUS` statement:

```

static struct st_mysql_show_var simple_status[]=
{
  { "Audit_null_called",
    (char *) &number_of_calls,
    SHOW_INT },
  { "Audit_null_general_log",
    (char *) &number_of_calls_general_log,
    SHOW_INT },
  { "Audit_null_general_error",
    (char *) &number_of_calls_general_error,
    SHOW_INT },
  { "Audit_null_general_result",
    (char *) &number_of_calls_general_result,
    SHOW_INT },
  { "Audit_null_general_status",
    (char *) &number_of_calls_general_status,
    SHOW_INT },
  { "Audit_null_connection_connect",
    (char *) &number_of_calls_connection_connect,
    SHOW_INT },
  { "Audit_null_connection_disconnect",
    (char *) &number_of_calls_connection_disconnect,
    SHOW_INT },
  { "Audit_null_connection_change_user",
    (char *) &number_of_calls_connection_change_user,
    SHOW_INT },
  { 0, 0, 0 }
};

```

The `audit_null_plugin_init` initialization function sets the status variables to zero when the plugin is loaded. The `audit_null_plugin_deinit` function performs cleanup with the plugin is unloaded. During operation, the plugin increments the first status variable for each notification it receives. It also increments the others according to the event class and subclass. In effect, the first variable is the aggregate of the counts for the event subclasses.

The `audit_null_descriptor` value in the general descriptor points to the type-specific descriptor. For audit plugins, this descriptor has the following structure:

```

struct st_mysql_audit
{
  int interface_version;
  void (*release_thd)(MYSQL_THD);
  void (*event_notify)(MYSQL_THD, unsigned int, const void *);
  unsigned long class_mask[MYSQL_AUDIT_CLASS_MASK_SIZE];
};

```

The type-specific descriptor has these members:

- `interface_version`: By convention, type-specific plugin descriptors begin with the interface version for the given plugin type. The server checks `interface_version` when it loads

the plugin to see whether the plugin is compatible with it. For audit plugins, the value of the `interface_version` member is `MYSQL_AUDIT_INTERFACE_VERSION` (defined in `plugin_audit.h`).

- `release_thd`: A function that the server calls to inform the plugin that it is being dissociated from its thread context. This should be `NULL` if there is no such function.
- `event_notify`: A function that the server calls to notify the plugin that an auditable event has occurred. This function should not be `NULL`; that would not make sense because no auditing would occur.
- `class_mask`: A bit mask that indicates the event classes for which the plugin wants to receive notification. If this value is 0, the server passes no events to the plugin.

The server uses the `event_notify` and `release_thd` functions together. They are called within the context of a specific thread, and a thread might perform an activity that produces several event notifications. The first time the server calls `event_notify` for a thread, it creates a binding of the plugin to the thread. The plugin cannot be uninstalled while this binding exists. When no more events for the thread will occur, the server informs the plugin of this by calling the `release_thd` function, and then destroys the binding. For example, when a client issues a statement, the thread processing the statement might notify audit plugins about the result set produced by the statement and about the statement being logged. After these notifications occur, the server releases the plugin before putting the thread to sleep until the client issues another statement.

This design enables the plugin to allocate resources needed for a given thread in the first call to the `event_notify` function and release them in the `release_thd` function:

```
event_notify function:
  if memory is needed to service the thread
    allocate memory
    ... rest of notification processing ...

release_thd function:
  if memory was allocated
    release memory
    ... rest of release processing ...
```

That is more efficient than allocating and releasing memory repeatedly in the notification function.

For the `NULL_AUDIT` example audit plugin, the type-specific descriptor looks like this:

```
static struct st_mysql_audit audit_null_descriptor=
{
  MYSQL_AUDIT_INTERFACE_VERSION,          /* interface version */
  NULL,                                    /* release_thd function */
  audit_null_notify,                       /* notify function */
  { (unsigned long) MYSQL_AUDIT_GENERAL_CLASSMASK |
    MYSQL_AUDIT_CONNECTION_CLASSMASK } /* class mask */
};
```

The server calls `audit_null_notify` to pass audit event information to the plugin. There is no `release_thd` function.

The event class mask indicates an interest in all events of the “general” and “connection” classes. `plugin_audit.h` defines symbols for these classes and their corresponding class masks:

```
#define MYSQL_AUDIT_GENERAL_CLASS 0
#define MYSQL_AUDIT_GENERAL_CLASSMASK (1 << MYSQL_AUDIT_GENERAL_CLASS)

#define MYSQL_AUDIT_CONNECTION_CLASS 1
#define MYSQL_AUDIT_CONNECTION_CLASSMASK (1 << MYSQL_AUDIT_CONNECTION_CLASS)
```

In the type-specific descriptor, the second and third parameters of the `event_notify` function prototype represent the event class and a generic pointer to an event structure:

```
void (*event_notify)(MYSQL_THD, unsigned int, const void *);
```

Events in different classes may have different structures, so the notification function should use the event class value to determine how to interpret the pointer to the event structure.

If the server calls the notification function with an event class of `MYSQL_AUDIT_GENERAL_CLASS`, it passes the event structure as a pointer to a `mysql_event_general` structure:

```
struct mysql_event_general
{
    unsigned int event_subclass;
    int general_error_code;
    unsigned long general_thread_id;
    const char *general_user;
    unsigned int general_user_length;
    const char *general_command;
    unsigned int general_command_length;
    const char *general_query;
    unsigned int general_query_length;
    struct charset_info_st *general_charset;
    unsigned long long general_time;
    unsigned long long general_rows;
};
```

Audit plugins can interpret `mysql_event_general` members as follows:

- `event_subclass`: The event subclass, one of the following values:

```
#define MYSQL_AUDIT_GENERAL_LOG 0
#define MYSQL_AUDIT_GENERAL_ERROR 1
#define MYSQL_AUDIT_GENERAL_RESULT 2
#define MYSQL_AUDIT_GENERAL_STATUS 3
```

- `general_error_code`: The error code. This is a value like that returned by the `mysql_errno()` C API function; 0 means “no error.”
- `general_thread_id`: The ID of the thread for which the event occurred.
- `general_user`: The current user for the event.
- `general_user_length`: The length of `general_user`, in bytes.
- `general_command`: For general query log events, the type of operation. Examples: `Connect`, `Query`, `Shutdown`. For error log events, the error message. This is a value like that returned by the `mysql_error()` C API function; an empty string means “no error.” For result events, this is empty.
- `general_command_length`: The length of `general_command`, in bytes.
- `general_query`: The SQL statement that was logged or produced a result.
- `general_query_length`: The length of `general_query`, in bytes.
- `general_charset`: Character set information for the event.
- `general_time`: A `TIMESTAMP` value indicating the time just before the notification function was called.
- `general_rows`: For general query log events, zero. For error log events, the row number at which an error occurred. For result events, the number of rows in the result plus one. For statements that produce no result set, the value is 0. This encoding enables statements that produce no result set to be distinguished from those that produce an empty result set. For example, for a `DELETE` statement, this value is 0. For a `SELECT`, the result is always 1 or more, where 1 represents an empty result set.

If the server calls the notification function with an event class of `MYSQL_AUDIT_CONNECTION_CLASS`, it passes the event structure as a pointer to a `mysql_event_connection` structure, which is similar to and interpreted much the same way as the `mysql_event_general` structure.

The `NULL_AUDIT` plugin notification function is quite simple. It increments a global event counter, determines the event class, then looks at the event subclass to determine which subclass counter to increment:

```
static void audit_null_notify(MYSQL_THD thd __attribute__((unused)),
                             unsigned int event_class,
                             const void *event)
{
    /* prone to races, oh well */
    number_of_calls++;
    if (event_class == MYSQL_AUDIT_GENERAL_CLASS)
    {
        const struct mysql_event_general *event_general=
            (const struct mysql_event_general *) event;
        switch (event_general->event_subclass)
        {
            case MYSQL_AUDIT_GENERAL_LOG:
                number_of_calls_general_log++;
                break;
            case MYSQL_AUDIT_GENERAL_ERROR:
                number_of_calls_general_error++;
                break;
            case MYSQL_AUDIT_GENERAL_RESULT:
                number_of_calls_general_result++;
                break;
            case MYSQL_AUDIT_GENERAL_STATUS:
                number_of_calls_general_status++;
                break;
            default:
                break;
        }
    }
    else if (event_class == MYSQL_AUDIT_CONNECTION_CLASS)
    {
        const struct mysql_event_connection *event_connection=
            (const struct mysql_event_connection *) event;
        switch (event_connection->event_subclass)
        {
            case MYSQL_AUDIT_CONNECTION_CONNECT:
                number_of_calls_connection_connect++;
                break;
            case MYSQL_AUDIT_CONNECTION_DISCONNECT:
                number_of_calls_connection_disconnect++;
                break;
            case MYSQL_AUDIT_CONNECTION_CHANGE_USER:
                number_of_calls_connection_change_user++;
                break;
            default:
                break;
        }
    }
}
```

To compile and install a plugin library object file, use the instructions in [Section 22.2.4.3, “Compiling and Installing Plugin Libraries”](#). To use the library file, it must be installed in the plugin directory (the directory named by the `plugin_dir` [525] system variable). For the `AUDIT_NULL` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `adt_null.so` (the suffix might differ depending on your platform).

To register the plugin at runtime, use this statement (change the suffix as necessary):

```
mysql> INSTALL PLUGIN NULL_AUDIT SONAME 'adt_null.so';
```

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement.

While the audit plugin is installed, it exposes status variables that indicate the events for which the plugin has been called:

```
mysql> SHOW STATUS LIKE 'Audit_null%';
+-----+
| Variable_name          | Value |
+-----+
| Audit_null_called      | 1388  |
| Audit_null_connection_change_user | 0     |
| Audit_null_connection_connect | 22    |
| Audit_null_connection_disconnect | 21    |
| Audit_null_general_error | 1     |
| Audit_null_general_log  | 513   |
| Audit_null_general_result | 415   |
| Audit_null_general_status | 416   |
+-----+

```

`Audit_null_called` counts all events, and the other variables count instances of event subclasses. For example, the preceding `SHOW STATUS` statement causes the server to send a result to the client and to write a message to the general query log if that log is enabled. Thus, a client that issues the statement repeatedly causes `Audit_null_called` and `Audit_null_general_result` to be incremented each time, and `Audit_null_general_log` to be incremented if the log is enabled.

To disable the plugin after testing it, use this statement to unload it:

```
mysql> UNINSTALL PLUGIN NULL_AUDIT;
```

### 22.2.4.9. Writing Authentication Plugins

MySQL supports pluggable authentication, in which plugins are invoked to authenticate client connections. Authentication plugins enable the use of authentication methods other than the built-in method of passwords stored in the `mysql.user` table. For example, plugins can be written to access external authentication methods. Also, authentication plugins can support the proxy user capability, such that the connecting user is a proxy for another user and is treated, for purposes of access control, as having the privileges of a different user. For more information, see [Section 6.3.7, “Pluggable Authentication”](#), and [Section 6.3.8, “Proxy Users”](#).

An authentication plugin can be written for the server side or the client side. Server-side plugins use the same plugin API that is used for the other server plugin types such as full-text parser or audit plugins (although with a different type-specific descriptor). Client-side plugins use the client plugin API.

Several header files contain information relevant to authentication plugins:

- `plugin.h`: Defines the `MYSQL_AUTHENTICATION_PLUGIN` server plugin type.
- `client_plugin.h`: Defines the API for client plugins. This includes the client plugin descriptor and function prototypes for client plugin C API calls (see [Section 21.8.13, “C API Client Plugin Functions”](#)).
- `plugin_auth.h`: Defines the part of the server plugin API specific to authentication plugins. This includes the type-specific descriptor for server-side authentication plugins and the `MYSQL_SERVER_AUTH_INFO` structure.
- `plugin_auth_common.h`: Contains common elements of client and server authentication plugins. This includes return value definitions and the `MYSQL_PLUGIN_VIO` structure.

To write an authentication plugin, include the following header files in the plugin source file. Other MySQL or general header files might also be needed.

- For a source file that implements a server authentication plugin, include this file:

```
#include <mysql/plugin_auth.h>
```

- For a source file that implements a client authentication plugin, or both client and server plugins, include these files:

```
#include <mysql/plugin_auth.h>
#include <mysql/client_plugin.h>
#include <mysql>
```

`plugin_auth.h` includes `plugin.h` and `plugin_auth_common.h`, so you need not include the latter files explicitly.

This section describes how to write a pair of simple server and client authentication plugins that work together.

### Warning

These plugins accept any non-empty password and the password is sent in clear text. This is insecure, so the plugins *should not be used in production environments*.

The server-side and client-side plugins developed here both are named `auth_simple`. As described in [Section 22.2.4.2, “Plugin Data Structures”](#), the plugin library file must have the same basename as the client plugin, so the source file name is `auth_simple.c` and produces a library named `auth_simple.so` (assuming that your system uses `.so` as the suffix for library files).

In MySQL source distributions, authentication plugin source is located in the `plugin/auth` directory and can be examined as a guide to writing other authentication plugins. Also, to see how the built-in authentication plugins are implemented, see `sql/sql_acl.cc` for plugins that are built in to the MySQL server and `sql-common/client.c` for plugins that are built in to the `libmysqlclient` client library. (For the built-in client plugins, note that the `auth_plugin_t` structures used there differ from the structures used with the usual client plugin declaration macros. In particular, the first two members are provided explicitly, not by declaration macros.)

#### 22.2.4.9.1. Writing the Server-Side Authentication Plugin

Declare the server-side plugin with the usual general descriptor format that is used for all server plugin types (see [Section 22.2.4.2.1, “Server Plugin Library and Plugin Descriptors”](#)). For the `auth_simple` plugin, the descriptor looks like this:

```
mysql_declare_plugin(auth_simple)
{
  MYSQL_AUTHENTICATION_PLUGIN,
  &auth_simple_handler,           /* type-specific descriptor */
  "auth_simple",                 /* plugin name */
  "Author Name",                 /* author */
  "Any-password authentication plugin", /* description */
  PLUGIN_LICENSE_GPL,           /* license type */
  NULL,                          /* no init function */
  NULL,                          /* no deinit function */
  0x0100,                        /* version = 1.0 */
  NULL,                          /* no status variables */
  NULL,                          /* no system variables */
  NULL,                          /* no reserved information */
  0                               /* no flags */
}
mysql_declare_plugin_end;
```

The `name` member (`auth_simple`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The `auth_simple_handler` member of the general descriptor points to the type-specific descriptor. For an authentication plugin, the type-specific descriptor is an instance of the `st_mysql_auth` structure (defined in `plugin_auth.h`):

```
struct st_mysql_auth
{
  int interface_version;
```

```
const char *client_auth_plugin;
int (*authenticate_user)(MYSQL_PLUGIN_VIO *vio, MYSQL_SERVER_AUTH_INFO *info);
};
```

The `st_mysql_auth` structure has three members: The type-specific API version number, the client plugin name, and a pointer to the main plugin function that communicates with the client. The `client_auth_plugin` member should indicate the name of the client plugin if a specific plugin is required. A value of `NULL` means “any plugin.” In the latter case, whatever plugin the client uses will do. This is useful if the server plugin does not care about the client plugin or what user name or password it sends. For example, this might be true if the server plugin authenticates only local clients and uses some property of the operating system rather than the information sent by the client plugin.

For `auth_simple`, the type-specific descriptor looks like this:

```
static struct st_mysql_auth auth_simple_handler =
{
    MYSQL_AUTHENTICATION_INTERFACE_VERSION,
    "auth_simple",          /* required client-side plugin name */
    auth_simple_server      /* server-side plugin main function */
};
```

The main function takes two arguments representing an I/O structure and a `MYSQL_SERVER_AUTH_INFO` structure. The structure definition is found in `plugin_auth.h`. It looks like this:

```
typedef struct st_mysql_server_auth_info
{
    char *user_name;
    unsigned int user_name_length;
    const char *auth_string;
    unsigned long auth_string_length;
    char authenticated_as[MYSQL_USERNAME_LENGTH+1];
    char external_user[512];
    int password_used;
    const char *host_or_ip;
    unsigned int host_or_ip_length;
} MYSQL_SERVER_AUTH_INFO;
```

The character set for string members is UTF-8. If there is a `_length` member associated with a string, it indicates the string length in bytes. Strings are also null-terminated.

When an authentication plugin is invoked by the server, it should interpret the `MYSQL_SERVER_AUTH_INFO` structure members as follows. Some of these are used to set the value of SQL functions or system variables within the client session, as indicated.

- `user_name`: The user name sent by the client. The value becomes the `USER()` [1273] function value.
- `user_name_length`: The length of `user_name` in bytes.
- `auth_string`: The value of the `authentication_string` column of the `mysql.user` table row for the matching account name (that is, the row that matches the client user name and host name and that the server uses to determine how to authenticate the client).

Suppose that you create an account using the following statement:

```
CREATE USER 'my_user'@'localhost'
    IDENTIFIED WITH my_plugin AS 'my_auth_string';
```

When `my_user` connects from the local host, the server invokes `my_plugin` and passes `'my_auth_string'` to it as the `auth_string` value.

- `auth_string_length`: The length of `auth_string` in bytes.
- `authenticated_as`: The server sets this to the user name (the value of `user_name`). The plugin can alter it to indicate that the client should have the privileges of a different user. For example, if

the plugin supports proxy users, the initial value is the name of the connecting (proxy) user, and the plugin can change this member to the proxied user name. The server then treats the proxy user as having the privileges of the proxied user (assuming that the other conditions for proxy user support are satisfied; see [Section 22.2.4.9.4, “Implementing Proxy User Support in Authentication Plugins”](#)). The value is represented as a string at most `MYSQL_USER_NAME_LENGTH` bytes long, plus a terminating null. The value becomes the `CURRENT_USER() [1267]` function value.

- `external_user`: The server sets this to the empty string (null terminated). Its value becomes the `external_user [482]` system variable value. If the plugin wants that system variable to have a different value, it should set this member accordingly; for example, to the connecting user name. The value is represented as a string at most 511 bytes long, plus a terminating null.
- `password_used`: This member applies when authentication fails. The plugin can set it or ignore it. The value is used to construct the failure error message of `Authentication fails. Password used: %s`. The value of `password_used` determines how `%s` is handled, as shown in the following table.

<code>password_used</code>	<code>%s Handling</code>
0	NO
1	YES
2	There will be no <code>%s</code>

- `host_or_ip`: The name of the client host if it can be resolved, or the IP address otherwise.
- `host_or_ip_length`: The length of `host_or_ip` in bytes.

The `auth_simple` main function, `auth_simple_server()`, reads the password (a null-terminated string) from the client and succeeds if the password is nonempty (first byte not null):

```
static int auth_simple_server (MYSQL_PLUGIN_VIO *vio,
                              MYSQL_SERVER_AUTH_INFO *info)
{
    unsigned char *pkt;
    int pkt_len;

    /* read the password as null-terminated string, fail on error */
    if ((pkt_len= vio->read_packet(vio, &pkt)) < 0)
        return CR_ERROR;

    /* fail on empty password */
    if (!pkt_len || *pkt == '\0')
    {
        info->password_used= PASSWORD_USED_NO;
        return CR_ERROR;
    }

    /* accept any nonempty password */
    info->password_used= PASSWORD_USED_YES;

    return CR_OK;
}
```

The main function should return one of the error codes shown in the following table.

Error Code	Meaning
<code>CR_OK</code>	Success
<code>CR_OK_HANDSHAKE_COMPLETE</code>	Do not send a status packet back to client
<code>CR_ERROR</code>	Error
<code>CR_AUTH_USER_CREDENTIALS</code>	Authentication failure
<code>CR_AUTH_HANDSHAKE</code>	Authentication handshake failure

Error Code	Meaning
<a href="#">CR_AUTH_PLUGIN_ERROR</a>	Internal plugin error

For an example of how the handshake works, see the [plugin/auth/dialog.c](#) source file.

The error codes following [CR\\_ERROR](#) are available from MySQL 5.6.5. The server counts plugin errors in the Performance Schema [host\\_cache](#) table, also available as of MySQL 5.6.5.

[auth\\_simple\\_server\\_main\(\)](#) is so basic that it does not use the authentication information structure except to set the member that indicates whether a password was received.

A plugin that supports proxy users must return to the server the name of the proxied user (the MySQL user whose privileges the client user should get). To do this, the plugin must set the [info->authenticated\\_as](#) member to the proxied user name. For information about proxying, see [Section 6.3.8, “Proxy Users”](#), and [Section 22.2.4.9.4, “Implementing Proxy User Support in Authentication Plugins”](#).

### 22.2.4.9.2. Writing the Client-Side Authentication Plugin

Declare the client-side plugin descriptor with the [mysql\\_declare\\_client\\_plugin\(\)](#) and [mysql\\_end\\_client\\_plugin](#) macros (see [Section 22.2.4.2.3, “Client Plugin Descriptors”](#)). For the [auth\\_simple](#) plugin, the descriptor looks like this:

```
mysql_declare_client_plugin(AUTHENTICATION)
    "auth_simple",          /* plugin name */
    "Author Name",        /* author */
    "Any-password authentication plugin", /* description */
    {1,0,0},              /* version = 1.0.0 */
    "GPL",                 /* license type */
    NULL,                  /* for internal use */
    NULL,                  /* no init function */
    NULL,                  /* no deinit function */
    NULL,                  /* no option-handling function */
    auth_simple_client     /* main function */
mysql_end_client_plugin;
```

The descriptor members common to all client plugins are the plugin name through the option-handling function. Following the common members, an authentication plugin also has one extra member. This is the “main” function, which handles communication with the server. The function takes two arguments representing an I/O structure and a connection handler. For our simple any-password plugin, the main function does nothing but write to the server the password provided by the user:

```
static int auth_simple_client (MYSQL_PLUGIN_VIO *vio, MYSQL *mysql)
{
    int res;

    /* send password as null-terminated string in clear text */
    res= vio->write_packet(vio, (const unsigned char *) mysql->passwd,
        strlen(mysql->passwd) + 1);

    return res ? CR_ERROR : CR_OK;
}
```

The main function should return one of the error codes shown in the following table.

Error Code	Meaning
<a href="#">CR_OK</a>	Success
<a href="#">CR_OK_HANDSHAKE_COMPLETE</a>	Success, client done
<a href="#">CR_ERROR</a>	Error

[CR\\_OK\\_HANDSHAKE\\_COMPLETE](#) indicates that the client has done its part successfully and has read the last packet. A client plugin may return [CR\\_OK\\_HANDSHAKE\\_COMPLETE](#) if the number of round

trips in the authentication protocol is not known in advance and the plugin must read another packet to determine whether authentication is finished.

### 22.2.4.9.3. Using the Authentication Plugins

To compile and install a plugin library object file, see the instructions in [Section 22.2.4.3, “Compiling and Installing Plugin Libraries”](#). To use the library file, it must be installed in the plugin directory (the directory named by the `plugin_dir` [525] system variable).

Register the server-side plugin with the server. For example, to load the plugin at server startup, use a `--plugin-load=auth_simple.so` [435] option (change the library suffix as necessary for your system).

Create a user for whom the server will use the `auth_simple` plugin for authentication:

```
mysql> CREATE USER 'x'@'localhost'
-> IDENTIFIED WITH auth_simple;
```

Use a client program to connect to the server as user `x`. The server-side `auth_simple` plugin communicates with the client program that it should use the client-side `auth_simple` plugin, and the latter sends the password to the server. The server plugin should reject connections that send an empty password and accept connections that send a nonempty password. Invoke the client program each way to verify this:

```
shell> mysql --user=x --skip-password
ERROR 1045 (28000): Access denied for user 'x'@'localhost' (using password: NO)

shell> mysql --user=x --password=abc
mysql>
```

Because the server plugin accepts any nonempty password, it should be considered insecure. After testing the plugin to verify that it works, restart the server without the `--plugin-load` [435] option so as not to inadvertently leave the server running with an insecure authentication plugin loaded. Also, drop the user with `DROP USER 'x'@'localhost'`.

For additional information about loading and using authentication plugins, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#), and [Section 6.3.7, “Pluggable Authentication”](#).

If you are writing a client program that supports the use of authentication plugins, normally such a program causes a plugin to be loaded by calling `mysql_options()` to set the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options:

```
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";

/* ... process command-line options ... */

mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept `--plugin-dir` and `--default-auth` options that enable users to override the default values.

Should a client program require lower-level plugin management, the client library contains functions that take an `st_mysql_client_plugin` argument. See [Section 21.8.13, “C API Client Plugin Functions”](#).

### 22.2.4.9.4. Implementing Proxy User Support in Authentication Plugins

One of the capabilities that pluggable authentication makes possible is proxy users (see [Section 6.3.8, “Proxy Users”](#)). For a server-side authentication plugin to participate in proxy user support, these conditions must be satisfied:

- When a connecting client should be treated as a proxy user, the plugin must return a different name in the `authenticated_as` member of the `MYSQL_SERVER_AUTH_INFO` structure, to indicate the proxied user name. It may also optionally set the `external_user` member, to set the value of the `external_user` [482] system variable.
- Proxy user accounts must be set up to be authenticated by the plugin. Use the `CREATE USER` or `GRANT` statement to associate accounts with plugins.
- Proxy user accounts must have the `PROXY` [755] privilege for the proxied accounts. Use the `GRANT` statement to grant this privilege.

In other words, the only aspect of proxy user support required of the plugin is that it set `authenticated_as` to the proxied user name. The rest is optional (setting `external_user`) or done by the DBA using SQL statements.

How does an authentication plugin determine which proxied user to return when the proxy user connects? That depends on the plugin. Typically, the plugin maps clients to proxied users based on the authentication string passed to it by the server. This string comes from the `AS` part of the `IDENTIFIED WITH` clause of the `CREATE USER` statement that specifies use of the plugin for authentication.

The plugin developer determines the syntax rules for the authentication string and implements the plugin according to those rules. Suppose that a plugin takes a comma-separated list of pairs that map external users to MySQL users. For example:

```
CREATE USER '@%.example.com'
  IDENTIFIED WITH my_plugin AS 'extuser1=mysqlusera, extuser2=mysqluserb'
CREATE USER '@%.example.org'
  IDENTIFIED WITH my_plugin AS 'extuser1=mysqluserc, extuser2=mysqluserd'
```

When the server invokes a plugin to authenticate a client, it passes the appropriate authentication string to the plugin. The plugin is responsible to:

1. Parse the string into its components to determine the mapping to use
2. Compare the client user name to the mapping
3. Return the proper MySQL user name

For example, if `extuser2` connects from an `example.com` host, the server passes `'extuser1=mysqlusera, extuser2=mysqluserb'` to the plugin, and the plugin should copy `mysqluserb` into `authenticated_as`, with a terminating null byte. If `extuser2` connects from an `example.org` host, the server passes `'extuser1=mysqluserc, extuser2=mysqluserd'`, and the plugin should copy `mysqluserd` instead.

If there is no match in the mapping, the action depends on the plugin. If a match is required, the plugin likely will return an error. Or the plugin might simply return the client name; in this case, it should not change `authenticated_as`, and the server will not treat the client as a proxy.

The following example demonstrates how to handle proxy users using a plugin named `auth_simple_proxy`. Like the `auth_simple` plugin described earlier, `auth_simple_proxy` accepts any nonempty password as valid (and thus should not be used in production environments). In addition, it examines the `auth_string` authentication string member and uses these very simple rules for interpreting it:

- If the string is empty, the plugin returns the user name as given and no proxying occurs. That is, the plugin leaves the value of `authenticated_as` unchanged.
- If the string is nonempty, the plugin treats it as the name of the proxied user and copies it to `authenticated_as` so that proxying occurs.

For testing, set up one account that is not proxied according to the preceding rules, and one that is. This means that one account has no `AS` clause, and one includes an `AS` clause that names the proxied user:

```
CREATE USER 'plugin_user1'@'localhost'
  IDENTIFIED WITH auth_simple_proxy;
CREATE USER 'plugin_user2'@'localhost'
  IDENTIFIED WITH auth_simple_proxy AS 'proxied_user';
```

In addition, create an account for the proxied user and grant `plugin_user2` the `PROXY` [755] privilege for it:

```
CREATE USER 'proxied_user'@'localhost'
  IDENTIFIED BY 'proxied_user_pass';
GRANT PROXY
  ON 'proxied_user'@'localhost'
  TO 'plugin_user2'@'localhost';
```

Before the server invokes an authentication plugin, it sets `authenticated_as` to the client user name. To indicate that the user is a proxy, the plugin should set `authenticated_as` to the proxied user name. For `auth_simple_proxy`, this means that it must examine the `auth_string` value, and, if the value is nonempty, copy it to the `authenticated_as` member to return it as the name of the proxied user. In addition, when proxying occurs, the plugin sets the `external_user` member to the client user name; this becomes the value of the `external_user` [482] system variable.

```
static int auth_simple_proxy_server (MYSQL_PLUGIN_VIO *vio,
                                     MYSQL_SERVER_AUTH_INFO *info)
{
  unsigned char *pkt;
  int pkt_len;

  /* read the password as null-terminated string, fail on error */
  if ((pkt_len= vio->read_packet(vio, &pkt)) < 0)
    return CR_ERROR;

  /* fail on empty password */
  if (!pkt_len || *pkt == '\0')
  {
    info->password_used= PASSWORD_USED_NO;
    return CR_ERROR;
  }

  /* accept any nonempty password */
  info->password_used= PASSWORD_USED_YES;

  /* if authentication string is nonempty, use as proxied user name */
  /* and use client name as external_user value */
  if (info->auth_string_length > 0)
  {
    strcpy (info->authenticated_as, info->auth_string);
    strcpy (info->external_user, info->user_name);
  }

  return CR_OK;
}
```

After a successful connection, the `USER()` [1273] function should indicate the connecting client user and host name, and `CURRENT_USER()` [1267] should indicate the account whose privileges apply during the session. The latter value should be the connecting user account if no proxying occurs or the proxied account if proxying does occur.

Compile and install the plugin, then test it. First, connect as `plugin_user1`:

```
shell> mysql --user=plugin_user1 --password=x
```

In this case, there should be no proxying:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user, @@external_user\G
***** 1. row *****
      USER(): plugin_user1@localhost
     CURRENT_USER(): plugin_user1@localhost
      @@proxy_user: NULL
     @@external_user: NULL
```

Then connect as `plugin_user2`:

```
shell> mysql --user=plugin_user2 --password=x
```

In this case, `plugin_user2` should be proxied to `proxied_user`:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user, @@external_user\G
***** 1. row *****
      USER(): plugin_user2@localhost
      CURRENT_USER(): proxied_user@localhost
      @@proxy_user: 'plugin_user2'@'localhost'
      @@external_user: 'plugin_user2'@'localhost'
```

## 22.2.4.10. Writing Password-Validation Plugins

This section describes how to write a password-validation server plugin. The instructions are based on the source code in the `plugin/password_validation` directory of MySQL source distributions. The `validate_password.cc` source file in that directory implements the the plugin named `validate_password`.

To write a password-validation plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed.

```
#include <mysql/plugin_validate_password.h>
```

`plugin_validate_password.h` includes `plugin.h`, so you need not include the latter file explicitly. `plugin.h` defines the `MYSQL_VALIDATE_PASSWORD_PLUGIN` server plugin type and the data structures needed to declare the plugin. `plugin_validate_password.h` defines data structures specific to password-validation plugins.

A password-validation plugin, like any MySQL server plugin, has a general plugin descriptor (see [Section 22.2.4.2.1, “Server Plugin Library and Plugin Descriptors”](#)). In `validate_password.cc`, the general descriptor looks like this:

```
mysql_declare_plugin(validate_password)
{
    MYSQL_VALIDATE_PASSWORD_PLUGIN, /* type */
    &validate_password_descriptor, /* descriptor */
    "validate_password", /* name */
    "Oracle Corporation", /* author */
    "check password strength", /* description */
    PLUGIN_LICENSE_GPL,
    validate_password_init, /* init function (when loaded) */
    validate_password_deinit, /* deinit function (when unloaded) */
    0x0100, /* version */
    NULL,
    validate_password_system_variables, /* system variables */
    NULL,
    0,
}
mysql_declare_plugin_end;
```

The `name` member (`validate_password`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

The general descriptor also refers to `validate_password_system_variables`, a structure that exposes several system variables to the `SHOW VARIABLES` statement:

```
static struct st_mysql_sys_var* validate_password_system_variables[]= {
    MYSQL_SYSVAR(length),
    MYSQL_SYSVAR(number_count),
    MYSQL_SYSVAR(mixed_case_count),
    MYSQL_SYSVAR(special_char_count),
    MYSQL_SYSVAR(policy),
    MYSQL_SYSVAR(dictionary_file),
```

```
NULL
};
```

The `validate_password_init` initialization function reads the dictionary file if one was specified, and the `validate_password_deinit` function frees data structures associated with the file.

The `validate_password_descriptor` value in the general descriptor points to the type-specific descriptor. For password-validation plugins, this descriptor has the following structure:

```
struct st_mysql_validate_password
{
    int interface_version;
    /*
     * This function returns TRUE for passwords which satisfy the password
     * policy (as chosen by plugin variable) and FALSE for all other
     * password
     */
    int (*validate_password)(mysql_string_handle password);
    /*
     * This function returns the password strength (0-100) depending
     * upon the policies
     */
    int (*get_password_strength)(mysql_string_handle password);
};
```

The type-specific descriptor has these members:

- `interface_version`: By convention, type-specific plugin descriptors begin with the interface version for the given plugin type. The server checks `interface_version` when it loads the plugin to see whether the plugin is compatible with it. For password-validation plugins, the value of the `interface_version` member is `MYSQL_VALIDATE_PASSWORD_INTERFACE_VERSION` (defined in `plugin_validate_password.h`).
- `validate_password`: A function that the server calls to test whether a password satisfies the current password policy. It returns 1 if the password is okay and 0 otherwise. The argument is the password, passed as a `mysql_string_handle` value. This data type is implemented by the `mysql_string` server service. For details, see the `string_service.h` and `string_service.cc` source files in the `sql` directory.
- `get_password_strength`: A function that the server calls to assess the strength of a password. It returns a value from 0 (weak) to 100 (strong). The argument is the password, passed as a `mysql_string_handle` value.

For the `validate_password` plugin, the type-specific descriptor looks like this:

```
static struct st_mysql_validate_password validate_password_descriptor=
{
    MYSQL_VALIDATE_PASSWORD_INTERFACE_VERSION,
    validate_password, /* validate function */
    get_password_strength /* validate strength function */
};
```

To compile and install a plugin library object file, use the instructions in [Section 22.2.4.3, “Compiling and Installing Plugin Libraries”](#). To use the library file, it must be installed in the plugin directory (the directory named by the `plugin_dir` [525] system variable). For the `validate_password` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `validate_password.so` (the extension might be different depending on your platform).

To register the plugin at runtime, use this statement (change the extension as necessary):

```
mysql> INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement.

While the `validate_password` plugin is installed, it exposes system variables that indicate the password-checking parameters:

```
mysql> SHOW VARIABLES LIKE 'validate_password%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| validate_password_dictionary_file |      |
| validate_password_length | 8 |
| validate_password_mixed_case_count | 1 |
| validate_password_number_count | 1 |
| validate_password_policy | MEDIUM |
| validate_password_special_char_count | 1 |
+-----+-----+
```

For descriptions of these variables, see [Section 6.1.2.6.2, “Password Validation Plugin Options and Variables”](#).

To disable the plugin after testing it, use this statement to unload it:

```
mysql> UNINSTALL PLUGIN validate_password;
```

## 22.2.5. MySQL Services for Plugins

MySQL server plugins have access to server “services.” The services interface exposes server functionality that plugins can call. It complements the plugin API and has these characteristics:

- Services enable plugins to access code inside the server using ordinary function calls.
- Services are portable and work on multiple platforms.
- The interface includes a versioning mechanism so that service versions supported by the server can be checked at load time against plugin versions. Versioning protects against incompatibilities between the version of a service that the server provides and the version of the service expected or required by a plugin.

Current services include the following, and others can be implemented:

- `my_plugin_log_service`: A service that enables plugins to report errors and specify error messages. The server writes the messages to the error log.
- `my_snprintf`: A string-formatting service that produces consistent results across platforms.
- `my_thd_scheduler`: A service for plugins to select a thread scheduler.
- `mysql_string`: A service for string manipulation.
- `thd_alloc`: A memory-allocation service.
- `thd_wait`: A service for plugins to report when they are going to sleep or stall.

The plugin services interface differs from the plugin API as follows:

- The plugin API enables plugins to be used by the server. The calling initiative lies with the server to invoke plugins. This enables plugins to extend server functionality or register to receive notifications about server processing.
- The plugin services interface enables plugins to call code inside the server. The calling initiative lies with plugins to invoke service functions. This enables functionality already implemented in the server to be used by many plugins; they need not individually implement it themselves.

For developers who wish to modify the server to add a new service, see [MySQL Services for Plugins](#).

The remainder of this section describes how a plugin uses server functionality that is available as a service. See also the source for the “daemon” example plugin, which uses the `my_snprintf` service. Within a MySQL source distribution, that plugin is located in the `plugin/daemon_example` directory.

To determine what services exist and what functions they provide, look in the `include/mysql` directory of a MySQL source distribution. The relevant files are:

- `plugin.h` includes `services.h`.
- `services.h` is the “umbrella” header that includes all available service-specific header files.
- Service-specific headers have names like `service_my_snprintf.h` or `service_thd_alloc.h`.

Each service-specific header should contain comments that provide full usage documentation for a given service, including what service functions are available, their calling sequences, and return values.

To use a service or services from within a plugin, the plugin source file must include the `plugin.h` header file to access service-related information:

```
#include <mysql/plugin.h>
```

This does not represent any additional setup cost. A plugin must include that file anyway because it contains definitions and structures that every plugin needs.

To access a service, a plugin calls service functions like any other function. For example, to format a string into a buffer for printing, call the `my_snprintf()` function provided by the service of the same name:

```
char buffer[BUFFER_SIZE];
my_snprintf(buffer, sizeof(buffer), format_string, argument_to_format, ...);
```

To report an error that the server will write to the error log, first choose an error level. `mysql/service_my_plugin_log.h` defines these levels:

```
enum plugin_log_level
{
    MY_ERROR_LEVEL,
    MY_WARNING_LEVEL,
    MY_INFORMATION_LEVEL
};
```

Then invoke `my_plugin_log_message()`:

```
int my_plugin_log_message(MYSQL_PLUGIN *plugin, enum plugin_log_level level,
    const char *format, ...);
```

For example:

```
my_plugin_log_message(plugin_ptr, MY_ERROR_LEVEL, "Cannot initialize plugin");
```

When you build your plugin, you must link in the `libmysqservices` library. Use the `-lmysqservices` flag at link time. For example, for `CMake`, put this in the top-level `CMakeLists.txt` file:

```
FIND_LIBRARY(MYSQLSERVICES_LIB mysqservices
    PATHS "${MYSQL_SRCDIR}/libservices" NO_DEFAULT_PATH)
```

Put this in the `CMakeLists.txt` file in the directory containing the plugin source:

```
# the plugin needs the mysql services library for error logging
```

```
TARGET_LINK_LIBRARIES (your_plugin_library_name ${MYSQLSERVICES_LIB})
```

## 22.3. Adding New Functions to MySQL

There are three ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as object files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See [Section 13.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”](#).
- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the `mysqld` server and become available on a permanent basis.
- Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is not covered here. See [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#).

Each method of creating compiled functions has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you don't need to do that.
- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.
- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as `ABS ( )` [1202] or `SOUNDEX ( )` [1184].

See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native MySQL functions.

For example source code that illustrates how to write UDFs, take a look at the `sql/udf_example.c` file that is provided in MySQL source distributions.

### 22.3.1. Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values and can accept arguments of those same types.
- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.
- Information is provided to functions that enables them to check the number, types, and names of the arguments passed to them.
- You can tell MySQL to coerce arguments to a given type before passing them to a function.
- You can indicate that a function returns `NULL` or that an error occurred.

### 22.3.2. Adding a New User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. MySQL source distributions include a file `sql/udf_example.c` that defines five UDF functions. Consult this file to see how UDF calling conventions work. The `include/mysql_com.h` header file defines UDF-related symbols and data structures, although you need not include this header file directly; it is included by `mysql.h`.

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to UDFs that were originally written for older servers. For information about these constraints, see [Section 2.9.4, “MySQL Source-Configuration Options”](#), and [Section 2.9.5, “Dealing with Problems Compiling MySQL”](#).

To be able to use UDFs, you must link `mysqld` dynamically. If you want to use a UDF that needs to access symbols from `mysqld` (for example, the `metaphone` function in `sql/udf_example.c` uses `default_charset_info`), you must link the program with `-rdynamic` (see `man dlopen`).

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To distinguish between SQL and C/C++ usage, `XXX()` (uppercase) indicates an SQL function call, and `xxx()` (lowercase) indicates a C/C++ function call.

#### Note

When using C++ you can encapsulate your C functions within:

```
extern "C" { ... }
```

This ensures that your C++ function names remain readable in the completed UDF.

The following list describes the C/C++ functions that you write to implement the interface for a function named `xxx()`. The main function, `xxx()`, is required. In addition, a UDF requires at least one of the other functions described here, for reasons discussed in [Section 22.3.2.6, “User-Defined Function Security Precautions”](#).

- `xxx()`

The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here.

SQL Type	C/C++ Type
STRING	<code>char *</code>
INTEGER	<code>long long</code>
REAL	<code>double</code>

It is also possible to declare a `DECIMAL` function, but currently the value is returned as a string, so you should write the UDF as though it were a `STRING` function. `ROW` functions are not implemented.

- `xxx_init()`

The initialization function for `xxx()`. If present, it can be used for the following purposes:

- To check the number of arguments to `xxx()`.
- To verify that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the required types when the main function is called.
- To allocate any memory required by the main function.

- To specify the maximum length of the result.
- To specify (for `REAL` functions) the maximum number of decimal places in the result.
- To specify whether the result can be `NULL`.
- `xxx_deinit()`

The deinitialization function for `xxx()`. If present, it should deallocate any memory allocated by the initialization function.

When an SQL statement invokes `XXX()`, MySQL calls the initialization function `xxx_init()` to let it perform any required setup, such as argument checking or memory allocation. If `xxx_init()` returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function `xxx()` once for each row. After all rows have been processed, MySQL calls the deinitialization function `xxx_deinit()` so that it can perform any required cleanup.

For aggregate functions that work like `SUM()` [1285], you must also provide the following functions:

- `xxx_clear()`

Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- `xxx_add()`

Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call `xxx_init()` to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the `GROUP BY` expression.
3. Call `xxx_clear()` for the first row in each new group.
4. Call `xxx_add()` for each row that belongs in the same group.
5. Call `xxx()` to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat steps 3 to 5 until all rows has been processed
7. Call `xxx_deinit()` to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not permitted to allocate any global or static variables that change! If you need memory, you should allocate it in `xxx_init()` and free it in `xxx_deinit()`.

### 22.3.2.1. UDF Calling Sequences for Simple Functions

This section describes the different functions that you need to define when you create a simple UDF. [Section 22.3.2, “Adding a New User-Defined Function”](#), describes the order in which MySQL calls these functions.

The main `xxx()` function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function `XXX()` to return `STRING`, `INTEGER`, or `REAL` in the `CREATE FUNCTION` statement:

For **STRING** functions:

```
char *xxx(UDF_INIT *initid, UDF_ARGS *args,
         char *result, unsigned long *length,
         char *is_null, char *error);
```

For **INTEGER** functions:

```
long long xxx(UDF_INIT *initid, UDF_ARGS *args,
             char *is_null, char *error);
```

For **REAL** functions:

```
double xxx(UDF_INIT *initid, UDF_ARGS *args,
          char *is_null, char *error);
```

**DECIMAL** functions return string values and should be declared the same way as **STRING** functions. **ROW** functions are not implemented.

The initialization and deinitialization functions are declared like this:

```
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);

void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a `UDF_INIT` structure that is used to communicate information between functions. The `UDF_INIT` structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- `my_bool maybe_null`

`xxx_init()` should set `maybe_null` to 1 if `xxx()` can return `NULL`. The default value is 1 if any of the arguments are declared `maybe_null`.

- `unsigned int decimals`

The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. For example, if the function is passed 1.34, 1.345, and 1.3, the default would be 3, because 1.345 has 3 decimal digits.

For arguments that have no fixed number of decimals, the `decimals` value is set to 31, which is 1 more than the maximum number of decimals permitted for the **DECIMAL**, **FLOAT**, and **DOUBLE** data types. In MySQL 5.6, this value is available as the constant `NOT_FIXED_DEC` in the `mysql_com.h` header file.

A `decimals` value of 31 is used for arguments in cases such as a **FLOAT** or **DOUBLE** column declared without an explicit number of decimals (for example, **FLOAT** rather than **FLOAT(10, 3)**) and for floating-point constants such as `1345E-3`. It is also used for string and other nonnumber arguments that might be converted within the function to numeric form.

The value to which the `decimals` member is initialized is only a default. It can be changed within the function to reflect the actual calculation performed. The default is determined such that the largest number of decimals of the arguments is used. If the number of decimals is `NOT_FIXED_DEC` for even one of the arguments, that is the value used for `decimals`.

- `unsigned int max_length`

The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- `char *ptr`

A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

```
initid->ptr = allocated_memory;
```

In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- `my_bool const_item`

`xxx_init()` should set `const_item` to 1 if `xxx()` always returns the same value and to 0 otherwise.

### 22.3.2.2. UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. Section 22.3.2, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

- `xxx_reset()`

This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

```
void xxx_reset(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

`xxx_reset()` is not needed or used in MySQL 5.6, in which the UDF interface uses `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work with older versions of the server. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- `xxx_clear()`

This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

```
void xxx_clear(UDF_INIT *initid, char *is_null, char *error);
```

`is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

`xxx_clear()` is required by MySQL 5.6.

- `xxx_add()`

This function is called for all rows that belong to the same group. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

```
void xxx_add(UDF_INIT *initid, UDF_ARGS *args,
            char *is_null, char *error);
```

The `xxx()` function for an aggregate UDF should be declared the same way as for a nonaggregate UDF. See [Section 22.3.2.1, “UDF Calling Sequences for Simple Functions”](#).

For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.

Return value handling in `xxx()` should be done the same way as for a nonaggregate UDF. See [Section 22.3.2.4, “UDF Return Values and Error Handling”](#).

The `xxx_reset()` and `xxx_add()` functions handle their `UDF_ARGS` argument the same way as functions for nonaggregate UDFs. See [Section 22.3.2.3, “UDF Argument Processing”](#).

The pointer arguments to `is_null` and `error` are the same for all calls to `xxx_reset()`, `xxx_clear()`, `xxx_add()` and `xxx()`. You can use this to remember that you got an error or whether the `xxx()` function should return `NULL`. You should not store a string into `*error! error` points to a single-byte variable, not to a string buffer.

`*is_null` is reset for each group (before calling `xxx_clear()`). `*error` is never reset.

If `*is_null` or `*error` are set when `xxx()` returns, MySQL returns `NULL` as the result for the group function.

### 22.3.2.3. UDF Argument Processing

The `args` parameter points to a `UDF_ARGS` structure that has the members listed here:

- `unsigned int arg_count`

The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

```
if (args->arg_count != 2)
{
    strcpy(message, "XXX() requires two arguments");
    return 1;
}
```

For other `UDF_ARGS` member values that are arrays, array references are zero-based. That is, refer to array members using index values from 0 to `args->arg_count - 1`.

- `enum Item_result *arg_type`

A pointer to an array containing the types for each argument. The possible type values are `STRING_RESULT`, `INT_RESULT`, `REAL_RESULT`, and `DECIMAL_RESULT`.

To make sure that arguments are of a given type and return an error if they are not, check the `arg_type` array in the initialization function. For example:

```
if (args->arg_type[0] != STRING_RESULT ||
    args->arg_type[1] != INT_RESULT)
{
    strcpy(message, "XXX() requires a string and an integer");
    return 1;
}
```

Arguments of type `DECIMAL_RESULT` are passed as strings, so you should handle them the same way as `STRING_RESULT` values.

As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the `arg_type` elements to the types you want. This causes MySQL to coerce arguments to those types for each call to `xxx()`. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in `xxx_init()`:

```
args->arg_type[0] = STRING_RESULT;
args->arg_type[1] = INT_RESULT;
```

Exact-value decimal arguments such as `1.3` or `DECIMAL` column values are passed with a type of `DECIMAL_RESULT`. However, the values are passed as strings. If you want to receive a number, use the initialization function to specify that the argument should be coerced to a `REAL_RESULT` value:

```
args->arg_type[2] = REAL_RESULT;
```

- `char **args`

`args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See later for instructions on how to access the value properly.) For a nonconstant argument, `args->args[i]` is `0`. A constant argument is an expression that uses only constants, such as `3` or `4*7-2` or `SIN(3.14)` [1208]. A nonconstant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with nonconstant arguments.

For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

If argument `i` represents `NULL`, `args->args[i]` is a null pointer (`0`). If the argument is not `NULL`, functions can refer to it as follows:

- An argument of type `STRING_RESULT` is given as a string pointer plus a length, to enable handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. Do not assume that the string is null-terminated.
- For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a `long long` value:

```
long long int_val;
int_val = *((long long*) args->args[i]);
```

- For an argument of type `REAL_RESULT`, you must cast `args->args[i]` to a `double` value:

```
double real_val;
real_val = *((double*) args->args[i]);
```

- For an argument of type `DECIMAL_RESULT`, the value is passed as a string and should be handled like a `STRING_RESULT` value.
- `ROW_RESULT` arguments are not implemented.

- `unsigned long *lengths`

For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types `INT_RESULT` or `REAL_RESULT`, `lengths` still contains the maximum length of the argument (as for the initialization function).

- `char *maybe_null`

For the initialization function, the `maybe_null` array indicates for each argument whether the argument value might be null (`0` if no, `1` if yes).

- `char **attributes`

`args->attributes` communicates information about the names of the UDF arguments. For argument `i`, the attribute name is available as a string in `args->attributes[i]` and the attribute length is `args->attribute_lengths[i]`. Do not assume that the string is null-terminated.

By default, the name of a UDF argument is the text of the expression used to specify the argument. For UDFs, an argument may also have an optional `[AS] alias_name` clause, in which case the argument name is `alias_name`. The `attributes` value for each argument thus depends on whether an alias was given.

Suppose that a UDF `my_udf()` is invoked as follows:

```
SELECT my_udf(expr1, expr2 AS alias1, expr3 alias2);
```

In this case, the `attributes` and `attribute_lengths` arrays will have these values:

```
args->attributes[0] = "expr1"
args->attribute_lengths[0] = 5

args->attributes[1] = "alias1"
args->attribute_lengths[1] = 6

args->attributes[2] = "alias2"
args->attribute_lengths[2] = 6
```

- `unsigned long *attribute_lengths`

The `attribute_lengths` array indicates the length of each argument name.

#### 22.3.2.4. UDF Return Values and Error Handling

The initialization function should return `0` if no error occurred and `1` otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function `xxx()` is the function value, for `long long` and `double` functions. A string function should return a pointer to the result and set `*length` to the length (in bytes) of the return value. For example:

```
memcpy(result, "result string", 13);
*length = 13;
```

MySQL passes a buffer to the `xxx()` function using the `result` parameter. This buffer is sufficiently long to hold 255 characters, which can be multi-byte characters. The `xxx()` function can store the result in this buffer if it fits, in which case the return value should be a pointer to the buffer. If the function stores the result in a different buffer, it should return a pointer to that buffer.

If your string function does not use the supplied buffer (for example, if it needs to return a string longer than 255 characters), you must allocate the space for your own buffer with `malloc()` in your `xxx_init()` function or your `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by future `xxx()` calls. See [Section 22.3.2.1, "UDF Calling Sequences for Simple Functions"](#).

To indicate a return value of `NULL` in the main function, set `*is_null` to `1`:

```
*is_null = 1;
```

To indicate an error return in the main function, set `*error` to `1`:

```
*error = 1;
```

If `xxx()` sets `*error` to `1` for any row, the function value is `NULL` for the current row and for any subsequent rows processed by the statement in which `xxx()` was invoked. (`xxx()` is not even called for subsequent rows.)

#### 22.3.2.5. Compiling and Installing User-Defined Functions

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.c` that is included in MySQL source distributions.

If a UDF will be referred to in statements that will be replicated to slave servers, you must ensure that every slave also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.c` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it is more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence([const int])` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP address for a host name.
- `reverse_lookup()` returns the host name for an IP address. The function may be called either with a single string argument of the form `'xxx.xxx.xxx.xxx'` or with four numbers.
- `avgcost()` returns an average cost. This is an aggregate function.

A dynamically loadable file should be compiled as a sharable object file, using a command something like this:

```
shell> gcc -shared -o udf_example.so udf_example.c
```

If you are using `gcc` with `CMake` (which is how MySQL is configured), you should be able to create `udf_example.so` with a simpler command:

```
shell> make udf_example
```

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from `udf_example.c` using `gcc` directly produces a file named `udf_example.so`. Copy the shared object to the server's plugin directory and name it `udf_example.so`. This directory is given by the value of the `plugin_dir` [525] system variable.

On some systems, the `ldconfig` program that configures the dynamic linker does not recognize a shared object unless its name begins with `lib`. In this case you should rename a file such as `udf_example.so` to `libudf_example.so`.

On Windows, you can compile user-defined functions by using the following procedure:

1. Obtain a MySQL source distribution. See [Section 2.1.3, "How to Get MySQL"](#).
2. Obtain the `CMake` build utility, if necessary, from <http://www.cmake.org>. (Version 2.6 or later is required).
3. In the source tree, look in the `sql` directory. There are files named `udf_example.def` and `udf_example.c` there. Copy both files from this directory to your working directory.
4. Create a `CMake` makefile (`CMakeLists.txt`) with these contents:

```
PROJECT(udf_example)
```

```
# Path for MySQL include directory
INCLUDE_DIRECTORIES("c:/mysql/include")

ADD_DEFINITIONS("-DHAVE_DLOPEN")
ADD_LIBRARY(udf_example MODULE udf_example.c udf_example.def)
TARGET_LINK_LIBRARIES(udf_example wsock32)
```

5. Create the VC project and solution files:

```
cmake -G "<Generator>"
```

Invoking `cmake --help` shows you a list of valid Generators.

6. Create `udf_example.dll`:

```
devenv udf_example.sln /build Release
```

After the shared object file has been installed, notify `mysqld` about the new functions with the following statements. If object files have a suffix different from `.so` on your system, substitute the correct suffix throughout (for example, `.dll` on Windows).

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION sequence RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION reverse_lookup
-> RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE AGGREGATE FUNCTION avgcost
-> RETURNS REAL SONAME 'udf_example.so';
```

To delete functions, use `DROP FUNCTION`:

```
mysql> DROP FUNCTION metaphon;
mysql> DROP FUNCTION myfunc_double;
mysql> DROP FUNCTION myfunc_int;
mysql> DROP FUNCTION sequence;
mysql> DROP FUNCTION lookup;
mysql> DROP FUNCTION reverse_lookup;
mysql> DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the `INSERT [755]` or `DELETE [754]` privilege for the `mysql` database to create or drop functions, respectively.

You should not use `CREATE FUNCTION` to add a function that has previously been created. If you need to reinstall a function, you should remove it with `DROP FUNCTION` and then reinstall it with `CREATE FUNCTION`. You would need to do this, for example, if you recompile a new version of your function, so that `mysqld` gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables [439]` option. In this case, UDF initialization is skipped and UDFs are unavailable.

### 22.3.2.6. User-Defined Function Security Precautions

MySQL takes several measures to prevent misuse of user-defined functions.

UDF object files cannot be placed in arbitrary directories. They must be located in the server's plugin directory. This directory is given by the value of the `plugin_dir [525]` system variable.

To use `CREATE FUNCTION` or `DROP FUNCTION`, you must have the `INSERT [755]` or `DELETE [754]` privilege, respectively, for the `mysql` database. This is necessary because those statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. `mysqld` also supports an `--allow-suspicious-udfs` [413] option that controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off, to prevent attempts at loading functions from shared object files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` [413] option. Otherwise, you should avoid enabling this capability.

### 22.3.3. Adding a New Native Function

To add a new native MySQL function, use the procedure described here, which requires that you use a source distribution. You cannot add native functions to a binary distribution because it is necessary to modify MySQL source code and compile MySQL from the modified source. If you migrate to another version of MySQL (for example, when a new version is released), you must repeat the procedure with the new version.

If the new native function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

To add a new native function, follow these steps to modify source files in the `sql` directory:

1. Create a subclass for the function in `item_create.cc`:
  - If the function takes a fixed number of arguments, create a subclass of `Create_func_arg0`, `Create_func_arg1`, `Create_func_arg2`, or `Create_func_arg3`, respectively, depending on whether the function takes zero, one, two, or three arguments. For examples, see the `Create_func_uuid`, `Create_func_abs`, `Create_func_pow`, and `Create_func_lpad` classes.
  - If the function takes a variable number of arguments, create a subclass of `Create_native_func`. For an example, see `Create_func_concat`.
2. To provide a name by which the function can be referred to in SQL statements, register the name in `item_create.cc` by adding a line to this array:

```
static Native_func_registry func_array[]
```

You can register several names for the same function. For example, see the lines for `"LCASE"` and `"LOWER"`, which are aliases for `Create_func_lcase`.

3. In `item_func.h`, declare a class inheriting from `Item_num_func` or `Item_str_func`, depending on whether your function returns a number or a string.
4. In `item_func.cc`, add one of the following declarations, depending on whether you are defining a numeric or string function:

```
double   Item_func_newname::val()
longlong Item_func_newname::val_int()
String   *Item_func_newname::Str(String *str)
```

If you inherit your object from any of the standard items (like `Item_num_func`), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the `Item_str_func` class defines a `val()` function that executes `atof()` on the value returned by `::str()`.

5. If the function is nondeterministic, include the following statement in the item constructor to indicate that function results should not be cached:

```
current_thd->lex->safe_to_cache_query=0;
```

A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations.

6. You should probably also define the following object function:

```
void Item_func_newname::fix_length_and_dec()
```

This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function can't return a `NULL` value. The function can check whether any of the function arguments can return `NULL` by checking the arguments' `maybe_null` variable. Look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

All functions must be thread-safe. In other words, do not use any global or static variables in the functions without protecting them with mutexes.

If you want to return `NULL` from `::val()`, `::val_int()`, or `::str()`, you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result, or `(char*) 0` if the result is `NULL`.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

## 22.4. Debugging and Porting MySQL

This appendix helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See [Section 2.1.1, “Operating Systems Supported by MySQL Community Server”](#). If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site (<http://www.mysql.com/>), recommending it to other users.

### Note

If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server.

To build MySQL from source, your system must satisfy the tool requirements listed at [Section 2.9, “Installing MySQL from Source”](#).

### Important

If you are trying to build MySQL 5.6 with `icc` on the IA64 platform, and need support for MySQL Cluster, you should first ensure that you are using `icc` version 9.1.043 or later. (For details, see Bug #21875.)

If you run into problems with a new port, you may have to do some debugging of MySQL! See [Section 22.4.1, “Debugging a MySQL Server”](#).

### Note

Before you start debugging `mysqld`, first get the test programs `mysys/thr_alarm` and `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to work!

## 22.4.1. Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` (which disables all new, potentially unsafe functionality). See [Section C.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

If `mysqld` doesn't want to start, you should verify that you don't have any `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults . . . .`

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients can't connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you haven't compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See [Chapter 5, \*MySQL Server Administration\*](#). You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See [Section 2.1, “General Installation Guidance”](#).

### 22.4.1.1. Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `-DWITH_DEBUG=1` [136] option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` [418] flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql . . . --debug` in this case.

If `mysqld` stops crashing when you compile it with `-DWITH_DEBUG=1` [136], you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` to the `CFLAGS` and `CXXFLAGS` environment variables and not use `-DWITH_DEBUG=1` [136]. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See [Section 1.6.1, “MySQL Mailing Lists”](#). If you believe that you have found a bug, please use the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).)

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

### 22.4.1.2. Creating Trace Files

If the `mysqld` server doesn't start or if you can cause it to crash quickly, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld` as of MySQL 4.1.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `C:\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` [440] flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

The trace file can become **very large**! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:0,/tmp/mysql.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something seems to go wrong! If you can't locate the wrong place, you can open a bug report and upload the trace file to the report, so that a MySQL developer can take a look at it. For instructions, see [Section 1.7, "How to Report Bugs or Problems"](#).

The trace file is made with the **DEBUG** package by Fred Fish. See [Section 22.4.3, "The DEBUG Package"](#).

### 22.4.1.3. Using `pdb` to create a Windows crashdump

Program Database files (extension `pdb`) are included in the Noinstall distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem.

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with Dr Watson, `WinDbg` and Visual Studio to debug `mysqld`.

For more information on PDB files, see [Microsoft Knowledge Base Article 121366](#). For more information on the debugging options available, see [Debugging Tools for Windows](#).

Dr Watson is installed with all Windows distributions, but if you have installed Windows development tools, Dr Watson may have been replaced with `WinDbg`, the debugger included with Visual Studio, or the debugging tools provided with Borland or Delphi.

To generate a crash file using Dr Watson, follow these steps:

1. Start Dr Watson by running `drwtsn32.exe` interactively using the `-i` option:

```
C:\> drwtsn32 -i
```

2. Set the **Log File Path** to the directory where you want to store trace files.
3. Make sure **Dump All Thread Contexts** and **Append To Existing Log File**.
4. Uncheck **Dump Symbol Table**, **Visual Notification**, **Sound Notification** and **Create Crash Dump File**.
5. Set the **Number of Instructions** to a suitable value to capture enough calls in the stacktrace. A value of at 25 should be enough.

Note that the file generated can become very large.

### 22.4.1.4. Debugging `mysqld` under `gdb`

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time. It is best to upgrade to `gdb` 5.1 because thread debugging works much better with this version!

NPTL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` [441] to be able to catch segfaults within `gdb`.

In MySQL 4.0.14 and above you should use the `--gdb` [423] option to `mysqld`. This installs an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` doesn't free the memory for old threads. You can avoid this problem by starting `mysqld` with `thread_cache_size` [552] set to a value equal to `max_connections` [503] + 1. In most cases just using `--thread_cache_size=5` [552] helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` [418] option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
shell> gdb mysqld core
gdb> backtrace full
gdb> quit
```

See [Section C.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

If you are using `gdb` 4.17.x or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

If you have problems debugging threads with `gdb`, you should download `gdb` 5.x and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug `mysqld`:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the preceding output in a bug report, which you can file using the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

If `mysqld` hangs, you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl [DBI](#) interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

### 22.4.1.5. Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See [Section 5.2.2, “The Error Log”](#). To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to `gcc`. See [Section 22.4.1.1, “Compiling MySQL for Debugging”](#).

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
mysqld(my_print_stacktrace+0x32)[0x9da402]
mysqld(handle_segfault+0x28a)[0x6648e9]
/lib/libpthread.so.0[0x7f1a5af000f0]
/lib/libc.so.6(strcmp+0x2)[0x7f1a5a10f0f2]
mysqld(_Z21check_change_passwordP3THDPKcS2_Pcj+0x7c)[0x7412cb]
mysqld(_ZN16set_var_password5checkEP3THD+0xd0)[0x688354]
mysqld(_Z17sql_set_variablesP3THDP4ListI12set_var_baseE+0x68)[0x688494]
mysqld(_Z21mysql_execute_commandP3THD+0x41a0)[0x67a170]
mysqld(_Z11mysql_parseP3THDPKcjPS2_+0x282)[0x67f0ad]
mysqld(_Z16dispatch_command19enum_server_commandP3THDPcj+0xbb7)[0x67fdf8]
mysqld(_Z10do_commandP3THD+0x24d)[0x6811b6]
mysqld(handle_one_connection+0x11c)[0x66e05e]
```

If resolution of function names for the trace fails, the trace contains less information:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
[0x9da402]
[0x6648e9]
[0x7f1a5af000f0]
[0x7f1a5a10f0f2]
[0x7412cb]
[0x688354]
[0x688494]
[0x67a170]
[0x67f0ad]
[0x67fdf8]
[0x6811b6]
[0x66e05e]
```

In the latter case, you can use the `resolve_stack_dump` utility to determine where `mysqld` died by using the following procedure:

1. Copy the numbers from the stack trace to a file, for example `mysqld.stack`. The numbers should not include the surrounding square brackets:

```
0x9da402
0x6648e9
0x7f1a5af000f0
0x7f1a5a10f0f2
0x7412cb
0x688354
0x688494
```

```
0x67a170
0x67f0ad
0x67fdf8
0x6811b6
0x66e05e
```

2. Make a symbol file for the `mysqld` server:

```
shell> nm -n libexec/mysqld > /tmp/mysqld.sym
```

If `mysqld` is not linked statically, use the following command instead:

```
shell> nm -D -n libexec/mysqld > /tmp/mysqld.sym
```

If you want to decode C++ symbols, use the `--demangle`, if available, to `nm`. If your version of `nm` does not have this option, you will need to use the `c++filt` command after the stack dump has been produced to demangle the C++ names.

3. Execute the following command:

```
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack
```

If you were not able to include demangled C++ names in your symbol file, process the `resolve_stack_dump` output using `c++filt`:

```
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack | c++filt
```

This prints out where `mysqld` died. If that does not help you find out why `mysqld` died, you should create a bug report and include the output from the preceding command with the bug report.

However, in most cases it does not help us to have just a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, in most cases we need to know the statement that killed `mysqld` and preferably a test case so that we can repeat the problem! See [Section 1.7, “How to Report Bugs or Problems”](#).

Newer versions of `glibc` stack trace functions also print the address as relative to the object. On `glibc`-based systems (Linux), the trace for a crash within a plugin looks something like:

```
plugin/auth/auth_test_plugin.so(+0x9a6)[0x7ff4d11c29a6]
```

To translate the relative address (`+0x9a6`) into a file name and line number, use this command:

```
shell> addr2line -fie auth_test_plugin.so 0x9a6
auth_test_plugin
mysql-trunk/plugin/auth/test_plugin.c:65
```

The `addr2line` utility is part of the `binutils` package on Linux.

On Solaris, the procedure is similar. The Solaris `printstack()` already prints relative addresses:

```
plugin/auth/auth_test_plugin.so:0x1510
```

To translate, use this command:

```
shell> gaddr2line -fie auth_test_plugin.so 0x1510
mysql-trunk/plugin/auth/test_plugin.c:88
```

Windows already prints the address, function name and line:

```
000007FEF07E10A4 auth_test_plugin.dll!auth_test_plugin()[test_plugin.c:72]
```

### 22.4.1.6. Using Server Logs to Find Causes of Errors in `mysqld`

Note that before starting `mysqld` with the general query log enabled, you should check all your tables with `myisamchk`. See [Chapter 5, MySQL Server Administration](#).

If `mysqld` dies or hangs, you should start `mysqld` with the general query log enabled. See [Section 5.2.3, “The General Query Log”](#). When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you use the default general query log file, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that didn't complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See [Section 13.8.2, “EXPLAIN Syntax”](#).

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See [Section 5.2.5, “The Slow Query Log”](#).

If you find the text `mysqld restarted` in the error log file (normally named `hostname.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see [Chapter 5, MySQL Server Administration](#)), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this doesn't help and you can't find anything in the `mysql` mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at <http://lists.mysql.com/>, which also has links to online list archives.

If you have started `mysqld` with `--myisam-recover-options` [432], MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file `'Warning: Checking table ...'` which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See [Section 5.1.3, “Server Command Options”](#).

In MySQL 5.6, when the server detects `MyISAM` table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: `Got an error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in bug reports.

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the `Checking table...` messages, but instead try to find out why `mysqld` died.

### 22.4.1.7. Making a Test Case If You Experience Table Corruption

If you get corrupted tables or if `mysqld` always fails after some update commands, you can test whether this bug is reproducible by doing the following:

- Take down the MySQL daemon (with `mysqladmin shutdown`).
- Make a backup of the tables (to guard against the very unlikely case that the repair does something bad).
- Check all tables with `myisamchk -s database/*.MYI`. Repair any wrong tables with `myisamchk -r database/table.MYI`.
- Make a second backup of the tables.
- Remove (or move away) any old log files from the MySQL data directory if you need more space.
- Start `mysqld` with the binary log enabled. If you want to find a query that crashes `mysqld`, you should start the server with both the general query log enabled as well. See [Section 5.2.3, “The General Query Log”](#), and [Section 5.2.4, “The Binary Log”](#).
- When you have gotten a crashed table, stop the `mysqld server`.

- Restore the backup.
- Restart the `mysqld` server **without** the binary log enabled.
- Re-execute the commands with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNN`.
- If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found a reproducible bug that should be easy to fix! FTP the tables and the binary log to our bugs database using the instructions given in [Section 1.7, "How to Report Bugs or Problems"](#). If you are a support customer, you can use the MySQL Customer Support Center <https://support.mysql.com/> to alert the MySQL team about the problem and have it fixed as soon as possible.

You can also use the script `mysql_find_rows` to just execute some of the update statements if you want to narrow down the problem.

## 22.4.2. Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `-DWITH_DEBUG=1` [136]. See [Section 2.9.4, "MySQL Source-Configuration Options"](#).

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See [Section 1.7, "How to Report Bugs or Problems"](#).

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

## 22.4.3. The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is debugging. See [Section 22.4.1.2, "Creating Trace Files"](#).

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `debug` directory of MySQL source distributions. It is best to use a recent distribution to get the most updated DBUG manual.

You use the debug package by invoking a program with the `--debug="..."` or the `-#...` option.

Most MySQL programs have a default debug string that is used if you don't specify an option to `--debug`. The default trace file is usually `/tmp/program_name.trace` on Unix and `\program_name.trace` on Windows.

The debug control string is a sequence of colon-separated fields as follows:

```
<field_1>:<field_2>:...:<field_N>
```

Each field consists of a mandatory flag character followed by an optional “,” and comma-separated list of modifiers:

```
flag[,modifier,modifier,...,modifier]
```

The following table shows the currently recognized flag characters.

Flag	Description
d	Enable output from <code>DEBUG_&lt;N&gt;</code> macros for the current state. May be followed by a list of keywords which selects output only for the <code>DEBUG</code> macros with that keyword. An empty list of keywords implies output for all macros.
D	Delay after each debugger output line. The argument is the number of tenths of seconds to delay, subject to machine capabilities. For example, <code>-#D,20</code> specifies a delay of two seconds.
f	Limit debugging, tracing, and profiling to the list of named functions. Note that a null list disables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.
F	Identify the source file name for each line of debug or trace output.
i	Identify the process with the PID or thread ID for each line of debug or trace output.
g	Enable profiling. Create a file called <code>ddebugmon.out</code> containing information that can be used to profile the program. May be followed by a list of keywords that select profiling only for the functions in that list. A null list implies that all functions are considered.
L	Identify the source file line number for each line of debug or trace output.
n	Print the current function nesting depth for each line of debug or trace output.
N	Number each line of debug output.
o	Redirect the debugger output stream to the specified file. The default output is <code>stderr</code> .
O	Like <code>o</code> , but the file is really flushed between each write. When needed, the file is closed and reopened between each write.
p	Limit debugger actions to specified processes. A process must be identified with the <code>DEBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.
P	Print the current process name for each line of debug or trace output.
r	When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.
S	Do function <code>_sanity(_file_,_line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0.
t	Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.

Some examples of debug control strings that might appear on a shell command line (the `-#` is typically used to introduce a control string to an application program) are:

```
-#d:t
-#d:f,main,subr1:F:L:t,20
-#d,input,output,files:n
-#d:t:i:0,\\mysqld.trace
```

In MySQL, common tags to print (with the `d` option) are `enter`, `exit`, `error`, `warning`, `info`, and `loop`.

---

## Chapter 23. MySQL Enterprise Edition

### Table of Contents

23.1. MySQL Enterprise Monitor .....	3553
23.2. MySQL Enterprise Backup .....	3554
23.3. MySQL Enterprise Security .....	3554
23.4. MySQL Enterprise Audit .....	3555
23.5. MySQL Thread Pool .....	3555

MySQL Enterprise Edition is a commercial product. Like MySQL Community Edition, MySQL Enterprise Edition includes MySQL Server, a fully integrated transaction-safe, ACID-compliant database with full commit, rollback, crash-recovery, and row-level locking capabilities. In addition, MySQL Enterprise Edition includes the following components designed to provide monitoring and online backup, as well as improved security and scalability:

The following sections briefly discuss each of these components and indicate where to find more detailed information. To learn more about commercial products, see <http://www.mysql.com/products/>.

- [MySQL Enterprise Monitor](#)
- [MySQL Enterprise Backup](#)
- [MySQL Enterprise Security](#)
- [MySQL Enterprise Audit](#)
- [MySQL Thread Pool](#)

### 23.1. MySQL Enterprise Monitor

MySQL Enterprise Monitor is an enterprise monitoring system for MySQL that keeps an eye on your MySQL servers, notifies you of potential issues and problems, and advises you how to fix the issues. MySQL Enterprise Monitor can monitor all kinds of configurations, from a single MySQL server that is important to your business, all the way up to a huge farm of MySQL servers powering a busy web site.

The following discussion briefly summarizes the basic components that make up the MySQL Enterprise Monitor product. For more information, see the MySQL Enterprise Monitor manual, available at <http://dev.mysql.com/doc/mysql-monitor/en/>.

MySQL Enterprise Monitor components can be installed in various configurations depending on your database and network topology, to give you the best combination of reliable and responsive monitoring data, with minimal overhead on the database server machines. A typical MySQL Enterprise Monitor installation consists of:

- One or more MySQL servers to monitor. MySQL Enterprise Monitor can monitor both Community and Enterprise MySQL server releases.
- A MySQL Enterprise Agent for each monitored MySQL server.
- A single MySQL Enterprise Service Manager, which collates information from the agents and provides the user interface to the collected data.

MySQL Enterprise Monitor is designed to monitor one or more MySQL servers. The monitoring information is collected by using an agent, *MySQL Enterprise Agent*. The agent communicates with the MySQL server that it monitors, collecting variables, status and health information, and sending this information to the MySQL Enterprise Service Manager. If you have multiple MySQL servers, then you have multiple MySQL Enterprise Agent processes monitoring each MySQL server.

The information collected by the agent about each MySQL server you are monitoring is sent to the *MySQL Enterprise Service Manager*. This server collates all of the information from the agents. As it collates the information sent by the agents, the MySQL Enterprise Service Manager continually tests the collected data, comparing the status of the server to reasonable values. When thresholds are reached, the server can trigger an event (including an alarm and notification) to highlight a potential issue, such as low memory, high CPU usage, or more complex conditions such as insufficient buffer sizes and status information. We call each test, with its associated threshold value, a *rule*.

These rules, and the alarms and notifications, are each known as a *MySQL Enterprise Advisor*. Advisors form a critical part of the MySQL Enterprise Service Manager, as they provide warning information and troubleshooting advice about potential problems.

The MySQL Enterprise Service Manager includes a web server, and you interact with it through any web browser. This interface, the MySQL Enterprise Dashboard, displays all of the information collected by the agents, and lets you view all of your servers and their current status as a group or individually. You control and configure all aspects of the service using the MySQL Enterprise Dashboard.

The information supplied by the MySQL Enterprise Agent processes also includes statistical and query information, which you can view in the form of graphs. For example, you can view aspects such as server load, query numbers, or index usage information as a graph over time. The graph lets you pinpoint problems or potential issues on your server, and can help diagnose the impact from database or external problems (such as external system or network failure) by examining the data from a specific time interval.

The MySQL Enterprise Agent can also be configured to collect detailed information about the queries executed on your server, including the row counts and performance times for executing each query. You can correlate the detailed query data with the graphical information to identify which queries were executing when you experienced a particularly high load, index or other issue. The query data is supported by a system called Query Analyzer, and the data can be presented in different ways depending on your needs.

## 23.2. MySQL Enterprise Backup

MySQL Enterprise Backup performs hot backup operations for MySQL databases. The product is architected for efficient and reliable backups of tables created by the InnoDB storage engine. For completeness, it can also back up tables from MyISAM and other storage engines.

The following discussion briefly summarizes MySQL Enterprise Backup. For more information, see the MySQL Enterprise Backup manual, available at <http://dev.mysql.com/doc/mysql-enterprise-backup/en/>.

Hot backups are performed while the database is running and applications are reading and writing to it. This type of backup does not block normal database operations, and it captures even changes that occur while the backup is happening. For these reasons, hot backups are desirable when your database “grows up” -- when the data is large enough that the backup takes significant time, and when your data is important enough to your business that you must capture every last change, without taking your application, web site, or web service offline.

MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. For efficient backup operations, you can designate InnoDB as the default storage engine for new tables, or convert existing tables to use the InnoDB storage engine.

## 23.3. MySQL Enterprise Security

MySQL Enterprise Edition provides plugins that implement authentication using external services:

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a

standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory.

- MySQL Enterprise Edition includes an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

For more information, see [Section 6.3.7.3, “The PAM Authentication Plugin”](#), and [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).

## 23.4. MySQL Enterprise Audit

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

For more information, see [Section 6.3.11, “MySQL Enterprise Audit Log Plugin”](#).

## 23.5. MySQL Thread Pool

MySQL Enterprise Edition includes the MySQL Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. In MySQL Enterprise Edition, a thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

For more information, see [Section 8.11.6, “The Thread Pool Plugin”](#).

---

## Chapter 24. MySQL Workbench

MySQL Workbench provides a graphical tool for working with MySQL Servers and databases. MySQL Workbench fully supports MySQL Server versions 5.1 and above. It is also compatible with MySQL Server 5.0, but not every feature of 5.0 may be supported. It does not support MySQL Server versions 4.x.

The following discussion briefly describes MySQL Workbench capabilities. For more information, see the MySQL Workbench manual, available at <http://dev.mysql.com/doc/workbench/en/>.

MySQL Workbench provides three main areas of functionality:

- **SQL Development:** Enables you to create and manage connections to database servers. As well as enabling you to configure connection parameters, MySQL Workbench provides the capability to execute SQL queries on the database connections using the built-in SQL Editor. This functionality replaces that previously provided by the Query Browser standalone application.
- **Data Modeling:** Enables you to create models of your database schema graphically, reverse and forward engineer between a schema and a live database, and edit all aspects of your database using the comprehensive Table Editor. The Table Editor provides easy-to-use facilities for editing Tables, Columns, Indexes, Triggers, Partitioning, Options, Inserts and Privileges, Routines and Views.
- **Server Administration:** Enables you to create and administer server instances. This functionality replaces that previously provided by the MySQL Administrator standalone application.

MySQL Workbench is available in two editions, the Community Edition and the Standard Edition. The Community Edition is available free of charge. The Standard Edition provides additional Enterprise features, such as database documentation generation, at low cost.

# Chapter 25. MySQL for Excel

## Table of Contents

25.1. Installing and Configuring .....	3559
25.2. Edit MySQL Data .....	3560
25.3. Import MySQL Data .....	3561
25.4. Append MySQL Data .....	3562
25.5. Export MySQL Data .....	3565
25.6. MySQL for Excel FAQ .....	3568

MySQL for Excel enables you to work with a MySQL database from within Microsoft Excel. MySQL data can be imported into Excel, Excel data can be exported into MySQL as a new table or appended to a current table, and MySQL for Excel enables you to edit the MySQL data directly from within Excel.

Visit the [MySQL for Excel forum](#) for additional MySQL for Excel help and support.

For release notes detailing the changes in each release of MySQL for Excel, see [MySQL for Excel Release Notes](#).

## 25.1. Installing and Configuring

MySQL for Excel is a product for Microsoft Windows, and it is installed with MySQL Installer. And typically you will not be required to install or configure additional tools to use MySQL for Excel.

### Note

To install, download and execute the [MySQL Installer](#). Select the MySQL for Excel product and then proceed with the installation. See the [MySQL Installer manual](#) for additional details.

## MySQL for Excel Requirements

The MySQL Installer installation process will check if these requirements are met, or notify you if further action is required before proceeding with the installation.

- .NET Framework 4.0 (Client or Full Profile).
- Microsoft Office Excel 2007 or greater, for Microsoft Windows.
- Visual Studio Tools for Office 4.0, and MySQL Installer may install this for you.
- An available MySQL Server connection.

MySQL for Excel is loaded and executed by selecting the **Data** menu tab in Excel, and then choosing the "MySQL for Excel" Database icon. This opens a new Excel sidebar with the available MySQL for Excel options. The navigation bar with the MySQL for Excel icon is shown in the following screenshot:

Figure 25.1. The MySQL for Excel navigation bar

## 25.2. Edit MySQL Data

MySQL for Excel enables you to load and edit MySQL data directly from Microsoft Excel. Changes are immediately committed if the **Auto-Commit** option is enabled, or done manually by pressing **Commit Changes**.

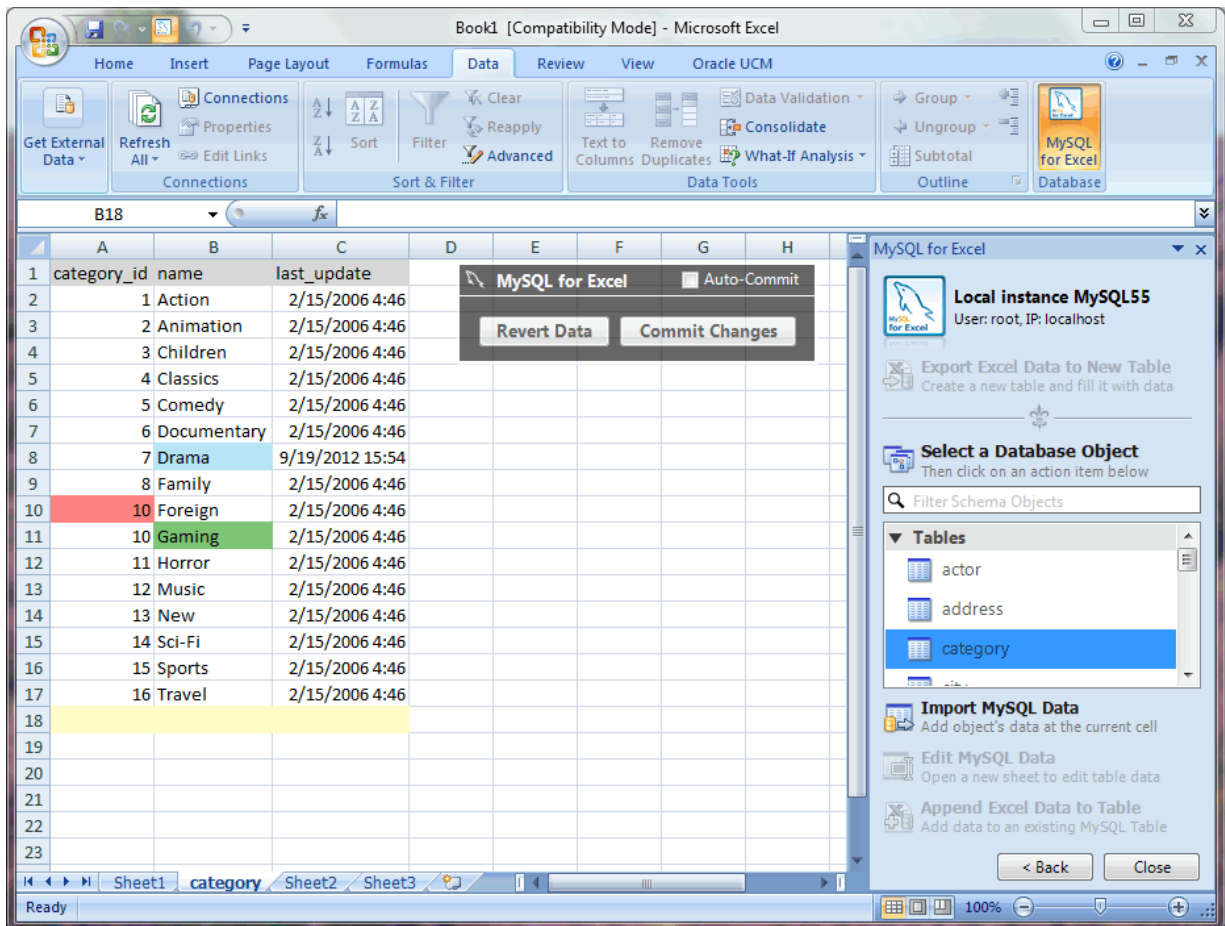

**Note**

The **Edit MySQL Data** feature exists as of MySQL for Excel 1.1.0.

The example below uses the `category` table of the example `sakila` database, but the screen will look the same for any table. Within MySQL for Excel, **Open a MySQL Connection**, click the `sakila` schema, **Next**, select the `category` table, click **Edit MySQL Data**, then choose **Import** to import the data into a new Microsoft Excel worksheet for editing.

**Figure 25.2. Editing table data with MySQL for Excel**

The background color represents the status of each cell, and there are four distinct colors that are used while editing table data:

**Table 25.1. Background cell colors**

Color	Description
White	Default color for all cells. This is either the original data, or the data after <b>Refresh from DB</b> is clicked.
Blue	Cells that were committed with success.

Color	Description
Green	Cells that were modified but have not yet been committed.
Red	Cells that generated an error when a commit was attempted. An error dialog is also displayed while the commit is attempted.
Yellow	Cells that accept new data. Data entered here is inserted into the MySQL table.

In our example, the blue "Drama" field was changed and then committed first, then the green "Gaming" field was changed but not committed, and then **Auto-Commit** was enabled before changing the "9" to a "10" in column 10, which generated an error because this commit would have added a duplicate value as primary key.

## 25.3. Import MySQL Data

Data can be imported from MySQL into a Microsoft Excel spreadsheet by using the **Import MySQL Data** option after selecting either a table, view, or procedure to import.

### Choosing columns to import

By default, all columns are selected and will be imported. Specific columns may be selected (or unselected) using the standard Microsoft Windows method of either **Control + Mouse click** to toggle the selection of individual columns, or **Shift + Mouse click** to select a range of columns.

The background color of a column shows the status of each column. The color white means that the column has been selected, and therefore it will be imported. Conversely, a gray background means that the column will not be imported.

Right-clicking anywhere in the preview grid opens a context-menu with either a **Select None** or **Select All** option, depending on the current status.

### Importing a table

The dialog while importing a table includes the following options:

- **Include Column Names as Headers**: Enabled by default, this inserts the column names at the top of the Microsoft Excel spreadsheet as a "headers" row.
- **Limit to \_\_\_ Rows and Start with Row \_\_\_**: Disabled by default, this limits the range of imported data. The **Limit to** option defaults to 1, and defines the number of rows to import. The **Start with Row** option defaults to 1 (the first row), and defines where the import begins. Each option has a maximum value of COUNT(rows) in the table.

Importing a table displays a dialog similar to the following:

**Figure 25.3. Importing table data with MySQL for Excel**

### Importing a view or procedure

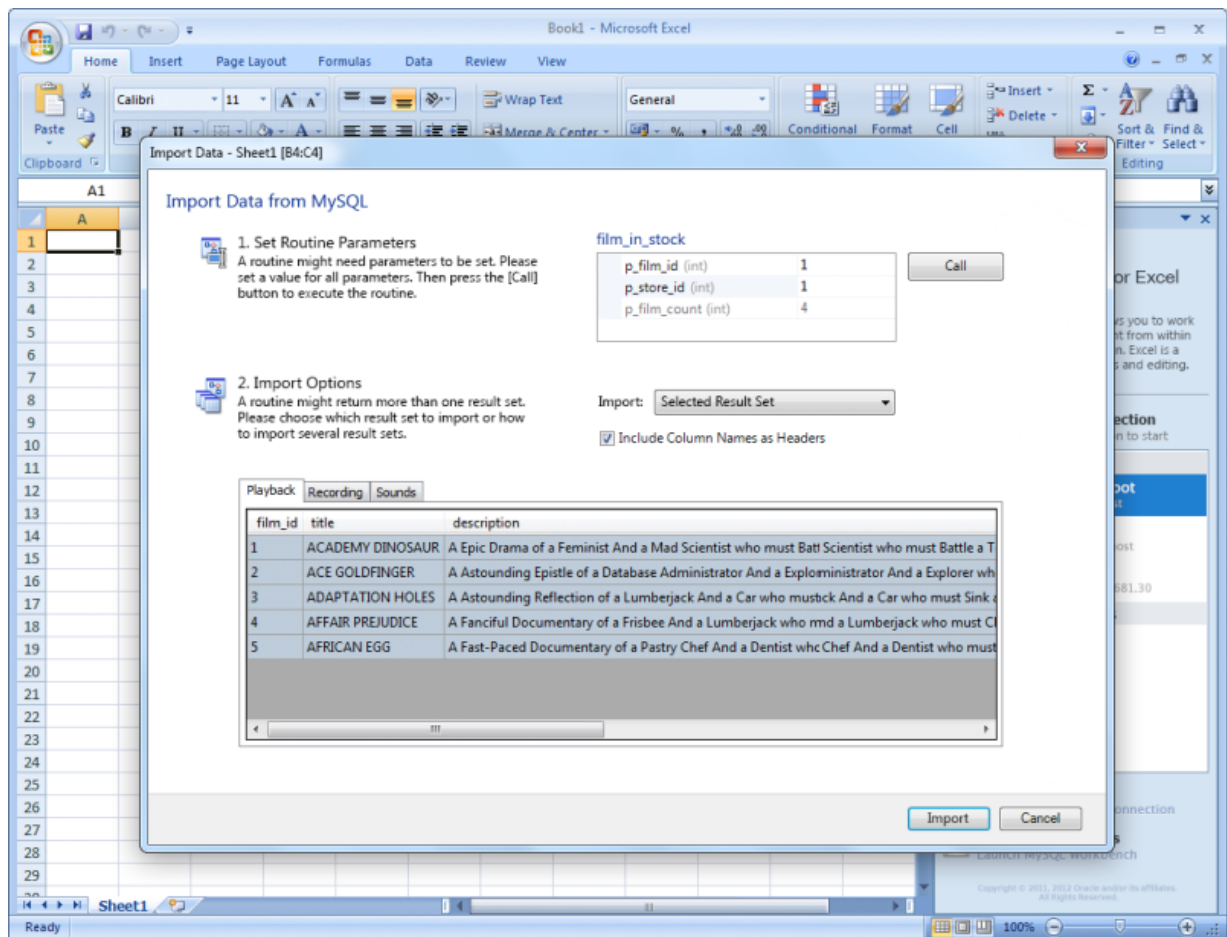

Importing a view or procedure displays a similar dialogue, but with the following options:

- **Include Column Names as Headers**: Enabled by default, this will insert the column names at the top of the Excel spreadsheet as a "headers" row.
- **Import**: Because a procedure might return multiple result sets, the import options include:
  - **Selected Result Set**: Imports the selected tab sheet. This is the default behavior.

- **All Result Sets - Arranged Horizontally:** Imports all result sets into the Excel Worksheet horizontally, and inserts one empty column between each result set.
- **All Result Sets - Arranged Vertically:** Imports all result sets into the Excel Worksheet vertically, and inserts one empty row between each result set.

For example, a dialogue like the following is displayed after importing a procedure and pressing the **Call** button to invoke the stored procedure:

**Figure 25.4. Importing called stored procedure data with MySQL for Excel**

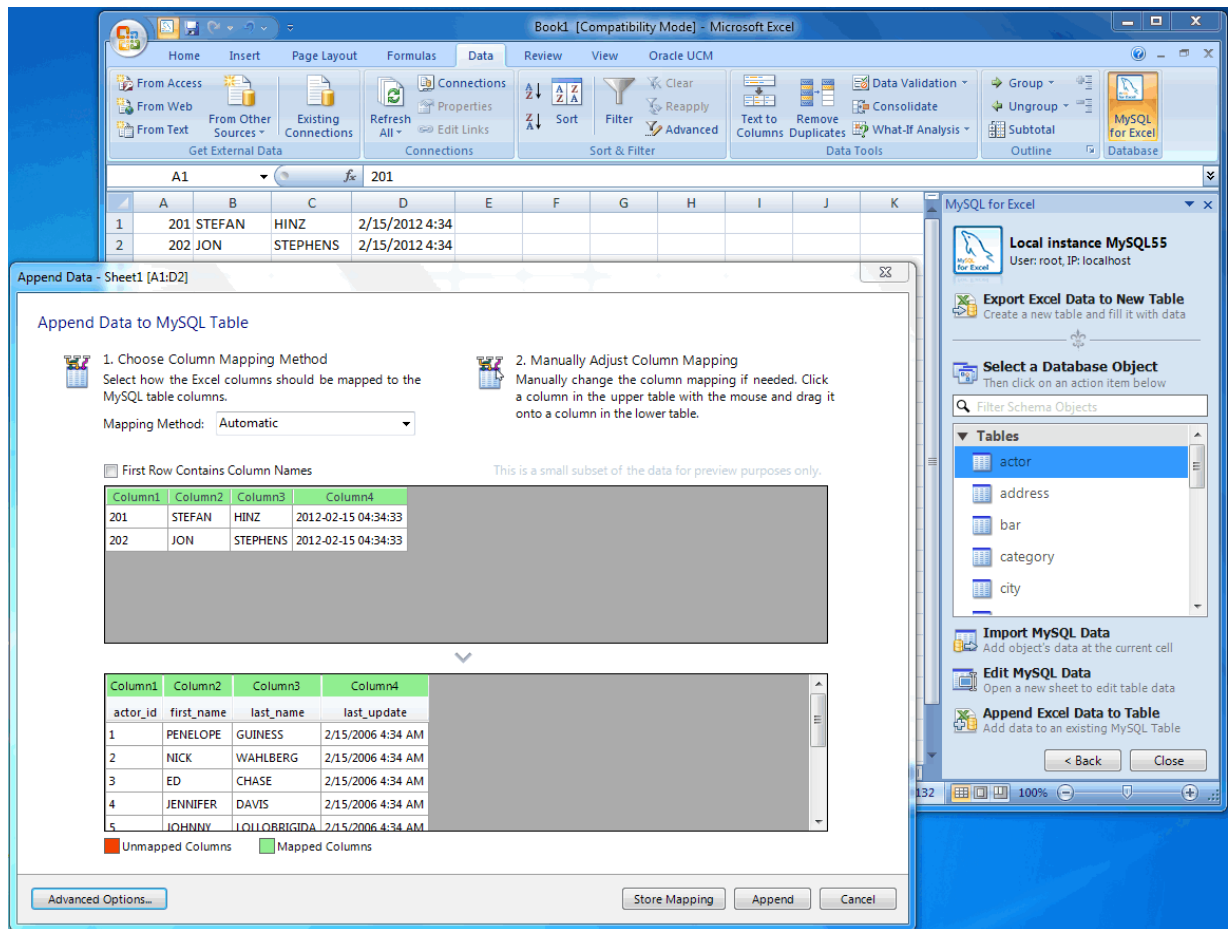

## 25.4. Append MySQL Data

Data from a Microsoft Excel spreadsheet can be appended to a MySQL database table by using the **Append Excel MySQL Data to Table** option.

### Column mappings

Mapping the Excel columns to the MySQL columns can be executed automatically (default), manually, or by using a stored mapping routine. An automatic mapping routine is the default, and can be can be tweaked if every column cannot be matched automatically. The following screenshot shows two columns of Excel data, and the preview dialog after choosing **Append Excel Data to Table**:

Figure 25.5. Appending Excel data to MySQL (Automatic mapping)

## General mapping information

It is common to tweak the column mappings. A few notes about the manual mapping process:

- Manual mapping is performed by dragging a column from the upper source grid (Excel spreadsheet) and dropping it into the lower target column MySQL table grid. Click anywhere within the column to initiate this dragging routine.
- The color of the header field for each column defines the current mapping status of the column. The colors include:
  - Green: A source column is mapped to a target column.
  - Red: A target column is not mapped.
  - Gray: A source column is not mapped.
- A source column may be mapped to multiple target columns, although this action generates a warning dialog.
- Right-clicking a target column shows a context menu with options to either **Remove Column Mapping** for a single column, or **Clear All Mappings** for all columns. Dragging a target column outside of the grid removes the mapping.

## Mapping methods

The three mapping methods are described below:

- **Automatic:** The automatic mapping method attempts to match the Excel source column names with the MySQL target table column names. It is then possible to manually tweak the mapping afterwards.

If the automatic process finds zero columns to match, then a simple 1 to 1 matching routine is attempted. Meaning, SourceColumn #1 to TargetColumn #1, SourceColumn #2 to TargetColumn #2, and so on.

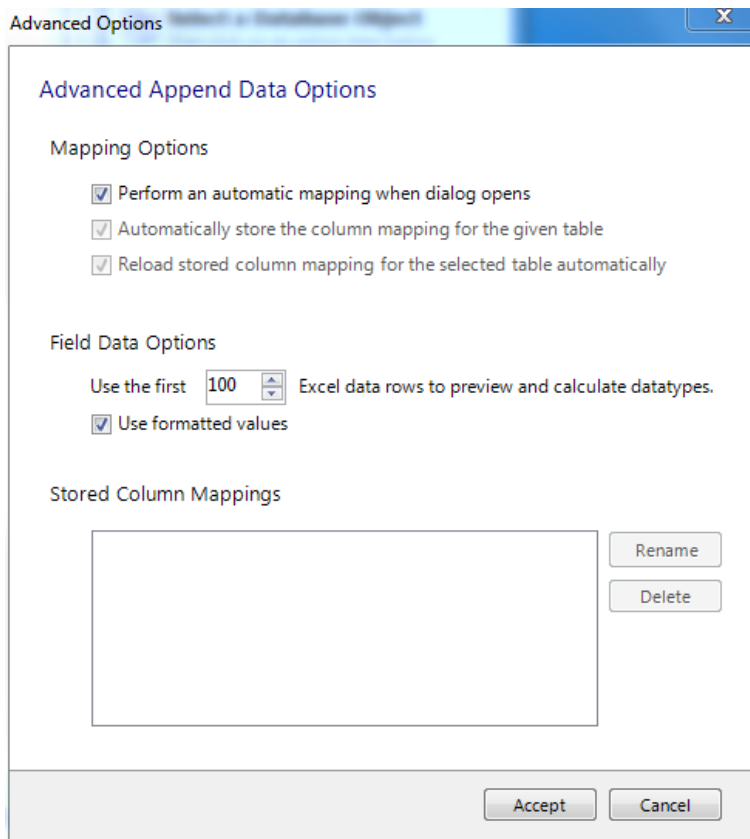

- **Manual:** The source column names are manually dragged (matched) with the target column names. Manual dragging can also be performed after the **Automatic** method is selected.
- **Stored:** Manual mapping styles may be saved using the **Store Mapping** button, which will also prompt for a name and then save it using a "*name* (dbname.tablename)" naming scheme. The saved mapping style will then be available alongside the **Automatic** and **Manual** options.

Stored mappings may be deleted or renamed within the **Advanced Options** dialog.

## Advanced Options

There are several advanced options that are configured and stored between sessions for each Excel user. The dialog looks similar to:

**Figure 25.6. Appending Excel data to MySQL (Advanced Options)**

The advanced **Mapping Options**:

- **Perform an automatic mapping when dialog opens:** Automatically attempt to map the target and source when the **Append Data** dialog is opened. This feature is enabled by default.
- **Automatically store the column mapping for the given table:** Stores each mapping routine after executing the **Append** operation. The mapping routine is saved using the "tablenameMapping (dbname.tablename)" format. This may also be performed manually using the **Store Mapping** button. It is enabled by default, and this feature was added in MySQL for Excel 1.1.0.

- **Reload stored column mapping for the selected table automatically:** If a stored mapping routine exists that matches all column names in the source grid with the target grid, then it is automatically be loaded. This is enabled by default, and this feature was added in MySQL for Excel 1.1.0.

The advanced **Field Data Options:**

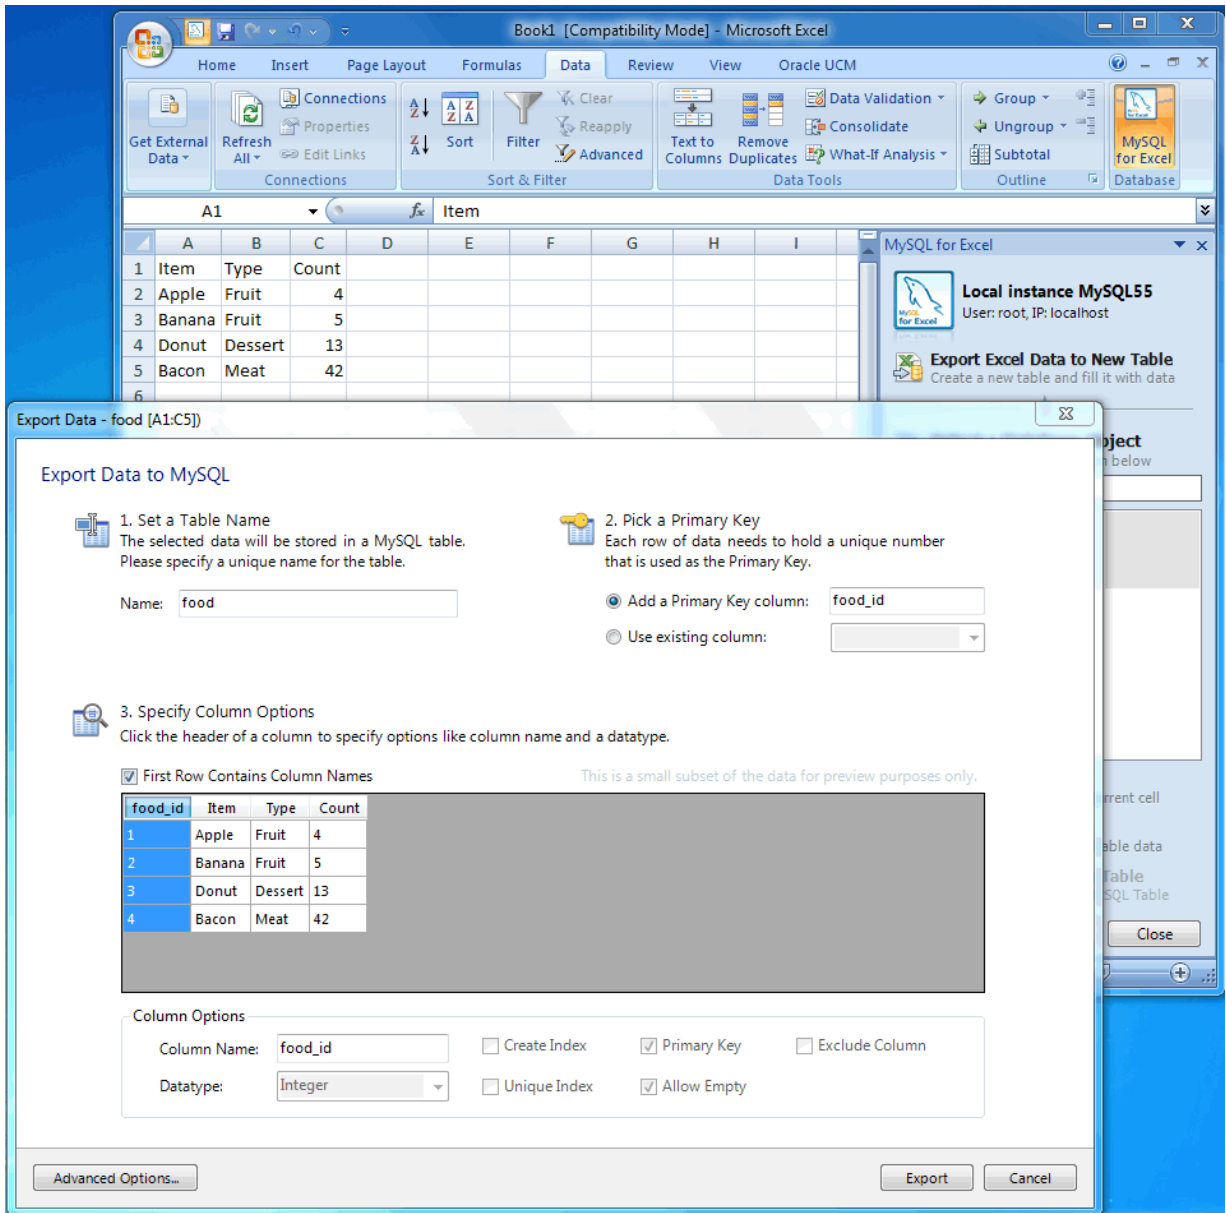

- **Use the first 100** (default) Excel data rows to preview and calculate data types. This determines the number of rows that the preview displays, and the values that affect the automatic mapping feature.
- **Use formatted values:** The data from Excel is treated as **Text**, **Double**, or **Date**. This is enabled by default. When disabled, data is never treated as a **Date** type, so for example, this means that a date would be represented as a number.

The **Stored Column Mappings** is a list of saved column mappings that were saved with with the "Automatically store the column mapping for the given table" feature, or manually with the **Store Mapping** option.

## 25.5. Export MySQL Data

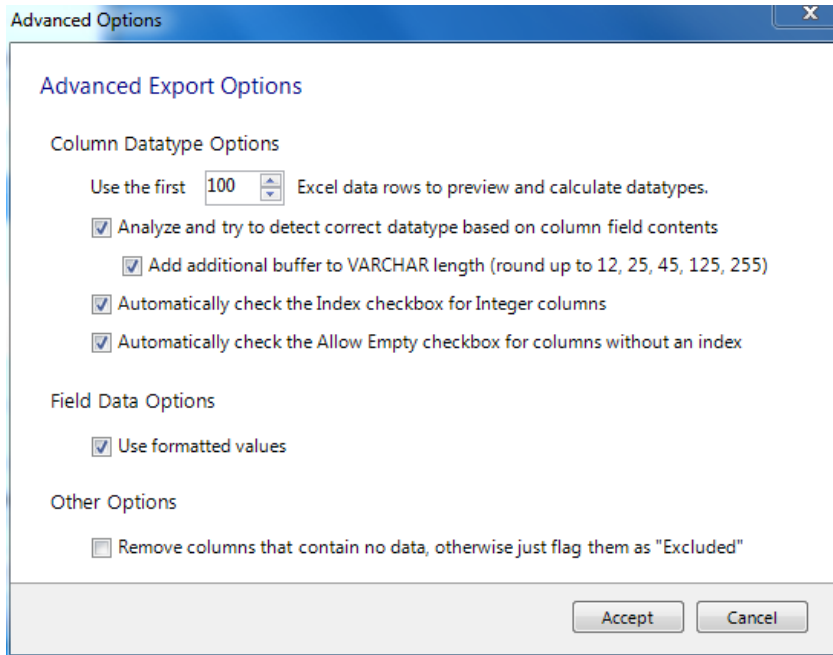

Data from a Microsoft Excel spreadsheet can be exported to a new MySQL database table by using the **Export Excel Data to New Table** option. Exporting data looks like so:

Figure 25.7. Exporting Excel data to MySQL

## Advanced Export options

Several advanced options enables you to tweak the exported data. The advanced options dialog looks like so:

**Figure 25.8. Exporting Excel data to MySQL (Advanced options)**

- **Column Datatype Options:**

- Use the first `100` (default) Excel data rows to preview and calculate data types: This determines the number of rows that the preview displays, and the values that affect the automatic mapping feature.
- Analyze and try to detect correct datatype based on column field contents: Attempts to analyze the data and determine the data type for the column. The column type is defined as `VARCHAR` if it contains multiple types.
- Add additional buffer to `VARCHAR` length (round up to 12, 25, 45, 125, 255): When the data type is automatically detected and is set to `VARCHAR`, then it calculates the maximum length for all rows within the column, and rounds up the maximum length to one of the defined lengths above.

If disabled, then the `VARCHAR` length is set to the length of the longest entry in the Excel spreadsheet.

- Automatically check the Index checkbox for Integer columns: If enabled (default), columns with an Integer data type will have the **Create Index** option enabled by default.
- Automatically check the Allow Empty checkbox for columns without an index: If enabled (default), columns without the **Create Index** checkbox checked will automatically enable the **Allow Empty** configuration option.

- **Field Data options:**

- Use formatted values: When enabled (default), the data from Excel is treated as `Text`, `Double`, or `Date`. When disabled, data is never treated as a `Date` type, so for example this means that a date would be represented as a number.

- **Other options:**

- Remove columns that contain no data, otherwise flag them as "Excluded": If enabled, columns without data in Excel are removed and not shown in the preview panel. If disabled (default), these columns will exist but have the **Exclude Column** option checked. This option was added in MySQL for Excel 1.1.0.

## 25.6. MySQL for Excel FAQ

Frequently Asked Questions, with Answers.

### Questions

- [26.6.1: \[3568\]](#) I installed the MySQL for Excel plugin, but can't find it in Microsoft Excel. How do I start it?

### Questions and Answers

**26.6.1: I installed the MySQL for Excel plugin, but can't find it in Microsoft Excel. How do I start it?**

The MySQL for Excel plugin is automatically added to Microsoft Excel's data menu when it is installed. Look for the MySQL for Excel icon, by default it will be listed on the right side of the main menu.

If it's not there, then you might have to reinstall the plugin. But before doing so, first check if it's listed under "Add/Remove Programs" in Microsoft Windows. If not, then it has not been installed. Next, check the Excel Add-Ins list. For Office 2007 this is found by clicking the Office logo in Excel (top left corner), click **Excel Options**, then select **Add-Ins**. Is MySQL for Excel listed as a COM Add-in? If so, then consider filing a bug report ([bugs.mysql.com](http://bugs.mysql.com)), or attempt to reinstall the plugin.

Licensed under the Apache 1.1 License Agreement, a copy of which is reproduced below.

The Apache Software License, Version 1.1

Copyright (c) 2001-2003 Ant-Contrib project. All rights reserved.

Redistribution and use in source and binary forms, with or without
modification, are permitted provided that the following conditions
are met:

1. Redistributions of source code must retain the above copyright
notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright
notice, this list of conditions and the following disclaimer in
the documentation and/or other materials provided with the
distribution.

3. The end-user documentation included with the redistribution, if
any, must include the following acknowledgement:
   "This product includes software developed by the
   Ant-Contrib project (http://sourceforge.net/projects/ant-contrib)."
   Alternately, this acknowledgement may appear in the software itself,
   if and wherever such third-party acknowledgements normally appear.

4. The name Ant-Contrib must not be used to endorse or promote
products derived from this software without prior written
permission. For written permission, please contact
ant-contrib-developers@lists.sourceforge.net.

5. Products derived from this software may not be called "Ant-Contrib"
nor may "Ant-Contrib" appear in their names without prior written
permission of the Ant-Contrib project.

THIS SOFTWARE IS PROVIDED ``AS IS'' AND ANY EXPRESSED OR IMPLIED
WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES

## A.3. Boost Library License

The following software may be included in this product:

### Boost C++ Libraries

Use of any of this software is governed by the terms of the license below:

Boost Software License - Version 1.0 - August 17th, 2003

Permission is hereby granted, free of charge, to any person or organization obtaining a copy of the software and accompanying documentation covered by this license (the "Software") to use, reproduce, display, distribute, execute, and transmit the Software, and to prepare derivative works of the Software, and to permit third-parties to whom the Software is furnished to do so, all subject to the following:

The copyright notices in the Software and this entire statement, including the above license grant, this restriction and the following disclaimer, must be included in all copies of the Software, in whole or in part, and all derivative works of the Software, unless such copies or derivative works are solely in the form of machine-executable object code generated by a source language processor.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE AND

```
NON-INFRINGEMENT. IN NO EVENT SHALL THE COPYRIGHT HOLDERS OR ANYONE
DISTRIBUTING THE SOFTWARE BE LIABLE FOR ANY DAMAGES OR OTHER
LIABILITY, WHETHER IN CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT
OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS
IN THE SOFTWARE.
```

## A.4. c3p0 JDBC Library License

You are receiving a copy of `c3p0-0.9.1-pre6.jar` in both source and object code in the following `/src/lib/c3p0-0.9.1-pre6.jar`. The terms of the Oracle license do NOT apply to `c3p0-0.9.1-pre6.jar`; it is licensed under the following license, separately from the Oracle programs you receive. If you do not wish to install this library, you may remove the file `/src/lib/c3p0-0.9.1-pre6.jar`, but the Oracle program might not operate properly or at all without the library.

This component is licensed under [Section A.15, "GNU Lesser General Public License Version 2.1, February 1999"](#).

## A.10. Fred Fish's Dbug Library License

The following software may be included in this product:

Fred Fish's Dbug Library

### N O T I C E

Copyright Abandoned, 1987, Fred Fish

This previously copyrighted work has been placed into the public domain by the author and may be freely used for any purpose, private or commercial.

Because of the number of inquiries I was receiving about the use of this product in commercially developed works I have decided to simply make it public domain to further its unrestricted use. I specifically would be most happy to see this material become a part of the standard Unix distributions by AT&T and the Berkeley Computer Science Research Group, and a standard part of the GNU system from the Free Software Foundation.

I would appreciate it, as a courtesy, if this notice is left in all copies and derivative works. Thank you.

The author makes no warranty of any kind with respect to this product and explicitly disclaims any implied warranties of mer-

chantability or fitness for any particular purpose.

The `debug_analyze.c` file is subject to the following notice:

Copyright June 1987, Binayak Banerjee  
All rights reserved.

This program may be freely distributed under the same terms and conditions as Fred Fish's Dbug package.

## A.11. getarg License

The following software may be included in this product:

`getarg` Function (`getarg.h`, `getarg.c` files)

Copyright (c) 1997 - 2000 Kungliga Tekniska Högskolan  
(Royal Institute of Technology, Stockholm, Sweden).  
All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. Neither the name of the Institute nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE INSTITUTE AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE INSTITUTE OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

## A.12. GLib License (for MySQL Proxy)

The following software may be included in this product:

GLib

You are receiving a copy of the GLib library in both source and object code in the following `[proxy install dir]/lib/` and `[proxy install dir]/licenses/lgpl` folders. The terms of the Oracle license do NOT apply to the GLib library; it is licensed under the following license, separately from the Oracle programs you receive. If you do not wish to install this library, you may create an "exclude" file and run tar with the X option, as in the following example, but the Oracle program might not operate properly or at all without the library:

```
tar -xvfX <package-tar-file> <exclude-file>
where the exclude-file contains, e.g.:
<package-name>/lib/libglib-2.0.so.0.1600.6
<package-name>/lib/libglib-2.0.so.0
...
```

```
Example:
tar -xvfX mysql-proxy-0.8.1-solaris10-x86-64bit.tar.gz Exclude

Exclude File:
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libglib-2.0.so
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libglib-2.0.so.0
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libglib-2.0.so.0.1600.6
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libgmodule-2.0.so
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libgmodule-2.0.so.0
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libgmodule-2.0.so.0.1600.6
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libgthread-2.0.so
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libgthread-2.0.so.0
mysql-proxy-0.8.1-solaris10-x86-64bit/lib/libgthread-2.0.so.0.1600.6
mysql-proxy-0.8.1-solaris10-x86-64bit/licenses/lgpl/glib-2.16.6.tar.gz
```

allowed.

### Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Lesser General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

GNU GENERAL PUBLIC LICENSE  
TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but

does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

- a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
- b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
- c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or

distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we

sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

<one line to give the program's name and a brief idea of what it does.>

Copyright (C) <year> <name of author>

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

Gnomovision version 69, Copyright (C) year name of author  
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details  
type 'show w'. This is free software, and you are welcome  
to redistribute it under certain conditions; type 'show c'  
for details.

The hypothetical commands 'show w' and 'show c' should show the appropriate parts of the General Public License. Of course, the

commands you use may be called something other than 'show w' and 'show c'; they could even be mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

```
Yoyodyne, Inc., hereby disclaims all copyright interest in the
program 'Gnomovision' (which makes passes at compilers) written
by James Hacker.
```

```
<signature of Ty Coon>, 1 April 1989
Ty Coon, President of Vice
```

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Lesser General Public License instead of this License.

## A.14. GNU General Public License Version 3.0, 29 June 2007 and GCC Runtime Library Exception Version 3.1, 31 March 2009

### GNU GENERAL PUBLIC LICENSE Version 3, 29 June 2007

Copyright (C) 2007 Free Software Foundation, Inc. <<http://fsf.org/>>  
Everyone is permitted to copy and distribute verbatim copies of  
this license document, but changing it is not allowed.

#### Preamble

The GNU General Public License is a free, copyleft license for software and other kinds of works.

The licenses for most software and other practical works are designed to take away your freedom to share and change the works. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change all versions of a program--to make sure it remains free software for all its users. We, the Free Software Foundation, use the GNU General Public License for most of our software; it applies also to any other work released this way by its authors. You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for them if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs, and that you know you can do these things.

To protect your rights, we need to prevent others from denying you these rights or asking you to surrender the rights. Therefore, you have certain responsibilities if you distribute copies of the software, or if you modify it: responsibilities to respect the freedom of others.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must pass on to the recipients the same freedoms that you received. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

Developers that use the GNU GPL protect your rights with two steps: (1) assert copyright on the software, and (2) offer you this License giving you legal permission to copy, distribute and/or modify it.

For the developers' and authors' protection, the GPL clearly explains that there is no warranty for this free software. For both users' and authors' sake, the GPL requires that modified versions be marked as changed, so that their problems will not be attributed erroneously to authors of previous versions.

Some devices are designed to deny users access to install or run modified versions of the software inside them, although the manufacturer can do so. This is fundamentally incompatible with the aim of protecting users' freedom to change the software. The systematic pattern of such abuse occurs in the area of products for individuals to use, which is precisely where it is most unacceptable. Therefore, we have designed this version of the GPL to prohibit the practice for those products. If such problems arise substantially in other domains, we stand ready to extend this provision to those domains in future versions of the GPL, as needed to protect the freedom of users.

Finally, every program is threatened constantly by software patents. States should not allow patents to restrict development and use of software on general-purpose computers, but in those that do, we wish to avoid the special danger that patents applied to a free program could make it effectively proprietary. To prevent this, the GPL assures that patents cannot be used to render the program non-free.

The precise terms and conditions for copying, distribution and modification follow.

#### TERMS AND CONDITIONS

##### 0. Definitions.

"This License" refers to version 3 of the GNU General Public License.

"Copyright" also means copyright-like laws that apply to other kinds of works, such as semiconductor masks.

"The Program" refers to any copyrightable work licensed under this License. Each licensee is addressed as "you". "Licensees" and "recipients" may be individuals or organizations.

To "modify" a work means to copy from or adapt all or part of the work in a fashion requiring copyright permission, other than the making of an exact copy. The resulting work is called a "modified version" of the earlier work or a work "based on" the earlier work.

A "covered work" means either the unmodified Program or a work based on the Program.

To "propagate" a work means to do anything with it that, without permission, would make you directly or secondarily liable for infringement under applicable copyright law, except executing it on a computer or modifying a private copy. Propagation includes copying, distribution (with or without modification), making available to the public, and in some countries other activities as well.

To "convey" a work means any kind of propagation that enables other parties to make or receive copies. Mere interaction with a user through a computer network, with no transfer of a copy, is not conveying.

An interactive user interface displays "Appropriate Legal Notices" to the extent that it includes a convenient and prominently visible feature that (1) displays an appropriate copyright notice, and (2) tells the user that there is no warranty for the work (except to the extent that warranties are provided), that licensees may convey the work under this License, and how to view a copy of this License. If the interface presents a list of user commands or options, such as a menu, a prominent item in the list meets this criterion.

##### 1. Source Code.

The "source code" for a work means the preferred form of the work for making modifications to it. "Object code" means any non-source form of a work.

A "Standard Interface" means an interface that either is an official standard defined by a recognized standards body, or, in the case of interfaces specified for a particular programming language, one that is widely used among developers working in that language.

The "System Libraries" of an executable work include anything, other than the work as a whole, that (a) is included in the normal form of packaging a Major Component, but which is not part of that Major Component, and (b) serves only to enable use of the work with that Major Component, or to implement a Standard Interface for which an implementation is available to the public in source code form. A "Major Component", in this context, means a major essential component (kernel, window system, and so on) of the specific operating system (if any) on which the executable work runs, or a compiler used to produce the work, or an object code interpreter used to run it.

The "Corresponding Source" for a work in object code form means all the source code needed to generate, install, and (for an executable work) run the object code and to modify the work, including scripts to control those activities. However, it does not include the work's System Libraries, or general-purpose tools or generally available free programs which are used unmodified in performing those activities but which are not part of the work. For example, Corresponding Source includes interface definition files associated with source files for the work, and the source code for shared libraries and dynamically linked subprograms that the work is specifically designed to require, such as by intimate data communication or control flow between those subprograms and other parts of the work.

The Corresponding Source need not include anything that users can regenerate automatically from other parts of the Corresponding Source.

The Corresponding Source for a work in source code form is that same work.

## 2. Basic Permissions.

All rights granted under this License are granted for the term of copyright on the Program, and are irrevocable provided the stated conditions are met. This License explicitly affirms your unlimited permission to run the unmodified Program. The output from running a covered work is covered by this License only if the output, given its content, constitutes a covered work. This License acknowledges your rights of fair use or other equivalent, as provided by copyright law.

You may make, run and propagate covered works that you do not convey, without conditions so long as your license otherwise remains in force. You may convey covered works to others for the sole purpose of having them make modifications exclusively for you, or provide you with facilities for running those works, provided that you comply with the terms of this License in conveying all material for which you do not control copyright. Those thus making or running the covered works for you must do so exclusively on your behalf, under your direction and control, on terms that prohibit them from making any copies of your copyrighted material outside their relationship with you.

Conveying under any other circumstances is permitted solely under the conditions stated below. Sublicensing is not allowed; section 10 makes it unnecessary.

## 3. Protecting Users' Legal Rights From Anti-Circumvention Law.

No covered work shall be deemed part of an effective technological

measure under any applicable law fulfilling obligations under article 11 of the WIPO copyright treaty adopted on 20 December 1996, or similar laws prohibiting or restricting circumvention of such measures.

When you convey a covered work, you waive any legal power to forbid circumvention of technological measures to the extent such circumvention is effected by exercising rights under this License with respect to the covered work, and you disclaim any intention to limit operation or modification of the work as a means of enforcing, against the work's users, your or third parties' legal rights to forbid circumvention of technological measures.

#### 4. Conveying Verbatim Copies.

You may convey verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice; keep intact all notices stating that this License and any non-permissive terms added in accord with section 7 apply to the code; keep intact all notices of the absence of any warranty; and give all recipients a copy of this License along with the Program.

You may charge any price or no price for each copy that you convey, and you may offer support or warranty protection for a fee.

#### 5. Conveying Modified Source Versions.

You may convey a work based on the Program, or the modifications to produce it from the Program, in the form of source code under the terms of section 4, provided that you also meet all of these conditions:

- a) The work must carry prominent notices stating that you modified it, and giving a relevant date.
- b) The work must carry prominent notices stating that it is released under this License and any conditions added under section 7. This requirement modifies the requirement in section 4 to "keep intact all notices".
- c) You must license the entire work, as a whole, under this License to anyone who comes into possession of a copy. This License will therefore apply, along with any applicable section 7 additional terms, to the whole of the work, and all its parts, regardless of how they are packaged. This License gives no permission to license the work in any other way, but it does not invalidate such permission if you have separately received it.
- d) If the work has interactive user interfaces, each must display Appropriate Legal Notices; however, if the Program has interactive interfaces that do not display Appropriate Legal Notices, your work need not make them do so.

A compilation of a covered work with other separate and independent works, which are not by their nature extensions of the covered work, and which are not combined with it such as to form a larger program, in or on a volume of a storage or distribution medium, is called an "aggregate" if the compilation and its resulting copyright are not used to limit the access or legal rights of the compilation's users beyond what the individual works permit. Inclusion of a covered work in an aggregate does not cause this License to apply to the other parts of the aggregate.

#### 6. Conveying Non-Source Forms.

You may convey a covered work in object code form under the terms of sections 4 and 5, provided that you also convey the machine-readable Corresponding Source under the terms of this License, in one of these ways:

- a) Convey the object code in, or embodied in, a physical product

(including a physical distribution medium), accompanied by the Corresponding Source fixed on a durable physical medium customarily used for software interchange.

b) Convey the object code in, or embodied in, a physical product (including a physical distribution medium), accompanied by a written offer, valid for at least three years and valid for as long as you offer spare parts or customer support for that product model, to give anyone who possesses the object code either (1) a copy of the Corresponding Source for all the software in the product that is covered by this License, on a durable physical medium customarily used for software interchange, for a price no more than your reasonable cost of physically performing this conveying of source, or (2) access to copy the Corresponding Source from a network server at no charge.

c) Convey individual copies of the object code with a copy of the written offer to provide the Corresponding Source. This alternative is allowed only occasionally and noncommercially, and only if you received the object code with such an offer, in accord with subsection 6b.

d) Convey the object code by offering access from a designated place (gratis or for a charge), and offer equivalent access to the Corresponding Source in the same way through the same place at no further charge. You need not require recipients to copy the Corresponding Source along with the object code. If the place to copy the object code is a network server, the Corresponding Source may be on a different server (operated by you or a third party) that supports equivalent copying facilities, provided you maintain clear directions next to the object code saying where to find the Corresponding Source. Regardless of what server hosts the Corresponding Source, you remain obligated to ensure that it is available for as long as needed to satisfy these requirements.

e) Convey the object code using peer-to-peer transmission, provided you inform other peers where the object code and Corresponding Source of the work are being offered to the general public at no charge under subsection 6d.

A separable portion of the object code, whose source code is excluded from the Corresponding Source as a System Library, need not be included in conveying the object code work.

A "User Product" is either (1) a "consumer product", which means any tangible personal property which is normally used for personal, family, or household purposes, or (2) anything designed or sold for incorporation into a dwelling. In determining whether a product is a consumer product, doubtful cases shall be resolved in favor of coverage. For a particular product received by a particular user, "normally used" refers to a typical or common use of that class of product, regardless of the status of the particular user or of the way in which the particular user actually uses, or expects or is expected to use, the product. A product is a consumer product regardless of whether the product has substantial commercial, industrial or non-consumer uses, unless such uses represent the only significant mode of use of the product.

"Installation Information" for a User Product means any methods, procedures, authorization keys, or other information required to install and execute modified versions of a covered work in that User Product from a modified version of its Corresponding Source. The information must suffice to ensure that the continued functioning of the modified object code is in no case prevented or interfered with solely because modification has been made.

If you convey an object code work under this section in, or with, or specifically for use in, a User Product, and the conveying occurs as part of a transaction in which the right of possession and use of the User Product is transferred to the recipient in perpetuity

or for a fixed term (regardless of how the transaction is characterized), the Corresponding Source conveyed under this section must be accompanied by the Installation Information. But this requirement does not apply if neither you nor any third party retains the ability to install modified object code on the User Product (for example, the work has been installed in ROM).

The requirement to provide Installation Information does not include a requirement to continue to provide support service, warranty, or updates for a work that has been modified or installed by the recipient, or for the User Product in which it has been modified or installed. Access to a network may be denied when the modification itself materially and adversely affects the operation of the network or violates the rules and protocols for communication across the network.

Corresponding Source conveyed, and Installation Information provided, in accord with this section must be in a format that is publicly documented (and with an implementation available to the public in source code form), and must require no special password or key for unpacking, reading or copying.

#### 7. Additional Terms.

"Additional permissions" are terms that supplement the terms of this License by making exceptions from one or more of its conditions. Additional permissions that are applicable to the entire Program shall be treated as though they were included in this License, to the extent that they are valid under applicable law. If additional permissions apply only to part of the Program, that part may be used separately under those permissions, but the entire Program remains governed by this License without regard to the additional permissions.

When you convey a copy of a covered work, you may at your option remove any additional permissions from that copy, or from any part of it. (Additional permissions may be written to require their own removal in certain cases when you modify the work.) You may place additional permissions on material, added by you to a covered work, for which you have or can give appropriate copyright permission.

Notwithstanding any other provision of this License, for material you add to a covered work, you may (if authorized by the copyright holders of that material) supplement the terms of this License with terms:

- a) Disclaiming warranty or limiting liability differently from the terms of sections 15 and 16 of this License; or
- b) Requiring preservation of specified reasonable legal notices or author attributions in that material or in the Appropriate Legal Notices displayed by works containing it; or
- c) Prohibiting misrepresentation of the origin of that material, or requiring that modified versions of such material be marked in reasonable ways as different from the original version; or
- d) Limiting the use for publicity purposes of names of licensors or authors of the material; or
- e) Declining to grant rights under trademark law for use of some trade names, trademarks, or service marks; or
- f) Requiring indemnification of licensors and authors of that material by anyone who conveys the material (or modified versions of it) with contractual assumptions of liability to the recipient, for any liability that these contractual assumptions directly impose on those licensors and authors.

All other non-permissive additional terms are considered "further restrictions" within the meaning of section 10. If the Program as you received it, or any part of it, contains a notice stating that

it is governed by this License along with a term that is a further restriction, you may remove that term. If a license document contains a further restriction but permits relicensing or conveying under this License, you may add to a covered work material governed by the terms of that license document, provided that the further restriction does not survive such relicensing or conveying.

If you add terms to a covered work in accord with this section, you must place, in the relevant source files, a statement of the additional terms that apply to those files, or a notice indicating where to find the applicable terms.

Additional terms, permissive or non-permissive, may be stated in the form of a separately written license, or stated as exceptions; the above requirements apply either way.

#### 8. Termination.

You may not propagate or modify a covered work except as expressly provided under this License. Any attempt otherwise to propagate or modify it is void, and will automatically terminate your rights under this License (including any patent licenses granted under the third paragraph of section 11).

However, if you cease all violation of this License, then your license from a particular copyright holder is reinstated (a) provisionally, unless and until the copyright holder explicitly and finally terminates your license, and (b) permanently, if the copyright holder fails to notify you of the violation by some reasonable means prior to 60 days after the cessation.

Moreover, your license from a particular copyright holder is reinstated permanently if the copyright holder notifies you of the violation by some reasonable means, this is the first time you have received notice of violation of this License (for any work) from that copyright holder, and you cure the violation prior to 30 days after your receipt of the notice.

Termination of your rights under this section does not terminate the licenses of parties who have received copies or rights from you under this License. If your rights have been terminated and not permanently reinstated, you do not qualify to receive new licenses for the same material under section 10.

#### 9. Acceptance Not Required for Having Copies.

You are not required to accept this License in order to receive or run a copy of the Program. Ancillary propagation of a covered work occurring solely as a consequence of using peer-to-peer transmission to receive a copy likewise does not require acceptance. However, nothing other than this License grants you permission to propagate or modify any covered work. These actions infringe copyright if you do not accept this License. Therefore, by modifying or propagating a covered work, you indicate your acceptance of this License to do so.

#### 10. Automatic Licensing of Downstream Recipients.

Each time you convey a covered work, the recipient automatically receives a license from the original licensors, to run, modify and propagate that work, subject to this License. You are not responsible for enforcing compliance by third parties with this License.

An "entity transaction" is a transaction transferring control of an organization, or substantially all assets of one, or subdividing an organization, or merging organizations. If propagation of a covered work results from an entity transaction, each party to that transaction who receives a copy of the work also receives whatever licenses to the work the party's predecessor in interest had or could give under the previous paragraph, plus a right to possession of the Corresponding Source of the work from the predecessor in interest, if the predecessor has it or can get it with reasonable efforts.

You may not impose any further restrictions on the exercise of the rights granted or affirmed under this License. For example, you may not impose a license fee, royalty, or other charge for exercise of rights granted under this License, and you may not initiate litigation (including a cross-claim or counterclaim in a lawsuit) alleging that any patent claim is infringed by making, using, selling, offering for sale, or importing the Program or any portion of it.

#### 11. Patents.

A "contributor" is a copyright holder who authorizes use under this License of the Program or a work on which the Program is based. The work thus licensed is called the contributor's "contributor version".

A contributor's "essential patent claims" are all patent claims owned or controlled by the contributor, whether already acquired or hereafter acquired, that would be infringed by some manner, permitted by this License, of making, using, or selling its contributor version, but do not include claims that would be infringed only as a consequence of further modification of the contributor version. For purposes of this definition, "control" includes the right to grant patent sublicenses in a manner consistent with the requirements of this License.

Each contributor grants you a non-exclusive, worldwide, royalty-free patent license under the contributor's essential patent claims, to make, use, sell, offer for sale, import and otherwise run, modify and propagate the contents of its contributor version.

In the following three paragraphs, a "patent license" is any express agreement or commitment, however denominated, not to enforce a patent (such as an express permission to practice a patent or covenant not to sue for patent infringement). To "grant" such a patent license to a party means to make such an agreement or commitment not to enforce a patent against the party.

If you convey a covered work, knowingly relying on a patent license, and the Corresponding Source of the work is not available for anyone to copy, free of charge and under the terms of this License, through a publicly available network server or other readily accessible means, then you must either (1) cause the Corresponding Source to be so available, or (2) arrange to deprive yourself of the benefit of the patent license for this particular work, or (3) arrange, in a manner consistent with the requirements of this License, to extend the patent license to downstream recipients. "Knowingly relying" means you have actual knowledge that, but for the patent license, your conveying the covered work in a country, or your recipient's use of the covered work in a country, would infringe one or more identifiable patents in that country that you have reason to believe are valid.

If, pursuant to or in connection with a single transaction or arrangement, you convey, or propagate by procuring conveyance of, a covered work, and grant a patent license to some of the parties receiving the covered work authorizing them to use, propagate, modify or convey a specific copy of the covered work, then the patent license you grant is automatically extended to all recipients of the covered work and works based on it.

A patent license is "discriminatory" if it does not include within the scope of its coverage, prohibits the exercise of, or is conditioned on the non-exercise of one or more of the rights that are specifically granted under this License. You may not convey a covered work if you are a party to an arrangement with a third party that is in the business of distributing software, under which you make payment to the third party based on the extent of your activity of conveying the work, and under which the third party grants, to any of the parties who would receive the covered work from you, a discriminatory patent license (a) in connection with copies of the covered work conveyed by you (or copies made from those copies), or (b) primarily for and in connection with specific products or compilations that

contain the covered work, unless you entered into that arrangement, or that patent license was granted, prior to 28 March 2007.

Nothing in this License shall be construed as excluding or limiting any implied license or other defenses to infringement that may otherwise be available to you under applicable patent law.

12. No Surrender of Others' Freedom.

If conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot convey a covered work so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not convey it at all. For example, if you agree to terms that obligate you to collect a royalty for further conveying from those to whom you convey the Program, the only way you could satisfy both those terms and this License would be to refrain entirely from conveying the Program.

13. Use with the GNU Affero General Public License.

Notwithstanding any other provision of this License, you have permission to link or combine any covered work with a work licensed under version 3 of the GNU Affero General Public License into a single combined work, and to convey the resulting work. The terms of this License will continue to apply to the part which is the covered work, but the special requirements of the GNU Affero General Public License, section 13, concerning interaction through a network will apply to the combination as such.

14. Revised Versions of this License.

The Free Software Foundation may publish revised and/or new versions of the GNU General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies that a certain numbered version of the GNU General Public License "or any later version" applies to it, you have the option of following the terms and conditions either of that numbered version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of the GNU General Public License, you may choose any version ever published by the Free Software Foundation.

If the Program specifies that a proxy can decide which future versions of the GNU General Public License can be used, that proxy's public statement of acceptance of a version permanently authorizes you to choose that version for the Program.

Later license versions may give you additional or different permissions. However, no additional obligations are imposed on any author or copyright holder as a result of your choosing to follow a later version.

15. Disclaimer of Warranty.

THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

16. Limitation of Liability.

IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING

WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MODIFIES AND/OR CONVEYS THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

17. Interpretation of Sections 15 and 16.

If the disclaimer of warranty and limitation of liability provided above cannot be given local legal effect according to their terms, reviewing courts shall apply local law that most closely approximates an absolute waiver of all civil liability in connection with the Program, unless a warranty or assumption of liability accompanies a copy of the Program in return for a fee.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively state the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

```
<one line to give the program's name and a brief idea of what it does.>  
Copyright (C) <year> <name of author>
```

```
This program is free software: you can redistribute it and/or  
modify it under the terms of the GNU General Public License  
as published by the Free Software Foundation, either version 3  
of the License, or (at your option) any later version.
```

```
This program is distributed in the hope that it will be useful,  
but WITHOUT ANY WARRANTY; without even the implied warranty of  
MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the  
GNU General Public License for more details.
```

```
You should have received a copy of the GNU General Public License  
along with this program. If not, see  
<http://www.gnu.org/licenses/>.
```

Also add information on how to contact you by electronic and paper mail.

If the program does terminal interaction, make it output a short notice like this when it starts in an interactive mode:

```
<program> Copyright (C) <year> <name of author>  
This program comes with ABSOLUTELY NO WARRANTY; for details type 'show w'.  
This is free software, and you are welcome to redistribute it  
under certain conditions; type 'show c' for details.
```

The hypothetical commands 'show w' and 'show c' should show the appropriate parts of the General Public License. Of course, your program's commands might be different; for a GUI interface, you would use an "about box".

You should also get your employer (if you work as a programmer) or school, if any, to sign a "copyright disclaimer" for the program, if necessary. For more information on this, and how to apply and follow the GNU GPL, see [<http://www.gnu.org/licenses/>](http://www.gnu.org/licenses/).

The GNU General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine

library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Lesser General Public License instead of this License. But first, please read <<http://www.gnu.org/philosophy/why-not-lgpl.html>>.

GCC RUNTIME LIBRARY EXCEPTION

Version 3.1, 31 March 2009

Copyright © 2009 Free Software Foundation, Inc. <<http://fsf.org/>>

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

This GCC Runtime Library Exception ("Exception") is an additional permission under section 7 of the GNU General Public License, version 3 ("GPLv3"). It applies to a given file (the "Runtime Library") that bears a notice placed by the copyright holder of the file stating that the file is governed by GPLv3 along with this Exception.

When you use GCC to compile a program, GCC may combine portions of certain GCC header files and runtime libraries with the compiled program. The purpose of this Exception is to allow compilation of non-GPL (including proprietary) programs to use, in this way, the header files and runtime libraries covered by this Exception.

#### 0. Definitions.

A file is an "Independent Module" if it either requires the Runtime Library for execution after a Compilation Process, or makes use of an interface provided by the Runtime Library, but is not otherwise based on the Runtime Library.

"GCC" means a version of the GNU Compiler Collection, with or without modifications, governed by version 3 (or a specified later version) of the GNU General Public License (GPL) with the option of using any subsequent versions published by the FSF.

"GPL-compatible Software" is software whose conditions of propagation, modification and use would permit combination with GCC in accord with the license of GCC.

"Target Code" refers to output from any compiler for a real or virtual target processor architecture, in executable form or suitable for input to an assembler, loader, linker and/or execution phase. Notwithstanding that, Target Code does not include data in any format that is used as a compiler intermediate representation, or used for producing a compiler intermediate representation.

The "Compilation Process" transforms code entirely represented in non-intermediate languages designed for human-written code, and/or in Java Virtual Machine byte code, into Target Code. Thus, for example, use of source code generators and preprocessors need not be considered part of the Compilation Process, since the Compilation Process can be understood as starting with the output of the generators or preprocessors.

A Compilation Process is "Eligible" if it is done using GCC, alone or with other GPL-compatible software, or if it is done without using any work based on GCC. For example, using non-GPL-compatible Software to optimize any GCC intermediate representations would not qualify as an Eligible Compilation Process.

#### 1. Grant of Additional Permission.

You have permission to propagate a work of Target Code formed by combining the Runtime Library with Independent Modules, even if such propagation would otherwise violate the terms of GPLv3, provided that all Target Code was generated by Eligible Compilation Processes. You may then convey such a combination under terms of your choice,

consistent with the licensing of the Independent Modules.

2. No Weakening of GCC Copyleft.

The availability of this Exception does not imply any general presumption that third-party software is unaffected by the copyleft requirements of the license of GCC.

## A.15. GNU Lesser General Public License Version 2.1, February 1999

The following applies to all products licensed under the GNU Lesser General Public License, Version 2.1: You may not use the identified files except in compliance with the GNU Lesser General Public License, Version 2.1 (the "License"). You may obtain a copy of the License at <http://www.gnu.org/licenses/lgpl-2.1.html>. A copy of the license is also reproduced below. Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

GNU LESSER GENERAL PUBLIC LICENSE  
Version 2.1, February 1999

Copyright (C) 1991, 1999 Free Software Foundation, Inc.  
51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA  
Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

[This is the first released version of the Lesser GPL. It also counts as the successor of the GNU Library Public License, version 2, hence the version number 2.1.]

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public Licenses are intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users.

This license, the Lesser General Public License, applies to some specially designated software packages--typically libraries--of the Free Software Foundation and other authors who decide to use it. You can use it too, but we suggest you first think carefully about whether this license or the ordinary General Public License is the better strategy to use in any particular case, based on the explanations below.

When we speak of free software, we are referring to freedom of use, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish); that you receive source code or can get it if you want it; that you can change the software and use pieces of it in new free programs; and that you are informed that you can do these things.

To protect your rights, we need to make restrictions that forbid distributors to deny you these rights or to ask you to surrender these rights. These restrictions translate to certain responsibilities for you if you distribute copies of the library or if you modify it.

For example, if you distribute copies of the library, whether gratis or for a fee, you must give the recipients all the rights that we gave you. You must make sure that they, too, receive or can get the source code. If you link other code with the library, you must provide complete object files to the recipients, so that they can relink them with the library after making changes to the library and recompiling

it. And you must show them these terms so they know their rights.

We protect your rights with a two-step method: (1) we copyright the library, and (2) we offer you this license, which gives you legal permission to copy, distribute and/or modify the library.

To protect each distributor, we want to make it very clear that there is no warranty for the free library. Also, if the library is modified by someone else and passed on, the recipients should know that what they have is not the original version, so that the original author's reputation will not be affected by problems that might be introduced by others.

Finally, software patents pose a constant threat to the existence of any free program. We wish to make sure that a company cannot effectively restrict the users of a free program by obtaining a restrictive license from a patent holder. Therefore, we insist that any patent license obtained for a version of the library must be consistent with the full freedom of use specified in this license.

Most GNU software, including some libraries, is covered by the ordinary GNU General Public License. This license, the GNU Lesser General Public License, applies to certain designated libraries, and is quite different from the ordinary General Public License. We use this license for certain libraries in order to permit linking those libraries into non-free programs.

When a program is linked with a library, whether statically or using a shared library, the combination of the two is legally speaking a combined work, a derivative of the original library. The ordinary General Public License therefore permits such linking only if the entire combination fits its criteria of freedom. The Lesser General Public License permits more lax criteria for linking other code with the library.

We call this license the "Lesser" General Public License because it does Less to protect the user's freedom than the ordinary General Public License. It also provides other software developers Less of an advantage over competing non-free programs. These disadvantages are the reason we use the ordinary General Public License for many libraries. However, the Lesser license provides advantages in certain special circumstances.

For example, on rare occasions, there may be a special need to encourage the widest possible use of a certain library, so that it becomes a de-facto standard. To achieve this, non-free programs must be allowed to use the library. A more frequent case is that a free library does the same job as widely used non-free libraries. In this case, there is little to gain by limiting the free library to free software only, so we use the Lesser General Public License.

In other cases, permission to use a particular library in non-free programs enables a greater number of people to use a large body of free software. For example, permission to use the GNU C Library in non-free programs enables many more people to use the whole GNU operating system, as well as its variant, the GNU/Linux operating system.

Although the Lesser General Public License is Less protective of the users' freedom, it does ensure that the user of a program that is linked with the Library has the freedom and the wherewithal to run that program using a modified version of the Library.

The precise terms and conditions for copying, distribution and modification follow. Pay close attention to the difference between a "work based on the library" and a "work that uses the library". The former contains code derived from the library, whereas the latter must be combined with the library in order to run.

GNU LESSER GENERAL PUBLIC LICENSE  
TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License Agreement applies to any software library or other program which contains a notice placed by the copyright holder or other authorized party saying it may be distributed under the terms of this Lesser General Public License (also called "this License"). Each licensee is addressed as "you".

A "library" means a collection of software functions and/or data prepared so as to be conveniently linked with application programs (which use some of those functions and data) to form executables.

The "Library", below, refers to any such software library or work which has been distributed under these terms. A "work based on the Library" means either the Library or any derivative work under copyright law: that is to say, a work containing the Library or a portion of it, either verbatim or with modifications and/or translated straightforwardly into another language. (Hereinafter, translation is included without limitation in the term "modification".)

"Source code" for a work means the preferred form of the work for making modifications to it. For a library, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the library.

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running a program using the Library is not restricted, and output from such a program is covered only if its contents constitute a work based on the Library (independent of the use of the Library in a tool for writing it). Whether that is true depends on what the Library does and what the program that uses the Library does.

1. You may copy and distribute verbatim copies of the Library's complete source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and distribute a copy of this License along with the Library.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Library or any portion of it, thus forming a work based on the Library, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

- a) The modified work must itself be a software library.
- b) You must cause the files modified to carry prominent notices stating that you changed the files and the date of any change.
- c) You must cause the whole of the work to be licensed at no charge to all third parties under the terms of this License.
- d) If a facility in the modified Library refers to a function or a table of data to be supplied by an application program that uses the facility, other than as an argument passed when the facility is invoked, then you must make a good faith effort to ensure that, in the event an application does not supply such function or table, the facility still operates, and performs whatever part of its purpose remains meaningful.

(For example, a function in a library to compute square roots has a purpose that is entirely well-defined independent of the application. Therefore, Subsection 2d requires that any application-supplied function or table used by this function must be optional: if the application does not supply it, the square root function must still compute square roots.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Library, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Library, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Library.

In addition, mere aggregation of another work not based on the Library with the Library (or with a work based on the Library) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may opt to apply the terms of the ordinary GNU General Public License instead of this License to a given copy of the Library. To do this, you must alter all the notices that refer to this License, so that they refer to the ordinary GNU General Public License, version 2, instead of to this License. (If a newer version than version 2 of the ordinary GNU General Public License has appeared, then you can specify that version instead if you wish.) Do not make any other change in these notices.

Once this change is made in a given copy, it is irreversible for that copy, so the ordinary GNU General Public License applies to all subsequent copies and derivative works made from that copy.

This option is useful when you wish to copy part of the code of the Library into a program that is not a library.

4. You may copy and distribute the Library (or a portion or derivative of it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange.

If distribution of object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place satisfies the requirement to distribute the source code, even though third parties are not compelled to copy the source along with the object code.

5. A program that contains no derivative of any portion of the Library, but is designed to work with the Library by being compiled or linked with it, is called a "work that uses the Library". Such a work, in isolation, is not a derivative work of the Library, and therefore falls outside the scope of this License.

However, linking a "work that uses the Library" with the Library creates an executable that is a derivative of the Library (because it contains portions of the Library), rather than a "work that uses the library". The executable is therefore covered by this License. Section 6 states terms for distribution of such executables.

When a "work that uses the Library" uses material from a header file that is part of the Library, the object code for the work may be a derivative work of the Library even though the source code is not. Whether this is true is especially significant if the work can be linked without the Library, or if the work is itself a library. The threshold for this to be true is not precisely defined by law.

If such an object file uses only numerical parameters, data structure layouts and accessors, and small macros and small inline functions (ten lines or less in length), then the use of the object

file is unrestricted, regardless of whether it is legally a derivative work. (Executables containing this object code plus portions of the Library will still fall under Section 6.)

Otherwise, if the work is a derivative of the Library, you may distribute the object code for the work under the terms of Section 6. Any executables containing that work also fall under Section 6, whether or not they are linked directly with the Library itself.

6. As an exception to the Sections above, you may also combine or link a "work that uses the Library" with the Library to produce a work containing portions of the Library, and distribute that work under terms of your choice, provided that the terms permit modification of the work for the customer's own use and reverse engineering for debugging such modifications.

You must give prominent notice with each copy of the work that the Library is used in it and that the Library and its use are covered by this License. You must supply a copy of this License. If the work during execution displays copyright notices, you must include the copyright notice for the Library among them, as well as a reference directing the user to the copy of this License. Also, you must do one of these things:

a) Accompany the work with the complete corresponding machine-readable source code for the Library including whatever changes were used in the work (which must be distributed under Sections 1 and 2 above); and, if the work is an executable linked with the Library, with the complete machine-readable "work that uses the Library", as object code and/or source code, so that the user can modify the Library and then relink to produce a modified executable containing the modified Library. (It is understood that the user who changes the contents of definitions files in the Library will not necessarily be able to recompile the application to use the modified definitions.)

b) Use a suitable shared library mechanism for linking with the Library. A suitable mechanism is one that (1) uses at run time a copy of the library already present on the user's computer system, rather than copying library functions into the executable, and (2) will operate properly with a modified version of the library, if the user installs one, as long as the modified version is interface-compatible with the version that the work was made with.

c) Accompany the work with a written offer, valid for at least three years, to give the same user the materials specified in Subsection 6a, above, for a charge no more than the cost of performing this distribution.

d) If distribution of the work is made by offering access to copy from a designated place, offer equivalent access to copy the above specified materials from the same place.

e) Verify that the user has already received a copy of these materials or that you have already sent this user a copy.

For an executable, the required form of the "work that uses the Library" must include any data and utility programs needed for reproducing the executable from it. However, as a special exception, the materials to be distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

It may happen that this requirement contradicts the license restrictions of other proprietary libraries that do not normally accompany the operating system. Such a contradiction means you cannot use both them and the Library together in an executable that you distribute.

7. You may place library facilities that are a work based on the

Library side-by-side in a single library together with other library facilities not covered by this License, and distribute such a combined library, provided that the separate distribution of the work based on the Library and of the other library facilities is otherwise permitted, and provided that you do these two things:

a) Accompany the combined library with a copy of the same work based on the Library, uncombined with any other library facilities. This must be distributed under the terms of the Sections above.

b) Give prominent notice with the combined library of the fact that part of it is a work based on the Library, and explaining where to find the accompanying uncombined form of the same work.

8. You may not copy, modify, sublicense, link with, or distribute the Library except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense, link with, or distribute the Library is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

9. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Library or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Library (or any work based on the Library), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Library or works based on it.

10. Each time you redistribute the Library (or any work based on the Library), the recipient automatically receives a license from the original licensor to copy, distribute, link with or modify the Library subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties with this License.

11. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Library at all. For example, if a patent license would not permit royalty-free redistribution of the Library by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Library.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply, and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

12. If the distribution and/or use of the Library is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Library under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

13. The Free Software Foundation may publish revised and/or new versions of the Lesser General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Library specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Library does not specify a license version number, you may choose any version ever published by the Free Software Foundation.

14. If you wish to incorporate parts of the Library into other free programs whose distribution conditions are incompatible with these, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

#### NO WARRANTY

15. BECAUSE THE LIBRARY IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE LIBRARY, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE LIBRARY "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE LIBRARY IS WITH YOU. SHOULD THE LIBRARY PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

16. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE LIBRARY AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE LIBRARY (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE LIBRARY TO OPERATE WITH ANY OTHER SOFTWARE), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

#### END OF TERMS AND CONDITIONS

#### How to Apply These Terms to Your New Libraries

If you develop a new library, and you want it to be of the greatest possible use to the public, we recommend making it free software that everyone can redistribute and change. You can do so by permitting redistribution under these terms (or, alternatively, under the terms of the ordinary General Public License).

To apply these terms, attach the following notices to the library. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

```
<one line to give the library's name and a brief idea of what it does.>  
Copyright (C) <year> <name of author>
```

```
This library is free software; you can redistribute it and/or
modify it under the terms of the GNU Lesser General Public
License as published by the Free Software Foundation; either
version 2.1 of the License, or (at your option) any later version.
```

```
This library is distributed in the hope that it will be useful,
but WITHOUT ANY WARRANTY; without even the implied warranty of
MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU
Lesser General Public License for more details.
```

```
You should have received a copy of the GNU Lesser General Public
License along with this library; if not, write to the Free Software
Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA
02110-1301 USA
```

Also add information on how to contact you by electronic and paper mail.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the library, if necessary. Here is a sample; alter the names:

```
Yoyodyne, Inc., hereby disclaims all copyright interest in the
library `Frob' (a library for tweaking knobs) written by James
Random Hacker.
```

```
<signature of Ty Coon>, 1 April 1990
Ty Coon, President of Vice
```

That's all there is to it!

## A.16. GNU Libtool License

The following software may be included in this product:

### GNU Libtool (The GNU Portable Library Tool)

```
If you are receiving a copy of the Oracle software in
source code, you are also receiving a copy of two files
(ltmain.sh and ltdl.h) generated by the GNU Libtool in
source code. If you received the Oracle software under
a license other than a commercial (non-GPL) license,
then the terms of the Oracle license do NOT apply to
these files from GNU Libtool; they are licensed under
the following licenses, separately from the Oracle
programs you receive.
```

```
Oracle elects to use GNU General Public License version
2 (GPL) for any software where a choice of GPL or GNU
Lesser/Library General Public License (LGPL) license
versions are made available with the language indicating
that GPL/LGPL or any later version may be used, or where
a choice of which version of the GPL/LGPL is applied is
unspecified.
```

From GNU Libtool:

```
ltmain.sh - Provide generalized library-building support
services.
NOTE: Changing this file will not affect anything until
you rerun configure.
Copyright (C) 1996, 1997, 1998, 1999, 2000, 2001, 2003, 2004,
2005, 2006, 2007 Free Software Foundation, Inc.
Originally by Gordon Matzigkeit, 1996
```

```
This program is free software; you can redistribute it
and/or modify it under the terms of the GNU General
Public License as published by the Free Software Foundation;
either version 2 of the License, or (at your option) any
later version.
```

```
This program is distributed in the hope that it will be
```

```
useful, but WITHOUT ANY WARRANTY; without even the implied
warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR
PURPOSE. See the GNU General Public License for more
details. You should have received a copy of the GNU General
Public License along with this program; if not, write to
the Free Software Foundation, Inc., 51 Franklin Street,
Fifth Floor, Boston, MA 02110-1301, USA.
```

```
As a special exception to the GNU General Public License,
if you distribute this file as part of a program that
contains a configuration script generated by Autoconf,
you may include it under the same distribution terms that
you use for the rest of that program.
```

This component is licensed under [Section A.13, "GNU General Public License Version 2.0, June 1991"](#)

## A.17. GNU Readline License

The following software may be included in this product:

### GNU Readline Library

```
GNU Readline Library
With respect to MySQL Server/Cluster software licensed
under GNU General Public License, you are receiving a
copy of the GNU Readline Library in source code. The
terms of any Oracle license that might accompany the
Oracle programs do NOT apply to the GNU Readline Library;
it is licensed under the following license, separately
from the Oracle programs you receive. Oracle elects to
use GNU General Public License version 2 (GPL) for any
software where a choice of GPL license versions are
made available with the language indicating that GPLv2
or any later version may be used, or where a choice of
which version of the GPL is applied is unspecified.
```

This component is licensed under [Section A.13, "GNU General Public License Version 2.0, June 1991"](#)

## A.18. GNU Standard C++ Library (libstdc++) License

The following software may be included in this product: GNU Standard C++ Library (libstdc++)

This component is licensed under [Section A.14, "GNU General Public License Version 3.0, 29 June 2007 and GCC Runtime Library Exception Version 3.1, 31 March 2009"](#).

LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS  
FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE  
COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT,  
INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING,  
BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES;  
LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER  
CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT  
LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN  
ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE  
POSSIBILITY OF SUCH DAMAGE.
```

## A.22. jboss-common-jdbc-wrapper.jar License

You are receiving a copy of `jboss-common-jdbc-wrapper.jar` in both source and object code in the following `/src/lib/jboss-common-jdbc-wrapper.jar`. The terms of the Oracle license do NOT apply to `jboss-common-jdbc-wrapper.jar`; it is licensed under the following license, separately from the Oracle programs you receive. If you do not wish to install this library, you may remove the file `/src/lib/jboss-common-jdbc-wrapper.jar`, but the Oracle program might not operate properly or at all without the library.

This component is licensed under [Section A.15, "GNU Lesser General Public License Version 2.1, February 1999"](#).

## A.23. lib\_sql.cc License

The following software may be included in this product:

`lib_sql.cc`

```
Copyright (c) 2000  
SWsoft company
```

```
This material is provided "as is", with absolutely no warranty  
expressed or implied. Any use is at your own risk.
```

```
Permission to use or copy this software for any purpose is hereby  
granted without fee, provided the above notices are retained on  
all copies. Permission to modify the code and to distribute modified  
code is granted, provided the above notices are retained, and a  
notice that the code was modified is included with the above copyright  
notice.
```

```
This code was modified by the MySQL team.
```

## A.24. Libaio License

The following software may be included in this product:

`libaio`

This component is licensed under [Section A.15, "GNU Lesser General Public License Version 2.1, February 1999"](#).

## A.25. libevent License

The following software may be included in this product:

```
libevent

Copyright (c) 2000-2007 Niels Provos <provos@citi.umich.edu>
All rights reserved.

Redistribution and use in source and binary forms, with or without
modification, are permitted provided that the following conditions
are met:
1. Redistributions of source code must retain the above copyright
   notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright
   notice, this list of conditions and the following disclaimer in the
   documentation and/or other materials provided with the distribution.
3. The name of the author may not be used to endorse or promote products
   derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE AUTHOR ``AS IS'' AND ANY EXPRESS OR

## A.26. Libiconv License

The following software may be included in this product:

## Libiconv

You are receiving a copy of the GNU LIBICONV Library. The terms of the Oracle license do NOT apply to the GNU LIBICONV Library; it is licensed under the following license, separately from the Oracle programs you receive. If you do not wish to install this program, you may delete [agent install dir]/lib/libiconv.\* and [agent install dir]/licenses/lgpl/iconv files.

This component is licensed under [Section A.15, "GNU Lesser General Public License Version 2.1, February 1999"](#).

## A.27. libintl License

The following software may be included in this product:

## libintl

Copyright (C) 1994 X Consortium

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE X CONSORTIUM BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

Except as contained in this notice, the name of the X Consortium shall not be used in advertising or otherwise to promote the sale, use or other dealings in this Software without prior written authorization from the X Consortium.

FSF changes to this file are in the public domain.

Copyright 1996-2007 Free Software Foundation, Inc. Taken from GNU libtool, 2001

Originally by Gordon Matzigkeit <gord@gnu.ai.mit.edu>, 1996

This file is free software; the Free Software Foundation gives unlimited permission to copy and/or distribute it, with or without modifications, as long as this notice is preserved.

You are receiving a copy of the libintl library. The terms of the Oracle license do NOT apply to the libintl library; it is licensed under the following license, separately from the Oracle programs you receive. If you do not wish to install this program, you may create an "exclude" file and run tar with the X option.

This component is licensed under [Section A.15, "GNU Lesser General Public License Version 2.1, February 1999"](#).

## A.28. Linux-PAM License

The following software may be included in this product:

Linux-PAM (pam-devel, Pluggable authentication modules for Linux)

Copyright Theodore Ts'o, 1996. All rights reserved.

(For the avoidance of doubt, Oracle uses and distributes this component under the terms below and elects not to do so under the GPL even though the GPL is referenced as an option below.)

Redistribution and use in source and binary forms, with or

without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, and the entire permission notice in its entirety, including the disclaimer of warranties.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. The name of the author may not be used to endorse or promote products derived from this software without specific prior written permission.

ALTERNATIVELY, this product may be distributed under the terms of the GNU Public License, in which case the provisions of the GPL are required INSTEAD OF the above restrictions. (This clause is necessary due to a potential bad interaction between the GPL and the restrictions contained in a BSD-style copyright.)

THIS SOFTWARE IS PROVIDED ``AS IS'' AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

## A.29. LPeg Library License

The following software may be included in this product:

LPeg

Use of any of this software is governed by the terms of the license below:

Copyright © 2008 Lua.org, PUC-Rio.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

## A.30. Lua (liblua) License

The following software may be included in this product:

Lua (liblua)

Copyright © 1994-2008 Lua.org, PUC-Rio.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish,

```
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject
to the following conditions:
```

```
The above copyright notice and this permission notice shall be
included in all copies or substantial portions of the Software.
```

```
THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES
OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND
NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT
HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY,
WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING
FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR
OTHER DEALINGS IN THE SOFTWARE.
```

## A.31. LuaFileSystem Library License

The following software may be included in this product:

```
LuaFileSystem
```

```
Copyright © 2003 Kepler Project.
```

```
Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
"Software"), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject
to the following conditions:
```

```
The above copyright notice and this permission notice shall be
included in all copies or substantial portions of the Software.
```

```
THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.
IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR
ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF
CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION
WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.
```

## A.32. md5 (Message-Digest Algorithm 5) License

The following software may be included in this product:

```
md5 (Message-Digest Algorithm 5)
```

```
This code implements the MD5 message-digest algorithm.
The algorithm is due to Ron Rivest. This code was
written by Colin Plumb in 1993, no copyright is claimed.
This code is in the public domain; do with it what you wish.
```

```
Equivalent code is available from RSA Data Security, Inc.
This code has been tested against that, and is equivalent,
except that you don't need to include two pages of legalese
with every copy.
```

```
The code has been modified by Mikael Ronstroem to handle
calculating a hash value of a key that is always a multiple
of 4 bytes long. Word 0 of the calculated 4-word hash value
is returned as the hash value.
```

## A.33. memcached License

The following software may be included in this product:

```
memcached
```

## A.34. mkpasswd.pl License

The following software may be included in this product:

mkpasswd.pl Perl module

Copyright (C) 2003-2004 by Chris Grau

This library is free software; you can redistribute it and/or modify it under the same terms as Perl itself, either Perl version 5.8.1 or, at your option, any later version of Perl 5 you may have available.

The Perl 5.8.1 license (from <http://www.cpan.org/src/5.0/perl-5.8.1.tar.gz> - main readme file):

Perl Kit, Version 5

Copyright (C) 1993, 1994, 1995, 1996, 1997, 1998  
1999, 2000, 2001, by Larry Wall and others

All rights reserved.

This program is free software; you can redistribute it and/or modify it under the terms of either:

a) the GNU General Public License as published by the Free Software Foundation; either version 1, or (at your option) any later version, or

b) the "Artistic License" which comes with this Kit.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See either the GNU General Public License or the Artistic License for more details.

You should have received a copy of the Artistic License with this Kit, in the file named "Artistic". If not, I'll be glad to provide one.

You should also have received a copy of the GNU General Public License

along with this program in the file named "Copying". If not, write to the  
  
Free Software Foundation, Inc., 59 Temple Place, Suite 330, Boston, MA  
02111-1307, USA or visit their web page on the internet at  
<http://www.gnu.org/copyleft/gpl.html>.

For those of you that choose to use the GNU General Public License,  
my interpretation of the GNU General Public License is that no Perl  
script falls under the terms of the GPL unless you explicitly put  
said script under the terms of the GPL yourself. Furthermore, any  
object code linked with perl does not automatically fall under the  
terms of the GPL, provided such object code only adds definitions  
of subroutines and variables, and does not otherwise impair the  
resulting interpreter from executing any standard Perl script. I  
consider linking in C subroutines in this manner to be the moral  
equivalent of defining subroutines in the Perl language itself. You  
may sell such an object file as proprietary provided that you provide  
or offer to provide the Perl source, as specified by the GNU General  
Public License. (This is merely an alternate way of specifying input  
to the program.) You may also sell a binary produced by the dumping of  
a running Perl script that belongs to you, provided that you provide or  
offer to provide the Perl source as specified by the GPL. (The  
fact that a Perl interpreter and your code are in the same binary file  
is, in this case, a form of mere aggregation.) This is my interpretation  
of the GPL. If you still have concerns or difficulties understanding  
my intent, feel free to contact me. Of course, the Artistic License  
spells all this out for your protection, so you may prefer to use that.

-----  
Perl is a language that combines some of the features of C, sed, awk  
and shell. See the manual page for more hype. There are also many Perl  
books available, covering a wide variety of topics, from various publishers.  
See `pod/perlbook.pod` for more information.

Please read all the directions below before you proceed any further, and  
then follow them carefully.

After you have unpacked your kit, you should have all the files listed  
in MANIFEST.

#### Installation

1) Detailed instructions are in the file "INSTALL", which you should  
read if you are either installing on a system resembling Unix  
or porting perl to another platform. For non-Unix platforms, see the  
corresponding README.

2) Read the manual entries before running perl.

3) IMPORTANT! Help save the world! Communicate any problems and suggested  
patches to [perlbug@perl.org](mailto:perlbug@perl.org) so we can keep the world in sync.  
If you have a problem, there's someone else out there who either has had  
or will have the same problem. It's usually helpful if you send the  
output of the "myconfig" script in the main perl directory.

If you've succeeded in compiling perl, the perlbug script in the "utils"  
subdirectory can be used to help mail in a bug report.

If possible, send in patches such that the patch program will apply them.  
Context diffs are the best, then normal diffs. Don't send ed scripts--  
I've probably changed my copy since the version you have.

The latest versions of perl are always available on the various CPAN  
(Comprehensive Perl Archive Network) sites around the world.  
See `<URL:http://www.cpan.org/src/>`.

Just a personal note: I want you to know that I create nice things like this  
because it pleases the Author of my story. If this bothers you, then your  
notion of Authorship needs some revision. But you can use perl anyway. :-)

The author.

=====

The "Artistic License"

Preamble

The intent of this document is to state the conditions under which a Package may be copied, such that the Copyright Holder maintains some semblance of artistic control over the development of the package, while giving the users of the package the right to use and distribute the Package in a more-or-less customary fashion, plus the right to make reasonable modifications.

Definitions:

"Package" refers to the collection of files distributed by the Copyright Holder, and derivatives of that collection of files created through textual modification.

"Standard Version" refers to such a Package if it has not been modified, or has been modified in accordance with the wishes of the Copyright Holder as specified below.

"Copyright Holder" is whoever is named in the copyright or copyrights for the package.

"You" is you, if you're thinking about copying or distributing this Package.

"Reasonable copying fee" is whatever you can justify on the basis of media cost, duplication charges, time of people involved, and so on. (You will not be required to justify it to the Copyright Holder, but only to the computing community at large as a market that must bear the fee.)

"Freely Available" means that no fee is charged for the item itself, though there may be fees involved in handling the item. It also means that recipients of the item may redistribute it under the same conditions they received it.

1. You may make and give away verbatim copies of the source form of the Standard Version of this Package without restriction, provided that you duplicate all of the original copyright notices and associated disclaimers.

2. You may apply bug fixes, portability fixes and other modifications derived from the Public Domain or from the Copyright Holder. A Package modified in such a way shall still be considered the Standard Version.

3. You may otherwise modify your copy of this Package in any way, provided that you insert a prominent notice in each changed file stating how and when you changed that file, and provided that you do at least ONE of the following:

a) place your modifications in the Public Domain or otherwise make them Freely Available, such as by posting said modifications to Usenet or an equivalent medium, or placing the modifications on a major archive site such as unet.uu.net, or by allowing the Copyright Holder to include your modifications in the Standard Version of the Package.

b) use the modified Package only within your corporation or organization.

c) rename any non-standard executables so the names do not conflict with standard executables, which must also be provided, and provide a separate manual page for each non-standard executable that clearly documents how it differs from the Standard Version.

d) make other distribution arrangements with the Copyright Holder.

4. You may distribute the programs of this Package in object code or executable form, provided that you do at least ONE of the following:

a) distribute a Standard Version of the executables and library files, together with instructions (in the manual page or equivalent) on where to get the Standard Version.

b) accompany the distribution with the machine-readable source of the Package with your modifications.

c) give non-standard executables non-standard names, and clearly document the differences in manual pages (or equivalent), together with instructions on where to get the Standard Version.

d) make other distribution arrangements with the Copyright Holder.

5. You may charge a reasonable copying fee for any distribution of this Package. You may charge any fee you choose for support of this Package. You may not charge a fee for this Package itself. However, you may distribute this Package in aggregate with other (possibly commercial) programs as part of a larger (possibly commercial) software distribution provided that you do not advertise this Package as a product of your own. You may embed this Package's interpreter within an executable of yours (by linking); this shall be construed as a mere form of aggregation, provided that the complete Standard Version of the interpreter is so embedded.

6. The scripts and library files supplied as input to or produced as output from the programs of this Package do not automatically fall under the copyright of this Package, but belong to whoever generated them, and may be sold commercially, and may be aggregated with this Package. If such scripts or library files are aggregated with this Package via the so-called "undump" or "unexec" methods of producing a binary executable image, then distribution of such an image shall neither be construed as a distribution of this Package nor shall it fall under the restrictions of Paragraphs 3 and 4, provided that you do not represent such an executable image as a Standard Version of this Package.

7. C subroutines (or comparably compiled subroutines in other languages) supplied by you and linked into this Package in order to emulate subroutines and variables of the language defined by this Package shall not be considered part of this Package, but are the equivalent of input as in Paragraph 6, provided these subroutines do not change the language in any way that would cause it to fail the regression tests for the language.

8. Aggregation of this Package with a commercial distribution is always permitted provided that the use of this Package is embedded; that is, when no overt attempt is made to make this Package's interfaces visible to the end user of the commercial distribution. Such use shall not be construed as a distribution of this Package.

9. The name of the Copyright Holder may not be used to endorse or promote products derived from this software without specific prior written permission.

10. THIS PACKAGE IS PROVIDED "AS IS" AND WITHOUT ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

The End

=====  
This product includes cryptographic software written by Eric Young (eay@cryptsoft.com). This product includes software written by Tim Hudson (tjh@cryptsoft.com).

Original SSLeay License

-----  
/ Copyright (C) 1995-1998 Eric Young (eay@cryptsoft.com)  
All rights reserved.  
This package is an SSL implementation written by Eric Young (eay@cryptsoft.com). The implementation was written so as to conform with Netscapes SSL. This library is free for commercial and non-commercial use as long as the following conditions are aheared to. The following conditions apply to all code found in this distribution, be it the RC4, RSA, lhash, DES, etc., code; not just the SSL code. The SSL documentation included with this distribution is covered by the same copyright terms except that the holder is Tim Hudson (tjh@cryptsoft.com). Copyright remains Eric Young's, and as such any Copyright notices in the code are not to be removed. If this package is used in a product, Eric Young should be given attribution as the author of the parts of the library used. This can be in the form of a textual message at program startup or in documentation (online or textual) provided with the package. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: 1. Redistributions of source code must retain the copyright notice, this list of conditions and the following disclaimer. 2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. 3. All advertising materials mentioning features or use of this software must display the following acknowledgement: "This product includes cryptographic software written by Eric Young (eay@cryptsoft.com)" The word 'cryptographic' can be left out if the routines from the library being used are not cryptographic related :-). 4. If you include any Windows specific code (or a derivative thereof) from the apps directory (application code) you must include an acknowledgement: "This product includes software written by Tim Hudson (tjh@cryptsoft.com)" THIS SOFTWARE IS PROVIDED BY ERIC YOUNG ``AS IS'' AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT

```
(INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF
THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. The
license and distribution terms for any publically available version or
derivative of this code cannot be changed. i.e. this code cannot simply be
copied and put under another distribution license [including the GNU Public
License.]
```

## A.38. PCRE License

The following software may be included in this product:

### PCRE (Perl Compatible Regular Expressions) Library

#### PCRE LICENCE

PCRE is a library of functions to support regular expressions whose syntax and semantics are as close as possible to those of the Perl 5 language.

Release 7 of PCRE is distributed under the terms of the "BSD" licence, as specified below. The documentation for PCRE, supplied in the "doc" directory, is distributed under the same terms as the software itself.

The basic library functions are written in C and are freestanding. Also included in the distribution is a set of C++ wrapper functions.

#### THE BASIC LIBRARY FUNCTIONS

```

## B.1. MySQL 5.6 FAQ: General

### Questions

- [B.1.1: \[3627\]](#) Which version of MySQL is production-ready (GA)?
- [B.1.2: \[3628\]](#) What is the state of development (non-GA) versions?
- [B.1.3: \[3628\]](#) Can MySQL 5.6 do subqueries?
- [B.1.4: \[3628\]](#) Can MySQL 5.6 perform multiple-table inserts, updates, and deletes?
- [B.1.5: \[3628\]](#) Does MySQL 5.6 have a Query Cache? Does it work on Server, Instance or Database?
- [B.1.6: \[3628\]](#) Does MySQL 5.6 have Sequences?
- [B.1.7: \[3628\]](#) Does MySQL 5.6 have a `NOW( ) [1220]` function with fractions of seconds?
- [B.1.8: \[3628\]](#) Does MySQL 5.6 work with multi-core processors?
- [B.1.9: \[3628\]](#) Why do I see multiple processes for `mysqld`?
- [B.1.10: \[3629\]](#) Have there been there any improvements in error reporting when foreign keys fail? Does MySQL now report which column and reference failed?
- [B.1.11: \[3629\]](#) Can MySQL 5.6 perform ACID transactions?

### Questions and Answers

#### B.1.1: Which version of MySQL is production-ready (GA)?

MySQL 5.6, MySQL 5.5, MySQL 5.1, and MySQL 5.0 are supported for production use.

MySQL 5.6 achieved General Availability (GA) status with MySQL 5.6.10, which was released for production use on 5 February 2013.

MySQL 5.5 achieved General Availability (GA) status with MySQL 5.5.8, which was released for production use on 3 December 2010.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008.

MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005. Note that active development for MySQL 5.0 has ended.

#### **B.1.2: What is the state of development (non-GA) versions?**

MySQL follows a milestone release model that introduces pre-production-quality features and stabilizes them to release quality (see <http://dev.mysql.com/doc/mysql-development-cycle/en/index.html>). This process then repeats, so releases cycle between pre-production and release quality status. Please check the change logs to identify the status of a given release.

MySQL 5.4 was a development series. Work on this series has ceased.

MySQL 5.7 is being actively developed using the milestone release methodology described above.

MySQL 6.0 was a development series. Work on this series has ceased.

#### **B.1.3: Can MySQL 5.6 do subqueries?**

Yes. See [Section 13.2.10, “Subquery Syntax”](#).

#### **B.1.4: Can MySQL 5.6 perform multiple-table inserts, updates, and deletes?**

Yes. For the syntax required to perform multiple-table updates, see [Section 13.2.11, “UPDATE Syntax”](#); for that required to perform multiple-table deletes, see [Section 13.2.2, “DELETE Syntax”](#).

A multiple-table insert can be accomplished using a trigger whose `FOR EACH ROW` clause contains multiple `INSERT` statements within a `BEGIN . . . END` block. See [Section 18.3, “Using Triggers”](#).

#### **B.1.5: Does MySQL 5.6 have a Query Cache? Does it work on Server, Instance or Database?**

Yes. The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See [Section 8.9.3, “The MySQL Query Cache”](#).

#### **B.1.6: Does MySQL 5.6 have Sequences?**

No. However, MySQL has an `AUTO_INCREMENT` system, which in MySQL 5.6 can also handle inserts in a multi-master replication setup. With the `auto_increment_increment` [1965] and `auto_increment_offset` [1968] system variables, you can set each server to generate auto-increment values that don't conflict with other servers. The `auto_increment_increment` [1965] value should be greater than the number of servers, and each server should have a unique offset.

#### **B.1.7: Does MySQL 5.6 have a `NOW()` [1220] function with fractions of seconds?**

No. This is on the MySQL roadmap as a “rolling feature”. This means that it is not a flagship feature, but will be implemented, development time permitting. Specific customer demand may change this scheduling.

However, MySQL does parse time strings with a fractional component. See [Section 11.3.2, “The `TIME` Type”](#).

#### **B.1.8: Does MySQL 5.6 work with multi-core processors?**

Yes. MySQL is fully multi-threaded, and will make use of multiple CPUs, provided that the operating system supports them.

#### **B.1.9: Why do I see multiple processes for `mysqld`?**

When using LinuxThreads, you should see a minimum of three `mysqld` processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

**B.1.10: Have there been any improvements in error reporting when foreign keys fail? Does MySQL now report which column and reference failed?**

The foreign key support in `InnoDB` has seen improvements in each major version of MySQL. Foreign key support generic to all storage engines is scheduled for MySQL 6.x; this should resolve any inadequacies in the current storage engine specific implementation.

**B.1.11: Can MySQL 5.6 perform ACID transactions?**

Yes. All current MySQL versions support transactions. The `InnoDB` storage engine offers full ACID transactions with row-level locking, multi-versioning, nonlocking repeatable reads, and all four SQL standard isolation levels.

The `NDB` storage engine supports the `READ COMMITTED` [1469] transaction isolation level only.

## B.2. MySQL 5.6 FAQ: Storage Engines

### Questions

- **B.2.1:** [3629] Where can I obtain complete documentation for MySQL storage engines?
- **B.2.2:** [3629] Are there any new storage engines in MySQL 5.6?
- **B.2.3:** [3629] Have any storage engines been removed in MySQL 5.6?
- **B.2.4:** [3629] What are the unique benefits of the `ARCHIVE` storage engine?
- **B.2.5:** [3629] Do the new features in MySQL 5.6 apply to all storage engines?

### Questions and Answers

**B.2.1: Where can I obtain complete documentation for MySQL storage engines?**

See [Chapter 14, Storage Engines](#). That chapter contains information about all MySQL storage engines except for the `NDB` storage engine used for MySQL Cluster; `NDB` is covered in [MySQL Cluster NDB 7.2](#).

**B.2.2: Are there any new storage engines in MySQL 5.6?**

The features from the optional `InnoDB Plugin` from MySQL 5.1 are folded into the built-in `InnoDB` storage engine, so you can take advantage of features such as the Barracuda file format, `InnoDB` table compression, and the new configuration options for performance. See [Section 14.2, “The InnoDB Storage Engine”](#) for details. `InnoDB` also becomes the default storage engine for new tables. See [Section 14.2.1.1, “InnoDB as the Default MySQL Storage Engine”](#) for details.

**B.2.3: Have any storage engines been removed in MySQL 5.6?**

No.

**B.2.4: What are the unique benefits of the `ARCHIVE` storage engine?**

The `ARCHIVE` storage engine is ideally suited for storing large amounts of data without indexes; it has a very small footprint, and performs selects using table scans. See [Section 14.6, “The ARCHIVE Storage Engine”](#), for details.

**B.2.5: Do the new features in MySQL 5.6 apply to all storage engines?**

The general new features such as views, stored procedures, triggers, `INFORMATION_SCHEMA`, precision math (`DECIMAL` column type), and the `BIT` column type, apply to all storage engines. There are also additions and changes for specific storage engines.

## B.3. MySQL 5.6 FAQ: Server SQL Mode

### Questions

- [B.3.1: \[3630\]](#) What are server SQL modes?
- [B.3.2: \[3630\]](#) How many server SQL modes are there?
- [B.3.3: \[3630\]](#) How do you determine the server SQL mode?
- [B.3.4: \[3630\]](#) Is the mode dependent on the database or connection?
- [B.3.5: \[3630\]](#) Can the rules for strict mode be extended?
- [B.3.6: \[3630\]](#) Does strict mode impact performance?
- [B.3.7: \[3630\]](#) What is the default server SQL mode when My SQL 5.6 is installed?

### Questions and Answers

#### B.3.1: What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see [Section 5.1.7, “Server SQL Modes”](#).

#### B.3.2: How many server SQL modes are there?

Each mode can be independently switched on and off. See [Section 5.1.7, “Server SQL Modes”](#), for a complete list of available modes.

#### B.3.3: How do you determine the server SQL mode?

You can set the default SQL mode (for `mysqld` startup) with the `--sql-mode [442]` option. Using the statement `SET [GLOBAL|SESSION] sql_mode='modes'`, you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a `SELECT @@sql_mode` statement.

#### B.3.4: Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. you can change these settings using `SET [GLOBAL|SESSION] sql_mode='modes'`.

#### B.3.5: Can the rules for strict mode be extended?

When we refer to *strict mode*, we mean a mode where at least one of the modes `TRADITIONAL [609]`, `STRICT_TRANS_TABLES [607]`, or `STRICT_ALL_TABLES [607]` is enabled. Options can be combined, so you can add restrictions to a mode. See [Section 5.1.7, “Server SQL Modes”](#), for more information.

#### B.3.6: Does strict mode impact performance?

The intensive validation of input data that some settings requires more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However—if you do require it—strict mode can provide such validation.

#### B.3.7: What is the default server SQL mode when My SQL 5.6 is installed?

By default, no special modes are enabled. See [Section 5.1.7, “Server SQL Modes”](#), for information about all available modes and MySQL's default behavior.

## B.4. MySQL 5.6 FAQ: Stored Procedures and Functions

### Questions

- [B.4.1: \[3632\]](#) Does MySQL 5.6 support stored procedures and functions?
- [B.4.2: \[3632\]](#) Where can I find documentation for MySQL stored procedures and stored functions?
- [B.4.3: \[3632\]](#) Is there a discussion forum for MySQL stored procedures?
- [B.4.4: \[3632\]](#) Where can I find the ANSI SQL 2003 specification for stored procedures?
- [B.4.5: \[3632\]](#) How do you manage stored routines?
- [B.4.6: \[3632\]](#) Is there a way to view all stored procedures and stored functions in a given database?
- [B.4.7: \[3632\]](#) Where are stored procedures stored?
- [B.4.8: \[3632\]](#) Is it possible to group stored procedures or stored functions into packages?
- [B.4.9: \[3632\]](#) Can a stored procedure call another stored procedure?
- [B.4.10: \[3632\]](#) Can a stored procedure call a trigger?
- [B.4.11: \[3632\]](#) Can a stored procedure access tables?
- [B.4.12: \[3633\]](#) Do stored procedures have a statement for raising application errors?
- [B.4.13: \[3633\]](#) Do stored procedures provide exception handling?
- [B.4.14: \[3633\]](#) Can MySQL 5.6 stored routines return result sets?
- [B.4.15: \[3633\]](#) Is `WITH RECOMPILE` supported for stored procedures?
- [B.4.16: \[3633\]](#) Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?
- [B.4.17: \[3633\]](#) Can I pass an array as input to a stored procedure?
- [B.4.18: \[3633\]](#) Can I pass a cursor as an `IN` parameter to a stored procedure?
- [B.4.19: \[3633\]](#) Can I return a cursor as an `OUT` parameter from a stored procedure?
- [B.4.20: \[3633\]](#) Can I print out a variable's value within a stored routine for debugging purposes?
- [B.4.21: \[3633\]](#) Can I commit or roll back transactions inside a stored procedure?
- [B.4.22: \[3633\]](#) Do MySQL 5.6 stored procedures and functions work with replication?
- [B.4.23: \[3633\]](#) Are stored procedures and functions created on a master server replicated to a slave?
- [B.4.24: \[3634\]](#) How are actions that take place inside stored procedures and functions replicated?
- [B.4.25: \[3634\]](#) Are there special security requirements for using stored procedures and functions together with replication?
- [B.4.26: \[3634\]](#) What limitations exist for replicating stored procedure and function actions?
- [B.4.27: \[3634\]](#) Do the preceding limitations affect MySQL's ability to do point-in-time recovery?
- [B.4.28: \[3634\]](#) What is being done to correct the aforementioned limitations?

### Questions and Answers

**B.4.1: Does MySQL 5.6 support stored procedures and functions?**

Yes. MySQL 5.6 supports two types of stored routines—stored procedures and stored functions.

**B.4.2: Where can I find documentation for MySQL stored procedures and stored functions?**

See [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#).

**B.4.3: Is there a discussion forum for MySQL stored procedures?**

Yes. See <http://forums.mysql.com/list.php?98>.

**B.4.4: Where can I find the ANSI SQL 2003 specification for stored procedures?**

Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books—such as *SQL-99 Complete, Really* by Peter Gulutzan and Trudy Pelzer—which give a comprehensive overview of the standard, including coverage of stored procedures.

**B.4.5: How do you manage stored routines?**

It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with `CREATE [FUNCTION|PROCEDURE]`, `ALTER [FUNCTION|PROCEDURE]`, `DROP [FUNCTION|PROCEDURE]`, and `SHOW CREATE [FUNCTION|PROCEDURE]`. You can obtain information about existing stored procedures using the `ROUTINES` table in the `INFORMATION_SCHEMA` database (see [Section 19.19, “The `INFORMATION\_SCHEMA` `ROUTINES` Table”](#)).

**B.4.6: Is there a way to view all stored procedures and stored functions in a given database?**

Yes. For a database named `dbname`, use this query on the `INFORMATION_SCHEMA.ROUTINES` table:

```
SELECT ROUTINE_TYPE, ROUTINE_NAME
FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_SCHEMA='dbname' ;
```

For more information, see [Section 19.19, “The `INFORMATION\_SCHEMA` `ROUTINES` Table”](#).

The body of a stored routine can be viewed using `SHOW CREATE FUNCTION` (for a stored function) or `SHOW CREATE PROCEDURE` (for a stored procedure). See [Section 13.7.5.11, “`SHOW CREATE PROCEDURE` Syntax”](#), for more information.

**B.4.7: Where are stored procedures stored?**

In the `proc` table of the `mysql` system database. However, you should not access the tables in the system database directly. Instead, use `SHOW CREATE FUNCTION` to obtain information about stored functions, and `SHOW CREATE PROCEDURE` to obtain information about stored procedures. See [Section 13.7.5.11, “`SHOW CREATE PROCEDURE` Syntax”](#), for more information about these statements.

You can also query the `ROUTINES` table in the `INFORMATION_SCHEMA` database—see [Section 19.19, “The `INFORMATION\_SCHEMA` `ROUTINES` Table”](#), for information about this table.

**B.4.8: Is it possible to group stored procedures or stored functions into packages?**

No. This is not supported in MySQL 5.6.

**B.4.9: Can a stored procedure call another stored procedure?**

Yes.

**B.4.10: Can a stored procedure call a trigger?**

A stored procedure can execute an SQL statement, such as an `UPDATE`, that causes a trigger to activate.

**B.4.11: Can a stored procedure access tables?**

Yes. A stored procedure can access one or more tables as required.

**B.4.12: Do stored procedures have a statement for raising application errors?**

Yes. MySQL 5.6 implements the SQL standard [SIGNAL](#) and [RESIGNAL](#) statements. See [Section 13.6.7, “Condition Handling”](#).

**B.4.13: Do stored procedures provide exception handling?**

MySQL implements [HANDLER](#) definitions according to the SQL standard. See [Section 13.6.7.2, “DECLARE . . . HANDLER Syntax”](#), for details.

**B.4.14: Can MySQL 5.6 stored routines return result sets?**

*Stored procedures* can, but stored functions cannot. If you perform an ordinary [SELECT](#) inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or above) client/server protocol for this to work. This means that—for instance—in PHP, you need to use the [mysqli](#) extension rather than the old [mysql](#) extension.

**B.4.15: Is [WITH RECOMPILE](#) supported for stored procedures?**

Not in MySQL 5.6.

**B.4.16: Is there a MySQL equivalent to using [mod\\_plsql](#) as a gateway on Apache to talk directly to a stored procedure in the database?**

There is no equivalent in MySQL 5.6.

**B.4.17: Can I pass an array as input to a stored procedure?**

Not in MySQL 5.6.

**B.4.18: Can I pass a cursor as an [IN](#) parameter to a stored procedure?**

In MySQL 5.6, cursors are available inside stored procedures only.

**B.4.19: Can I return a cursor as an [OUT](#) parameter from a stored procedure?**

In MySQL 5.6, cursors are available inside stored procedures only. However, if you do not open a cursor on a [SELECT](#), the result will be sent directly to the client. You can also [SELECT INTO](#) variables. See [Section 13.2.9, “SELECT Syntax”](#).

**B.4.20: Can I print out a variable's value within a stored routine for debugging purposes?**

Yes, you can do this in a *stored procedure*, but not in a stored function. If you perform an ordinary [SELECT](#) inside a stored procedure, the result set is returned directly to the client. You will need to use the MySQL 4.1 (or above) client/server protocol for this to work. This means that—for instance—in PHP, you need to use the [mysqli](#) extension rather than the old [mysql](#) extension.

**B.4.21: Can I commit or roll back transactions inside a stored procedure?**

Yes. However, you cannot perform transactional operations within a stored function.

**B.4.22: Do MySQL 5.6 stored procedures and functions work with replication?**

Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in [Section 18.7, “Binary Logging of Stored Programs”](#).

**B.4.23: Are stored procedures and functions created on a master server replicated to a slave?**

Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. [ALTER](#) and [DROP](#) statements for stored procedures and functions are also replicated.

**B.4.24: How are actions that take place inside stored procedures and functions replicated?**

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

**B.4.25: Are there special security requirements for using stored procedures and functions together with replication?**

Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the `SUPER` [756] privilege.
2. Alternatively, a DBA can set the `log_bin_trust_function_creators` [497] system variable to 1, which enables anyone with the standard `CREATE ROUTINE` [754] privilege to create stored functions.

**B.4.26: What limitations exist for replicating stored procedure and function actions?**

Nondeterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Note that declaring stored functions to be `DETERMINISTIC` or setting the `log_bin_trust_function_creators` [497] system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, nontransactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the `IGNORE` keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

**B.4.27: Do the preceding limitations affect MySQL's ability to do point-in-time recovery?**

The same limitations that affect replication do affect point-in-time recovery.

**B.4.28: What is being done to correct the aforementioned limitations?**

You can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier.

*Mixed* replication is also available (by starting the server with `--binlog-format=mixed` [415]). This hybrid, "smart" form of replication "knows" whether statement-level replication can safely be used, or row-level replication is required.

For additional information, see [Section 16.1.2, "Replication Formats"](#).

## B.5. MySQL 5.6 FAQ: Triggers

### Questions

- [B.5.1: \[3635\]](#) Where can I find the documentation for MySQL 5.6 triggers?

- [B.5.2: \[3635\]](#) Is there a discussion forum for MySQL Triggers?
- [B.5.3: \[3635\]](#) Does MySQL 5.6 have statement-level or row-level triggers?
- [B.5.4: \[3635\]](#) Are there any default triggers?
- [B.5.5: \[3635\]](#) How are triggers managed in MySQL?
- [B.5.6: \[3635\]](#) Is there a way to view all triggers in a given database?
- [B.5.7: \[3636\]](#) Where are triggers stored?
- [B.5.8: \[3636\]](#) Can a trigger call a stored procedure?
- [B.5.9: \[3636\]](#) Can triggers access tables?
- [B.5.10: \[3636\]](#) Can triggers call an external application through a UDF?
- [B.5.11: \[3636\]](#) Is it possible for a trigger to update tables on a remote server?
- [B.5.12: \[3636\]](#) Do triggers work with replication?
- [B.5.13: \[3636\]](#) How are actions carried out through triggers on a master replicated to a slave?

### Questions and Answers

#### **B.5.1: Where can I find the documentation for MySQL 5.6 triggers?**

See [Section 18.3, “Using Triggers”](#).

#### **B.5.2: Is there a discussion forum for MySQL Triggers?**

Yes. It is available at <http://forums.mysql.com/list.php?99>.

#### **B.5.3: Does MySQL 5.6 have statement-level or row-level triggers?**

In MySQL 5.6, all triggers are `FOR EACH ROW`—that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.6 does not support triggers using `FOR EACH STATEMENT`.

#### **B.5.4: Are there any default triggers?**

Not explicitly. MySQL does have specific special behavior for some `TIMESTAMP` columns, as well as for columns which are defined using `AUTO_INCREMENT`.

#### **B.5.5: How are triggers managed in MySQL?**

In MySQL 5.6, triggers can be created using the `CREATE TRIGGER` statement, and dropped using `DROP TRIGGER`. See [Section 13.1.15, “CREATE TRIGGER Syntax”](#), and [Section 13.1.24, “DROP TRIGGER Syntax”](#), for more about these statements.

Information about triggers can be obtained by querying the `INFORMATION_SCHEMA.TRIGGERS` table. See [Section 19.27, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

#### **B.5.6: Is there a way to view all triggers in a given database?**

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the `INFORMATION_SCHEMA.TRIGGERS` table such as the one shown here:

```
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
FROM INFORMATION_SCHEMA.TRIGGERS
WHERE TRIGGER_SCHEMA='dbname' ;
```

For more information about this table, see [Section 19.27, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

You can also use the `SHOW TRIGGERS` statement, which is specific to MySQL. See [Section 13.7.5.39](#), “`SHOW TRIGGERS Syntax`”.

**B.5.7: Where are triggers stored?**

Triggers for a table are currently stored in `.TRG` files, with one such file one per table.

**B.5.8: Can a trigger call a stored procedure?**

Yes.

**B.5.9: Can triggers access tables?**

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

**B.5.10: Can triggers call an external application through a UDF?**

Yes. For example, a trigger could invoke the `sys_exec()` UDF.

**B.5.11: Is it possible for a trigger to update tables on a remote server?**

Yes. A table on a remote server could be updated using the `FEDERATED` storage engine. (See [Section 14.9](#), “`The FEDERATED Storage Engine`”).

**B.5.12: Do triggers work with replication?**

Yes. However, the way in which they work depends whether you are using MySQL's “classic” statement-based replication available in all versions of MySQL, or the row-based replication format introduced in MySQL 5.1.

When using statement-based replication, triggers on the slave are executed by statements that are executed on the master (and replicated to the slave).

When using row-based replication, triggers are not executed on the slave due to statements that were run on the master and then replicated to the slave. Instead, when using row-based replication, the changes caused by executing the trigger on the master are applied on the slave.

For more information, see [Section 16.4.1.30](#), “`Replication and Triggers`”.

**B.5.13: How are actions carried out through triggers on a master replicated to a slave?**

Again, this depends on whether you are using statement-based or row-based replication.

**Statement-based replication.** First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well. The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replication slave picks up the `INSERT` statement to `EMP` and executes it.
5. The `AFTER` trigger on `EMP` that exists on the slave activates.

**Row-based replication.** When you use row-based replication, the changes caused by executing the trigger on the master are applied on the slave. However, the triggers themselves are not actually executed on the slave under row-based replication. This is because, if both the master and the slave

applied the changes from the master and—in addition—the trigger causing these changes were applied on the slave, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

In most cases, the outcome is the same for both row-based and statement-based replication. However, if you use different triggers on the master and slave, you cannot use row-based replication. (This is because the row-based format replicates the changes made by triggers executing on the master to the slaves, rather than the statements that caused the triggers to execute, and the corresponding triggers on the slave are not executed.) Instead, any statements causing such triggers to be executed must be replicated using statement-based replication.

For more information, see [Section 16.4.1.30, “Replication and Triggers”](#).

## B.6. MySQL 5.6 FAQ: Views

### Questions

- [B.6.1: \[3637\]](#) Where can I find documentation covering MySQL Views?
- [B.6.2: \[3637\]](#) Is there a discussion forum for MySQL Views?
- [B.6.3: \[3637\]](#) What happens to a view if an underlying table is dropped or renamed?
- [B.6.4: \[3637\]](#) Does MySQL 5.6 have table snapshots?
- [B.6.5: \[3637\]](#) Does MySQL 5.6 have materialized views?
- [B.6.6: \[3637\]](#) Can you insert into views that are based on joins?

### Questions and Answers

#### **B.6.1: Where can I find documentation covering MySQL Views?**

See [Section 18.5, “Using Views”](#).

#### **B.6.2: Is there a discussion forum for MySQL Views?**

Yes. See <http://forums.mysql.com/list.php?100>

#### **B.6.3: What happens to a view if an underlying table is dropped or renamed?**

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the `CHECK TABLE` statement. (See [Section 13.7.2.2, “CHECK TABLE Syntax”](#).)

#### **B.6.4: Does MySQL 5.6 have table snapshots?**

No.

#### **B.6.5: Does MySQL 5.6 have materialized views?**

No.

#### **B.6.6: Can you insert into views that are based on joins?**

It is possible, provided that your `INSERT` statement has a column list that makes it clear there is only one table involved.

You *cannot* insert into multiple tables with a single insert on a view.

## B.7. MySQL 5.6 FAQ: [INFORMATION\\_SCHEMA](#)

### Questions

- **B.7.1:** [3638] Where can I find documentation for the MySQL `INFORMATION_SCHEMA` database?
- **B.7.2:** [3638] Is there a discussion forum for `INFORMATION_SCHEMA`?
- **B.7.3:** [3638] Where can I find the ANSI SQL 2003 specification for `INFORMATION_SCHEMA`?
- **B.7.4:** [3638] What is the difference between the Oracle Data Dictionary and MySQL's `INFORMATION_SCHEMA`?
- **B.7.5:** [3638] Can I add to or otherwise modify the tables found in the `INFORMATION_SCHEMA` database?

### Questions and Answers

#### **B.7.1: Where can I find documentation for the MySQL `INFORMATION_SCHEMA` database?**

See [Chapter 19, `INFORMATION\_SCHEMA` Tables](#)

#### **B.7.2: Is there a discussion forum for `INFORMATION_SCHEMA`?**

See <http://forums.mysql.com/list.php?101>.

#### **B.7.3: Where can I find the ANSI SQL 2003 specification for `INFORMATION_SCHEMA`?**

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available—such as *SQL-99 Complete, Really* by Peter Gulutzan and Trudy Pelzer—which give a comprehensive overview of the standard, including `INFORMATION_SCHEMA`.

#### **B.7.4: What is the difference between the Oracle Data Dictionary and MySQL's `INFORMATION_SCHEMA`?**

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names. MySQL's implementation is more similar to those found in DB2 and SQL Server, which also support `INFORMATION_SCHEMA` as defined in the SQL standard.

#### **B.7.5: Can I add to or otherwise modify the tables found in the `INFORMATION_SCHEMA` database?**

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, *we cannot support bugs or other issues which result from modifying `INFORMATION_SCHEMA` tables or data.*

## B.8. MySQL 5.6 FAQ: Migration

### Questions

- **B.8.1:** [3638] Where can I find information on how to migrate from MySQL 5.5 to MySQL 5.6?
- **B.8.2:** [3639] How has storage engine (table type) support changed in MySQL 5.6 from previous versions?

### Questions and Answers

#### **B.8.1: Where can I find information on how to migrate from MySQL 5.5 to MySQL 5.6?**

For detailed upgrade information, see [Section 2.11.1, “Upgrading MySQL”](#). Do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but it will you save time and trouble—if you encounter problems during the upgrade, their origin will be easier to identify, either by you or—if you have a MySQL Enterprise subscription—by MySQL support.

**B.8.2: How has storage engine (table type) support changed in MySQL 5.6 from previous versions?**

Storage engine support has changed as follows:

- Support for [ISAM](#) tables was removed in MySQL 5.0 and you should now use the [MyISAM](#) storage engine in place of [ISAM](#). To convert a table *tblname* from [ISAM](#) to [MyISAM](#), simply issue a statement such as this one:

```
ALTER TABLE tblname ENGINE=MYISAM;
```

- Internal [RAID](#) for [MyISAM](#) tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern file systems allow for larger tables; in addition, there are now other solutions such as [MERGE](#) tables and views.
- The [VARCHAR](#) column type now retains trailing spaces in all storage engines.
- [MEMORY](#) tables (formerly known as [HEAP](#) tables) can also contain [VARCHAR](#) columns.

## B.9. MySQL 5.6 FAQ: Security

### Questions

- [B.9.1: \[3639\]](#) Where can I find documentation that addresses security issues for MySQL?
- [B.9.2: \[3639\]](#) Does MySQL 5.6 have native support for SSL?
- [B.9.3: \[3640\]](#) Is SSL support be built into MySQL binaries, or must I recompile the binary myself to enable it?
- [B.9.4: \[3640\]](#) Does MySQL 5.6 have built-in authentication against LDAP directories?
- [B.9.5: \[3640\]](#) Does MySQL 5.6 include support for Roles Based Access Control (RBAC)?

### Questions and Answers

**B.9.1: Where can I find documentation that addresses security issues for MySQL?**

The best place to start is [Chapter 6, Security](#).

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

- [Section 6.1.1, "Security Guidelines"](#).
- [Section 6.1.3, "Making MySQL Secure Against Attackers"](#).
- [Section C.5.4.1, "How to Reset the Root Password"](#).
- [Section 6.1.5, "How to Run MySQL as a Normal User"](#).
- [Section 22.3.2.6, "User-Defined Function Security Precautions"](#).
- [Section 6.1.4, "Security-Related `mysqld` Options and Variables"](#).
- [Section 6.1.6, "Security Issues with `LOAD DATA LOCAL`"](#).
- [Section 2.10, "Postinstallation Setup and Testing"](#).
- [Section 6.3.9.1, "Basic SSL Concepts"](#).

**B.9.2: Does MySQL 5.6 have native support for SSL?**

Most 5.6 binaries have support for SSL connections between the client and server. See [Section 6.3.9, "Using SSL for Secure Connections"](#).

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see [Section 6.3.10, “Connecting to MySQL Remotely from Windows with SSH”](#).

**B.9.3: Is SSL support be built into MySQL binaries, or must I recompile the binary myself to enable it?**

Most 5.6 binaries have SSL enabled for client-server connections that are secured, authenticated, or both. See [Section 6.3.9, “Using SSL for Secure Connections”](#).

**B.9.4: Does MySQL 5.6 have built-in authentication against LDAP directories?**

Not at this time.

**B.9.5: Does MySQL 5.6 include support for Roles Based Access Control (RBAC)?**

Not at this time.

## B.10. MySQL 5.6 FAQ: MySQL Cluster

In the following section, we answer questions that are frequently asked about MySQL Cluster and the [NDB](#) storage engine.

### Questions

- [B.10.1: \[3640\]](#) Which versions of the MySQL software support Cluster? Do I have to compile from source?

### Questions and Answers

**B.10.1: Which versions of the MySQL software support Cluster? Do I have to compile from source?**

MySQL Cluster is not supported in MySQL Server 5.6 releases. Instead, MySQL Cluster is released as a separate product, available as MySQL Cluster NDB 7.1 and MySQL Cluster NDB 7.2. You should use MySQL Cluster NDB 7.2 for new deployments, and plan to upgrade if you are using a previous version of MySQL Cluster. For an overview of improvements made in MySQL Cluster NDB 7.1, see [MySQL Cluster Development in MySQL Cluster NDB 7.1](#); for information about improvements made in MySQL Cluster NDB 7.2, see [MySQL Cluster Development in MySQL Cluster NDB 7.2](#).

For detailed information about deploying and using MySQL Cluster, see [MySQL Cluster NDB 6.1 - 7.1](#) and [MySQL Cluster NDB 7.2](#).

## B.11. MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL's Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

### Questions

- [B.11.1: \[3641\]](#) What CJK character sets are available in MySQL?
- [B.11.2: \[3642\]](#) I have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters?
- [B.11.3: \[3643\]](#) What problems should I be aware of when working with the Big5 Chinese character set?
- [B.11.4: \[3644\]](#) Why do Japanese character set conversions fail?

- [B.11.5: \[3645\]](#) What should I do if I want to convert SJIS 81CA to cp932?
- [B.11.6: \[3645\]](#) How does MySQL represent the Yen (¥) sign?
- [B.11.7: \[3645\]](#) Does MySQL plan to make a separate character set where 5C is the Yen sign, as at least one other major DBMS does?
- [B.11.8: \[3645\]](#) Of what issues should I be aware when working with Korean character sets in MySQL?
- [B.11.9: \[3645\]](#) Why do I get `Incorrect string value` error messages?
- [B.11.10: \[3646\]](#) Why does my GUI front end or browser not display CJK characters correctly in my application using Access, PHP, or another API?
- [B.11.11: \[3647\]](#) I've upgraded to MySQL 5.6. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?
- [B.11.12: \[3648\]](#) Why do some `LIKE [1190]` and `FULLTEXT` searches with CJK characters fail?
- [B.11.13: \[3649\]](#) How do I know whether character `x` is available in all character sets?
- [B.11.14: \[3650\]](#) Why do CJK strings sort incorrectly in Unicode? (I)
- [B.11.15: \[3651\]](#) Why do CJK strings sort incorrectly in Unicode? (II)
- [B.11.16: \[3651\]](#) Why are my supplementary characters rejected by MySQL?
- [B.11.17: \[3651\]](#) Shouldn't it be "CJKV"?
- [B.11.18: \[3652\]](#) Does MySQL allow CJK characters to be used in database and table names?
- [B.11.19: \[3652\]](#) Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?
- [B.11.20: \[3652\]](#) Where can I get help with CJK and related issues in MySQL?

## Questions and Answers

### B.11.1: What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the `ucjps` character set was not supported prior to MySQL 5.0.3. However, since the name of the applicable language appears in the `DESCRIPTION` column for every entry in the `INFORMATION_SCHEMA.CHARACTER_SETS` table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```
mysql> SELECT CHARACTER_SET_NAME, DESCRIPTION
-> FROM INFORMATION_SCHEMA.CHARACTER_SETS
-> WHERE DESCRIPTION LIKE '%Chinese%'
-> OR DESCRIPTION LIKE '%Japanese%'
-> OR DESCRIPTION LIKE '%Korean%'
-> ORDER BY CHARACTER_SET_NAME;
```

CHARACTER_SET_NAME	DESCRIPTION
big5	Big5 Traditional Chinese
cp932	SJIS for Windows Japanese
ucjps	UJIS for Windows Japanese
euckr	EUC-KR Korean
gb2312	GB2312 Simplified Chinese
gbk	GBK Simplified Chinese
sjis	Shift-JIS Japanese
ujis	EUC-JP Japanese

```
8 rows in set (0.01 sec)
```

(See [Section 19.1](#), “[The INFORMATION\\_SCHEMA CHARACTER\\_SETS Table](#)”, for more information.)

MySQL supports the two common variants of the *GB* (*Guojia Biaozhun*, or *National Standard*, or *Simplified Chinese*) character sets which are official in the People's Republic of China: [gb2312](#) and [gbk](#). Sometimes people try to insert [gbk](#) characters into [gb2312](#), and it works most of the time because [gbk](#) is a superset of [gb2312](#)—but eventually they try to insert a rarer Chinese character and it doesn't work. (See [Bug #16072](#) for an example).

Here, we try to clarify exactly what characters are legitimate in [gb2312](#) or [gbk](#), with reference to the official documents. Please check these references before reporting [gb2312](#) or [gbk](#) bugs.

- For a complete listing of the [gb2312](#) characters, ordered according to the [gb2312\\_chinese\\_ci](#) collation: [gb2312](#)
- MySQL's [gbk](#) is in reality “Microsoft code page 936”. This differs from the official [gbk](#) for characters [A1A4](#) (middle dot), [A1AA](#) (em dash), [A6E0–A6F5](#), and [A8BB–A8C0](#).
- For a listing of [gbk](#)/Unicode mappings, see <http://www.unicode.org/Public/MAPPINGS/VENDORS/MICSFT/WINDOWS/CP936.TXT>.
- For MySQL's listing of [gbk](#) characters, see [gbk](#).

### B.11.2: I have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters?

This problem is usually due to a setting in MySQL that doesn't match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- *Be certain of what MySQL version you are using.*

Use the statement `SELECT VERSION();` to determine this.

- *Make sure that the database is actually using the desired character set.*

People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of `SHOW CREATE TABLE tablename` or—better yet—by using this statement:

```
SELECT character_set_name, collation_name
FROM information_schema.columns
WHERE table_schema = your_database_name
AND table_name = your_table_name
AND column_name = your_column_name;
```

- *Determine the hexadecimal value of the character or characters that are not being displayed correctly.*

You can obtain this information for a column `column_name` in the table `table_name` using the following query:

```
SELECT HEX(column_name)
FROM table_name;
```

`3F` is the encoding for the `?` character; this means that `?` is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.

- *Make sure that a round trip possible—that is, when you select `literal` (or `_introducer hexadecimal-value`), you obtain `literal` as a result.*

For example, the Japanese *Katakana* character *Pe* (ペ) exists in all CJK character sets, and has the code point value (hexadecimal coding) `0x30da`. To test a round trip for this character, use this query:

```
SELECT 'ㄹ' AS `ㄹ`;          /* or SELECT _ucs2 0x30da; */
```

If the result is not also ㄹ, then the round trip has failed.

For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('ㄹ');`. Then we can determine whether the client encoding is correct.

- *Make sure that the problem is not with the browser or other application, rather than with MySQL.*

Use the `mysql` client program (on Windows: `mysql.exe`) to accomplish this task. If `mysql` displays correctly but your application doesn't, then your problem is probably due to system settings.

To find out what your settings are, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

```
mysql> SHOW VARIABLES LIKE 'char%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_client | utf8 |
| character_set_connection | utf8 |
| character_set_database | latin1 |
| character_set_filesystem | binary |
| character_set_results | utf8 |
| character_set_server | latin1 |
| character_set_system | utf8 |
| character_sets_dir | /usr/local/mysql/share/mysqlCharsets/ |
+-----+-----+
8 rows in set (0.03 sec)
```

These are typical character-set settings for an international-oriented client (notice the use of `utf8` Unicode) connected to a server in the West (`latin1` is a West Europe character set and a default for MySQL).

Although Unicode (usually the `utf8` variant on Unix, and the `ucs2` variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as `cp932` for Japanese Windows, is suitable.

If you cannot control the server settings, and you have no idea what your underlying computer is, then try changing to a common character set for the country that you're in (`euckr` = Korea; `gb2312` or `gbk` = People's Republic of China; `big5` = Taiwan; `sjis`, `ujis`, `cp932`, or `eucljms` = Japan; `ucs2` or `utf8` = anywhere). Usually it is necessary to change only the client and connection and results settings. There is a simple statement which changes all three at once: `SET NAMES`. For example:

```
SET NAMES 'big5';
```

Once the setting is correct, you can make it permanent by editing `my.cnf` or `my.ini`. For example you might add lines looking like these:

```
[mysqld]
character-set-server=big5
[client]
default-character-set=big5
```

It is also possible that there are issues with the API configuration setting being used in your application; see *Why does my GUI front end or browser not display CJK characters correctly...?* for more information.

### B.11.3: What problems should I be aware of when working with the Big5 Chinese character set?

MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). MySQL's `big5` is in reality Microsoft code page 950, which is very similar to the original `big5` character set. We changed to this character set starting with MySQL version 4.1.16 / 5.0.16 (as a result

of Bug #12476). For example, the following statements work in current versions of MySQL, but not in old versions:

```
mysql> CREATE TABLE big5 (BIG5 CHAR(1) CHARACTER SET BIG5);
Query OK, 0 rows affected (0.13 sec)

mysql> INSERT INTO big5 VALUES (0xf9dc);
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM big5;
+-----+
| big5 |
+-----+
| 嫺 |
+-----+
1 row in set (0.02 sec)
```

A feature request for adding [HKSCS](#) extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

#### B.11.4: Why do Japanese character set conversions fail?

MySQL supports the [sjis](#), [ujis](#), [cp932](#), and [eucjpms](#) character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with [sjis](#) or [ujis](#)) and a Windows client (typically with [cp932](#)).

In the following conversion table, the [ucs2](#) column represents the source, and the [sjis](#), [cp932](#), [ujis](#), and [eucjpms](#) columns represent the destinations—that is, the last 4 columns provide the hexadecimal result when we use [CONVERT\(ucs2\)](#) [1245] or we assign a [ucs2](#) column containing the value to an [sjis](#), [cp932](#), [ujis](#), or [eucjpms](#) column.

Character Name	ucs2	sjis	cp932	ujis	eucjpms
BROKEN BAR	00A6	3F	3F	8FA2C3	3F
FULLWIDTH BROKEN BAR	FFE4	3F	FA55	3F	8FA2
YEN SIGN	00A5	3F	3F	20	3F
FULLWIDTH YEN SIGN	FFE5	818F	818F	A1EF	3F
TILDE	007E	7E	7E	7E	7E
OVERLINE	203E	3F	3F	20	3F
HORIZONTAL BAR	2015	815C	815C	A1BD	A1BD
EM DASH	2014	3F	3F	3F	3F
REVERSE SOLIDUS	005C	815F	5C	5C	5C
FULLWIDTH ""	FF3C	3F	815F	3F	A1C0
WAVE DASH	301C	8160	3F	A1C1	3F
FULLWIDTH TILDE	FF5E	3F	8160	3F	A1C1
DOUBLE VERTICAL LINE	2016	8161	3F	A1C2	3F
PARALLEL TO	2225	3F	8161	3F	A1C2
MINUS SIGN	2212	817C	3F	A1DD	3F
FULLWIDTH HYPHEN-MINUS	FF0D	3F	817C	3F	A1DD
CENT SIGN	00A2	8191	3F	A1F1	3F
FULLWIDTH CENT SIGN	FFE0	3F	8191	3F	A1F1
POUND SIGN	00A3	8192	3F	A1F2	3F
FULLWIDTH POUND SIGN	FFE1	3F	8192	3F	A1F2
NOT SIGN	00AC	81CA	3F	A2CC	3F

Character Name	ucs2	sjis	cp932	ujis	eucjpms
FULLWIDTH NOT SIGN	FFE2	3F	81CA	3F	A2CC

Now consider the following portion of the table.

	ucs2	sjis	cp932
NOT SIGN	00AC	81CA	3F
FULLWIDTH NOT SIGN	FFE2	3F	81CA

This means that MySQL converts the `NOT SIGN` (Unicode `U+00AC`) to `sjis` code point `0x81CA` and to `cp932` code point `3F`. (`3F` is the question mark (“?”)—this is what is always used when the conversion cannot be performed.

#### B.11.5: What should I do if I want to convert SJIS `81CA` to `cp932`?

Our answer is: “?”. There are serious complaints about this: many people would prefer a “loose” conversion, so that `81CA` (`NOT SIGN`) in `sjis` becomes `81CA` (`FULLWIDTH NOT SIGN`) in `cp932`. We are considering a change to this behavior.

#### B.11.6: How does MySQL represent the Yen (¥) sign?

A problem arises because some versions of Japanese character sets (both `sjis` and `euc`) treat `5C` as a *reverse solidus* (`\`—also known as a backslash), and others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, `5C` is always the *reverse solidus* (`\`).

#### B.11.7: Does MySQL plan to make a separate character set where `5C` is the Yen sign, as at least one other major DBMS does?

This is one possible solution to the Yen sign issue; however, this will not happen in MySQL 5.1 or 6.0.

#### B.11.8: Of what issues should I be aware when working with Korean character sets in MySQL?

In theory, while there have been several versions of the `euckr` (*Extended Unix Code Korea*) character set, only one problem has been noted.

We use the “ASCII” variant of EUC-KR, in which the code point `0x5c` is REVERSE SOLIDUS, that is `\`, instead of the “KS-Roman” variant of EUC-KR, in which the code point `0x5c` is `WON SIGN`(₩). This means that you cannot convert Unicode `U+20A9` to `euckr`:

```
mysql> SELECT
  ->   CONVERT('₩' USING euckr) AS euckr,
  ->   HEX(CONVERT('₩' USING euckr)) AS hexeuckr;
+-----+-----+
| euckr | hexeuckr |
+-----+-----+
| ?    | 3F      |
+-----+-----+
1 row in set (0.00 sec)
```

MySQL's graphic Korean chart is here: [euckr](#).

#### B.11.9: Why do I get **Incorrect string value** error messages?

For illustration, we'll create a table with one Unicode (`ucs2`) column and one Chinese (`gb2312`) column.

```
mysql> CREATE TABLE ch
  ->   (ucs2 CHAR(3) CHARACTER SET ucs2,
  ->   gb2312 CHAR(3) CHARACTER SET gb2312);
```

```
Query OK, 0 rows affected (0.05 sec)
```

We'll try to place the rare character ㄸ in both columns.

```
mysql> INSERT INTO ch VALUES ('AㄸB','AㄸB');
Query OK, 1 row affected, 1 warning (0.00 sec)
```

Ah, there is a warning. Use the following statement to see what it is:

```
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1366
Message: Incorrect string value: '\xE6\xB1\x8CB' for column 'gb2312' at row 1
1 row in set (0.00 sec)
```

So it is a warning about the `gb2312` column only.

```
mysql> SELECT ucs2,HEX(ucs2),gb2312,HEX(gb2312) FROM ch;
+-----+-----+-----+-----+
| ucs2 | HEX(ucs2) | gb2312 | HEX(gb2312) |
+-----+-----+-----+-----+
| AㄸB | 00416C4C0042 | A?B | 413F42 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Several things need explanation here:

1. The fact that it is a “warning” rather than an “error” is characteristic of MySQL. We like to try to do what we can, to get the best fit, rather than give up.
2. The ㄸ character is not in the `gb2312` character set. We described that problem earlier.
3. If you are using an old version of MySQL, you will probably see a different message.
4. With `sql_mode=TRADITIONAL` [545], there would be an error message, rather than a warning.

#### B.11.10: Why does my GUI front end or browser not display CJK characters correctly in my application using Access, PHP, or another API?

Obtain a direct connection to the server using the `mysql` client (Windows: `mysql.exe`), and try the same query there. If `mysql` responds correctly, then the trouble may be that your application interface requires initialization. Use `mysql` to tell you what character set or sets it uses with the statement `SHOW VARIABLES LIKE 'char%'`. If you are using Access, then you are most likely connecting with Connector/ODBC. In this case, you should check [Section 21.1.4, “Configuring Connector/ODBC”](#). If, for instance, you use `big5`, you would enter `SET NAMES 'big5'`. (Note that no `;` is required in this case). If you are using ASP, you might need to add `SET NAMES` in the code. Here is an example that has worked in the past:

```
<%
Session.CodePage=0
Dim strConnection
Dim Conn
strConnection="driver={MySQL ODBC 3.51 Driver};server=server;uid=username;" \
& "pwd=password;database=database;stmt=SET NAMES 'big5';"
Set Conn = Server.CreateObject("ADODB.Connection")
Conn.Open strConnection
%>
```

In much the same way, if you are using any character set other than `latin1` with Connector/Net, then you must specify the character set in the connection string. See [Section 21.2.5.1, “Connecting to MySQL Using Connector/Net”](#), for more information.

If you are using PHP, try this:

```
<?php
```

```

$link = mysql_connect($host, $usr, $pwd);

mysql_select_db($db);

if( mysql_error() ) { print "Database ERROR: " . mysql_error(); }
mysql_query("SET NAMES 'utf8'", $link);
?>

```

In this case, we used `SET NAMES` to change `character_set_client` [467] and `character_set_connection` [467] and `character_set_results` [468].

We encourage the use of the newer `mysqli` extension, rather than `mysql`. Using `mysqli`, the previous example could be rewritten as shown here:

```

<?php
$link = new mysqli($host, $usr, $pwd, $db);

if( mysqli_connect_errno() )
{
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$link->query("SET NAMES 'utf8'");
?>

```

Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a `<meta>` tag suffices to correct the problem: for example, to insure that the user agent interprets page content as UTF-8, you should include `<meta http-equiv="Content-Type" content="text/html; charset=utf-8">` in the `<head>` of the HTML page.

If you are using Connector/J, see [Section 21.3.5.4, “Using Character Sets and Unicode”](#).

#### **B.11.11: I've upgraded to MySQL 5.6. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?**

In MySQL Version 4.0, there was a single “global” character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a “handshake”, as described in [Section 10.1.4, “Connection Character Sets and Collations”](#):

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client` [467], `character_set_results` [468], and `character_set_connection` [467] system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

The effect of this is that you cannot control the client character set by starting `mysqld` with `--character-set-server=utf8` [417]. However, some of our Asian customers have said that they prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a `mysqld` switch, `--character-set-client-handshake` [416], which can be turned off with `--skip-character-set-client-handshake` [416]. If you start `mysqld` with `--skip-character-set-client-handshake` [416], then, when a client connects, it sends to the server the name of the character set that it wants to use—however, *the server ignores this request from the client*.

By way of example, suppose that your favorite server character set is `latin1` (unlikely in a CJK area, but this is the default value). Suppose further that the client uses `utf8` because this is what the client's operating system supports. Now, start the server with `latin1` as its default character set:

```
mysqld --character-set-server=latin1
```

And then start the client with the default character set `utf8`:

```
mysql --default-character-set=utf8
```

The current settings can be seen by viewing the output of `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'char%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_client | utf8 |
| character_set_connection | utf8 |
| character_set_database | latin1 |
| character_set_filesystem | binary |
| character_set_results | utf8 |
| character_set_server | latin1 |
| character_set_system | utf8 |
| character_sets_dir | /usr/local/mysql/share/mysqlCharsets/ |
+-----+-----+
8 rows in set (0.01 sec)
```

Now stop the client, and then stop the server using `mysqldadmin`. Then start the server again, but this time tell it to skip the handshake like so:

```
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with `utf8` once again as the default character set, then display the current settings:

```
mysql> SHOW VARIABLES LIKE 'char%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_client | latin1 |
| character_set_connection | latin1 |
| character_set_database | latin1 |
| character_set_filesystem | binary |
| character_set_results | latin1 |
| character_set_server | latin1 |
| character_set_system | utf8 |
| character_sets_dir | /usr/local/mysql/share/mysqlCharsets/ |
+-----+-----+
8 rows in set (0.01 sec)
```

As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client's initial settings if the `--skip-character-set-client-handshake` [416] is used.

#### B.11.12: Why do some `LIKE` [1190] and `FULLTEXT` searches with CJK characters fail?

There is a very simple problem with `LIKE` [1190] searches on `BINARY` and `BLOB` columns: we need to know the end of a character. With multi-byte character sets, different characters might have different octet lengths. For example, in `utf8`, `A` requires one byte but `^` requires three bytes, as shown here:

```
+-----+-----+
| OCTET_LENGTH(utf8 'A') | OCTET_LENGTH(utf8 '^') |
+-----+-----+
| 1 | 3 |
+-----+-----+
1 row in set (0.00 sec)
```

If we don't know where the first character ends, then we don't know where the second character begins, in which case even very simple searches such as `LIKE '_A%'` [1190] fail. The solution is to use a regular CJK character set in the first place, or to convert to a CJK character set before comparing.

This is one reason why MySQL cannot allow encodings of nonexistent characters. If it is not strict about rejecting bad input, then it has no way of knowing where characters end.

For `FULLTEXT` searches, we need to know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary—

the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings. However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

### B.11.13: How do I know whether character *x* is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese *Kana* characters appear in all CJK character sets. This stored procedure accepts a [UCS-2](#) Unicode character, converts it to all other character sets, and displays the results in hexadecimal.

```
DELIMITER //

CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN

CREATE TABLE tj
    (ucs2 CHAR(1) character set ucs2,
    utf8 CHAR(1) character set utf8,
    big5 CHAR(1) character set big5,
    cp932 CHAR(1) character set cp932,
    eucjpms CHAR(1) character set eucjpms,
    euckr CHAR(1) character set euckr,
    gb2312 CHAR(1) character set gb2312,
    gbk CHAR(1) character set gbk,
    sjis CHAR(1) character set sjis,
    ujis CHAR(1) character set ujis);

INSERT INTO tj (ucs2) VALUES (ucs2_char);

UPDATE tj SET utf8=ucs2,
    big5=ucs2,
    cp932=ucs2,
    eucjpms=ucs2,
    euckr=ucs2,
    gb2312=ucs2,
    gbk=ucs2,
    sjis=ucs2,
    ujis=ucs2;

/* If there is a conversion problem, UPDATE will produce a warning. */

SELECT hex(ucs2) AS ucs2,
    hex(utf8) AS utf8,
    hex(big5) AS big5,
    hex(cp932) AS cp932,
    hex(eucjpms) AS eucjpms,
    hex(euckr) AS euckr,
    hex(gb2312) AS gb2312,
    hex(gbk) AS gbk,
    hex(sjis) AS sjis,
    hex(ujis) AS ujis
FROM tj;

DROP TABLE tj;

END//
```

The input can be any single `ucs2` character, or it can be the code point value (hexadecimal representation) of that character. For example, from Unicode's list of `ucs2` encodings and names (<http://www.unicode.org/Public/UNIDATA/UnicodeData.txt>), we know that the *Katakana* character *Pe* appears in all CJK character sets, and that its code point value is `0x30da`. If we use this value as the argument to `p_convert()`, the result is as shown here:

```
mysql> CALL p_convert(0x30da)//
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| ucs2 | utf8   | big5   | cp932 | eucjpms | euckr | gb2312 | gbk   | sjis   | ujis   |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 0x30 | 0x30da | 0x30da | 0x30da | 0x30da  | 0x30da | 0x30da  | 0x30da | 0x30da | 0x30da |
```

```
| 30DA | E3839A | C772 | 8379 | A5DA | ABDA | A5DA | A5DA | 8379 | A5DA |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.04 sec)
```

Since none of the column values is 3F—that is, the question mark character (?)—we know that every conversion worked.

#### B.11.14: Why do CJK strings sort incorrectly in Unicode? (I)

Sometimes people observe that the result of a `utf8_unicode_ci` or `ucs2_unicode_ci` search, or of an `ORDER BY` sort is not what they think a native would expect. Although we never rule out the possibility that there is a bug, we have found in the past that many people do not read correctly the standard table of weights for the Unicode Collation Algorithm. MySQL uses the table found at <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>. This is not the first table you will find by navigating from the [unicode.org](http://www.unicode.org) home page, because MySQL uses the older 4.0.0 “allkeys” table, rather than the more recent 4.1.0 table. (The newer ‘520’ collations in MySQL 5.6 use the 5.2 “allkeys” table.) This is because we are very wary about changing ordering which affects indexes, lest we bring about situations such as that reported in Bug #16526, illustrated as follows:

```
mysql> CREATE TABLE tj (s1 CHAR(1) CHARACTER SET utf8 COLLATE utf8_unicode_ci);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO tj VALUES ('が'),('か');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM tj WHERE s1 = 'か';
+-----+
| s1    |
+-----+
| が    |
| か    |
+-----+
2 rows in set (0.00 sec)
```

The character in the first result row is not the one that we searched for. Why did MySQL retrieve it? First we look for the Unicode code point value, which is possible by reading the hexadecimal number for the `ucs2` version of the characters:

```
mysql> SELECT s1, HEX(CONVERT(s1 USING ucs2)) FROM tj;
+-----+-----+
| s1    | HEX(CONVERT(s1 USING ucs2)) |
+-----+-----+
| が    | 304C                          |
| か    | 304B                          |
+-----+-----+
2 rows in set (0.03 sec)
```

Now we search for 304B and 304C in the 4.0.0 `allkeys` table, and find these lines:

```
304B ; [.1E57.0020.000E.304B] # HIRAGANA LETTER KA
304C ; [.1E57.0020.000E.304B][.0000.0140.0002.3099] # HIRAGANA LETTER GA; QQCM
```

The official Unicode names (following the “#” mark) tell us the Japanese syllabary (Hiragana), the informal classification (letter, digit, or punctuation mark), and the Western identifier (`KA` or `GA`, which happen to be voiced and unvoiced components of the same letter pair). More importantly, the *primary weight* (the first hexadecimal number inside the square brackets) is 1E57 on both lines. For comparisons in both searching and sorting, MySQL pays attention to the primary weight only, ignoring all the other numbers. This means that we are sorting が and か correctly according to the Unicode specification. If we wanted to distinguish them, we’d have to use a non-UCA (Unicode Collation Algorithm) collation (`utf8_bin` or `utf8_general_ci`), or to compare the `HEX()` [1180] values, or use `ORDER BY CONVERT(s1 USING sjis)`. Being correct “according to Unicode” isn’t enough, of course: the person who submitted the bug was equally correct. We plan to add another collation for Japanese according to the JIS X 4061 standard, in which voiced/unvoiced letter pairs like `KA/GA` are distinguishable for ordering purposes.

**B.11.15: Why do CJK strings sort incorrectly in Unicode? (II)**

If you are using Unicode (`ucs2` or `utf8`), and you know what the Unicode sort order is (see [Section B.11, “MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”](#)), but MySQL still seems to sort your table incorrectly, then you should first verify the table character set:

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
Table: t
Create Table: CREATE TABLE `t` (
`s1` char(1) CHARACTER SET ucs2 DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Since the character set appears to be correct, let's see what information the `INFORMATION_SCHEMA.COLUMNS` table can provide about this column:

```
mysql> SELECT COLUMN_NAME, CHARACTER_SET_NAME, COLLATION_NAME
-> FROM INFORMATION_SCHEMA.COLUMNS
-> WHERE COLUMN_NAME = 's1'
-> AND TABLE_NAME = 't';
+-----+-----+-----+
| COLUMN_NAME | CHARACTER_SET_NAME | COLLATION_NAME |
+-----+-----+-----+
| s1          | ucs2               | ucs2_general_ci |
+-----+-----+-----+
1 row in set (0.01 sec)
```

(See [Section 19.4, “The INFORMATION\\_SCHEMA COLUMNS Table”](#), for more information.)

You can see that the collation is `ucs2_general_ci` instead of `ucs2_unicode_ci`. The reason why this is so can be found using `SHOW CHARSET`, as shown here:

```
mysql> SHOW CHARSET LIKE 'ucs2%';
+-----+-----+-----+-----+
| Charset | Description      | Default collation | Maxlen |
+-----+-----+-----+-----+
| ucs2    | UCS-2 Unicode   | ucs2_general_ci  | 2      |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

For `ucs2` and `utf8`, the default collation is “general”. To specify a Unicode collation, use `COLLATE ucs2_unicode_ci`.

**B.11.16: Why are my supplementary characters rejected by MySQL?**

Before MySQL 5.5.3, MySQL does not support supplementary characters—that is, characters which need more than 3 bytes—for `UTF-8`. We support only what Unicode calls the *Basic Multilingual Plane / Plane 0*. Only a few very rare Han characters are supplementary; support for them is uncommon. This has led to reports such as that found in Bug #12600, which we rejected as “not a bug”. With `utf8`, we must truncate an input string when we encounter bytes that we don't understand. Otherwise, we wouldn't know how long the bad multi-byte character is.

One possible workaround is to use `ucs2` instead of `utf8`, in which case the “bad” characters are changed to question marks; however, no truncation takes place. You can also change the data type to `BLOB` or `BINARY`, which perform no validity checking.

As of MySQL 5.5.3, Unicode support is extended to include supplementary characters by means of additional Unicode character sets: `utf16`, `utf32`, and 4-byte `utf8mb4`. These character sets support supplementary Unicode characters outside the Basic Multilingual Plane (BMP).

**B.11.17: Shouldn't it be “CJKV”?**

No. The term “CJKV” (*Chinese Japanese Korean Vietnamese*) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL has no plan to support the old Vietnamese

script using Han characters. MySQL does of course support the modern Vietnamese script with Western characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in [Section 10.1.14.1, “Unicode Character Sets”](#).

#### **B.11.18: Does MySQL allow CJK characters to be used in database and table names?**

This issue is fixed in MySQL 5.1, by automatically rewriting the names of the corresponding directories and files.

For example, if you create a database named 椿 on a server whose operating system does not support CJK in directory names, MySQL creates a directory named @0w@00a5@00ae. which is just a fancy way of encoding E6A5AE—that is, the Unicode hexadecimal representation for the 椿 character. However, if you run a `SHOW DATABASES` statement, you can see that the database is listed as 椿.

#### **B.11.19: Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?**

A Simplified Chinese version of the Manual, current for MySQL 5.1.12, can be found at <http://dev.mysql.com/doc/>. The Japanese translation of the MySQL 4.1 manual can be downloaded from <http://dev.mysql.com/doc/>.

#### **B.11.20: Where can I get help with CJK and related issues in MySQL?**

The following resources are available:

- A listing of MySQL user groups can be found at <http://dev.mysql.com/user-groups/>.
- View feature requests relating to character set issues at <http://tinyurl.com/y6xcuf>.
- Visit the MySQL [Character Sets, Collation, Unicode Forum](#). We are also in the process of adding foreign-language forums at <http://forums.mysql.com/>.

## **B.12. MySQL 5.6 FAQ: Connectors & APIs**

For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:

- [Section 21.8.14, “Common Questions and Problems When Using the C API”](#)
- [Section 21.9.12, “Common Problems with MySQL and PHP”](#)
- [Section 21.1.7, “Connector/ODBC Notes and Tips”](#)
- [Section 21.2.5, “Connector/Net Programming”](#)
- [Section 21.3, “MySQL Connector/J”](#)

## **B.13. MySQL 5.6 FAQ: Replication**

In the following section, we provide answers to questions that are most frequently asked about MySQL Replication.

### **Questions**

- **B.13.1:** [\[3653\]](#) Must the slave be connected to the master all the time?
- **B.13.2:** [\[3653\]](#) Must I enable networking on my master and slave to enable replication?
- **B.13.3:** [\[3653\]](#) How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

- [B.13.4: \[3654\]](#) How do I force the master to block updates until the slave catches up?
- [B.13.5: \[3654\]](#) What issues should I be aware of when setting up two-way replication?
- [B.13.6: \[3654\]](#) How can I use replication to improve performance of my system?
- [B.13.7: \[3654\]](#) What should I do to prepare client code in my own applications to use performance-enhancing replication?
- [B.13.8: \[3654\]](#) When and how much can MySQL replication improve the performance of my system?
- [B.13.9: \[3655\]](#) How can I use replication to provide redundancy or high availability?
- [B.13.10: \[3656\]](#) How do I tell whether a master server is using statement-based or row-based binary logging format?
- [B.13.11: \[3656\]](#) How do I tell a slave to use row-based replication?
- [B.13.12: \[3656\]](#) How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?
- [B.13.13: \[3656\]](#) Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?
- [B.13.14: \[3656\]](#) Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

## Questions and Answers

### **B.13.1: Must the slave be connected to the master all the time?**

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchrony with the master unless you take some special measures.

To ensure that catchup can occur for a slave that has been disconnected, you must not remove binary log files from the master that contain information that has not yet been replicated to the slaves. Asynchronous replication can work only if the slave is able to continue reading the binary log from the point where it last read events.

### **B.13.2: Must I enable networking on my master and slave to enable replication?**

Yes, networking must be enabled on the master and slave. If networking is not enabled, the slave cannot connect to the master and transfer the binary log. Check that the `skip-networking` [\[440\]](#) option has not been enabled in the configuration file for either server.

### **B.13.3: How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?**

Check the `Seconds_Behind_Master` column in the output from `SHOW SLAVE STATUS`. See [Section 16.1.5.1, "Checking Replication Status"](#).

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see large `Time` values such

as 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This is because the slave is executing statements that are one hour old. See [Section 16.2.1, “Replication Implementation Details”](#).

#### B.13.4: How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the current binary log file name and position) from the output of the `SHOW` statement.

2. On the slave, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` [1279] function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
```

The `SELECT` statement blocks until the slave reaches the specified log file and position. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to enable the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

#### B.13.5: What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

#### B.13.6: How can I use replication to improve performance of my system?

Set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the `--skip-innodb` [1698], `--low-priority-updates` [430], and `--delay-key-write=ALL` [421] options to get speed improvements on the slave end. In this case, the slave uses nontransactional `MyISAM` tables instead of `InnoDB` tables to get more speed by eliminating transactional overhead.

#### B.13.7: What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, [Section 16.3.3, “Using Replication for Scale-Out”](#).

#### B.13.8: When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let `reads` and `writes` denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `reads` is  $1200 - 2 * \text{writes}$ . In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the master and each slave have the same capacity, and that we have one master and  $N$  slaves. Then we have for each server (master or slave):

$$\text{reads} = 1200 - 2 * \text{writes}$$

$$\text{reads} = 9 * \text{writes} / (N + 1) \text{ (reads are split, but writes replicated to all slaves)}$$

$$9 * \text{writes} / (N + 1) + 2 * \text{writes} = 1200$$

$$\text{writes} = 1200 / (2 + 9/(N + 1))$$

The last equation indicates the maximum number of writes for  $N$  slaves, given a maximum possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If  $N = 0$  (which means we have no replication), our system can handle about  $1200/11 = 109$  writes per second.
- If  $N = 1$ , we get up to 184 writes per second.
- If  $N = 8$ , we get up to 400 writes per second.
- If  $N = 17$ , we get up to 480 writes per second.
- Eventually, as  $N$  approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

Note that these computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add  $N$  replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many slaves do you have bandwidth available on your network?

#### **B.13.9: How can I use replication to provide redundancy or high availability?**

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see [Section 16.3.6, “Switching Masters During Failover”](#).

#### **B.13.10: How do I tell whether a master server is using statement-based or row-based binary logging format?**

Check the value of the `binlog_format` [2010] system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown will be one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, row-based logging is preferred but replication switches automatically to statement-based logging under certain conditions; for information about when this may occur, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

#### **B.13.11: How do I tell a slave to use row-based replication?**

Slaves automatically know which format to use.

#### **B.13.12: How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?**

Start the server with the `--replicate-wild-ignore-table=mysql.%` [1980] option to ignore replication for tables in the `mysql` database.

#### **B.13.13: Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?**

Yes.

#### **B.13.14: Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?**

Yes.

## **B.14. MySQL 5.6 FAQ: MySQL Enterprise Scalability Thread Pool**

### **Questions**

- [B.14.1: \[3656\]](#) What is the Thread Pool and what problem does it solve?
- [B.14.2: \[3657\]](#) How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput?
- [B.14.3: \[3657\]](#) How is the Thread Pool different from the client side Connection Pool?
- [B.14.4: \[3657\]](#) When should I use the Thread Pool?
- [B.14.5: \[3657\]](#) Are there recommended Thread Pool configurations?

### **Questions and Answers**

#### **B.14.1: What is the Thread Pool and what problem does it solve?**

The MySQL Thread Pool is a MySQL server plugin that extends the default connection-handling capabilities of the MySQL server to limit the number of concurrently executing statements/queries and transactions to ensure that each has sufficient CPU and memory resources to fulfill its task. Commercial distributions of MySQL 5.5 and 5.6 include the Thread Pool plugin.

The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance

degrades. The Thread Pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The Thread Pool plugin increases server performance by efficiently managing statement execution threads for large numbers of client connections, especially on modern multi-CPU/Core systems.

For more information, see [Section 8.11.6, “The Thread Pool Plugin”](#).

**B.14.2: How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput?**

The Thread Pool uses a “divide and conquer” approach to limiting and balancing concurrency. Unlike the default connection handling of the MySQL Server, the Thread Pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. The Thread Pool then manages client connections within configurable thread groups, where they are prioritized and queued based on the nature of the work they were submitted to accomplish.

For more information, see [Section 8.11.6.2, “Thread Pool Operation”](#).

**B.14.3: How is the Thread Pool different from the client side Connection Pool?**

The MySQL Connection Pool operates on the client side to ensure that a MySQL client does not constantly connect to and disconnect from the MySQL server. It is designed to cache idle connections in the MySQL client for use by other users as they are needed. This minimizes the overhead and expense of establishing and tearing down connections as queries are submitted to the MySQL server. The MySQL Connection Pool has no visibility as to the query handling capabilities or load of the backend MySQL server. By contrast, the Thread Pool operates on the MySQL server side and is designed to manage the execution of inbound concurrent connections and queries as they are received from the client connections accessing the backend MySQL database. Because of the separation of duties, the MySQL Connection Pool and Thread Pool are orthogonal and can be used independent of each other.

MySQL Connection Pooling via the MySQL Connectors is covered in [Chapter 21, Connectors and APIs](#).

**B.14.4: When should I use the Thread Pool?**

There are a few rules of thumb to consider for optimal Thread Pool use cases:

The MySQL `Threads_running` [601] variable keeps track of the number of concurrent statements currently executing in the MySQL Server. If this variable consistently exceeds a region where the server won't operate optimally (usually going beyond 40 for InnoDB workloads), the Thread Pool will be beneficial, especially in extreme parallel overload situations.

If you are using the `innodb_thread_concurrency` [1751] to limit the number of concurrently executing statements, you will find the Thread Pool solves the same problem, only better, by assigning connections to thread groups, then queuing executions based on transactional content, user defined designations, and so forth.

Lastly, if your workload comprises mainly short queries, the Thread Pool will be beneficial.

To learn more, see [Section 8.11.6.3, “Thread Pool Tuning”](#).

**B.14.5: Are there recommended Thread Pool configurations?**

The Thread Pool has a number of user case driven configuration parameters that affect its performance. To learn about these and tips on tuning, see [Section 8.11.6.3, “Thread Pool Tuning”](#).

# Appendix C. Errors, Error Codes, and Common Problems

## Table of Contents

C.1. Sources of Error Information .....	3659
C.2. Types of Error Values .....	3659
C.3. Server Error Codes and Messages .....	3660
C.4. Client Error Codes and Messages .....	3718
C.5. Problems and Common Errors .....	3722
C.5.1. How to Determine What Is Causing a Problem .....	3722
C.5.2. Common Errors When Using MySQL Programs .....	3723
C.5.3. Installation-Related Issues .....	3735
C.5.4. Administration-Related Issues .....	3736
C.5.5. Query-Related Issues .....	3743
C.5.6. Optimizer-Related Issues .....	3749
C.5.7. Table Definition-Related Issues .....	3750
C.5.8. Known Issues in MySQL .....	3751

This appendix lists common problems and errors that may occur and potential resolutions, in addition to listing the errors that may appear when you call MySQL from any host language. The first section covers problems and resolutions. Detailed information on errors is provided: One list displays server error messages. Another list displays client program messages.

## C.1. Sources of Error Information

There are several sources of error information in MySQL:

- Each SQL statement executed results in an error code, an SQLSTATE value, and an error message, as described in [Section C.2, “Types of Error Values”](#). These errors are returned from the server side; see [Section C.3, “Server Error Codes and Messages”](#).
- Errors can occur on the client side, usually involving problems communicating with the server; see [Section C.4, “Client Error Codes and Messages”](#).
- SQL statement warning and error information is available through the `SHOW WARNINGS` and `SHOW ERRORS` statements. The `warning_count` [564] system variable indicates the number of errors, warnings, and notes. The `error_count` [480] system variable indicates the number of errors. Its value excludes warnings and notes.
- `SHOW SLAVE STATUS` statement output includes information about replication errors occurring on the slave side.
- `SHOW ENGINE INNODB STATUS` statement output includes information about the most recent foreign key error if a `CREATE TABLE` statement for an `InnoDB` table fails.
- The `percona` program provides information from the command line about error numbers. See [Section 4.8.1, “percona — Explain Error Codes”](#).

Descriptions of server and client errors are provided later in this Appendix. For information about errors related to `InnoDB`, see [Section 14.2.3.14, “InnoDB Error Handling”](#).

## C.2. Types of Error Values

When an error occurs in MySQL, the server returns two types of error values:

- A MySQL-specific error code. This value is numeric. It is not portable to other database systems.
- An SQLSTATE value. The value is a five-character string (for example, `'42S02'`). The values are taken from ANSI SQL and ODBC and are more standardized.

A message string that provides a textual description of the error is also available.

When an error occurs, the MySQL error code, SQLSTATE value, and message string are available using C API functions:

- MySQL error code: Call `mysql_errno()`
- SQLSTATE value: Call `mysql_sqlstate()`
- Error message: Call `mysql_error()`

For prepared statements, the corresponding error functions are `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()`. All error functions are described in [Section 21.8, “MySQL C API”](#).

The number of errors, warnings, and notes for the previous statement can be obtained by calling `mysql_warning_count()`. See [Section 21.8.6.73, “mysql\\_warning\\_count\(\)”](#).

The first two characters of an SQLSTATE value indicate the error class:

- Class = '00' indicates success.
- Class = '01' indicates a warning.
- Class = '02' indicates “not found.” This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- Class > '02' indicates an exception.

## C.3. Server Error Codes and Messages

MySQL programs have access to several types of error information when the server returns an error. For example, the `mysql` client program displays errors using the following format:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

The message displayed contains three types of information:

- A numeric error code ([1146](#)). This number is MySQL-specific and is not portable to other database systems.
- A five-character SQLSTATE value ('[42S02](#)'). The values are taken from ANSI SQL and ODBC and are more standardized. Not all MySQL error numbers have corresponding SQLSTATE values. In these cases, '[HY000](#)' (general error) is used.
- A message string that provides a textual description of the error.

For error checking, use error codes, not error messages. Error messages do not change often, but it is possible. Also if the database administrator changes the language setting, that affects the language of error messages.

Error codes are stable across GA releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and subject to change.

Server error information comes from the following source files. For details about the way that error information is defined, see the [MySQL Internals Manual](#).

- Error message information is listed in the `share/errmsg.txt` file. `%d` and `%s` represent numbers and strings, respectively, that are substituted into the Message values when they are displayed.
- The Error values listed in `share/errmsg.txt` are used to generate the definitions in the `include/mysql_d_error.h` and `include/mysql_d_ename.h` MySQL source files.

- The SQLSTATE values listed in [share/errmsg.txt](#) are used to generate the definitions in the [include/sql\\_state.h](#) MySQL source file.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.

- Error: 1000 SQLSTATE: HY000 ([ER\\_HASHCHK \[3661\]](#))  
Message: hashchk
- Error: 1001 SQLSTATE: HY000 ([ER\\_NISAMCHK \[3661\]](#))  
Message: isamchk
- Error: 1002 SQLSTATE: HY000 ([ER\\_NO \[3661\]](#))  
Message: NO
- Error: 1003 SQLSTATE: HY000 ([ER\\_YES \[3661\]](#))  
Message: YES
- Error: 1004 SQLSTATE: HY000 ([ER\\_CANT\\_CREATE\\_FILE \[3661\]](#))  
Message: Can't create file '%s' (errno: %d - %s)
- Error: 1005 SQLSTATE: HY000 ([ER\\_CANT\\_CREATE\\_TABLE \[3661\]](#))  
Message: Can't create table '%s' (errno: %d)
- Error: 1006 SQLSTATE: HY000 ([ER\\_CANT\\_CREATE\\_DB \[3661\]](#))  
Message: Can't create database '%s' (errno: %d)
- Error: 1007 SQLSTATE: HY000 ([ER\\_DB\\_CREATE\\_EXISTS \[3661\]](#))  
Message: Can't create database '%s'; database exists
- Error: 1008 SQLSTATE: HY000 ([ER\\_DB\\_DROP\\_EXISTS \[3661\]](#))  
Message: Can't drop database '%s'; database doesn't exist
- Error: 1009 SQLSTATE: HY000 ([ER\\_DB\\_DROP\\_DELETE \[3661\]](#))  
Message: Error dropping database (can't delete '%s', errno: %d)
- Error: 1010 SQLSTATE: HY000 ([ER\\_DB\\_DROP\\_RMDIR \[3661\]](#))  
Message: Error dropping database (can't rmdir '%s', errno: %d)
- Error: 1011 SQLSTATE: HY000 ([ER\\_CANT\\_DELETE\\_FILE \[3661\]](#))  
Message: Error on delete of '%s' (errno: %d - %s)
- Error: 1012 SQLSTATE: HY000 ([ER\\_CANT\\_FIND\\_SYSTEM\\_REC \[3661\]](#))  
Message: Can't read record in system table
- Error: 1013 SQLSTATE: HY000 ([ER\\_CANT\\_GET\\_STAT \[3661\]](#))  
Message: Can't get status of '%s' (errno: %d - %s)
- Error: 1014 SQLSTATE: HY000 ([ER\\_CANT\\_GET\\_WD \[3661\]](#))  
Message: Can't get working directory (errno: %d - %s)

- Error: 1015 SQLSTATE: HY000 (ER\_CANT\_LOCK [3662])  
Message: Can't lock file (errno: %d - %s)
- Error: 1016 SQLSTATE: HY000 (ER\_CANT\_OPEN\_FILE [3662])  
Message: Can't open file: '%s' (errno: %d - %s)
- Error: 1017 SQLSTATE: HY000 (ER\_FILE\_NOT\_FOUND [3662])  
Message: Can't find file: '%s' (errno: %d - %s)
- Error: 1018 SQLSTATE: HY000 (ER\_CANT\_READ\_DIR [3662])  
Message: Can't read dir of '%s' (errno: %d - %s)
- Error: 1019 SQLSTATE: HY000 (ER\_CANT\_SET\_WD [3662])  
Message: Can't change dir to '%s' (errno: %d - %s)
- Error: 1020 SQLSTATE: HY000 (ER\_CHECKREAD [3662])  
Message: Record has changed since last read in table '%s'
- Error: 1021 SQLSTATE: HY000 (ER\_DISK\_FULL [3662])  
Message: Disk full (%s); waiting for someone to free some space... (errno: %d - %s)
- Error: 1022 SQLSTATE: 23000 (ER\_DUP\_KEY [3662])  
Message: Can't write; duplicate key in table '%s'
- Error: 1023 SQLSTATE: HY000 (ER\_ERROR\_ON\_CLOSE [3662])  
Message: Error on close of '%s' (errno: %d - %s)
- Error: 1024 SQLSTATE: HY000 (ER\_ERROR\_ON\_READ [3662])  
Message: Error reading file '%s' (errno: %d - %s)
- Error: 1025 SQLSTATE: HY000 (ER\_ERROR\_ON\_RENAME [3662])  
Message: Error on rename of '%s' to '%s' (errno: %d - %s)
- Error: 1026 SQLSTATE: HY000 (ER\_ERROR\_ON\_WRITE [3662])  
Message: Error writing file '%s' (errno: %d - %s)
- Error: 1027 SQLSTATE: HY000 (ER\_FILE\_USED [3662])  
Message: '%s' is locked against change
- Error: 1028 SQLSTATE: HY000 (ER\_FILSORT\_ABORT [3662])  
Message: Sort aborted
- Error: 1029 SQLSTATE: HY000 (ER\_FORM\_NOT\_FOUND [3662])  
Message: View '%s' doesn't exist for '%s'
- Error: 1030 SQLSTATE: HY000 (ER\_GET\_ERRNO [3662])  
Message: Got error %d from storage engine
- Error: 1031 SQLSTATE: HY000 (ER\_ILLEGAL HA [3662])

Message: Table storage engine for '%s' doesn't have this option

- Error: [1032](#) SQLSTATE: [HY000](#) ([ER\\_KEY\\_NOT\\_FOUND](#) [\[3663\]](#))

Message: Can't find record in '%s'

- Error: [1033](#) SQLSTATE: [HY000](#) ([ER\\_NOT\\_FORM\\_FILE](#) [\[3663\]](#))

Message: Incorrect information in file: '%s'

- Error: [1034](#) SQLSTATE: [HY000](#) ([ER\\_NOT\\_KEYFILE](#) [\[3663\]](#))

Message: Incorrect key file for table '%s'; try to repair it

- Error: [1035](#) SQLSTATE: [HY000](#) ([ER\\_OLD\\_KEYFILE](#) [\[3663\]](#))

Message: Old key file for table '%s'; repair it!

- Error: [1036](#) SQLSTATE: [HY000](#) ([ER\\_OPEN\\_AS\\_READONLY](#) [\[3663\]](#))

Message: Table '%s' is read only

- Error: [1037](#) SQLSTATE: [HY001](#) ([ER\\_OUTOFMEMORY](#) [\[3663\]](#))

Message: Out of memory; restart server and try again (needed %d bytes)

- Error: [1038](#) SQLSTATE: [HY001](#) ([ER\\_OUT\\_OF\\_SORTMEMORY](#) [\[3663\]](#))

Message: Out of sort memory, consider increasing server sort buffer size

- Error: [1039](#) SQLSTATE: [HY000](#) ([ER\\_UNEXPECTED\\_EOF](#) [\[3663\]](#))

Message: Unexpected EOF found when reading file '%s' (errno: %d - %s)

- Error: [1040](#) SQLSTATE: [08004](#) ([ER\\_CON\\_COUNT\\_ERROR](#) [\[3663\]](#))

Message: Too many connections

- Error: [1041](#) SQLSTATE: [HY000](#) ([ER\\_OUT\\_OF\\_RESOURCES](#) [\[3663\]](#))

Message: Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space

- Error: [1042](#) SQLSTATE: [08S01](#) ([ER\\_BAD\\_HOST\\_ERROR](#) [\[3663\]](#))

Message: Can't get hostname for your address

- Error: [1043](#) SQLSTATE: [08S01](#) ([ER\\_HANDSHAKE\\_ERROR](#) [\[3663\]](#))

Message: Bad handshake

- Error: [1044](#) SQLSTATE: [42000](#) ([ER\\_DBACCESS\\_DENIED\\_ERROR](#) [\[3663\]](#))

Message: Access denied for user '%s'@'%s' to database '%s'

- Error: [1045](#) SQLSTATE: [28000](#) ([ER\\_ACCESS\\_DENIED\\_ERROR](#) [\[3663\]](#))

Message: Access denied for user '%s'@'%s' (using password: %s)

- Error: [1046](#) SQLSTATE: [3D000](#) ([ER\\_NO\\_DB\\_ERROR](#) [\[3663\]](#))

Message: No database selected

- Error: [1047](#) SQLSTATE: [08S01](#) ([ER\\_UNKNOWN\\_COM\\_ERROR](#) [\[3663\]](#))

Message: Unknown command

- Error: 1048 SQLSTATE: 23000 (ER\_BAD\_NULL\_ERROR [3664])

Message: Column '%s' cannot be null

- Error: 1049 SQLSTATE: 42000 (ER\_BAD\_DB\_ERROR [3664])

Message: Unknown database '%s'

- Error: 1050 SQLSTATE: 42S01 (ER\_TABLE\_EXISTS\_ERROR [3664])

Message: Table '%s' already exists

- Error: 1051 SQLSTATE: 42S02 (ER\_BAD\_TABLE\_ERROR [3664])

Message: Unknown table '%s'

- Error: 1052 SQLSTATE: 23000 (ER\_NON\_UNIQ\_ERROR [3664])

Message: Column '%s' in %s is ambiguous

- Error: 1053 SQLSTATE: 08S01 (ER\_SERVER\_SHUTDOWN [3664])

Message: Server shutdown in progress

- Error: 1054 SQLSTATE: 42S22 (ER\_BAD\_FIELD\_ERROR [3664])

Message: Unknown column '%s' in '%s'

- Error: 1055 SQLSTATE: 42000 (ER\_WRONG\_FIELD\_WITH\_GROUP [3664])

Message: '%s' isn't in GROUP BY

- Error: 1056 SQLSTATE: 42000 (ER\_WRONG\_GROUP\_FIELD [3664])

Message: Can't group on '%s'

- Error: 1057 SQLSTATE: 42000 (ER\_WRONG\_SUM\_SELECT [3664])

Message: Statement has sum functions and columns in same statement

- Error: 1058 SQLSTATE: 21S01 (ER\_WRONG\_VALUE\_COUNT [3664])

Message: Column count doesn't match value count

- Error: 1059 SQLSTATE: 42000 (ER\_TOO\_LONG\_IDENT [3664])

Message: Identifier name '%s' is too long

- Error: 1060 SQLSTATE: 42S21 (ER\_DUP\_FIELDNAME [3664])

Message: Duplicate column name '%s'

- Error: 1061 SQLSTATE: 42000 (ER\_DUP\_KEYNAME [3664])

Message: Duplicate key name '%s'

- Error: 1062 SQLSTATE: 23000 (ER\_DUP\_ENTRY [3664])

Message: Duplicate entry '%s' for key %d

As of MySQL 5.1.20, the message returned with this error uses the format string for [ER\\_DUP\\_ENTRY\\_WITH\\_KEY\\_NAME \[3698\]](#).

- Error: 1063 SQLSTATE: 42000 ([ER\\_WRONG\\_FIELD\\_SPEC \[3665\]](#))  
Message: Incorrect column specifier for column '%s'
- Error: 1064 SQLSTATE: 42000 ([ER\\_PARSE\\_ERROR \[3665\]](#))  
Message: %s near '%s' at line %d
- Error: 1065 SQLSTATE: 42000 ([ER\\_EMPTY\\_QUERY \[3665\]](#))  
Message: Query was empty
- Error: 1066 SQLSTATE: 42000 ([ER\\_NONUNIQ\\_TABLE \[3665\]](#))  
Message: Not unique table/alias: '%s'
- Error: 1067 SQLSTATE: 42000 ([ER\\_INVALID\\_DEFAULT \[3665\]](#))  
Message: Invalid default value for '%s'
- Error: 1068 SQLSTATE: 42000 ([ER\\_MULTIPLE\\_PRI\\_KEY \[3665\]](#))  
Message: Multiple primary key defined
- Error: 1069 SQLSTATE: 42000 ([ER\\_TOO\\_MANY\\_KEYS \[3665\]](#))  
Message: Too many keys specified; max %d keys allowed
- Error: 1070 SQLSTATE: 42000 ([ER\\_TOO\\_MANY\\_KEY\\_PARTS \[3665\]](#))  
Message: Too many key parts specified; max %d parts allowed
- Error: 1071 SQLSTATE: 42000 ([ER\\_TOO\\_LONG\\_KEY \[3665\]](#))  
Message: Specified key was too long; max key length is %d bytes
- Error: 1072 SQLSTATE: 42000 ([ER\\_KEY\\_COLUMN\\_DOES\\_NOT\\_EXIST \[3665\]](#))  
Message: Key column '%s' doesn't exist in table
- Error: 1073 SQLSTATE: 42000 ([ER\\_BLOB\\_USED\\_AS\\_KEY \[3665\]](#))  
Message: BLOB column '%s' can't be used in key specification with the used table type
- Error: 1074 SQLSTATE: 42000 ([ER\\_TOO\\_BIG\\_FIELDLENGTH \[3665\]](#))  
Message: Column length too big for column '%s' (max = %lu); use BLOB or TEXT instead
- Error: 1075 SQLSTATE: 42000 ([ER\\_WRONG\\_AUTO\\_KEY \[3665\]](#))  
Message: Incorrect table definition; there can be only one auto column and it must be defined as a key

- Error: [1549](#) SQLSTATE: [HY000](#) ([ER\\_EVENT\\_CANNOT\\_DELETE](#) [\[3695\]](#))  
Message: Failed to delete the event from mysql.event
- Error: [1550](#) SQLSTATE: [HY000](#) ([ER\\_EVENT\\_COMPILE\\_ERROR](#) [\[3695\]](#))  
Message: Error during compilation of event's body
- Error: [1551](#) SQLSTATE: [HY000](#) ([ER\\_EVENT\\_SAME\\_NAME](#) [\[3695\]](#))

Message: Same old and new event name

- Error: 1552 SQLSTATE: HY000 (ER\_EVENT\_DATA\_TOO\_LONG [3696])

Message: Data for column '%s' too long

- Error: 1553 SQLSTATE: HY000 (ER\_DROP\_INDEX\_FK [3696])

Message: Cannot drop index '%s': needed in a foreign key constraint

- Error: 1554 SQLSTATE: HY000 (ER\_WARN\_DEPRECATED\_SYNTAX\_WITH\_VER [3696])

Message: The syntax '%s' is deprecated and will be removed in MySQL %s. Please use %s instead

- Error: 1555 SQLSTATE: HY000 (ER\_CANT\_WRITE\_LOCK\_LOG\_TABLE [3696])

Message: You can't write-lock a log table. Only read access is possible

- Error: 1556 SQLSTATE: HY000 (ER\_CANT\_LOCK\_LOG\_TABLE [3696])

Message: You can't use locks with log tables.

- Error: 1557 SQLSTATE: 23000 (ER\_FOREIGN\_DUPLICATE\_KEY\_OLD\_UNUSED [3696])

Message: Upholding foreign key constraints for table '%s', entry '%s', key %d would lead to a duplicate entry

- Error: 1558 SQLSTATE: HY000 (ER\_COL\_COUNT\_DOESNT\_MATCH\_PLEASE\_UPDATE [3696])

Message: Column count of mysql.%s is wrong. Expected %d, found %d. Created with MySQL %d, now running %d. Please use mysql\_upgrade to fix this error.

- Error: 1559 SQLSTATE: HY000 (ER\_TEMP\_TABLE\_PREVENTS\_SWITCH\_OUT\_OF\_RBR [3696])

Message: Cannot switch out of the row-based binary log format when the session has open temporary tables

- Error: 1560 SQLSTATE: HY000 (ER\_STORED\_FUNCTION\_PREVENTS\_SWITCH\_BINLOG\_FORMAT [3696])

Message: Cannot change the binary logging format inside a stored function or trigger

- Error: 1561 SQLSTATE: HY000 (ER\_NDB\_CANT\_SWITCH\_BINLOG\_FORMAT [3696])

Message: The NDB cluster engine does not support changing the binlog format on the fly yet

- Error: 1562 SQLSTATE: HY000 (ER\_PARTITION\_NO\_TEMPORARY [3696])

Message: Cannot create temporary table with partitions

- Error: 1563 SQLSTATE: HY000 (ER\_PARTITION\_CONST\_DOMAIN\_ERROR [3696])

Message: Partition constant is out of partition function domain

- Error: 1564 SQLSTATE: HY000 (ER\_PARTITION\_FUNCTION\_IS\_NOT\_ALLOWED [3696])

Message: This partition function is not allowed

- Error: 1565 SQLSTATE: HY000 (ER\_DDL\_LOG\_ERROR [3696])

Message: Error in DDL log

- Error: 1566 SQLSTATE: HY000 (ER\_NULL\_IN\_VALUES\_LESS\_THAN [3696])

Message: Not allowed to use NULL value in VALUES LESS THAN

- Error: [1567](#) SQLSTATE: [HY000](#) ([ER\\_WRONG\\_PARTITION\\_NAME](#) [\[3697\]](#))

Message: Incorrect partition name

- Error: [1568](#) SQLSTATE: [25001](#) ([ER\\_CANT\\_CHANGE\\_TX\\_CHARACTERISTICS](#) [\[3697\]](#))

Message: Transaction characteristics can't be changed while a transaction is in progress

- Error: [1569](#) SQLSTATE: [HY000](#) ([ER\\_DUP\\_ENTRY\\_AUTOINCREMENT\\_CASE](#) [\[3697\]](#))

Message: ALTER TABLE causes auto\_increment resequencing, resulting in duplicate entry '%s' for key '%s'

- Error: [1570](#) SQLSTATE: [HY000](#) ([ER\\_EVENT\\_MODIFY\\_QUEUE\\_ERROR](#) [\[3697\]](#))

Message: Internal scheduler error %d

- Error: [1571](#) SQLSTATE: [HY000](#) ([ER\\_EVENT\\_SET\\_VAR\\_ERROR](#) [\[3697\]](#))

Message: Error during starting/stopping of the scheduler. Error code %u

- Error: [1572](#) SQLSTATE: [HY000](#) ([ER\\_PARTITION\\_MERGE\\_ERROR](#) [\[3697\]](#))

Message: Engine cannot be used in partitioned tables

- Error: [1573](#) SQLSTATE: [HY000](#) ([ER\\_CANT\\_ACTIVATE\\_LOG](#) [\[3697\]](#))

Message: Cannot activate '%s' log

- Error: [1574](#) SQLSTATE: [HY000](#) ([ER\\_RBR\\_NOT\\_AVAILABLE](#) [\[3697\]](#))

Message: The server was not built with row-based replication

- Error: [1575](#) SQLSTATE: [HY000](#) ([ER\\_BASE64\\_DECODE\\_ERROR](#) [\[3697\]](#))

Message: Decoding of base64 string failed

- Error: [1576](#) SQLSTATE: [HY000](#) ([ER\\_EVENT\\_RECURSION\\_FORBIDDEN](#) [\[3697\]](#))

Message: Recursion of EVENT DDL statements is forbidden when body is present

- Error: [1577](#) SQLSTATE: [HY000](#) ([ER\\_EVENTS\\_DB\\_ERROR](#) [\[3697\]](#))

Message: Cannot proceed because system tables used by Event Scheduler were found damaged at server start

- Error: [1578](#) SQLSTATE: [HY000](#) ([ER\\_ONLY\\_INTEGERS\\_ALLOWED](#) [\[3697\]](#))

Message: Only integers allowed as number here

- Error: [1579](#) SQLSTATE: [HY000](#) ([ER\\_UNSUPPORTED\\_LOG\\_ENGINE](#) [\[3697\]](#))

Message: This storage engine cannot be used for log tables"

- Error: [1580](#) SQLSTATE: [HY000](#) ([ER\\_BAD\\_LOG\\_STATEMENT](#) [\[3697\]](#))

Message: You cannot '%s' a log table if logging is enabled

- Error: [1581](#) SQLSTATE: [HY000](#) ([ER\\_CANT\\_RENAME\\_LOG\\_TABLE](#) [\[3697\]](#))

Message: Cannot rename '%s'. When logging enabled, rename to/from log table must rename two tables: the log table to an archive table and another table back to '%s'

- Error: [1582](#) SQLSTATE: [42000](#) ([ER\\_WRONG\\_PARAMCOUNT\\_TO\\_NATIVE\\_FCT](#) [\[3698\]](#))  
Message: Incorrect parameter count in the call to native function '%s'
- Error: [1583](#) SQLSTATE: [42000](#) ([ER\\_WRONG\\_PARAMETERS\\_TO\\_NATIVE\\_FCT](#) [\[3698\]](#))  
Message: Incorrect parameters in the call to native function '%s'
- Error: [1584](#) SQLSTATE: [42000](#) ([ER\\_WRONG\\_PARAMETERS\\_TO\\_STORED\\_FCT](#) [\[3698\]](#))  
Message: Incorrect parameters in the call to stored function '%s'
- Error: [1585](#) SQLSTATE: [HY000](#) ([ER\\_NATIVE\\_FCT\\_NAME\\_COLLISION](#) [\[3698\]](#))  
Message: This function '%s' has the same name as a native function
- Error: [1586](#) SQLSTATE: [23000](#) ([ER\\_DUP\\_ENTRY\\_WITH\\_KEY\\_NAME](#) [\[3698\]](#))  
Message: Duplicate entry '%s' for key '%s'  
  
As of MySQL 5.1.20, the format string for this error is also used with [ER\\_DUP\\_ENTRY](#) [\[3664\]](#).
- Error: [1587](#) SQLSTATE: [HY000](#) ([ER\\_BINLOG\\_PURGE\\_EMFILE](#) [\[3698\]](#))  
Message: Too many files opened, please execute the command again
- Error: [1588](#) SQLSTATE: [HY000](#) ([ER\\_EVENT\\_CANNOT\\_CREATE\\_IN\\_THE\\_PAST](#) [\[3698\]](#))  
Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
- Error: [1589](#) SQLSTATE: [HY000](#) ([ER\\_EVENT\\_CANNOT ALTER\\_IN\\_THE\\_PAST](#) [\[3698\]](#))  
Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was not changed. Specify a time in the future.
- Error: [1590](#) SQLSTATE: [HY000](#) ([ER\\_SLAVE\\_INCIDENT](#) [\[3698\]](#))  
Message: The incident %s occurred on the master. Message: %s
- Error: [1591](#) SQLSTATE: [HY000](#) ([ER\\_NO\\_PARTITION\\_FOR\\_GIVEN\\_VALUE\\_SILENT](#) [\[3698\]](#))

Message: Cannot execute the current event group in the parallel mode. Encountered event %s, relay-log name %s, position %s which prevents execution of this event group in parallel mode. Reason: %s.
- Error: [1756](#) SQLSTATE: [HY000](#) ([ER\\_MTS\\_INCONSISTENT\\_DATA](#) [\[3709\]](#))  
Message: %s
- Error: [1757](#) SQLSTATE: [HY000](#) ([ER\\_FULLTEXT\\_NOT\\_SUPPORTED\\_WITH\\_PARTITIONING](#) [\[3709\]](#))  
Message: FULLTEXT index is not supported for partitioned tables.
- Error: [1758](#) SQLSTATE: [35000](#) ([ER\\_DA\\_INVALID\\_CONDITION\\_NUMBER](#) [\[3709\]](#))  
Message: Invalid condition number
- Error: [1759](#) SQLSTATE: [HY000](#) ([ER\\_INSECURE\\_PLAIN\\_TEXT](#) [\[3709\]](#))

Message: Sending passwords in plain text without SSL/TLS is extremely insecure.

- Error: 1760 SQLSTATE: HY000 (ER\_INSECURE\_CHANGE\_MASTER [3710])

Message: Storing MySQL user name or password information in the master.info repository is not secure and is therefore not recommended. Please see the MySQL Manual for more about this issue and possible alternatives.

- Error: 1761 SQLSTATE: 23000 (ER\_FOREIGN\_DUPLICATE\_KEY\_WITH\_CHILD\_INFO [3710])

Message: Foreign key constraint for table '%s', record '%s' would lead to a duplicate entry in table '%s', key '%s'

- Error: 1762 SQLSTATE: 23000 (ER\_FOREIGN\_DUPLICATE\_KEY\_WITHOUT\_CHILD\_INFO [3710])

Message: Foreign key constraint for table '%s', record '%s' would lead to a duplicate entry in a child table

- Error: 1763 SQLSTATE: HY000 (ER\_SQLTHREAD\_WITH\_SECURE\_SLAVE [3710])

Message: Setting authentication options is not possible when only the Slave SQL Thread is being started.

- Error: 1764 SQLSTATE: HY000 (ER\_TABLE\_HAS\_NO\_FT [3710])

Message: The table does not have FULLTEXT index to support this query

- Error: 1765 SQLSTATE: HY000 (ER\_VARIABLE\_NOT\_SETTABLE\_IN\_SF\_OR\_TRIGGER [3710])

Message: The system variable %s cannot be set in stored functions or triggers.

- Error: 1766 SQLSTATE: HY000 (ER\_VARIABLE\_NOT\_SETTABLE\_IN\_TRANSACTION [3710])

Message: The system variable %s cannot be set when there is an ongoing transaction.

- Error: 1767 SQLSTATE: HY000 (ER\_GTID\_NEXT\_IS\_NOT\_IN\_GTID\_NEXT\_LIST [3710])

Message: The system variable @@SESSION.GTID\_NEXT has the value %s, which is not listed in @@SESSION.GTID\_NEXT\_LIST.

- Error: 1768 SQLSTATE: HY000 (ER\_CANT\_CHANGE\_GTID\_NEXT\_IN\_TRANSACTION\_WHEN\_GTID\_NEXT\_LIST\_IS\_NULL [3710])

Message: When @@SESSION.GTID\_NEXT\_LIST == NULL, the system variable @@SESSION.GTID\_NEXT cannot change inside a transaction.

- Error: 1769 SQLSTATE: HY000 (ER\_SET\_STATEMENT\_CANNOT\_INVOKE\_FUNCTION [3710])

Message: The statement 'SET %s' cannot invoke a stored function.

- Error: 1770 SQLSTATE: HY000 (ER\_GTID\_NEXT\_CANT\_BE\_AUTOMATIC\_IF\_GTID\_NEXT\_LIST\_IS\_NON\_NULL [3710])

Message: The system variable @@SESSION.GTID\_NEXT cannot be 'AUTOMATIC' when @@SESSION.GTID\_NEXT\_LIST is non-NULL.

- Error: 1771 SQLSTATE: HY000 (ER\_SKIPPING\_LOGGED\_TRANSACTION [3710])

Message: Skipping transaction %s because it has already been executed and logged.

- Error: 1772 SQLSTATE: HY000 (ER\_MALFORMED\_GTID\_SET\_SPECIFICATION [3710])

Message: Malformed GTID set specification '%s'.

- Error: 1773 SQLSTATE: HY000 (ER\_MALFORMED\_GTID\_SET\_ENCODING [3711])  
Message: Malformed GTID set encoding.
- Error: 1774 SQLSTATE: HY000 (ER\_MALFORMED\_GTID\_SPECIFICATION [3711])  
Message: Malformed GTID specification '%s'.
- Error: 1775 SQLSTATE: HY000 (ER\_GNO\_EXHAUSTED [3711])  
Message: Impossible to generate Global Transaction Identifier: the integer component reached the maximal value. Restart the server with a new server\_uuid.
- Error: 1776 SQLSTATE: HY000 (ER\_BAD\_SLAVE\_AUTO\_POSITION [3711])  
Message: Parameters MASTER\_LOG\_FILE, MASTER\_LOG\_POS, RELAY\_LOG\_FILE and RELAY\_LOG\_POS cannot be set when MASTER\_AUTO\_POSITION is active.
- Error: 1777 SQLSTATE: HY000 (ER\_AUTO\_POSITION\_REQUIRES\_GTID\_MODE\_ON [3711])  
Message: CHANGE MASTER TO MASTER\_AUTO\_POSITION = 1 can only be executed when @@GLOBAL.GTID\_MODE = ON.
- Error: 1778 SQLSTATE: HY000 (ER\_CANT\_DO\_IMPLICIT\_COMMIT\_IN\_TRX\_WHEN\_GTID\_NEXT\_IS\_SET [3711])  
Message: Cannot execute statements with implicit commit inside a transaction when @@SESSION.GTID\_NEXT != AUTOMATIC or @@SESSION.GTID\_NEXT\_LIST != NULL.
- Error: 1779 SQLSTATE: HY000 (ER\_GTID\_MODE\_2\_OR\_3\_REQUIRES\_ENFORCE\_GTID\_CONSISTENCY\_ON [3711])  
Message: @@GLOBAL.GTID\_MODE = ON or UPGRADE\_STEP\_2 requires @@GLOBAL.ENFORCE\_GTID\_CONSISTENCY = 1.
- Error: 1780 SQLSTATE: HY000 (ER\_GTID\_MODE\_REQUIRES\_BINLOG [3711])  
Message: @@GLOBAL.GTID\_MODE = ON or UPGRADE\_STEP\_1 or UPGRADE\_STEP\_2 requires --log-bin and --log-slave-updates.
- Error: 1781 SQLSTATE: HY000 (ER\_CANT\_SET\_GTID\_NEXT\_TO\_GTID\_WHEN\_GTID\_MODE\_IS\_OFF [3711])  
Message: @@SESSION.GTID\_NEXT cannot be set to UUID:NUMBER when @@GLOBAL.GTID\_MODE = OFF.
- Error: 1782 SQLSTATE: HY000 (ER\_CANT\_SET\_GTID\_NEXT\_TO\_ANONYMOUS\_WHEN\_GTID\_MODE\_IS\_ON [3711])  
Message: @@SESSION.GTID\_NEXT cannot be set to ANONYMOUS when @@GLOBAL.GTID\_MODE = ON.
- Error: 1783 SQLSTATE: HY000 (ER\_CANT\_SET\_GTID\_NEXT\_LIST\_TO\_NON\_NULL\_WHEN\_GTID\_MODE\_IS\_OFF [3711])  
Message: @@SESSION.GTID\_NEXT\_LIST cannot be set to a non-NULL value when @@GLOBAL.GTID\_MODE = OFF.
- Error: 1784 SQLSTATE: HY000 (ER\_FOUND\_GTID\_EVENT\_WHEN\_GTID\_MODE\_IS\_OFF [3711])  
Message: Found a Gtid\_log\_event or Previous\_gtids\_log\_event when @@GLOBAL.GTID\_MODE = OFF.

- Error: 1785 SQLSTATE: HY000 ([ER\\_GTID\\_UNSAFE\\_NON\\_TRANSACTIONAL\\_TABLE \[3712\]](#))

Message: When @@GLOBAL.ENFORCE\_GTID\_CONSISTENCY = 1, updates to non-transactional tables can only be done in either autocommitted statements or single-statement transactions, and never in the same statement as updates to transactional tables.

- Error: 1786 SQLSTATE: HY000 ([ER\\_GTID\\_UNSAFE\\_CREATE\\_SELECT \[3712\]](#))

Message: CREATE TABLE ... SELECT is forbidden when @@GLOBAL.ENFORCE\_GTID\_CONSISTENCY = 1.

- Error: 1787 SQLSTATE: HY000 ([ER\\_GTID\\_UNSAFE\\_CREATE\\_DROP\\_TEMPORARY\\_TABLE\\_IN\\_TRANSACTION \[3712\]](#))

Message: When @@GLOBAL.ENFORCE\_GTID\_CONSISTENCY = 1, the statements CREATE TEMPORARY TABLE and DROP TEMPORARY TABLE can be executed in a non-transactional context only, and require that AUTOCOMMIT = 1.

- Error: 1788 SQLSTATE: HY000 ([ER\\_GTID\\_MODE\\_CAN\\_ONLY\\_CHANGE\\_ONE\\_STEP\\_AT\\_A\\_TIME \[3712\]](#))

Message: The value of @@GLOBAL.GTID\_MODE can only change one step at a time: OFF <-> UPGRADE\_STEP\_1 <-> UPGRADE\_STEP\_2 <-> ON. Also note that this value must be stepped up or down simultaneously on all servers; see the Manual for instructions.

- Error: 1789 SQLSTATE: HY000 ([ER\\_MASTER\\_HAS\\_PURGED\\_REQUIRED\\_GTIDS \[3712\]](#))

Message: The slave is connecting using CHANGE MASTER TO MASTER\_AUTO\_POSITION = 1, but the master has purged binary logs containing GTIDs that the slave requires.

- Error: 1790 SQLSTATE: HY000 ([ER\\_CANT\\_SET\\_GTID\\_NEXT\\_WHEN\\_OWNING\\_GTID \[3712\]](#))

Message: @@SESSION.GTID\_NEXT cannot be changed by a client that owns a GTID. The client owns %s. Ownership is released on COMMIT or ROLLBACK.

- Error: 1791 SQLSTATE: HY000 ([ER\\_UNKNOWN\\_EXPLAIN\\_FORMAT \[3712\]](#))

Message: Unknown EXPLAIN format name: '%s'

- Error: 1792 SQLSTATE: 25006 ([ER\\_CANT\\_EXECUTE\\_IN\\_READ\\_ONLY\\_TRANSACTION \[3712\]](#))

Message: Cannot execute statement in a READ ONLY transaction.

- Error: 1793 SQLSTATE: HY000 ([ER\\_TOO\\_LONG\\_TABLE\\_PARTITION\\_COMMENT \[3712\]](#))

Message: Comment for table partition '%s' is too long (max = %lu)

- Error: 1794 SQLSTATE: HY000 ([ER\\_SLAVE\\_CONFIGURATION \[3712\]](#))

Message: Slave is not configured or failed to initialize properly. You must at least set --server-id to enable either a master or a slave. Additional error messages can be found in the MySQL error log.

- Error: 1795 SQLSTATE: HY000 ([ER\\_INNODB\\_FT\\_LIMIT \[3712\]](#))

Message: InnoDB presently supports one FULLTEXT index creation at a time

- Error: 1796 SQLSTATE: HY000 ([ER\\_INNODB\\_NO\\_FT\\_TEMP\\_TABLE \[3712\]](#))

Message: Cannot create FULLTEXT index on temporary InnoDB table

- Error: 1797 SQLSTATE: HY000 ([ER\\_INNODB\\_FT\\_WRONG\\_DOCID\\_COLUMN \[3712\]](#))

Message: Column '%s' is of wrong type for an InnoDB FULLTEXT index

- Error: [1798](#) SQLSTATE: [HY000](#) ([ER\\_INNOODB\\_FT\\_WRONG\\_DOCID\\_INDEX](#) [\[3713\]](#))  
Message: Index '%s' is of wrong type for an InnoDB FULLTEXT index
- Error: [1799](#) SQLSTATE: [HY000](#) ([ER\\_INNOODB\\_ONLINE\\_LOG\\_TOO\\_BIG](#) [\[3713\]](#))  
Message: Creating index '%s' required more than 'innodb\_online\_alter\_log\_max\_size' bytes of modification log. Please try again.
- Error: [1800](#) SQLSTATE: [HY000](#) ([ER\\_UNKNOWN\\_ALTER\\_ALGORITHM](#) [\[3713\]](#))  
Message: Unknown ALGORITHM '%s'
- Error: [1801](#) SQLSTATE: [HY000](#) ([ER\\_UNKNOWN\\_ALTER\\_LOCK](#) [\[3713\]](#))  
Message: Unknown LOCK type '%s'
- Error: [1802](#) SQLSTATE: [HY000](#) ([ER\\_MTS\\_CHANGE\\_MASTER\\_CANT\\_RUN\\_WITH\\_GAPS](#) [\[3713\]](#))  
Message: CHANGE MASTER cannot be executed when the slave was stopped with an error or killed in MTS mode. Consider using RESET SLAVE or START SLAVE UNTIL.
- Error: [1803](#) SQLSTATE: [HY000](#) ([ER\\_MTS\\_RECOVERY\\_FAILURE](#) [\[3713\]](#))  
Message: Cannot recover after SLAVE errored out in parallel execution mode. Additional error messages can be found in the MySQL error log.
- Error: [1804](#) SQLSTATE: [HY000](#) ([ER\\_MTS\\_RESET\\_WORKERS](#) [\[3713\]](#))  
Message: Cannot clean up worker info tables. Additional error messages can be found in the MySQL error log.
- Error: [1805](#) SQLSTATE: [HY000](#) ([ER\\_COL\\_COUNT\\_DOESNT\\_MATCH\\_CORRUPTED\\_V2](#) [\[3713\]](#))  
Message: Column count of %s.%s is wrong. Expected %d, found %d. The table is probably corrupted
- Error: [1806](#) SQLSTATE: [HY000](#) ([ER\\_SLAVE\\_SILENT\\_RETRY\\_TRANSACTION](#) [\[3713\]](#))  
Message: Slave must silently retry current transaction
- Error: [1807](#) SQLSTATE: [HY000](#) ([ER\\_DISCARD\\_FK\\_CHECKS\\_RUNNING](#) [\[3713\]](#))  
Message: There is a foreign key check running on table '%s'. Cannot discard the table.
- Error: [1808](#) SQLSTATE: [HY000](#) ([ER\\_TABLE\\_SCHEMA\\_MISMATCH](#) [\[3713\]](#))  
Message: Schema mismatch (%s)
- Error: [1809](#) SQLSTATE: [HY000](#) ([ER\\_TABLE\\_IN\\_SYSTEM\\_TABLESPACE](#) [\[3713\]](#))  
Message: Table '%s' in system tablespace
- Error: [1810](#) SQLSTATE: [HY000](#) ([ER\\_IO\\_READ\\_ERROR](#) [\[3713\]](#))  
Message: IO Read error: (%lu, %s) %s
- Error: [1811](#) SQLSTATE: [HY000](#) ([ER\\_IO\\_WRITE\\_ERROR](#) [\[3713\]](#))  
Message: IO Write error: (%lu, %s) %s
- Error: [1812](#) SQLSTATE: [HY000](#) ([ER\\_TABLESPACE\\_MISSING](#) [\[3713\]](#))  
Message: Tablespace is missing for table '%s'

- Error: [1813](#) SQLSTATE: [HY000](#) ([ER\\_TABLESPACE\\_EXISTS](#) [\[3714\]](#))  
Message: Tablespace for table '%s' exists. Please DISCARD the tablespace before IMPORT.
- Error: [1814](#) SQLSTATE: [HY000](#) ([ER\\_TABLESPACE\\_DISCARDED](#) [\[3714\]](#))  
Message: Tablespace has been discarded for table '%s'
- Error: [1815](#) SQLSTATE: [HY000](#) ([ER\\_INTERNAL\\_ERROR](#) [\[3714\]](#))  
Message: Internal error: %s
- Error: [1816](#) SQLSTATE: [HY000](#) ([ER\\_INNODB\\_IMPORT\\_ERROR](#) [\[3714\]](#))  
Message: ALTER TABLE '%s' IMPORT TABLESPACE failed with error %lu : '%s'
- Error: [1817](#) SQLSTATE: [HY000](#) ([ER\\_INNODB\\_INDEX\\_CORRUPT](#) [\[3714\]](#))  
Message: Index corrupt: %s
- Error: [1818](#) SQLSTATE: [HY000](#) ([ER\\_INVALID\\_YEAR\\_COLUMN\\_LENGTH](#) [\[3714\]](#))  
Message: YEAR(%lu) column type is deprecated. Creating YEAR(4) column instead.
- Error: [1819](#) SQLSTATE: [HY000](#) ([ER\\_NOT\\_VALID\\_PASSWORD](#) [\[3714\]](#))  
Message: Your password does not satisfy the current policy requirements
- Error: [1820](#) SQLSTATE: [HY000](#) ([ER\\_MUST\\_CHANGE\\_PASSWORD](#) [\[3714\]](#))

([ER\\_ALTER\\_OPERATION\\_NOT\\_SUPPORTED\\_REASON\\_HIDDEN\\_FTS \[3717\]](#))  
Message: Cannot replace hidden FTS\_DOC\_ID with a user-visible one
- Error: 1856 SQLSTATE: HY000  
([ER\\_ALTER\\_OPERATION\\_NOT\\_SUPPORTED\\_REASON\\_CHANGE\\_FTS \[3717\]](#))  
Message: Cannot drop or rename FTS\_DOC\_ID
- Error: 1857 SQLSTATE: HY000 ([ER\\_ALTER\\_OPERATION\\_NOT\\_SUPPORTED\\_REASON\\_FTS \[3717\]](#))  
Message: Fulltext index creation requires a lock
- Error: 1858 SQLSTATE: HY000  
([ER\\_SQL\\_SLAVE\\_SKIP\\_COUNTER\\_NOT\\_SETTABLE\\_IN\\_GTID\\_MODE \[3717\]](#))  
Message: sql\_slave\_skip\_counter can not be set when the server is running with @@GLOBAL.GTID\_MODE = ON. Instead, for each transaction that you want to skip, generate an empty transaction with the same GTID as the transaction
- Error: 1859 SQLSTATE: 23000 ([ER\\_DUP\\_UNKNOWN\\_IN\\_INDEX \[3717\]](#))  
Message: Duplicate entry for key '%s'
- Error: 1860 SQLSTATE: HY000 ([ER\\_IDENT\\_CAUSES\\_TOO\\_LONG\\_PATH \[3717\]](#))  
Message: Long database name and identifier for object resulted in path length exceeding %d characters. Path: '%s'.
- Error: 1861 SQLSTATE: HY000  
([ER\\_ALTER\\_OPERATION\\_NOT\\_SUPPORTED\\_REASON\\_NOT\\_NULL \[3717\]](#))  
Message: cannot silently convert NULL values, as required in this SQL\_MODE
- Error: 1862 SQLSTATE: HY000 ([ER\\_MUST\\_CHANGE\\_PASSWORD\\_LOGIN \[3717\]](#))  
Message: Your password has expired. To log in you must change it using a client that supports expired passwords.
- Error: 1863 SQLSTATE: HY000 ([ER\\_ROW\\_IN\\_WRONG\\_PARTITION \[3717\]](#))  
Message: Found a row in wrong partition %s
- Error: 1864 SQLSTATE: HY000 ([ER\\_MTS\\_EVENT\\_BIGGER\\_PENDING\\_JOBS\\_SIZE\\_MAX \[3717\]](#))  
Message: Cannot schedule event %s, relay-log name %s, position %s to Worker thread because its size %lu exceeds %lu of slave\_pending\_jobs\_size\_max.
- Error: 1865 SQLSTATE: HY000 ([ER\\_INNODB\\_NO\\_FT\\_USES\\_PARSER \[3717\]](#))  
Message: Cannot CREATE FULLTEXT INDEX WITH PARSER on InnoDB table
- Error: 1866 SQLSTATE: HY000 ([ER\\_BINLOG\\_LOGICAL\\_CORRUPTION \[3717\]](#))  
Message: The binary log file '%s' is logically corrupted: %s
- Error: 1867 SQLSTATE: HY000 ([ER\\_WARN\\_PURGE\\_LOG\\_IN\\_USE \[3717\]](#))  
Message: file %s was not purged because it was being read by %d thread(s), purged only %d out of %d files.
- Error: 1868 SQLSTATE: HY000 ([ER\\_WARN\\_PURGE\\_LOG\\_IS\\_ACTIVE \[3717\]](#))

Message: file %s was not purged because it is the active log file.

## C.4. Client Error Codes and Messages

Client error information comes from the following source files:

- The Error values and the symbols in parentheses correspond to definitions in the `include/errmsg.h` MySQL source file.
- The Message values correspond to the error messages that are listed in the `libmysql/errmsg.c` file. `%d` and `%s` represent numbers and strings, respectively, that are substituted into the messages when they are displayed.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.

- Error: [2000 \(CR\\_UNKNOWN\\_ERROR \[3718\]\)](#)  
Message: Unknown MySQL error
- Error: [2001 \(CR\\_SOCKET\\_CREATE\\_ERROR \[3718\]\)](#)  
Message: Can't create UNIX socket (%d)

## C.5. Problems and Common Errors

This section lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

### C.5.1. How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

- If you have one of the following symptoms, then it is probably a hardware problems (such as memory, motherboard, CPU, or hard disk) or kernel problem:
  - The keyboard does not work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light does not change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
  - The mouse pointer does not move.
  - The machine does not answer to a remote machine's pings.
  - Other programs that are not related to MySQL do not behave correctly.
  - Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as [glibc](#)) are up to date.

It is always good to use a machine with ECC memory to discover memory problems early.

- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.
- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL's log files. See [Section 5.2](#), "MySQL Server Logs".
- If you do not think you have hardware problems, you should try to find out which program is causing problems. Try using `top`, `ps`, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.
- Use `top`, `df`, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.
- If the problem is some runaway process, you can always try to kill it. If it does not want to die, there is probably a bug in the operating system.

If after you have examined all other possibilities and you have concluded that the MySQL server or a MySQL client is causing the problem, it is time to create a bug report for our mailing list or our support team. In the bug report, try to give a very detailed description of how the system is behaving and what

you think is happening. You should also state why you think that MySQL is causing the problem. Take into consideration all the situations in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system does not work.” This provides us with no information about what could be the problem.

If a program fails, it is always useful to know the following information:

- Has the program in question made a segmentation fault (did it dump core)?
- Is the program taking up all available CPU time? Check with `top`. Let the program run for a while, it may simply be evaluating something computationally intensive.
- If the `mysqld` server is causing problems, can you get any response from it with `mysqladmin -u root ping` or `mysqladmin -u root processlist`?
- What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in [Section 1.7, “How to Report Bugs or Problems”](#).

## C.5.2. Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

### C.5.2.1. Access denied

An `Access denied` error can have many causes. Often the problem is related to the MySQL accounts that the server permits client programs to use when connecting. See [Section 6.2, “The MySQL Access Privilege System”](#), and [Section 6.2.7, “Causes of Access-Denied Errors”](#).

### C.5.2.2. Can't connect to [local] MySQL server

A MySQL client on Unix can connect to the `mysqld` server in two different ways: By using a Unix socket file to connect through a file in the file system (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you do not specify a host name or if you specify the special host name `localhost`.

If the MySQL server is running on Windows, you can connect using TCP/IP. If the server is started with the `--enable-named-pipe [421]` option, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you do not give a host name when connecting to `mysqld`, a MySQL client first tries to connect to the named pipe. If that does not work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using `.` as the host name.

The error (2002) `Can't connect to ...` normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket file name or TCP/IP port number when trying to connect to the server. You should also check that the TCP/IP port you are using has not been blocked by a firewall or port blocking service.

The error (2003) `Can't connect to MySQL server on 'server' (10061)` indicates that the network connection has been refused. You should check that there is a MySQL server running, that it has network connections enabled, and that the network port you specified is the one configured on the server.

Start by checking whether there is a process named `mysqld` running on your server host. (Use `ps xa | grep mysqld` on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See [Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”](#).

If a `mysqld` process is running, you can check it by trying the following commands. The port number or Unix socket file name might be different in your setup. `host_ip` represents the IP address of the machine where the server is running.

```
shell> mysqladmin version
shell> mysqladmin variables
shell> mysqladmin -h `hostname` version variables
shell> mysqladmin -h `hostname` --port=3306 version
shell> mysqladmin -h host_ip version
shell> mysqladmin --protocol=SOCKET --socket=/tmp/mysql.sock version
```

Note the use of backticks rather than forward quotation marks with the `hostname` command; these cause the output of `hostname` (that is, the current host name) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the host name of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking` [440], it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1` [414], it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.

Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.

Here are some reasons the [Can't connect to local MySQL server](#) error might occur:

- `mysqld` is not running on the local host. Check your operating system's process list to ensure the `mysqld` process is present.
- You're running a MySQL server on Windows with many TCP/IP connections to it. If you're experiencing that quite often your clients get that error, you can find a workaround here: [Section C.5.2.2.1, “Connection to MySQL Server Failing on Windows”](#).
- Someone has removed the Unix socket file that `mysqld` uses (`/tmp/mysql.sock` by default). For example, you might have a `cron` job that removes old files from the `/tmp` directory. You can always run `mysqladmin version` to check whether the Unix socket file that `mysqladmin` is trying to use really exists. The fix in this case is to change the `cron` job to not remove `mysql.sock` or to place the socket file somewhere else. See [Section C.5.4.5, “How to Protect or Change the MySQL Unix Socket File”](#).
- You have started the `mysqld` server with the `--socket=/path/to/socket` [442] option, but forgotten to tell client programs the new name of the socket file. If you change the socket path name for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` [211] option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

```
shell> netstat -ln | grep mysql
```

See [Section C.5.4.5, “How to Protect or Change the MySQL Unix Socket File”](#).

- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other `mysqld` threads (for example, with `kill` or with the `mysql_zap` script) before you can restart the MySQL server. See [Section C.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

- The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart `mysqld` with a `--socket [442]` option that specifies a socket file name in a directory where the server can create it and where client programs can access it.

If you get the error message `Can't connect to MySQL server on some_host`, you can try the following things to find out what the problem is:

- Check whether the server is running on that host by executing `telnet some_host 3306` and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as `telnet: Unable to connect to remote host: Connection refused`, then there is no server running on the given port.
- If the server is running on the local host, try using `mysqladmin -h localhost variables` to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the `port [525]` variable.)
- If you are running under Linux and Security-Enhanced Linux (SELinux) is enabled, make sure you have disabled SELinux protection for the `mysqld` process.

#### C.5.2.2.1. Connection to MySQL Server Failing on Windows

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a `Can't connect to MySQL server` error, the reason might be that Windows does not allow for enough ephemeral (short-lived) ports to serve those connections.

The purpose of `TIME_WAIT` is to keep a connection accepting packets even after the connection has been closed. This is because Internet routing can cause a packet to take a slow route to its destination and it may arrive after both sides have agreed to close. If the port is in use for a new connection, that packet from the old connection could break the protocol or compromise personal information from the original connection. The `TIME_WAIT` delay prevents this by ensuring that the port cannot be reused until after some time has been permitted for those delayed packets to arrive.

It is safe to reduce `TIME_WAIT` greatly on LAN connections because there is little chance of packets arriving at very long delays, as they could through the Internet with its comparatively large distances and latencies.

Windows permits ephemeral (short-lived) TCP ports to the user. After any port is closed it will remain in a `TIME_WAIT` status for 120 seconds. The port will not be available again until this time expires. The default range of port numbers depends on the version of Windows, with a more limited number of ports in older versions:

- Windows through Server 2003: Ports in range 1025–5000
- Windows Vista, Server 2008, and newer: Ports in range 49152–65535

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the `TIME_WAIT` status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

**IMPORTANT: The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore,**

and edit the registry, view the following article in the Microsoft Knowledge Base: <http://support.microsoft.com/kb/256986/EN-US/>.

1. Start Registry Editor (`Regedt32.exe`).
2. Locate the following key in the registry:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters
```

3. On the **Edit** menu, click **Add Value**, and then add the following registry value:

```
Value Name: MaxUserPort
Data Type: REG_DWORD
Value: 65534
```

This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).

4. On the **Edit** menu, click **Add Value**, and then add the following registry value:

```
Value Name: TcpTimedWaitDelay
Data Type: REG_DWORD
Value: 30
```

This sets the number of seconds to hold a TCP port connection in `TIME_WAIT` state before closing. The valid range is between 0 (zero) and 300 (decimal). The default value is 0x78 (120 decimal).

5. Quit Registry Editor.
6. Reboot the machine.

Note: Undoing the above should be as simple as deleting the registry entries you've created.

### C.5.2.3. Lost connection to MySQL server

There are three likely causes for this error message.

Usually it indicates network connectivity trouble and you should check the condition of your network if this error occurs frequently. If the error message includes “during query,” this is probably the case you are experiencing.

Sometimes the “during query” form happens when millions of rows are being sent as part of one or more queries. If you know that this is happening, you should try increasing `net_read_timeout` [515] from its default of 30 seconds to 60 seconds or longer, sufficient for the data transfer to complete.

More rarely, it can happen when the client is attempting the initial connection to the server. In this case, if your `connect_timeout` [472] value is set to only a few seconds, you may be able to resolve the problem by increasing it to ten seconds, perhaps more if you have a very long distance or slow connection. You can determine whether you are experiencing this more uncommon cause by using `SHOW GLOBAL STATUS LIKE 'Aborted_connects'`. It will increase by one for each initial connection attempt that the server aborts. You may see “reading authorization packet” as part of the error message; if so, that also suggests that this is the solution that you need.

If the cause is none of those just described, you may be experiencing a problem with `BLOB` values that are larger than `max_allowed_packet` [502], which can cause this error with some clients. Sometime you may see an `ER_NET_PACKET_TOO_LARGE` [3670] error, and that confirms that you need to increase `max_allowed_packet` [502].

### C.5.2.4. Client does not support authentication protocol

The current implementation of the authentication protocol uses a password hashing algorithm that is incompatible with that used by older (pre-4.1) clients. Attempts to connect to a 4.1 or newer server with an older client may fail with the following message:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

To deal with this problem, the preferred solution is to upgrade all client programs to use a 4.1.1 or newer client library. If that is not possible, use one of the following approaches:

- To connect to the server with a pre-4.1 client program, use an account that still has a pre-4.1-style password.
- Reset the password to pre-4.1 style for each user that needs to use a pre-4.1 client program. This can be done using the `SET PASSWORD` statement and the `OLD_PASSWORD()` [1263] function. As of MySQL 5.6.6, it is also necessary to first ensure that the authentication plugin for the account is `mysql_old_password`:

```
mysql> UPDATE mysql.user SET plugin = 'mysql_old_password'
mysql> WHERE User = 'some_user' AND Host = 'some_host';
mysql> FLUSH PRIVILEGES;
mysql> SET PASSWORD FOR
-> 'some_user'@'some_host' = OLD_PASSWORD('newpwd');
```

Substitute the password you want to use for “*newpwd*” in the preceding example. MySQL cannot tell you what the original password was, so you'll need to pick a new one.

- Tell the server to use the older password hashing algorithm by default:
  1. Start `mysqld` with the `old_passwords` [517] system variable set to 1.
  2. Assign an old-format password to each account that has had its password updated to the longer 4.1 format. You can identify these accounts with the following query:

```
mysql> SELECT Host, User, Password FROM mysql.user
-> WHERE LENGTH>Password) > 16;
```

For each account record displayed by the query, use the `Host` and `User` values and assign a password using one of the methods described previously.

The `Client does not support authentication protocol` error also can occur if multiple versions of MySQL are installed but client programs are dynamically linked and link to an older library. Make sure that clients use the most recent library version with which they are compatible. The procedure to do this will depend on your system.

#### Note

The `mysql` extension does not support the authentication protocol in MySQL 4.1.1 and higher. This is true regardless of the PHP version being used. If you wish to use the `mysql` extension with MySQL 4.1 or newer, you may need to follow one of the options discussed above for configuring MySQL to work with old clients. The `mysqli` extension (stands for “MySQL, Improved”; added in PHP 5) is compatible with the improved password hashing employed in MySQL 4.1 and higher, and no special configuration of MySQL need be done to use this MySQL client library. For more information about the `mysqli` extension, see <http://php.net/mysqli>.

For additional background on password hashing and authentication, see [Section 6.1.2.4, “Password Hashing in MySQL”](#).

### C.5.2.5. Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a `--password` [211] or `-p` option that has no following password value:

```
shell> mysql -u user_name -p
```

```
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

### C.5.2.6. Host '*host\_name*' is blocked

If the following error occurs, it means that `mysqld` has received many connection requests from the given host that were interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The value of the `max_connect_errors` [502] system variable determines how many successive interrupted connection requests are permitted. (See [Section 5.1.4, "Server System Variables"](#).) After `max_connect_errors` [502] failed requests without a successful connection, `mysqld` assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connections until you issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command.

By default, `mysqld` blocks a host after 10 connection errors. You can adjust the value by setting `max_connect_errors` [502] at server startup:

```
shell> mysqld_safe --max_connect_errors=10000 &
```

The value can also be set at runtime:

```
mysql> SET GLOBAL max_connect_errors=10000;
```

If you get the `Host 'host_name' is blocked` error message for a given host, you should first verify that there is nothing wrong with TCP/IP connections from that host. If you are having network problems, it does you no good to increase the value of the `max_connect_errors` [502] variable.

### C.5.2.7. Too many connections

If you get a `Too many connections` error when you try to connect to the `mysqld` server, this means that all available connections are in use by other clients.

The number of connections permitted is controlled by the `max_connections` [503] system variable. The default value is 151 to improve performance when MySQL is used with the Apache Web server. (Previously, the default was 100.) If you need to support more connections, you should set a larger value for this variable.

`mysqld` actually permits `max_connections+1` [503] clients to connect. The extra connection is reserved for use by accounts that have the `SUPER` [756] privilege. By granting the `SUPER` [756] privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See [Section 13.7.5.30, "SHOW PROCESSLIST Syntax"](#).

The maximum number of connections MySQL can support depends on the quality of the thread library on a given platform, the amount of RAM available, how much RAM is used for each connection, the workload from each connection, and the desired response time. Linux or Solaris should be able to support at 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding. Windows is limited to (open tables × 2 + open connections) < 2048 due to the Posix compatibility layer used on that platform.

Increasing `open-files-limit` [434] may be necessary. Also see [Section 2.5, “Installing MySQL on Linux”](#), for how to raise the operating system limit on how many handles can be used by MySQL.

### C.5.2.8. Out of memory

If you issue a query using the `mysql` client program and receive an error like the following one, it means that `mysql` does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke `mysql` with the `--quick` [252] option. This causes it to use the `mysql_use_result()` C API function to retrieve the result set, which places less of a load on the client (but more on the server).

### C.5.2.9. MySQL server has gone away

This section also covers the related `Lost connection to server during query` error.

The most common reason for the `MySQL server has gone away` error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent).

Error Code	Description
<code>CR_SERVER_GONE_ERROR</code> [3718]	The client couldn't send a question to the server.
<code>CR_SERVER_LOST</code> [3719]	The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question.

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the `wait_timeout` [563] variable when you start `mysqld`. See [Section 5.1.4, “Server System Variables”](#).

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the `mysql` command-line client).

Some other common reasons for the `MySQL server has gone away` error are:

- You (or the db administrator) has killed the running thread with a `KILL` statement or a `mysqladmin kill` command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- A client application running on a different host does not have the necessary privileges to connect to the MySQL server from that host.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: `mysql_options(..., MYSQL_OPT_READ_TIMEOUT,...)` or `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...)`. In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the `reconnect` flag in the `MYSQL` structure is equal to 0).
- You are using a Windows client and the server had dropped the connection (probably because `wait_timeout` [563] expired) before the command was issued.

The problem on Windows is that in some cases MySQL does not get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from the connection.

The solution to this is to either do a `mysql_ping()` on the connection if there has been a long time since the last query (this is what Connector/ODBC does) or set `wait_timeout` [563] on the `mysqld` server so high that it in practice never times out.

- You can also get these errors if you send a query to the server that is incorrect or too large. If `mysqld` receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big `BLOB` columns), you can increase the query limit by setting the server's `max_allowed_packet` [502] variable, which has a default value of 1MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in [Section C.5.2.10, "Packet Too Large"](#).

An `INSERT` or `REPLACE` statement that inserts a great many rows can also cause these sorts of errors. Either one of these statements sends a single request to the server irrespective of the number of rows to be inserted; thus, you can often avoid the error by reducing the number of rows sent per `INSERT` or `REPLACE`.

- You also get a lost connection if you are sending a packet 16MB or larger if your client is older than 4.0.8 and your server is 4.0.8 and above, or the other way around.
- It is also possible to see this error if host name lookups fail (for example, if the DNS server on which your server or network relies goes down). This is because MySQL is dependent on the host system for name resolution, but has no way of knowing whether it is working—from MySQL's point of view the problem is indistinguishable from any other network timeout.

You may also see the `MySQL server has gone away` error if MySQL is started with the `--skip-networking` [440] option.

Another networking issue that can cause this error occurs if the MySQL port (default 3306) is blocked by your firewall, thus preventing any connections at all to the MySQL server.

- You can also encounter this error with applications that fork child processes, all of which try to use the same connection to the MySQL server. This can be avoided by using a separate connection for each child process.
- You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing `mysqladmin version` and examining the server's uptime. If the client connection was broken because `mysqld` crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See [Section C.5.4.2, "What to Do If MySQL Keeps Crashing"](#).

You can get more information about the lost connections by starting `mysqld` with the `--log-warnings=2` [430] option. This logs some of the disconnected errors in the `hostname.err` file. See [Section 5.2.2, "The Error Log"](#).

If you want to create a bug report regarding this problem, be sure that you include the following information:

- Indicate whether the MySQL server died. You can find information about this in the server error log. See [Section C.5.4.2, "What to Do If MySQL Keeps Crashing"](#).
- If a specific query kills `mysqld` and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See [MySQL Internals: Porting to Other Systems](#).

- What is the value of the `wait_timeout` [563] system variable in the MySQL server? (`mysqladmin variables` gives you the value of this variable.)
- Have you tried to run `mysqld` with the general query log enabled to determine whether the problem query appears in the log? (See [Section 5.2.3, “The General Query Log”](#).)

See also [Section C.5.2.11, “Communication Errors and Aborted Connections”](#), and [Section 1.7, “How to Report Bugs or Problems”](#).

### C.5.2.10. Packet Too Large

A communication packet is a single SQL statement sent to the MySQL server, a single row that is sent to the client, or a binary log event sent from a master replication server to a slave.

The largest possible packet that can be transmitted to or from a MySQL 5.6 server or client is 1GB.

When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` [502] bytes, it issues an `ER_NET_PACKET_TOO_LARGE` [3670] error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` [502] variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` [502] variable is 16MB. To set a larger value, start `mysql` like this:

```
shell> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` [502] value is 1MB. You can increase this if the server needs to handle big queries (for example, if you are working with big `BLOB` columns). For example, to set the variable to 16MB, start the server like this:

```
shell> mysqld --max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet` [502]. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large `BLOB` values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

### C.5.2.11. Communication Errors and Aborted Connections

If connection problems occur such as communication errors or aborted connections, use these sources of information to diagnose problems:

- The error log. See [Section 5.2.2, “The Error Log”](#).
- The general query log. See [Section 5.2.3, “The General Query Log”](#).
- The `Aborted_xxx` and `Connection_errors_xxx` status variables. See [Section 5.1.6, “Server Status Variables”](#).

- The host cache, which is accessible using the `host_cache` Performance Schema table. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#), and [Section 20.9.9.1, “The host\\_cache Table”](#).

If you start the server with the `--log-warnings [430]` option, you might find messages like this in your error log:

```
010301 14:38:23 Aborted connection 854 to db:
'users' user: 'josh'
```

If a client successfully connects but later disconnects improperly or is terminated, the server increments the `Aborted_clients [585]` status variable, and logs an `Aborted connection` message to the error log. The cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout [563]` or `interactive_timeout [490]` seconds without issuing any requests to the server. See [Section 5.1.4, “Server System Variables”](#).
- The client program ended abruptly in the middle of a data transfer.

If a client is unable even to connect, the server increments the `Aborted_connects [585]` status variable. Unsuccessful connection attempts can occur for the following reasons:

- A client does not have privileges to connect to a database.
- A client uses an incorrect password.
- A connection packet does not contain the right information.
- It takes more than `connect_timeout [472]` seconds to get a connect packet. See [Section 5.1.4, “Server System Variables”](#).

If these kinds of things happen, it might indicate that someone is trying to break into your server! Messages for these types of problems are logged to the general query log if it is enabled.

Other reasons for problems with aborted clients or aborted connections:

- The `max_allowed_packet [502]` variable value is too small or queries require more memory than you have allocated for `mysqld`. See [Section C.5.2.10, “Packet Too Large”](#).
- Use of Ethernet protocol with Linux, both half and full duplex. Many Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file using FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. Switch the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and test the results to determine the best setting.
- A problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

See also [Section C.5.2.9, “MySQL server has gone away”](#).

### C.5.2.12. The table is full

If a table-full error occurs, it may be that the disk is full or that the table has reached its maximum size. The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. See [Section E.10.3, “Limits on Table Size”](#).

### C.5.2.13. Can't create/write to file

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` [446] option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See [Section 4.2.3.3, "Using Option Files"](#).

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` [559] directory.

Check also the error code that you get with `pererror`. One reason the server cannot write to a table is that the file system is full:

```
shell> pererror 28
OS error code 28: No space left on device
```

If you get an error of the following type during startup, it indicates that the file system or directory used for storing data files is write protected. Providing the write error is to a test file, This error is not serious and can be safely ignored.

```
Can't create test file /usr/local/mysql/data/master.lower-test
```

#### C.5.2.14. Commands out of sync

If you get `Commands out of sync; you can't run this command now` in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

#### C.5.2.15. Ignoring user

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

```
Found wrong password for user 'some_user'@'some_host'; ignoring user
```

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of `mysqld` with an old `user` table. You can check this by executing `mysqlshow mysql user` to see whether the `Password` column is shorter than 16 characters. If so, you can correct this condition by running the `scripts/add_long_password` script.
- The account has an old password (eight characters long). Update the account in the `user` table to have a new password.
- You have specified a password in the `user` table without using the `PASSWORD()` [1263] function. Use `mysql` to update the account in the `user` table with a new password, making sure to use the `PASSWORD()` [1263] function:

```
mysql> UPDATE user SET Password=PASSWORD('newpwd')
```

```
-> WHERE User='some_user' AND Host='some_host';
```

### C.5.2.16. Table '*tbl\_name*' doesn't exist

If you get either of the following errors, it usually means that no table exists in the default database with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case sensitive if they are located on a file system that has case-sensitive file names.
- Even for file systems that are not case sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See [Section 13.7.5, “SHOW Syntax”](#).

### C.5.2.17. Can't initialize character set

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```

This error can have any of the following causes:

- The character set is a multi-byte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running `CMake` with the `-DDEFAULT_CHARSET=charset_name` [134] or `-DWITH_EXTRA_CHARSETS=charset_name` [136] option. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

All standard MySQL binaries are compiled with `-DWITH_EXTRA_CHARSETS=complex` [136], which enables support for all multi-byte character sets. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- The character set is a simple character set that is not compiled into `mysqld`, and the character set definition files are not in the place where the client expects to find them.

In this case, you need to use one of the following methods to solve the problem:

- Recompile the client with support for the character set. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).
- Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.
- Copy the character definition files to the path where the client expects them to be.

### C.5.2.18. '*File*' Not Found and Similar Errors

If you get `ERROR '...' not found (errno: 23), Can't open file: ... (errno: 24)`, or any other error with `errno 23` or `errno 24` from MySQL, it means that you haven't allocated enough file descriptors for the MySQL server. You can use the `pererror` utility to get a description of what the error number means:

```
shell> pererror 23
OS error code 23: File table overflow
shell> pererror 24
OS error code 24: Too many open files
shell> pererror 11
OS error code 11: Resource temporarily unavailable
```

The problem here is that `mysqld` is trying to keep open too many files simultaneously. You can either tell `mysqld` not to open so many files at once or increase the number of file descriptors available to `mysqld`.

To tell `mysqld` to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_open_cache` [551] system variable (the default value is 64). This may not entirely prevent running out of file descriptors because in some circumstances the server may attempt to extend the cache size temporarily, as described in [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#). Reducing the value of `max_connections` [503] also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to `mysqld`, you can use the `--open-files-limit` [228] option to `mysqld_safe` or set the `open_files_limit` [518] system variable. See [Section 5.1.4, “Server System Variables”](#). The easiest way to set these values is to add an option to your option file. See [Section 4.2.3.3, “Using Option Files”](#). If you have an old version of `mysqld` that does not support setting the open files limit, you can edit the `mysqld_safe` script. There is a commented-out line `ulimit -n 256` in the script. You can remove the “#” character to uncomment this line, and change the number 256 to set the number of file descriptors to be made available to `mysqld`.

`--open-files-limit` [228] and `ulimit` can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you start `mysqld_safe` or `mysqld` as `root` (just remember that you also need to start the server with the `--user` [446] option in this case so that it does not continue to run as `root` after it starts up). If you need to increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

#### Note

If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect values when you ask for the current limits. In this case, you should start `mysqld_safe` using `sh`.

### C.5.2.19. Table-Corruption Issues

If you have started `mysqld` with `--myisam-recover-options` [432], MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file `'Warning: Checking table ...'` which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further.

In MySQL 5.6, when the server detects `MyISAM` table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: `Got an error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in bug reports.

See also [Section 5.1.3, “Server Command Options”](#), and [Section 22.4.1.7, “Making a Test Case If You Experience Table Corruption”](#).

## C.5.3. Installation-Related Issues

### C.5.3.1. Problems with File Permissions

If you have problems with file permissions, the `UMASK` environment variable might be set incorrectly when `mysqld` starts. For example, MySQL might issue the following error message when you create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` value is 0660. You can change this behavior by starting `mysqld_safe` as follows:

```
shell> UMASK=384 # = 600 in octal
shell> export UMASK
shell> mysqld_safe &
```

By default, MySQL creates database directories with an access permission value of `0700`. You can modify this behavior by setting the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, if you want to give group access to all new directories, you can do this:

```
shell> UMASK_DIR=504 # = 770 in octal
shell> export UMASK_DIR
shell> mysqld_safe &
```

MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero.

See [Section 2.12, “Environment Variables”](#).

## C.5.4. Administration-Related Issues

### C.5.4.1. How to Reset the Root Password

If you have never set a `root` password for MySQL, the server does not require a password at all for connecting as `root`. However, this is insecure. For instructions on assigning passwords, see [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

If you know the `root` password, but want to change it, see [Section 13.7.1.7, “SET PASSWORD Syntax”](#).

If you set a `root` password previously, but have forgotten it, you can set a new password. The following sections provide instructions for Windows and Unix systems, as well as generic instructions that apply to any system.

#### C.5.4.1.1. Resetting the Root Password: Windows Systems

On Windows, use the following procedure to reset the password for all MySQL `root` accounts:

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list and stop it.

If your server is not running as a service, you may need to use the Task Manager to force it to stop.

3. Create a text file containing the following statements. Replace the password with the password that you want to use.

```
UPDATE mysql.user SET Password=PASSWORD('MyNewPass') WHERE User='root';
FLUSH PRIVILEGES;
```

Write the `UPDATE` and `FLUSH` statements each on a single line. The `UPDATE` statement resets the password for all `root` accounts, and the `FLUSH` statement tells the server to reload the grant tables into memory so that it notices the password change.

4. Save the file. For this example, the file will be named `C:\mysql-init.txt`.
5. Open a console window to get to the command prompt: From the Start menu, select Run, then enter `cmd` as the command to be run.
6. Start the MySQL server with the special `--init-file [424]` option (notice that the backslash in the option value is doubled):

```
C:\> C:\mysql\bin\mysqld --init-file=C:\mysql-init.txt
```

If you installed MySQL to a location other than `C:\mysql`, adjust the command accordingly.

The server executes the contents of the file named by the `--init-file` [424] option at startup, changing each `root` account password.

You can also add the `--console` [417] option to the command if you want server output to appear in the console window rather than in a log file.

If you installed MySQL using the MySQL Installation Wizard, you may need to specify a `--defaults-file` [219] option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld.exe"
      --defaults-file="C:\Program Files\MySQL\MySQL Server 5.6\my.ini"
      --init-file=C:\mysql-init.txt
```

The appropriate `--defaults-file` [219] setting can be found using the Services Manager: From the **Start** menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list, right-click it, and choose the **Properties** option. The **Path to executable** field contains the `--defaults-file` [219] setting.

7. After the server has started successfully, delete `C:\mysql-init.txt`.

You should now be able to connect to the MySQL server as `root` using the new password. Stop the MySQL server, then restart it in normal mode again. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

#### C.5.4.1.2. Resetting the Root Password: Unix Systems

On Unix, use the following procedure to reset the password for all MySQL `root` accounts. The instructions assume that you will start the server so that it runs using the Unix login account that you normally use for running the server. For example, if you run the server using the `mysql` login account, you should log in as `mysql` before using the instructions. Alternatively, you can log in as `root`, but in this case you *must* start `mysqld` with the `--user=mysql` [446] option. If you start the server as `root` without using `--user=mysql` [446], the server may create `root`-owned files in the data directory, such as log files, and these may cause permission-related problems for future server startups. If that happens, you will need to either change the ownership of the files to `mysql` or remove them.

1. Log on to your system as the Unix user that the `mysqld` server runs as (for example, `mysql`).
2. Locate the `.pid` file that contains the server's process ID. The exact location and name of this file depend on your distribution, host name, and configuration. Common locations are `/var/lib/mysql/`, `/var/run/mysqld/`, and `/usr/local/mysql/data/`. Generally, the file name has an extension of `.pid` and begins with either `mysqld` or your system's host name.

You can stop the MySQL server by sending a normal `kill` (not `kill -9`) to the `mysqld` process, using the path name of the `.pid` file in the following command:

```
shell> kill `cat /mysql-data-directory/host_name.pid`
```

Use backticks (not forward quotation marks) with the `cat` command. These cause the output of `cat` to be substituted into the `kill` command.

3. Create a text file containing the following statements. Replace the password with the password that you want to use.

```
UPDATE mysql.user SET Password=PASSWORD('MyNewPass') WHERE User='root';
FLUSH PRIVILEGES;
```

Write the `UPDATE` and `FLUSH` statements each on a single line. The `UPDATE` statement resets the password for all `root` accounts, and the `FLUSH` statement tells the server to reload the grant tables into memory so that it notices the password change.

4. Save the file. For this example, the file will be named `/home/me/mysql-init`. The file contains the password, so it should not be saved where it can be read by other users. If you are not logged in as `mysql` (the user the server runs as), make sure that the file has permissions that permit `mysql` to read it.
5. Start the MySQL server with the special `--init-file` [424] option:

```
shell> mysqld_safe --init-file=/home/me/mysql-init &
```

The server executes the contents of the file named by the `--init-file` [424] option at startup, changing each `root` account password.

6. After the server has started successfully, delete `/home/me/mysql-init`.

You should now be able to connect to the MySQL server as `root` using the new password. Stop the server and restart it normally.

### C.5.4.1.3. Resetting the Root Password: Generic Instructions

The preceding sections provide password-resetting instructions for Windows and Unix systems. Alternatively, on any platform, you can set the new password using the `mysql` client (but this approach is less secure):

1. Stop `mysqld` and restart it with the `--skip-grant-tables` [439] option. This enables anyone to connect without a password and with all privileges. Because this is insecure, you might want to use `--skip-grant-tables` [439] in conjunction with `--skip-networking` [440] to prevent remote clients from connecting.
2. Connect to the `mysqld` server with this command:

```
shell> mysql
```

3. Issue the following statements in the `mysql` client. Replace the password with the password that you want to use.

```
mysql> UPDATE mysql.user SET Password=PASSWORD('MyNewPass')
-> WHERE User='root';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement tells the server to reload the grant tables into memory so that it notices the password change.

You should now be able to connect to the MySQL server as `root` using the new password. Stop the server, then restart it normally (without the `--skip-grant-tables` [439] and `--skip-networking` [440] options).

### C.5.4.2. What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This does not mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the `mysqld` server dies or whether your problem has to do with your client. You can check how long your `mysqld` server has been up by executing `mysqladmin version`. If `mysqld` has died and restarted, you may find the reason by looking in the server's error log. See [Section 5.2.2, "The Error Log"](#).

On some systems, you can find in the error log a stack trace of where `mysqld` died that you can resolve with the `resolve_stack_dump` program. See [MySQL Internals: Porting to Other Systems](#). Note that the variable values written in the error log may not always be 100% correct.

Many server crashes are caused by corrupted data files or index files. MySQL updates the files on disk with the `write()` system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with `--delay-key-write` [421], in which case data files are written but not index files.) This means that data file contents are safe even if `mysqld` crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting `mysqld` with the `--flush` [423] option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in `mysqld` that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as `mysqld` without locking the table properly.
- You are running many `mysqld` servers using the same data directory on a system that does not support good file system locks (normally handled by the `lockd` lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused `mysqld`.
- You have found a bug in the data storage code. This isn't likely, but it is at least possible. In this case, you can try to change the storage engine to another engine by using `ALTER TABLE` on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others crash for you. Try the following things:

- Stop the `mysqld` server with `mysqladmin shutdown`, run `myisamchk --silent --force */*.MYI` from the data directory to check all MyISAM tables, and restart `mysqld`. This ensures that you are running from a clean state. See [Chapter 5, MySQL Server Administration](#).
- Start `mysqld` with the general query log enabled (see [Section 5.2.3, "The General Query Log"](#)). Then try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See [Section 5.2.3, "The General Query Log"](#). If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have isolated the bug and should submit a bug report for it. See [Section 1.7, "How to Report Bugs or Problems"](#).
- Try to make a test case that we can use to repeat the problem. See [MySQL Internals: Porting to Other Systems](#).
- Try running the tests in the `mysql-test` directory and the MySQL benchmarks. See [Section 22.1.2, "The MySQL Test Suite"](#). They test MySQL rather well. You can also add code to the benchmarks that simulates your application. The benchmarks are in the `sql-bench` directory in a source distribution or, for a binary distribution, in the `sql-bench` directory under your MySQL installation directory.
- Try the `fork_big.pl` script. (It is located in the `tests` directory of source distributions.)
- Configuring MySQL for debugging makes it much easier to gather information about possible errors if something goes wrong. Reconfigure MySQL with the `-DWITH_DEBUG=1` [136] option to `CMake` and then recompile. See [MySQL Internals: Porting to Other Systems](#).
- Make sure that you have applied the latest patches for your operating system.
- Use the `--skip-external-locking` [439] option to `mysqld`. On some systems, the `lockd` lock manager does not work properly; the `--skip-external-locking` [439] option tells `mysqld` not

to use external locking. (This means that you cannot run two `mysqld` servers on the same data directory and that you must be careful if you use `myisamchk`. Nevertheless, it may be instructive to try the option as a test.)

- If `mysqld` appears to be running but not responding, try `mysqladmin -u root processlist`. Sometimes `mysqld` is not hung even though it seems unresponsive. The problem may be that all connections are in use, or there may be some internal lock problem. `mysqladmin -u root processlist` usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.
- Run the command `mysqladmin -i 5 status` or `mysqladmin -i 5 -r status` in a separate window to produce statistics while running other queries.
- Try the following:
  1. Start `mysqld` from `gdb` (or another debugger). See [MySQL Internals: Porting to Other Systems](#).
  2. Run your test scripts.
  3. Print the backtrace and the local variables at the three lowest levels. In `gdb`, you can do this with the following commands when `mysqld` has crashed inside `gdb`:

```
backtrace
info local
up
info local
up
info local
```

With `gdb`, you can also examine which threads exist with `info threads` and switch to a specific thread with `thread N`, where `N` is the thread ID.

- Try to simulate your application with a Perl script to force MySQL to crash or misbehave.
- Send a normal bug report. See [Section 1.7, “How to Report Bugs or Problems”](#). Be even more detailed than usual. Because MySQL works for many people, the crash might result from something that exists only on your computer (for example, an error that is related to your particular system libraries).
- If you have a problem with tables containing dynamic-length rows and you are using only `VARCHAR` columns (not `BLOB` or `TEXT` columns), you can try to change all `VARCHAR` to `CHAR` with `ALTER TABLE`. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Consider the possibility of hardware faults when diagnosing problems. Defective hardware can be the cause of data corruption. Pay particular attention to your memory and disk subsystems when troubleshooting hardware.

### C.5.4.3. How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to `MyISAM` tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:

- It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.
- Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, take the following actions:

- To continue, you only have to free enough disk space to insert all records.
- Alternatively, to abort the thread, use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).
- Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition enables the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA INFILE` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

#### C.5.4.4. Where MySQL Stores Temporary Files

On Unix, MySQL uses the value of the `TMPDIR` environment variable as the path name of the directory in which to store temporary files. If `TMPDIR` is not set, MySQL uses the system default, which is usually `/tmp`, `/var/tmp`, or `/usr/tmp`.

On Windows, MySQL checks in order the values of the `TMPDIR`, `TEMP`, and `TMP` environment variables. For the first one found to be set, MySQL uses it and does not check those remaining. If none of `TMPDIR`, `TEMP`, or `TMP` are set, MySQL uses the Windows system default, which is usually `C:\windows\temp\`.

If the file system containing your temporary file directory is too small, you can use the `--tmpdir [446]` option to `mysqld` to specify a directory in a file system where you have enough space.

In MySQL 5.6, the `--tmpdir [446]` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (“:”) on Unix and semicolon characters (“;”) on Windows.

#### Note

To spread the load effectively, these paths should be located on different *physical* disks, not different partitions of the same disk.

If the MySQL server is acting as a replication slave, you should not set `--tmpdir [446]` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

MySQL arranges that temporary files are removed if `mysqld` is terminated. On platforms that support it (such as Unix), this is done by unlinking the file after opening it. The disadvantage of this is that the name does not appear in directory listings and you do not see a big temporary file that fills up the file system in which the temporary file directory is located. (In such cases, `ls +Ll` may be helpful in identifying large files associated with `mysqld`.)

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

```
(length of what is sorted + sizeof(row pointer))
```

```
* number of matched rows
* 2
```

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some `SELECT` queries, MySQL also creates temporary SQL tables. These are not hidden and have names of the form `SQL_*`.

`ALTER TABLE` creates a temporary table in the same directory as the original table.

#### C.5.4.5. How to Protect or Change the MySQL Unix Socket File

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On some versions of Unix, anyone can delete files in the `/tmp` directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (`root`). To do this, set the `sticky` bit on the `/tmp` directory by logging in as `root` and using the following command:

```
shell> chmod +t /tmp
```

You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

```
[mysqld]
socket=/path/to/socket

[client]
socket=/path/to/socket
```

See [Section 4.2.3.3, “Using Option Files”](#).

- Specify a `--socket [211]` option on the command line to `mysqld_safe` and when you run client programs.
- Set the `MYSQL_UNIX_PORT` environment variable to the path of the Unix socket file.
- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the `MYSQL_UNIX_ADDR [135]` option when you run `CMake`. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

You can test whether the new socket location works by attempting to connect to the server with this command:

```
shell> mysqladmin --socket=/path/to/socket version
```

#### C.5.4.6. Time Zone Problems

If you have a problem with `SELECT NOW()` returning values in UTC and not your local time, you have to tell the server your current time zone. The same applies if `UNIX_TIMESTAMP()` [\[1226\]](#) returns the wrong value. This should be done for the environment in which the server runs; for example, in `mysqld_safe` or `mysql.server`. See [Section 2.12, “Environment Variables”](#).

You can set the time zone for the server with the `--timezone=timezone_name` [229] option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`.

The permissible values for `--timezone` [229] or `TZ` are system dependent. Consult your operating system documentation to see what values are acceptable.

## C.5.5. Query-Related Issues

### C.5.5.1. Case Sensitivity in String Searches

For nonbinary strings (`CHAR`, `VARCHAR`, `TEXT`), string searches use the collation of the comparison operands. For binary strings (`BINARY`, `VARBINARY`, `BLOB`), comparisons use the numeric values of the bytes in the operands; this means that for alphabetic characters, comparisons will be case sensitive.

A comparison between a nonbinary string and binary string is treated as a comparison of binary strings.

Simple comparison operations (`>=`, `>`, `=`, `<`, `<=`, sorting, and grouping) are based on each character's "sort value." Characters with the same sort value are treated as the same character. For example, if "e" and "é" have the same sort value in a given collation, they compare as equal.

The default character set and collation are `latin1` and `latin1_swedish_ci`, so nonbinary string comparisons are case insensitive by default. This means that if you search with `col_name LIKE 'a %'`, you get all column values that start with `A` or `a`. To make this search case sensitive, make sure that one of the operands has a case sensitive or binary collation. For example, if you are comparing a column and a string that both have the `latin1` character set, you can use the `COLLATE` operator to cause either operand to have the `latin1_general_cs` or `latin1_bin` collation:

```
col_name COLLATE latin1_general_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_general_cs
col_name COLLATE latin1_bin LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_bin
```

If you want a column always to be treated in case-sensitive fashion, declare it with a case sensitive or binary collation. See [Section 13.1.14, "CREATE TABLE Syntax"](#).

To cause a case-sensitive comparison of nonbinary strings to be case insensitive, use `COLLATE` to name a case-insensitive collation. The strings in the following example normally are case sensitive, but `COLLATE` changes the comparison to be case insensitive:

```
mysql> SET @s1 = 'MySQL' COLLATE latin1_bin,
->      @s2 = 'mysql' COLLATE latin1_bin;
mysql> SELECT @s1 = @s2;
+-----+
| @s1 = @s2 |
+-----+
|          0 |
+-----+
mysql> SELECT @s1 COLLATE latin1_swedish_ci = @s2;
+-----+
| @s1 COLLATE latin1_swedish_ci = @s2 |
+-----+
|                                     1 |
+-----+
```

A binary string is case sensitive in comparisons. To compare the string as case insensitive, convert it to a nonbinary string and use `COLLATE` to name a case-insensitive collation:

```
mysql> SET @s = BINARY 'MySQL';
mysql> SELECT @s = 'mysql';
+-----+
| @s = 'mysql' |
+-----+
|          0 |
+-----+
mysql> SELECT CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql';
+-----+
```

```
| CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql' |
+-----+
|  |
|  |
|  |
+-----+
|  |
|  |
|  |
+-----+
```

To determine whether a value will compare as a nonbinary or binary string, use the `COLLATION()` [1267] function. This example shows that `VERSION()` [1273] returns a string that has a case-insensitive collation, so comparisons are case insensitive:

```
mysql> SELECT COLLATION(VERSION());
+-----+
| COLLATION(VERSION()) |
+-----+
| utf8_general_ci     |
+-----+
```

For binary strings, the collation value is `binary`, so comparisons will be case sensitive. One context in which you will see `binary` is for compression and encryption functions, which return binary strings as a general rule: string:

```
mysql> SELECT COLLATION(ENCRYPT('x')), COLLATION(SHA1('x'));
+-----+
| COLLATION(ENCRYPT('x')) | COLLATION(SHA1('x')) |
+-----+
| binary                 | binary                |
+-----+
```

To check the sort value of a string, the `WEIGHT_STRING()` [1187] may be helpful. See [Section 12.5, “String Functions”](#).

### C.5.5.2. Problems Using `DATE` Columns

The format of a `DATE` value is `'YYYY-MM-DD'`. According to standard SQL, no other format is permitted. You should use this format in `UPDATE` expressions and in the `WHERE` clause of `SELECT` statements. For example:

```
SELECT * FROM t1 WHERE date >= '2003-05-05';
```

As a convenience, MySQL automatically converts a date to a number if the date is used in a numeric context and vice versa. MySQL also permits a “relaxed” string format when updating and in a `WHERE` clause that compares a date to a `DATE`, `DATETIME`, or `TIMESTAMP` column. “Relaxed” format means that any punctuation character may be used as the separator between parts. For example, `'2004-08-15'` and `'2004#08#15'` are equivalent. MySQL can also convert a string containing no separators (such as `'20040815'`), provided it makes sense as a date.

When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` to a constant string with the `<`, `<=`, `=`, `>=`, `>`, or `BETWEEN` operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more “relaxed” string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` column to an expression
- When you use any comparison method other than those just listed, such as `IN` or `STRCMP()` [1192].

For those exceptions, the comparison is done by converting the objects to strings and performing a string comparison.

To be on the safe side, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special “zero” date `'0000-00-00'` can be stored and retrieved as `'0000-00-00'`. When a `'0000-00-00'` date is used through Connector/ODBC, it is automatically converted to `NULL` because ODBC cannot handle that kind of date.

Because MySQL performs the conversions just described, the following statements work (assume that `idate` is a `DATE` column):

```
INSERT INTO t1 (idate) VALUES (19970505);
INSERT INTO t1 (idate) VALUES ('19970505');
INSERT INTO t1 (idate) VALUES ('97-05-05');
INSERT INTO t1 (idate) VALUES ('1997.05.05');
INSERT INTO t1 (idate) VALUES ('1997 05 05');
INSERT INTO t1 (idate) VALUES ('0000-00-00');

SELECT idate FROM t1 WHERE idate >= '1997-05-05';
SELECT idate FROM t1 WHERE idate >= 19970505;
SELECT MOD(idate,100) FROM t1 WHERE idate >= 19970505;
SELECT idate FROM t1 WHERE idate >= '19970505';
```

However, the following statement does not work:

```
SELECT idate FROM t1 WHERE STRCMP(idate,'20030505')=0;
```

`STRCMP()` [1192] is a string function, so it converts `idate` to a string in `'YYYY-MM-DD'` format and performs a string comparison. It does not convert `'20030505'` to the date `'2003-05-05'` and perform a date comparison.

If you enable the `ALLOW_INVALID_DATES` [603] SQL mode, MySQL permits you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12. This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

MySQL permits you to store dates where the day or month and day are zero. This is convenient if you want to store a birthdate in a `DATE` column and you know only part of the date. To disallow zero month or day parts in dates, enable the `NO_ZERO_IN_DATE` [606] SQL mode.

MySQL permits you to store a “zero” value of `'0000-00-00'` as a “dummy date.” This is in some cases more convenient than using `NULL` values. If a date to be stored in a `DATE` column cannot be converted to any reasonable value, MySQL stores `'0000-00-00'`. To disallow `'0000-00-00'`, enable the `NO_ZERO_DATE` [606] SQL mode.

To have MySQL check all dates and accept only legal dates (unless overridden by `IGNORE`), set the `sql_mode` [545] system variable to `"NO_ZERO_IN_DATE,NO_ZERO_DATE"`.

### C.5.5.3. Problems with `NULL` Values

The concept of the `NULL` value is a common source of confusion for newcomers to SQL, who often think that `NULL` is the same thing as an empty string `' '`. This is not the case. For example, the following statements are completely different:

```
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the `phone` column, but the first inserts a `NULL` value and the second inserts an empty string. The meaning of the first can be regarded as “phone number is not known” and the meaning of the second can be regarded as “the person is known to have no phone, and thus no phone number.”

To help with `NULL` handling, you can use the `IS NULL` [1168] and `IS NOT NULL` [1168] operators and the `IFNULL()` [1175] function.

In SQL, the `NULL` value is never true in comparison to any other value, even `NULL`. An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return `NULL`:

```
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

To search for column values that are `NULL`, you cannot use an `expr = NULL` test. The following statement returns no rows, because `expr = NULL` is never true for any expression:

```
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for `NULL` values, you must use the `IS NULL` [1168] test. The following statements show how to find the `NULL` phone number and the empty phone number:

```
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See [Section 3.3.4.6, “Working with `NULL` Values”](#), for additional information and examples.

You can add an index on a column that can have `NULL` values if you are using the `MyISAM`, `InnoDB`, or `MEMORY` storage engine. Otherwise, you must declare an indexed column `NOT NULL`, and you cannot insert `NULL` into the column.

When reading data with `LOAD DATA INFILE`, empty or missing columns are updated with `' '`. To load a `NULL` value into a column, use `\N` in the data file. The literal word “`NULL`” may also be used under some circumstances. See [Section 13.2.6, “`LOAD DATA INFILE` Syntax”](#).

When using `DISTINCT`, `GROUP BY`, or `ORDER BY`, all `NULL` values are regarded as equal.

When using `ORDER BY`, `NULL` values are presented first, or last if you specify `DESC` to sort in descending order.

Aggregate (summary) functions such as `COUNT()` [1283], `MIN()` [1284], and `SUM()` [1285] ignore `NULL` values. The exception to this is `COUNT(*)` [1283], which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-`NULL` values in the `age` column:

```
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles `NULL` values specially. If you insert `NULL` into a `TIMESTAMP` column, the current date and time is inserted. If you insert `NULL` into an integer or floating-point column that has the `AUTO_INCREMENT` attribute, the next number in the sequence is inserted.

#### C.5.5.4. Problems with Column Aliases

An alias can be used in a query select list to give a column a different name. You can use the alias in `GROUP BY`, `ORDER BY`, or `HAVING` clauses to refer to the column:

```
SELECT SQRT(a*b) AS root FROM tbl_name
GROUP BY root HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name
GROUP BY id HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL disallows references to column aliases in a `WHERE` clause. This restriction is imposed because when the `WHERE` clause is evaluated, the column value may not yet have been determined. For example, the following query is illegal:

```
SELECT id, COUNT(*) AS cnt FROM tbl_name
WHERE cnt > 0 GROUP BY id;
```

The `WHERE` clause determines which rows should be included in the `GROUP BY` clause, but it refers to the alias of a column value that is not known until after the rows have been selected, and grouped by the `GROUP BY`.

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
SELECT 1 AS `one`, 2 AS 'two';
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal. For example, this statement groups by the values in column `id`, referenced using the alias ``a``:

```
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
GROUP BY `a`;
```

But this statement groups by the literal string `'a'` and will not work as expected:

```
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
GROUP BY 'a';
```

### C.5.5.5. Rollback Failure for Nontransactional Tables

If you receive the following message when trying to perform a `ROLLBACK`, it means that one or more of the tables you used in the transaction do not support transactions:

```
Warning: Some non-transactional changed tables couldn't be rolled back
```

These nontransactional tables are not affected by the `ROLLBACK` statement.

If you were not deliberately mixing transactional and nontransactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your `mysqld` server (or that was disabled with a startup option). If `mysqld` does not support a storage engine, it instead creates the table as a `MyISAM` table, which is nontransactional.

You can check the storage engine for a table by using either of these statements:

```
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See [Section 13.7.5.37](#), “`SHOW TABLE STATUS Syntax`”, and [Section 13.7.5.12](#), “`SHOW CREATE TABLE Syntax`”.

To check which storage engines your `mysqld` server supports, use this statement:

```
SHOW ENGINES;
```

See [Section 13.7.5.17](#), “`SHOW ENGINES Syntax`” for full details.

### C.5.5.6. Deleting Rows from Related Tables

If the total length of the `DELETE` statement for `related_table` is more than 1MB (the default value of the `max_allowed_packet` [502] system variable), you should split it into smaller parts and execute multiple `DELETE` statements. You probably get the fastest `DELETE` by specifying only 100 to 1,000 `related_column` values per statement if the `related_column` is indexed. If the `related_column` isn't indexed, the speed is independent of the number of arguments in the `IN` clause.

### C.5.5.7. Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that returns no rows, you should use the following procedure to find out what is wrong:

1. Test the query with `EXPLAIN` to check whether you can find something that is obviously wrong. See [Section 13.8.2](#), “`EXPLAIN Syntax`”.
2. Select only those columns that are used in the `WHERE` clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it is a good idea to use `LIMIT 10` with the query.

4. Issue a `SELECT` for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing `FLOAT` or `DOUBLE` columns with numbers that have decimals, you cannot use equality (`=`) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the `FLOAT` to a `DOUBLE` fixes this. See [Section C.5.5.8, “Problems with Floating-Point Values”](#).
6. If you still cannot figure out what is wrong, create a minimal test that can be run with `mysql test < query.sql` that shows your problems. You can create a test file by dumping the tables with `mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql`. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your `SELECT` statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```
shell> mysqladmin create test2
shell> mysql test2 < query.sql
```

Attach the test file to a bug report, which you can file using the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

### C.5.5.8. Problems with Floating-Point Values

Floating-point numbers sometimes cause confusion because they are approximate and not stored as exact values. A floating-point value as written in an SQL statement may not be the same as the value represented internally. Attempts to treat floating-point values as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. The `FLOAT` and `DOUBLE` data types are subject to these issues. For `DECIMAL` columns, MySQL performs operations with a precision of 65 decimal digits, which should solve most common inaccuracy problems.

The following example uses `DOUBLE` to demonstrate how calculations that are done using floating-point operations are subject to floating-point error.

```
mysql> CREATE TABLE t1 (i INT, d1 DOUBLE, d2 DOUBLE);
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
-> (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
-> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
-> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
-> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
-> (6, 0.00, 0.00), (6, -51.40, 0.00);

mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
-> FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
1	21.4	21.4
2	76.8	76.8
3	7.4	7.4
4	15.4	15.4
5	7.2	7.2
6	-51.4	0

The result is correct. Although the first five records look like they should not satisfy the comparison (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

If columns `d1` and `d2` had been defined as `DECIMAL` rather than `DOUBLE`, the result of the `SELECT` query would have contained only one row—the last one shown above.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
-> GROUP BY i HAVING ABS(a - b) > 0.0001;
+-----+-----+-----+
| i     | a     | b     |
+-----+-----+-----+
| 6     | -51.4 | 0     |
+-----+-----+-----+
1 row in set (0.00 sec)
```

Conversely, to get rows where the numbers are the same, the test should find differences within the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
-> GROUP BY i HAVING ABS(a - b) <= 0.0001;
+-----+-----+-----+
| i     | a     | b     |
+-----+-----+-----+
| 1     | 21.4  | 21.4  |
| 2     | 76.8  | 76.8  |
| 3     | 7.4   | 7.4   |
| 4     | 15.4  | 15.4  |
| 5     | 7.2   | 7.2   |
+-----+-----+-----+
5 rows in set (0.03 sec)
```

Floating-point values are subject to platform or implementation dependencies. Suppose that you execute the following statements:

```
CREATE TABLE t1(c1 FLOAT(53,0), c2 FLOAT(53,0));
INSERT INTO t1 VALUES('1e+52', '-1e+52');
SELECT * FROM t1;
```

On some platforms, the `SELECT` statement returns `inf` and `-inf`. On others, it returns `0` and `-0`.

An implication of the preceding issues is that if you attempt to create a replication slave by dumping table contents with `mysqldump` on the master and reloading the dump file into the slave, tables containing floating-point columns might differ between the two hosts.

## C.5.6. Optimizer-Related Issues

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL does not have enough information about the data at hand and has to make “educated” guesses about the data.

For the cases when MySQL does not do the “right” thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

```
mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
```

`EXPLAIN` is discussed in more detail in [Section 13.8.2, “EXPLAIN Syntax”](#).

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See [Section 13.7.2.1, “ANALYZE TABLE Syntax”](#).
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

`USE INDEX` and `IGNORE INDEX` may also be useful. See [Section 13.2.9.3, “Index Hint Syntax”](#).

- Global and table-level `STRAIGHT_JOIN`. See [Section 13.2.9, “SELECT Syntax”](#).
- You can tune global or thread-specific system variables. For example, start `mysqld` with the `--max-seeks-for-key=1000 [507]` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See [Section 5.1.4, “Server System Variables”](#).

## C.5.7. Table Definition-Related Issues

### C.5.7.1. Problems with `ALTER TABLE`

If you get a duplicate-key error when using `ALTER TABLE` to change the character set or collation of a character column, the cause is either that the new column collation maps two keys to the same value or that the table is corrupted. In the latter case, you should run `REPAIR TABLE` on the table.

If `ALTER TABLE` dies with the following error, the problem may be that MySQL crashed during an earlier `ALTER TABLE` operation and there is an old table named `A-xxx` or `B-xxx` lying around:

```
Error on rename of './database/name.frm'
to './database/B-xxx.frm' (Errcode: 17)
```

In this case, go to the MySQL data directory and delete all files that have names starting with `A-` or `B-`. (You may want to move them elsewhere instead of deleting them.)

`ALTER TABLE` works in the following way:

- Create a new table named `A-xxx` with the requested structural changes.
- Copy all rows from the original table to `A-xxx`.
- Rename the original table to `B-xxx`.
- Rename `A-xxx` to your original table name.
- Delete `B-xxx`.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn't happen), MySQL may leave the old table as `B-xxx`. A simple rename of the table files at the system level should get your data back.

If you use `ALTER TABLE` on a transactional table or if you are using Windows, `ALTER TABLE` unlocks the table if you had done a `LOCK TABLE` on it. This is done because `InnoDB` and these operating systems cannot drop a table that is in use.

### C.5.7.2. `TEMPORARY` Table Problems

The following list indicates limitations on the use of `TEMPORARY` tables:

- A `TEMPORARY` table can only be of type `MEMORY`, `MyISAM`, `MERGE`, or `InnoDB`.

Temporary tables are not supported for MySQL Cluster.

- You cannot refer to a `TEMPORARY` table more than once in the same query. For example, the following does not work:

```
mysql> SELECT * FROM temp_table, temp_table AS t2;
ERROR 1137: Can't reopen table: 'temp_table'
```

This error also occurs if you refer to a temporary table multiple times in a stored function under different aliases, even if the references occur in different statements within the function.

- The `SHOW TABLES` statement does not list `TEMPORARY` tables.
- You cannot use `RENAME` to rename a `TEMPORARY` table. However, you can use `ALTER TABLE` instead:

```
mysql> ALTER TABLE orig_name RENAME new_name;
```

- There are known issues in using temporary tables with replication. See [Section 16.4.1, “Replication Features and Issues”](#), for more information.

## C.5.8. Known Issues in MySQL

This section lists known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and porting instructions in [Section 2.1, “General Installation Guidance”](#), and [MySQL Internals: Porting to Other Systems](#).

The following problems are known:

- Subquery optimization for `IN` is not as effective as for `=`.
- Even if you use `lower_case_table_names=2` (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function `DATABASE()` [1268] or within the various logs (on case-insensitive systems).
- Dropping a `FOREIGN KEY` constraint does not work in replication because the constraint may have another name on the slave.
- `REPLACE` (and `LOAD DATA` with the `REPLACE` option) does not trigger `ON DELETE CASCADE`.
- `DISTINCT` with `ORDER BY` does not work inside `GROUP_CONCAT()` [1283] if you do not use all and only those columns that are in the `DISTINCT` list.
- When inserting a big integer value (between  $2^{63}$  and  $2^{64}-1$ ) into a decimal or string column, it is inserted as a negative value because the number is evaluated in a signed integer context.
- `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` may cause problems on nontransactional tables for which you are using `INSERT DELAYED`.
- With statement-based binary logging, the master writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases. However, it is possible for the data on the master and slave to become different if a query is designed in such a way that the data modification is nondeterministic (generally not a recommended practice, even outside of replication).

For example:

- `CREATE TABLE ... SELECT` or `INSERT ... SELECT` statements that insert zero or `NULL` values into an `AUTO_INCREMENT` column.
- `DELETE` if you are deleting rows from a table that has foreign keys with `ON DELETE CASCADE` properties.
- `REPLACE ... SELECT`, `INSERT IGNORE ... SELECT` if you have duplicate key values in the inserted data.

**If and only if the preceding queries have no `ORDER BY` clause guaranteeing a deterministic order.**

For example, for `INSERT ... SELECT` with no `ORDER BY`, the `SELECT` may return rows in a different order (which results in a row having different ranks, hence getting a different number in the `AUTO_INCREMENT` column), depending on the choices made by the optimizers on the master and slave.

A query is optimized differently on the master and slave only if:

- The table is stored using a different storage engine on the master than on the slave. (It is possible to use different storage engines on the master and slave. For example, you can use `InnoDB` on the master, but `MyISAM` on the slave if the slave has less available disk space.)
- MySQL buffer sizes (`key_buffer_size` [492], and so on) are different on the master and slave.
- The master and slave run different MySQL versions, and the optimizer code differs between these versions.

This problem may also affect database restoration using `mysqlbinlog|mysql`.

The easiest way to avoid this problem is to add an `ORDER BY` clause to the aforementioned nondeterministic queries to ensure that the rows are always stored or modified in the same order. Using row-based or mixed logging format also avoids the problem.

- Log file names are based on the server host name if you do not specify a file name with the startup option. To retain the same log file names if you change your host name to something else, you must explicitly use options such as `--log-bin=old_host_name-bin` [2002]. See Section 5.1.3, “Server Command Options”. Alternatively, rename the old files to reflect your host name change. If these are binary logs, you must edit the binary log index file and fix the binary log file names there as well. (The same is true for the relay logs on a slave server.)
- `mysqlbinlog` does not delete temporary files left after a `LOAD DATA INFILE` statement. See Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”.
- `RENAME` does not work with `TEMPORARY` tables or tables used in a `MERGE` table.
- When using `SET CHARACTER SET`, you cannot use translated characters in database, table, and column names.
- You cannot use “\_” or “%” with `ESCAPE` in `LIKE ... ESCAPE` [1190].
- Only the first `max_sort_length` [508] bytes are used when comparing data values. This means that values cannot reliably be used in `GROUP BY`, `ORDER BY` or `DISTINCT` if they are not distinct in the first `max_sort_length` [508] bytes. To work around this, increase the variable value. The default value of `max_sort_length` [508] is 1024 and can be changed at server startup time or at runtime.
- Numeric calculations are done with `BIGINT` or `DOUBLE` (both are normally 64 bits long). Which precision you get depends on the function. The general rule is that bit functions are performed with `BIGINT` precision, `IF()` [1174] and `ELT()` [1179] with `BIGINT` or `DOUBLE` precision, and the rest with `DOUBLE` precision. You should try to avoid using unsigned long long values if they resolve to be larger than 63 bits (9223372036854775807) for anything other than bit fields.
- You can have up to 255 `ENUM` and `SET` columns in one table.
- In `MIN()` [1284], `MAX()` [1284], and other aggregate functions, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set.
- In an `UPDATE` statement, columns are updated from left to right. If you refer to an updated column, you get the updated value instead of the original value. For example, the following statement increments `KEY` by 2, **not** 1:

```
mysql> UPDATE tbl_name SET KEY=KEY+1,KEY=KEY+1;
```

- You can refer to multiple temporary tables in the same query, but you cannot refer to any given temporary table more than once. For example, the following does not work:

```
mysql> SELECT * FROM temp_table, temp_table AS t2;
ERROR 1137: Can't reopen table: 'temp_table'
```

- The optimizer may handle `DISTINCT` differently when you are using “hidden” columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns do not participate in the `DISTINCT` comparison.

An example of this is:

```
SELECT DISTINCT mp3id FROM band_downloads
WHERE userid = 9 ORDER BY id DESC;
```

and

```
SELECT DISTINCT band_downloads.mp3id
FROM band_downloads,band_mp3
WHERE band_downloads.userid = 9
AND band_mp3.id = band_downloads.mp3id
ORDER BY band_downloads.id DESC;
```

In the second case, using MySQL Server 3.23.x, you may get two identical rows in the result set (because the values in the hidden `id` column may differ).

Note that this happens only for queries that do not have the `ORDER BY` columns in the result.

- If you execute a `PROCEDURE` on a query that returns an empty set, in some cases the `PROCEDURE` does not transform the columns.
- Creation of a table of type `MERGE` does not check whether the underlying tables are compatible types.
- If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table and then add a normal index on the `MERGE` table, the key order is different for the tables if there was an old, non-`UNIQUE` key in the table. This is because `ALTER TABLE` puts `UNIQUE` indexes before normal indexes to be able to detect duplicate keys as early as possible.

---

## Appendix D. MySQL Release Notes

Release notes for MySQL Server and associated products are no longer published in the MySQL Reference Manual. Instead, see these release notes documents:

- [MySQL 5.6 Release Notes](#)
- [MySQL Connector/ODBC Release Notes](#)
- [MySQL Connector/Net Release Notes](#) (includes MySQL Visual Studio Plugin release notes)
- [MySQL Connector/J Release Notes](#)
- [MySQL Connector/C++ Release Notes](#)
- [MySQL Proxy Release Notes](#)
- [MySQL for Excel Release Notes](#)
- [MySQL Installer Release Notes](#)

---

## Appendix E. Restrictions and Limits

### Table of Contents

E.10.6. Windows Platform Limitations .....	3771

The discussion here describes restrictions that apply to the use of MySQL features such as subqueries or views.

### E.1. Restrictions on Stored Programs

These restrictions apply to the features described in [Chapter 18, \*Stored Programs and Views\*](#).

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. There are also some [restrictions specific to stored functions](#) but not to stored procedures.

The restrictions for stored functions also apply to triggers. There are also some [restrictions specific to triggers](#).

The restrictions for stored procedures also apply to the `DO` clause of Event Scheduler event definitions. There are also some [restrictions specific to events](#).

### SQL Statements Not Permitted in Stored Routines

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

- The locking statements `LOCK TABLES` and `UNLOCK TABLES`.
- `ALTER VIEW`.
- `LOAD DATA` and `LOAD TABLE`.
- SQL prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE`) can be used in stored procedures, but not stored functions or triggers. Thus, stored functions and triggers cannot use dynamic SQL (where you construct statements as strings and then execute them).
- Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see [Section 13.5, “SQL Syntax for Prepared Statements”](#). Exceptions are `SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS`, which are not permissible as prepared statements but are permitted in stored programs.

- Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 13.5.1, “PREPARE Syntax”](#).
- Inserts cannot be delayed. `INSERT DELAYED` syntax is accepted, but the statement is handled as a normal `INSERT`.
- Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

## Restrictions for Stored Functions

The following additional statements or operations are not permitted within stored functions. They are permitted within stored procedures, except stored procedures that are invoked from within a stored function or trigger. For example, if you use `FLUSH` in a stored procedure, that stored procedure cannot be called from a stored function or trigger.

- Statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.
- Statements that return a result set. This includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. A function can process a result set either with `SELECT ... INTO var_list` or by using a cursor and `FETCH` statements. See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#), and [Section 13.6.6, “Cursors”](#).
- `FLUSH` statements.
- Stored functions cannot be used recursively.
- A stored function or trigger cannot modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.
- If you refer to a temporary table multiple times in a stored function under different aliases, a `Can't reopen table: 'tbl_name'` error occurs, even if the references occur in different statements within the function.
- `HANDLER ... READ` statements that invoke stored functions can cause replication errors and are disallowed.

## Restrictions for Triggers

For triggers, the following additional restrictions apply:

- Triggers currently are not activated by foreign key actions.
- When using row-based replication, triggers on the slave are not activated by statements originating on the master. The triggers on the slave are activated when using statement-based replication. For more information, see [Section 16.4.1.30, “Replication and Triggers”](#).
- The `RETURN` statement is not permitted in triggers, which cannot return a value. To exit a trigger immediately, use the `LEAVE` statement.
- Triggers are not permitted on tables in the `mysql` database.
- The trigger cache does not detect when metadata of the underlying objects has changed. If a trigger uses a table and the table has changed since the trigger was loaded into the cache, the trigger operates using the outdated metadata.

## Name Conflicts within Stored Routines

The same identifier might be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
  BEGIN
    DECLARE i INT DEFAULT 1;
    SELECT i FROM t;
  END;
END;
```

In such cases, the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column.
- A routine parameter takes precedence over a table column.
- A local variable in an inner block takes precedence over a local variable in an outer block.

The behavior that variables take precedence over table columns is nonstandard.

## Replication Considerations

Use of stored routines can cause replication problems. This issue is discussed further in [Section 18.7, “Binary Logging of Stored Programs”](#).

The `--replicate-wild-do-table=db_name.tbl_name [1979]` option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

## Debugging Considerations

There are no stored routine debugging facilities.

## Unsupported Syntax from the SQL:2003 Standard

The MySQL stored routine syntax is based on the SQL:2003 standard. The following items from that standard are not currently supported:

- [UNDO](#) handlers
- [FOR](#) loops

## Concurrency Considerations

To prevent problems of interaction between sessions, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. While the statement executes, it does not see changes to routines performed by other sessions.

For maximum concurrency, stored functions should minimize their side-effects; in particular, updating a table within a stored function can reduce concurrent operations on that table. A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. When statement-based binary logging is used, statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log, even for statement-based binary logging. See [Section 18.7, “Binary Logging of Stored Programs”](#).

## Event Scheduler Restrictions

The following limitations are specific to the Event Scheduler:

- Event names are handled in case-insensitive fashion. For example, you cannot have two events in the same database with the names `anEvent` and `AnEvent`.
- An event may not be created, altered, or dropped by a stored routine, trigger, or another event. An event also may not create, alter, or drop stored routines or triggers. (Bug #16409, Bug #18896)
- DDL statements on events are prohibited while a `LOCK TABLES` statement is in effect.
- Event timings using the intervals `YEAR`, `QUARTER`, `MONTH`, and `YEAR_MONTH` are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition—due to rounding, the nature of threaded applications, and the fact that a nonzero length of time is required to create events and to signal their execution—events may be delayed by as much as 1 or 2 seconds. However, the time shown in the `INFORMATION_SCHEMA.EVENTS` table's `LAST_EXECUTED` column or the `mysql.event` table's `last_executed` column is always accurate to within one second of the actual event execution time. (See also Bug #16522.)
- Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements has no effect in a given user session on the server's statement counts such as `Com_select` and `Com_insert` that are displayed by `SHOW STATUS`. However, such counts are updated in the global scope. (Bug #16422)
- Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Such dates are specifically not permitted by the Event Scheduler. (Bug #16396)
- References to stored functions, user-defined functions, and tables in the `ON SCHEDULE` clauses of `CREATE EVENT` and `ALTER EVENT` statements are not supported. These sorts of references are not permitted. (See Bug #22830 for more information.)

## E.2. Restrictions on Condition Handling

`SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS` are not permissible as prepared statements. For example, this statement is invalid:

```
PREPARE stmt1 FROM 'SIGNAL SQLSTATE "02000"';
```

`SQLSTATE` values in class `'04'` are not treated specially. They are handled the same as other exceptions.

Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL syntax includes `GET STACKED DIAGNOSTICS` for referring to stacked areas. MySQL does not support the `STACKED` keyword because there is a single diagnostics area containing information from the most recent statement that wrote to it. See also [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

In standard SQL, the first condition relates to the `SQLSTATE` value returned for the previous SQL statement. In MySQL, this is not guaranteed, so to get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, do this:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

## E.3. Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set

to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a `MEMORY` table, but is converted to a `MyISAM` table when its size exceeds the minimum value of the `max_heap_table_size` [504] and `tmp_table_size` [558] system variables. Note that the same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See [Section 8.4.3.3, “How MySQL Uses Internal Temporary Tables”](#). One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

`UPDATE WHERE CURRENT OF` and `DELETE WHERE CURRENT OF` are not implemented, because updatable cursors are not supported.

Cursors are nonholdable (not held open after a commit).

Cursors are asensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLE`, `HANDLER READ`, and `SHOW BINLOG EVENTS`.

## E.4. Restrictions on Subqueries

- Subquery optimization for `IN` is not as effective as for the `=` operator or for the `IN(value_list)` [1169] operator.

A typical case for poor `IN` subquery performance is when the subquery returns a small number of rows but the outer query returns a large number of rows to be compared to the subquery result.

The problem is that, for a statement that uses an `IN` subquery, the optimizer rewrites it as a correlated subquery. Consider the following statement that uses an uncorrelated subquery:

```
SELECT ... FROM t1 WHERE t1.a IN (SELECT b FROM t2);
```

The optimizer rewrites the statement to a correlated subquery:

```
SELECT ... FROM t1 WHERE EXISTS (SELECT 1 FROM t2 WHERE t2.b = t1.a);
```

If the inner and outer queries return  $M$  and  $N$  rows, respectively, the execution time becomes on the order of  $O(M \times N)$ , rather than  $O(M+N)$  as it would be for an uncorrelated subquery.

An implication is that an `IN` subquery can be much slower than a query written using an `IN(value_list)` [1169] operator that lists the same values that the subquery would return.

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

```
DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
```

Exception: The preceding prohibition does not apply if you are using a subquery for the modified table in the `FROM` clause. Example:

```
UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS _t ...);
```

Here the result from the subquery in the `FROM` clause is stored as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

- Row comparison operations are only partially supported:
  - For `expr [NOT] IN subquery`, `expr` can be an  $n$ -tuple (specified using row constructor syntax) and the subquery can return rows of  $n$ -tuples. The permitted syntax is therefore more specifically expressed as `row_constructor [NOT] IN table_subquery`
  - For `expr op {ALL|ANY|SOME} subquery`, `expr` must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of  $n$ -tuples, this is supported:

```
(expr_1, ..., expr_n) [NOT] IN table_subquery
```

But this is not supported:

```
(expr_1, ..., expr_n) op {ALL|ANY|SOME} subquery
```

The reason for supporting row comparisons for `IN` but not for the others is that `IN` is implemented by rewriting it as a sequence of `=` [1166] comparisons and `AND` [1171] operations. This approach cannot be used for `ALL`, `ANY`, or `SOME`.

- Subqueries in the `FROM` clause cannot be correlated subqueries. They are materialized in whole (evaluated to produce a result set) during query execution, so they cannot be evaluated per row of the outer query. Before MySQL 5.6.3, materialization takes place before evaluation of the outer query. As of 5.6.3, the optimizer delays materialization until the result is needed, which may permit materialization to be avoided. See [Section 8.13.16.3](#), “Optimizing Subqueries in the `FROM` Clause (Derived Tables)”.
- MySQL does not support `LIMIT` in subqueries for certain subquery operators:

```
mysql> SELECT * FROM t1
-> WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
ERROR 1235 (42000): This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'
```

- The optimizer is more mature for joins than for subqueries, so in many cases a statement that uses a subquery can be executed more efficiently if you rewrite it as a join.

An exception occurs for the case where an `IN` subquery can be rewritten as a `SELECT DISTINCT` join. Example:

```
SELECT col FROM t1 WHERE id_col IN (SELECT id_col2 FROM t2 WHERE condition);
```

That statement can be rewritten as follows:

```
SELECT DISTINCT col FROM t1, t2 WHERE t1.id_col = t2.id_col AND condition;
```

- MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if `f()` inserts rows, the following query can modify data:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

This behavior is an extension to the SQL standard. In MySQL, it can produce indeterminate results because `f()` might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the master and its slaves.

- Before MySQL 5.6.3, a subquery in the `FROM` clause is evaluated by materializing the result into a temporary table, and this table does not use indexes. As of 5.6.3, the optimizer creates an index on the materialized table if this will result in faster query execution. See [Section 8.13.16.3, “Optimizing Subqueries in the `FROM` Clause \(Derived Tables\)”](#).

## E.5. Restrictions on Views

View processing is not optimized:

- It is not possible to create an index on a view.
- Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Subqueries cannot be used in the `FROM` clause of a view.

There is a general principle that you cannot modify a table and select from the same table in a subquery. See [Section E.4, “Restrictions on Subqueries”](#).

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);
UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you *can* select from the table in the view subquery and still modify that table in the outer query. In this case the view will be stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying `ALGORITHM = TEMPTABLE` in the view definition.)

You can use `DROP TABLE` or `ALTER TABLE` to drop or alter a table that is used in a view definition. No warning results from the `DROP` or `ALTER` operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. `CHECK TABLE` can be used to check for views that have been invalidated by `DROP` or `ALTER` operations.

A view definition is “frozen” by certain statements:

- If a statement prepared by `PREPARE` refers to a view, the view definition seen each time the statement is executed later will be the definition of the view at the time it was prepared. This is true even if the view definition is changed after the statement is prepared and before it is executed.

Example:

```
CREATE VIEW v AS SELECT RAND();
PREPARE s FROM 'SELECT * FROM v';
ALTER VIEW v AS SELECT NOW();
EXECUTE s;
```

The result returned by the `EXECUTE` statement is a random number, not the current date and time.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. This includes views that have `UNION` in their definition. Currently, not all views that are theoretically updatable can be updated. The initial view implementation was deliberately written this way to get usable, updatable views into MySQL as quickly as possible. Many theoretically updatable views can be updated now, but limitations still exist:

- Updatable views with subqueries anywhere other than in the `WHERE` clause. Some views that have subqueries in the `SELECT` list may be updatable.
- You cannot use `UPDATE` to update more than one underlying table of a view that is defined as a join.

- You cannot use `DELETE` to update a view that is defined as a join.

There exists a shortcoming with the current implementation of views. If a user is granted the basic privileges necessary to create a view (the `CREATE VIEW` [754] and `SELECT` [755] privileges), that user will be unable to call `SHOW CREATE VIEW` on that object unless the user is also granted the `SHOW VIEW` [756] privilege.

That shortcoming can lead to problems backing up a database with `mysqldump`, which may fail due to insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the `SHOW VIEW` [756] privilege to users who are granted `CREATE VIEW` [754], since MySQL doesn't grant it implicitly when views are created.

Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view is not permitted.

`SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64 characters. This can cause problems in the following circumstances for views with too-long aliases:

- View definitions fail to replicate to newer slaves that enforce the column-length restriction.
- Dump files created with `mysqldump` cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view will replicate properly, and can be dumped and reloaded without causing an error. To modify the definition, drop and create the view again with `DROP VIEW` and `CREATE VIEW`, or replace the definition with `CREATE OR REPLACE VIEW`.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its `CREATE VIEW` statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.

## E.6. Restrictions on XA Transactions

XA transaction support is limited to the `InnoDB` storage engine.

For “external XA,” a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For “Internal XA”, storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for `InnoDB`.

For `XA START`, the `JOIN` and `RESUME` clauses are not supported.

For `XA END`, the `SUSPEND [FOR MIGRATE]` clause is not supported.

The requirement that the `bqual` part of the `xid` value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

If an XA transaction has reached the `PREPARED` state and the MySQL server is killed (for example, with `kill -9` on Unix) or shuts down abnormally, the transaction can be continued after the server restarts. However, if the client reconnects and commits the transaction, the transaction will be absent

from the binary log even though it has been committed. This means the data and the binary log have gone out of synchrony. An implication is that XA cannot be used safely together with replication.

It is possible that the server will roll back a pending XA transaction, even one that has reached the `PREPARED` state. This happens if a client connection terminates and the server continues to run, or if clients are connected and the server shuts down gracefully. (In the latter case, the server marks each connection to be terminated, and then rolls back the `PREPARED` XA transaction associated with it.) It should be possible to commit or roll back a `PREPARED` XA transaction, but this cannot be done without changes to the binary logging mechanism.

## E.7. Restrictions on Character Sets

- Identifiers are stored in `mysql` database tables (`user`, `db`, and so forth) using `utf8`, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.
- The `ucs2`, `utf16`, `utf16le`, and `utf32` character sets have the following restrictions:
  - They cannot be used as a client character set, which means that they do not work for `SET NAMES` or `SET CHARACTER SET`. (See [Section 10.1.4, “Connection Character Sets and Collations”](#).)
  - It is currently not possible to use `LOAD DATA INFILE` to load data files that use these character sets.
  - `FULLTEXT` indexes cannot be created on a column that uses any of these character sets. However, you can perform `IN BOOLEAN MODE` searches on the column without an index.
  - The use of `ENCRYPT()` [1262] with these character sets is not recommended because the underlying system call expects a string terminated by a zero byte.
- The `REGEXP` [1193] and `RLIKE` [1193] operators work in byte-wise fashion, so they are not multi-byte safe and may produce unexpected results with multi-byte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

## E.8. Restrictions on Performance Schema

The Performance Schema avoids using mutexes to collect or produce data, so there are no guarantees of consistency and results can sometimes be incorrect. Event values in `performance_schema` tables are nondeterministic and nonrepeatable.

If you save event information in another table, you should not assume that the original events will still be available later. For example, if you select events from a `performance_schema` table into a temporary table, intending to join that table with the original table later, there might be no matches.

`mysqldump` and `BACKUP DATABASE` ignore tables in the `performance_schema` database.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_XXX` tables.

Tables in the `performance_schema` database cannot be indexed.

Results for queries that refer to tables in the `performance_schema` database are not saved in the query cache.

Tables in the `performance_schema` database are not replicated.

The Performance Schema is not available in `libmysqld`, the embedded server.

The types of timers might vary per platform. The `performance_timers` table shows which event timers are available. If the values in this table for a given timer name are `NULL`, that timer is not supported on your platform.

Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer.

## E.9. Restrictions on Pluggable Authentication

The first part of this section describes general restrictions on the applicability of the pluggable authentication framework described at [Section 6.3.7, “Pluggable Authentication”](#). The second part describes how third-party connector developers can determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

The term “native authentication” used here refers to authentication against passwords stored in the `Password` column of the `mysql.user` table. This is the same authentication method provided by older MySQL servers, before pluggable authentication was implemented. It remains the default method, although now it is implemented using plugins. “Windows native authentication” refers to authentication using the credentials of a user who has already logged in to Windows, as implemented by the Windows Native Authentication plugin (“Windows plugin” for short).

### General Pluggable Authentication Restrictions

- **Connector/C, Connector/C++:** Clients that use these connectors can connect to the server only through accounts that use native authentication.

Exception: A connector supports pluggable authentication if it was built to link to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed, or if the connector is recompiled from source to link against the current `libmysqlclient`.

- **Connector/J:** Clients that use this connector can connect to the server only through accounts that use native authentication.
- **Connector/Net:** Before Connector/Net 6.4.4, clients that use this connector can connect to the server only through accounts that use native authentication. As of 6.4.4, clients can also connect to the server through accounts that use the Windows plugin.
- **Connector/ODBC:** Before Connector/ODBC 3.51.29 and 5.1.9, clients that use this connector can connect to the server only through accounts that use native authentication. As of 3.51.29 and 5.1.9, clients that use binary releases of this connector for Windows can also connect to the server through accounts that use the PAM or Windows plugins. (These capabilities result from linking the Connector/ODBC binaries against the MySQL 5.5.16 `libmysqlclient` rather than the MySQL 5.1 `libmysqlclient` used previously. The newer `libmysqlclient` includes the client-side support needed for the server-side PAM and Windows authentication plugins.)
- **Connector/PHP:** Clients that use this connector can connect to the server only through accounts that use native authentication, when compiled using the MySQL native driver for PHP (`mysqlnd`).
- **MySQL Proxy:** Before MySQL Proxy 0.8.2, clients can connect to the server only through accounts that use native authentication. As of 0.8.2, clients can also connect to the server through accounts that use the PAM plugin. As of 0.8.3, clients can also connect to the server through accounts that use the Windows plugin.
- **MySQL Enterprise Backup:** MySQL Enterprise Backup before version 3.6.1 supports connections to the server only through accounts that use native authentication. As of 3.6.1, MySQL Enterprise Backup can connect to the server through accounts that use nonnative authentication.
- **Windows native authentication:** Connecting through an account that uses the Windows plugin requires Windows Domain setup. Without it, NTLM authentication is used and then only local connections are possible; that is, the client and server must run on the same computer.
- **Proxy users:** Proxy user support is available to the extent that clients can connect through accounts authenticated with plugins that implement proxy user capability (that is, plugins that can return a user

name different from that of the connecting user). For example, the native authentication plugins do not support proxy users, whereas the PAM and Windows plugins do.

- **Replication:** Before MySQL 5.6.4, replication slaves can connect to the master server only through master accounts that use native authentication. As of 5.6.4, replication slaves can also connect through master accounts that use nonnative authentication if the required client-side plugin is available. If the plugin is built into `libmysqlclient`, it is available by default. Otherwise, the plugin must be installed on the slave side in the directory named by the slave `plugin_dir` [525] system variable.
- **FEDERATED tables:** A `FEDERATED` table can access the remote table only through accounts on the remote server that use native authentication.

## Pluggable Authentication and Third-Party Connectors

Third-party connector developers can use the following guidelines to determine readiness of a connector to take advantage of pluggable authentication capabilities and what steps to take to become more compliant:

- An existing connector to which no changes have been made uses native authentication and clients that use the connector can connect to the server only through accounts that use native authentication. *However, you should test the connector against a recent version of the server to verify that such connections still work without problem.*

Exception: A connector might work with pluggable authentication without any changes if it links to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed.

- To take advantage of pluggable authentication capabilities, a connector that is `libmysqlclient`-based should be relinked against the current version of `libmysqlclient`. This enables the connector to support connections through accounts that require client-side plugins now built into `libmysqlclient` (such as the cleartext plugin needed for PAM authentication and the Windows plugin needed for Windows native authentication). Linking with a current `libmysqlclient` also enables the connector to access client-side plugins installed in the default MySQL plugin directory (typically the directory named by the default value of the local server's `plugin_dir` [525] system variable).

If a connector links to `libmysqlclient` dynamically, it must be ensured that the newer version of `libmysqlclient` is installed on the client host and that the connector loads it at runtime.

- Another way for a connector to support a given authentication method is to implement it directly in the client/server protocol. Connector/Net uses this approach to provide support for Windows native authentication.
- If a connector should be able to load client-side plugins from a directory different from the default plugin directory, it must implement some means for client users to specify the directory. Possibilities for this include a command-line option or environment variable from which the connector can obtain the directory name. Standard MySQL client programs such as `mysql` and `mysqladmin` implement a `--plugin-dir` option. See also [Section 21.8.13, “C API Client Plugin Functions”](#).
- Proxy user support by a connector depends, as described earlier in this section, on whether the authentication methods that it supports permit proxy users.

## E.10. Limits in MySQL

This section lists current limits in MySQL 5.6.

### E.10.1. Limits of Joins

The maximum number of tables that can be referenced in a single join is 61. This also applies to the number of tables that can be referenced in the definition of a view.

## E.10.2. Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. [InnoDB](#) permits up to 4 billion tables.

## E.10.3. Limits on Table Size

The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. The following table lists some examples of operating system file-size limits. This is only a rough guide and is not intended to be definitive. For the most up-to-date information, be sure to check the documentation specific to your operating system.

Operating System	File-size Limit
Win32 w/ FAT/FAT32	2GB/4GB
Win32 w/ NTFS	2TB (possibly larger)
Linux 2.2-Intel 32-bit	2GB (LFS: 4GB)
Linux 2.4+	(using ext3 file system) 4TB
Solaris 9/10	16TB
Mac OS X w/ HFS+	2TB

Windows users, please note that FAT and VFAT (FAT32) are *not* considered suitable for production use with MySQL. Use NTFS instead.

On Linux 2.2, you can get [MyISAM](#) tables larger than 2GB in size by using the Large File Support (LFS) patch for the ext2 file system. Most current Linux distributions are based on kernel 2.4 or higher and include all the required LFS patches. On Linux 2.4, patches also exist for ReiserFS to get support for big files (up to 2TB). With JFS and XFS, petabyte and larger files are possible on Linux.

For a detailed overview about LFS in Linux, have a look at Andreas Jaeger's *Large File Support in Linux* page at [http://www.suse.de/~aj/linux\\_lfs.html](http://www.suse.de/~aj/linux_lfs.html).

If you do encounter a full-table error, there are several reasons why it might have occurred:

- The disk might be full.
- The [InnoDB](#) storage engine maintains [InnoDB](#) tables within a tablespace that can be created from several files. This enables a table to exceed the maximum individual file size. The tablespace can include raw disk partitions, which permits extremely large tables. The maximum tablespace size is 64TB.

If you are using [InnoDB](#) tables and run out of room in the [InnoDB](#) tablespace. In this case, the solution is to extend the [InnoDB](#) tablespace. See [Section 14.2.2.2, “Adding, Removing, or Resizing InnoDB Data and Log Files”](#).

- You are using [MyISAM](#) tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.
- You are using a [MyISAM](#) table and the space required for the table exceeds what is permitted by the internal pointer size. [MyISAM](#) permits data and index files to grow up to 256TB by default, but this limit can be changed up to the maximum permissible size of 65,536TB ( $256^7 - 1$  bytes).

If you need a [MyISAM](#) table that is larger than the default limit and your operating system supports large files, the `CREATE TABLE` statement supports `AVG_ROW_LENGTH` and `MAX_ROWS` options. See [Section 13.1.14, “CREATE TABLE Syntax”](#). The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with `ALTER TABLE` to increase a table's maximum permissible size. See [Section 13.1.6, “ALTER TABLE Syntax”](#).

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify `AVG_ROW_LENGTH` only for tables with `BLOB` or `TEXT` columns; in this case, MySQL can't optimize the space required based only on the number of rows.

To change the default size limit for `MyISAM` tables, set the `myisam_data_pointer_size` [511], which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the `MAX_ROWS` option. The value of `myisam_data_pointer_size` [511] can be from 2 to 7. A value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB.

You can check the maximum data and index sizes by using this statement:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name' ;
```

You also can use `myisamchk -dv /path/to/table-index-file`. See [Section 13.7.5, “SHOW Syntax”](#), or [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

Other ways to work around file-size limits for `MyISAM` tables are as follows:

- If your large table is read only, you can use `myisampack` to compress it. `myisampack` usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. `myisampack` also can merge multiple tables into a single table. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).
- MySQL includes a `MERGE` library that enables you to handle a collection of `MyISAM` tables that have identical structure as a single `MERGE` table. See [Section 14.8, “The MERGE Storage Engine”](#).
- You are using the `MEMORY (HEAP)` storage engine; in this case you need to increase the value of the `max_heap_table_size` [504] system variable. See [Section 5.1.4, “Server System Variables”](#).

## E.10.4. Limits on Table Column Count and Row Size

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact limit depends on several interacting factors.

- Every table (regardless of storage engine) has a maximum row size of 65,535 bytes. Storage engines may place additional constraints on this limit, reducing the effective maximum row size.

The maximum row size constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. For example, `utf8` characters require up to three bytes per character, so for a `CHAR(255) CHARACTER SET utf8` column, the server must allocate  $255 \times 3 = 765$  bytes per value. Consequently, a table cannot contain more than  $65,535 / 765 = 85$  such columns.

Storage for variable-length columns includes length bytes, which are assessed against the row size. For example, a `VARCHAR(255) CHARACTER SET utf8` column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

`BLOB` and `TEXT` columns count from one to four plus eight bytes each toward the row-size limit because their contents are stored separately from the rest of the row.

Declaring columns `NULL` can reduce the maximum number of columns permitted. For `MyISAM` tables, `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte. The maximum row length in bytes can be calculated as follows:

```
row length = 1
```

```
+ (sum of column lengths)
+ (number of NULL columns + delete_flag + 7)/8
+ (number of variable-length columns)
```

`delete_flag` is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header. For information about `MyISAM` table formats, see [Section 14.3.3, “MyISAM Table Storage Formats”](#).

For `InnoDB` tables, storage size is the same for `NULL` and `NOT NULL` columns, so the preceding calculations do not apply.

The following statement to create table `t1` succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

```
mysql> CREATE TABLE t1
-> (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
-> ENGINE = MyISAM CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The following statement to create table `t2` fails because the columns are `NULL` and `MyISAM` requires additional space that causes the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t2
-> (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
-> ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

The following statement to create table `t3` fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t3
-> (c1 VARCHAR(65535) NOT NULL)
-> ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

Reducing the column length to 65,533 or less permits the statement to succeed.

- Individual storage engines might impose additional restrictions that limit table column count. Examples:
  - `InnoDB` permits up to 1000 columns.
  - `InnoDB` restricts row size to something less than half a database page (approximately 8000 bytes), not including `VARBINARY`, `VARCHAR`, `BLOB`, or `TEXT` columns.
  - Different `InnoDB` storage formats (`COMPRESSED`, `REDUNDANT`) use different amounts of page header and trailer data, which affects the amount of storage available for rows.
- Each table has an `.frm` file that contains the table definition. The definition affects the content of this file in ways that may affect the number of columns permitted in the table. For more information, see [Section E.10.5, “Limits Imposed by `.frm` File Structure”](#).

## E.10.5. Limits Imposed by `.frm` File Structure

Each table has an `.frm` file that contains the table definition. The server uses the following expression to check some of the table information stored in the file against an upper limit of 64KB:

```
if (info_length+(ulong) create_fields.elements*FCOMP+288+
    n_length+int_length+com_length > 65535L || int_count > 255)
```

The portion of the information stored in the `.frm` file that is checked against the expression cannot grow beyond the 64KB limit, so if the table definition reaches this size, no more columns can be added.

The relevant factors in the expression are:

- `info_length` is space needed for “screens.” This is related to MySQL's Unireg heritage.
- `create_fields.elements` is the number of columns.
- `FCOMP` is 17.
- `n_length` is the total length of all column names, including one byte per name as a separator.
- `int_length` is related to the list of values for `ENUM` and `SET` columns. In this context, “int” does not mean “integer.” It means “interval,” a term that refers collectively to `ENUM` and `SET` columns.
- `int_count` is the number of unique `ENUM` and `SET` definitions.
- `com_length` is the total length of column comments.

The expression just described has several implications for permitted table definitions:

- Using long column names can reduce the maximum number of columns, as can the inclusion of `ENUM` or `SET` columns, or use of column comments.
- A table can have no more than 255 unique `ENUM` and `SET` definitions. Columns with identical element lists are considered the same against this limit. For example, if a table contains these two columns, they count as one (not two) toward this limit because the definitions are identical:

```
e1 ENUM('a','b','c')
e2 ENUM('a','b','c')
```

- The sum of the length of element names in the unique `ENUM` and `SET` definitions counts toward the 64KB limit, so although the theoretical limit on number of elements in a given `ENUM` column is 65,535, the practical limit is less than 3000.

## E.10.6. Windows Platform Limitations

The following limitations apply to use of MySQL on the Windows platform:

- **Process memory**

On Windows 32-bit platforms, it is not possible by default to use more than 2GB of RAM within a single process, including MySQL. This is because the physical address limit on Windows 32-bit is 4GB and the default setting within Windows is to split the virtual address space between kernel (2GB) and user/applications (2GB).

Some versions of Windows have a boot time setting to enable larger applications by reducing the kernel application. Alternatively, to use more than 2GB, use a 64-bit version of Windows.

- **File system aliases**

When using `MyISAM` tables, you cannot use aliases within Windows link to the data files on another volume and then link back to the main MySQL `datadir` [418] location.

This facility is often used to move the data and index files to a RAID or other fast solution, while retaining the main `.frm` files in the default data directory configured with the `datadir` [418] option.

- **Limited number of ports**

Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients

connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Note that ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

For more information about this problem, see <http://support.microsoft.com/default.aspx?scid=kb;en-us;196271>.

- **DATA DIRECTORY and INDEX DIRECTORY**

The `DATA DIRECTORY` option for `CREATE TABLE` is supported on Windows only for `InnoDB` tables, as described in [Section 5.4.1.2, “Specifying the Location of a Tablespace”](#). For `MyISAM` and other storage engines, the `DATA DIRECTORY` and `INDEX DIRECTORY` options for `CREATE TABLE` are ignored on Windows and any other platforms with a nonfunctional `realpath()` call.

- **DROP DATABASE**

You cannot drop a database that is in use by another session.

- **Case-insensitive names**

File names are not case sensitive on Windows, so MySQL database and table names are also not case sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See [Section 9.2.2, “Identifier Case Sensitivity”](#).

- **Directory and file names**

On Windows, MySQL Server supports only directory and file names that are compatible with the current ANSI code pages. For example, the following Japanese directory name will not work in the Western locale (code page 1252):

```
datadir="C:/私たちのプロジェクトのデータ"
```

The same limitation applies to directory and file names referred to in SQL statements, such as the data file path name in `LOAD DATA INFILE`.

- **The “\” path name separator character**

Path name components in Windows are separated by the “\” character, which is also the escape character in MySQL. If you are using `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, use Unix-style file names with “/” characters:

```
mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;
mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;
```

Alternatively, you must double the “\” character:

```
mysql> LOAD DATA INFILE 'C:\\tmp\\skr.txt' INTO TABLE skr;
mysql> SELECT * INTO OUTFILE 'C:\\tmp\\skr.txt' FROM skr;
```

- **Problems with pipes**

Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character `^Z / CHAR(24)`, Windows thinks that it has encountered end-of-file and aborts the program.

This is mainly a problem when you try to apply a binary log as follows:

```
C:\> mysqlbinlog binary_log_file | mysql --user=root
```

If you have a problem applying the log and suspect that it is because of a `^Z / CHAR(24)` character, you can use the following workaround:

```
C:\> mysqlbinlog binary_log_file --result-file=/tmp/bin.sql
C:\> mysql --user=root --execute "source /tmp/bin.sql"
```

The latter command also can be used to reliably read in any SQL file that may contain binary data.

---

# MySQL Glossary

These terms are commonly used in information about the MySQL database server. This glossary originated as a reference for terminology about the InnoDB storage engine, and the majority of definitions are InnoDB-related.

## A

### .ARM file

Metadata for ARCHIVE tables. Contrast with **.ARZ file**. Files with this extension are always included in backups produced by the `mysqlbackup` command of the **MySQL Enterprise Backup** product. See Also [.ARZ file](#), [MySQL Enterprise Backup](#), [mysqlbackup command](#).

### .ARZ file

Data for ARCHIVE tables. Contrast with **.ARM file**. Files with this extension are always included in backups produced by the `mysqlbackup` command of the **MySQL Enterprise Backup** product. See Also [.ARM file](#), [MySQL Enterprise Backup](#), [mysqlbackup command](#).

### ACID

An acronym standing for atomicity, consistency, isolation, and durability. These properties are all desirable in a database system, and are all closely tied to the notion of a **transaction**. The transactional features of InnoDB adhere to the ACID principles.

Transactions are **atomic** units of work that can be **committed** or **rolled back**. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

The database remains in a consistent state at all times -- after each commit or rollback, and while transactions are in progress. If related data is being updated across multiple tables, queries see either all old values or all new values, not a mix of old and new values.

Transactions are protected (isolated) from each other while they are in progress; they cannot interfere with each other or see each other's uncommitted data. This isolation is achieved through the **locking** mechanism. Experienced users can adjust the **isolation level**, trading off less protection in favor of increased performance and **concurrency**, when they can be sure that the transactions really do not interfere with each other.

The results of transactions are durable: once a commit operation succeeds, the changes made by that transaction are safe from power failures, system crashes, race conditions, or other potential dangers that many non-database applications are vulnerable to. Durability typically involves writing to disk storage, with a certain amount of redundancy to protect against power failures or software crashes during write operations. (In InnoDB, the **doublewrite buffer** assists with durability.)

See Also [atomic](#), [commit](#), [concurrency](#), [doublewrite buffer](#), [isolation level](#), [locking](#), [rollback](#), [transaction](#).

### adaptive flushing

An algorithm for **InnoDB** tables that smooths out the I/O overhead introduced by **checkpoints**. Instead of **flushing** all modified **pages** from the **buffer pool** to the **data files** at once, MySQL periodically flushes small sets of modified pages. The adaptive flushing algorithm extends this process by estimating the optimal rate to perform these periodic flushes, based on the rate of flushing and how fast **redo** information is generated. First introduced in MySQL 5.1, in the InnoDB Plugin.

See Also [buffer pool](#), [checkpoint](#), [data files](#), [flush](#), [InnoDB](#), [page](#), [redo log](#).

### adaptive hash index

An optimization for InnoDB tables that can speed up lookups using `=` and `IN` operators, by constructing a **hash index** in memory. MySQL monitors index searches for InnoDB tables, and if queries could benefit from a hash index, it builds one automatically for index **pages** that are frequently accessed. In a sense, the adaptive hash index configures MySQL at runtime to take advantage of ample main memory, coming closer to the architecture of main-memory databases. This feature is controlled by the `innodb_adaptive_hash_index` [1701] configuration option. Because this feature benefits some workloads and not others, and the memory used for the hash index is reserved in the **buffer pool**, typically you should benchmark with this feature both enabled and disabled.

---

The hash index is always built based on an existing InnoDB **secondary index**, which is organized as a **B-tree** structure. MySQL can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches against the index. A hash index can be partial; the whole B-tree index does not need to be cached in the buffer pool.

In MySQL 5.6 and higher, another way to take advantage of fast single-value lookups with InnoDB tables is to use the **memcached** interface to InnoDB. See [Section 14.2.9, “InnoDB Integration with memcached”](#) for details.

See Also [B-tree](#), [buffer pool](#), [hash index](#), [memcached](#), [page](#), [secondary index](#).

#### AHI

Acronym for **adaptive hash index**.

See Also [adaptive hash index](#).

#### AIO

Acronym for **asynchronous I/O**. You might see this acronym in InnoDB messages or keywords.

See Also [asynchronous I/O](#).

#### Antelope

The code name for the original InnoDB **file format**. It supports the **redundant** and **compact** row formats, but not the newer **dynamic** and **compressed** row formats available in the **Barracuda** file format.

If your application could benefit from InnoDB table **compression**, or uses BLOBs or large text columns that could benefit from the dynamic row format, you might switch some tables to Barracuda format. You select the file format to use by setting the `innodb_file_format` [1716] option before creating the table.

See Also [Barracuda](#), [compact row format](#), [compressed row format](#), [dynamic row format](#), [file format](#), [innodb\\_file\\_format](#), [redundant row format](#).

#### application programming interface (API)

A set of functions or procedures. An API provides a stable set of names and types for functions, procedures, parameters, and return values.

#### apply

When a backup produced by the **MySQL Enterprise Backup** product does not include the most recent changes that occurred while the backup was underway, the process of updating the backup files to include those changes is known as the **apply** step. It is specified by the `apply-log` option of the `mysqlbackup` command.

Before the changes are applied, we refer to the files as a **raw backup**. After the changes are applied, we refer to the files as a **prepared backup**. The changes are recorded in the `ibbackup_logfile` file; once the apply step is finished, this file is no longer necessary.

See Also [hot backup](#), [ibbackup\\_logfile](#), [MySQL Enterprise Backup](#), [prepared backup](#), [raw backup](#).

#### asynchronous I/O

A type of I/O operation that allows other processing to proceed before the I/O is completed. Also known as **non-blocking I/O** and abbreviated as **AIO**. InnoDB uses this type of I/O for certain operations that can run in parallel without affecting the reliability of the database, such as reading pages into the **buffer pool** that have not actually been requested, but might be needed soon.

Historically, InnoDB has used asynchronous I/O on Windows systems only. Starting with the InnoDB Plugin 1.1, InnoDB uses asynchronous I/O on Linux systems. This change introduces a dependency on `libaio`. On other Unix-like systems, InnoDB uses synchronous I/O only.

See Also [buffer pool](#), [non-blocking I/O](#).

#### atomic

In the SQL context, **transactions** are units of work that either succeed entirely (when **committed**) or have no effect at all (when **rolled back**). The indivisible ("atomic") property of transactions is the "A" in the acronym **ACID**.

See Also [ACID](#), [commit](#), [rollback](#), [transaction](#).

---

## atomic instruction

Special instructions provided by the CPU, to ensure that critical low-level operations cannot be interrupted.

## auto-increment

A property of a table column (specified by the [AUTO\\_INCREMENT](#) keyword) that automatically adds an ascending sequence of values in the column. InnoDB supports auto-increment only for **primary key** columns.

It saves work for the developer, not to have to produce new unique values when inserting new rows. It provides useful information for the query optimizer, because the column is known to be not null and with unique values. The values from such a column can be used as lookup keys in various contexts, and because they are auto-generated there is no reason to ever change them; for this reason, primary key columns are often specified as auto-incrementing.

Auto-increment columns can be problematic with statement-based replication, because replaying the statements on a slave might not produce the same set of column values as on the master, due to timing issues. When you have an auto-incrementing primary key, you can use statement-based replication only with the setting `innodb_autoinc_lock_mode=1` [1705]. If you have `innodb_autoinc_lock_mode=2`, which allows higher concurrency for insert operations, use **row-based replication** rather than **statement-based replication**. The setting `innodb_autoinc_lock_mode=0` is the previous (traditional) default setting and should not be used except for compatibility purposes.

See Also [auto-increment locking](#), `innodb_autoinc_lock_mode`, [primary key](#), [row-based replication](#), [statement-based replication](#).

## auto-increment locking

The convenience of an **auto-increment** primary key involves some tradeoff with concurrency. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values. InnoDB includes optimizations, and the `innodb_autoinc_lock_mode` [1705] option, so that you can choose how to trade off between predictable sequences of auto-increment values and maximum **concurrency** for insert operations.

See Also [auto-increment](#), [concurrency](#), `innodb_autoinc_lock_mode`.

## autocommit

A setting that causes a **commit** operation after each **SQL** statement. This mode is not recommended for working with InnoDB tables with **transactions** that span several statements. It can help performance for **read-only transactions** on InnoDB tables, where it minimizes overhead from **locking** and generation of **undo** data, especially in MySQL 5.6.4 and up. It is also appropriate for working with MyISAM tables, where transactions are not applicable.

See Also [commit](#), [locking](#), [read-only transaction](#), [SQL](#), [transaction](#), [undo](#).

## availability

The ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Often paired with **scalability** as critical aspects of a large-scale deployment.

See Also [scalability](#).

# B

## B-tree

A tree data structure that is popular for use in database indexes. The structure is kept sorted at all times, enabling fast lookup for exact matches (equals operator) and ranges (for example, greater than, less than, and [BETWEEN](#) operators). This type of index is available for most storage engines, such as InnoDB and MyISAM.

Because B-tree nodes can have many children, a B-tree is not the same as a binary tree, which is limited to 2 children per node.

Contrast with **hash index**, which is only available in the MEMORY storage engine. The MEMORY storage engine can also use B-tree indexes, and you should choose B-tree indexes for MEMORY tables if some queries use range operators.

---

See Also [hash index](#).

#### backticks

Identifiers within MySQL SQL statements must be quoted using the backtick character ( ``` ) if they contain special characters or reserved words. For example, to refer to a table named `FOO#BAR` or a column named `SELECT`, you would specify the identifiers as ``FOO#BAR`` and ``SELECT``. Since the backticks provide an extra level of safety, they are used extensively in program-generated SQL statements, where the identifier names might not be known in advance.

Many other database systems use double quotation marks ( `"` ) around such special names. For portability, you can enable `ANSI_QUOTES` mode in MySQL and use double quotation marks instead of backticks to qualify identifier names.

See Also [SQL](#).

#### backup

The process of copying some or all table data and metadata from a MySQL instance, for safekeeping. Can also refer to the set of copied files. This is a crucial task for DBAs. The reverse of this process is the **restore** operation.

With MySQL, **physical backups** are performed by the **MySQL Enterprise Backup** product, and **logical backups** are performed by the `mysqldump` command. These techniques have different characteristics in terms of size and representation of the backup data, and speed (especially speed of the restore operation).

Backups are further classified as **hot**, **warm**, or **cold** depending on how much they interfere with normal database operation. (Hot backups have the least interference, cold backups the most.)

See Also [cold backup](#), [hot backup](#), [logical backup](#), [MySQL Enterprise Backup](#), [mysqldump](#), [physical backup](#), [warm backup](#).

#### Barracuda

The code name for an InnoDB **file format** that supports compression for table data. This file format was first introduced in the InnoDB Plugin. It supports the **compressed** row format that enables InnoDB table compression, and the **dynamic** row format that improves the storage layout for BLOB and large text columns. You can select it through the `innodb_file_format [1716]` option.

Because the InnoDB **system tablespace** is stored in the original **Antelope** file format, to use the Barracuda file format you must also enable the **file-per-table** setting, which puts newly created tables in their own tablespaces separate from the system tablespace.

The **MySQL Enterprise Backup** product version 3.5 and above supports backing up tablespaces that use the Barracuda file format.

See Also [Antelope](#), [compact row format](#), [compressed row format](#), [dynamic row format](#), [file format](#), [file-per-table](#), [innodb\\_file\\_format](#), [MySQL Enterprise Backup](#), [row format](#), [system tablespace](#).

#### beta

An early stage in the life of a software product, when it is available only for evaluation, typically without a definite release number or a number less than 1. InnoDB does not use the beta designation, preferring an **early adopter** phase that can extend over several point releases, leading to a **GA** release.

See Also [early adopter](#), [GA](#).

#### binary log

A file containing a record of all statements that attempt to change table data. These statements can be replayed to bring slave servers up to date in a **replication** scenario, or to bring a database up to date after restoring table data from a backup. The binary logging feature can be turned on and off, although Oracle recommends always enabling it if you use replication or perform backups.

You can examine the contents of the binary log, or replay those statements during replication or recovery, by using the `mysqlbinlog` command. For full information about the binary log, see [Section 5.2.4, “The Binary Log”](#). For MySQL configuration options related to the binary log, see [Section 16.1.4.4, “Binary Log Options and Variables”](#).

---

For the **MySQL Enterprise Backup** product, the file name of the binary log and the current position within the file are important details. To record this information for the master server when taking a backup in a replication context, you can specify the `--slave-info` option.

Prior to MySQL 5.0, a similar capability was available, known as the update log. In MySQL 5.0 and higher, the binary log replaces the update log.

See Also [binlog](#), [MySQL Enterprise Backup](#), [replication](#).

#### binlog

An informal name for the **binary log** file. For example, you might see this abbreviation used in e-mail messages or forum discussions.

See Also [binary log](#).

#### blind query expansion

A special mode of **full-text search** enabled by the `WITH QUERY EXPANSION` clause. It performs the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. This technique is mainly applicable for short search phrases, perhaps only a single word. It can uncover relevant matches where the precise search term does not occur in the document.

See Also [full-text search](#).

#### bottleneck

A portion of a system that is constrained in size or capacity, that has the effect of limiting overall throughput. For example, a memory area might be smaller than necessary; access to a single required resource might prevent multiple CPU cores from running simultaneously; or waiting for disk I/O to complete might prevent the CPU from running at full capacity. Removing bottlenecks tends to improve **concurrency**. For example, the ability to have multiple InnoDB **buffer pool** instances reduces contention when multiple sessions read from and write to the buffer pool simultaneously.

See Also [buffer pool](#), [concurrency](#).

#### bounce

A **shutdown** operation immediately followed by a restart. Ideally with a relatively short **warmup** period so that performance and throughput quickly return to a high level.

See Also [shutdown](#).

#### buddy allocator

A mechanism for managing different-sized **pages** in the InnoDB **buffer pool**.

See Also [buffer pool](#), [page](#), [page size](#).

#### buffer

A memory or disk area used for temporary storage. Data is buffered in memory so that it can be written to disk efficiently, with a few large I/O operations rather than many small ones. Data is buffered on disk for greater reliability, so that it can be recovered even when a **crash** or other failure occurs at the worst possible time. The main types of buffers used by InnoDB are the **buffer pool**, the **doublewrite buffer**, and the **insert buffer**.

See Also [buffer pool](#), [crash](#), [doublewrite buffer](#), [insert buffer](#).

#### buffer pool

The memory area that holds cached InnoDB data for both tables and indexes. For efficiency of high-volume read operations, the buffer pool is divided into **pages** that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the **LRU** algorithm. On systems with large memory, you can improve concurrency by dividing the buffer pool into multiple **buffer pool instances**.

Several InnoDB status variables, `information_schema` tables, and `performance_schema` tables help to monitor the internal workings of the buffer pool. Starting in MySQL 5.6, you can also dump and restore the contents of the buffer pool, either automatically during shutdown and restart, or manually at any time, through a set of InnoDB configuration variables such as `innodb_buffer_pool_dump_at_shutdown` [1705] and `innodb_buffer_pool_load_at_startup` [1707].

See Also [buffer pool instance](#), [LRU](#), [page](#), [warm up](#).

---

## buffer pool instance

Any of the multiple regions into which the **buffer pool** can be divided, controlled by the `innodb_buffer_pool_instances` [1706] configuration option. The total memory size specified by the `innodb_buffer_pool_size` [1708] is divided among all the instances. Typically, multiple buffer pool instances are appropriate for systems devoting multiple gigabytes to the InnoDB buffer pool, with each instance 1 gigabyte or larger. On systems loading or looking up large amounts of data in the buffer pool from many concurrent sessions, having multiple instances reduces the contention for exclusive access to the data structures that manage the buffer pool.

See Also [buffer pool](#).

## built-in

The built-in InnoDB storage engine within MySQL is the original form of distribution for the storage engine. Contrast with the **InnoDB Plugin**. Starting with MySQL 5.5, the InnoDB Plugin is merged back into the MySQL code base as the built-in InnoDB storage engine (known as InnoDB 1.1).

This distinction is important mainly in MySQL 5.1, where a feature or bug fix might apply to the InnoDB Plugin but not the built-in InnoDB, or vice versa.

See Also [InnoDB](#), [plugin](#).

## business rules

The relationships and sequences of actions that form the basis of business software, used to run a commercial company. Sometimes these rules are dictated by law, other times by company policy. Careful planning ensures that the relationships encoded and enforced by the database, and the actions performed through application logic, accurately reflect the real policies of the company and can handle real-life situations.

For example, an employee leaving a company might trigger a sequence of actions from the human resources department. The human resources database might also need the flexibility to represent data about a person who has been hired, but not yet started work. Closing an account at an online service might result in data being removed from a database, or the data might be moved or flagged so that it could be recovered if the account is re-opened. A company might establish policies regarding salary maximums, minimums, and adjustments, in addition to basic sanity checks such as the salary not being a negative number. A retail database might not allow a purchase with the same serial number to be returned more than once, or might not allow credit card purchases above a certain value, while a database used to detect fraud might allow these kinds of things.

See Also [relational](#).

# C

## .cfg file

A metadata file used with the **InnoDB transportable tablespace** feature. It is produced by the command `FLUSH TABLES ... FOR EXPORT`, puts one or more tables in a consistent state that can be copied to another server. The `.cfg` file is copied along with the corresponding **.ibd file**, and used to adjust the internal values of the `.ibd` file, such as the **space ID**, during the `ALTER TABLE ... IMPORT TABLESPACE` step.

See Also [.ibd file](#), [space ID](#), [transportable tablespace](#).

## cache

The general term for any memory area that stores copies of data for frequent or high-speed retrieval. In InnoDB, the primary kind of cache structure is the **buffer pool**.

See Also [buffer](#), [buffer pool](#).

## cardinality

The number of different values in a table **column**. When queries refer to columns that have an associated **index**, the cardinality of each column influences which access method is most efficient. For example, for a column with a **unique constraint**, the number of different values is equal to the number of rows in the table. If a table has a million rows but only 10 different values for a particular column, each value occurs (on average) 100,000 times. A query such as `SELECT c1 FROM t1 WHERE c1 = 50;` thus might return 1 row or a huge number of rows, and the database server might process the query differently depending on the cardinality of `c1`.

---

If the values in a column have a very uneven distribution, the cardinality might not be a good way to determine the best query plan. For example, `SELECT c1 FROM t1 WHERE c1 = x;` might return 1 row when `x=50` and a million rows when `x=30`. In such a case, you might need to use **index hints** to pass along advice about which lookup method is more efficient for a particular query.

Cardinality can also apply to the number of distinct values present in multiple columns, as in a **composite index**.

For InnoDB, the process of estimating cardinality for indexes is influenced by the [innodb\\_stats\\_sample\\_pages \[1748\]](#) and the [innodb\\_stats\\_on\\_metadata \[1747\]](#) configuration options. The estimated values are more stable when the **persistent statistics** feature is enabled (in MySQL 5.6 and higher).

See Also [column](#), [composite index](#), [index](#), [index hint](#), [persistent statistics](#), [random dive](#), [selectivity](#), [unique constraint](#).

#### change buffer

A special data structure that records changes to **pages** in **secondary indexes**. These values could result from SQL `INSERT`, `UPDATE`, or `DELETE` statements (**DML**). The set of features involving the change buffer is known collectively as **change buffering**, consisting of **insert buffering**, **delete buffering**, and **purge buffering**.

Changes are only recorded in the change buffer when the relevant page from the secondary index is not in the **buffer pool**. When the relevant index page is brought into the buffer pool while associated changes are still in the change buffer, the changes for that page are applied in the buffer pool (**merged**) using the data from the change buffer. Periodically, the **purge** operation that runs during times when the system is mostly idle, or during a slow shutdown, writes the new index pages to disk. The purge operation can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Physically, the change buffer is part of the **system tablespace**, so that the index changes remain buffered across database restarts. The changes are only applied (**merged**) when the pages are brought into the buffer pool due to some other read operation.

The kinds and amount of data stored in the change buffer are governed by the [innodb\\_change\\_buffering \[1709\]](#) and [innodb\\_change\\_buffer\\_max\\_size \[1709\]](#) configuration options. To see information about the current data in the change buffer, issue the `SHOW ENGINE INNODB STATUS` command.

Formerly known as the **insert buffer**.

See Also [buffer pool](#), [change buffering](#), [delete buffering](#), [DML](#), [insert buffer](#), [insert buffering](#), [merge](#), [page](#), [purge](#), [purge buffering](#), [secondary index](#), [system tablespace](#).

#### change buffering

The general term for the features involving the **change buffer**, consisting of **insert buffering**, **delete buffering**, and **purge buffering**. Index changes resulting from SQL statements, which could normally involve random I/O operations, are held back and performed periodically by a background **thread**. This sequence of operations can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately. Controlled by the [innodb\\_change\\_buffering \[1709\]](#) and [innodb\\_change\\_buffer\\_max\\_size \[1709\]](#) configuration options.

See Also [change buffer](#), [delete buffering](#), [insert buffering](#), [purge buffering](#).

#### checkpoint

As changes are made to data pages that are cached in the **buffer pool**, those changes are written to the **data files** sometime later, a process known as **flushing**. The checkpoint is a record of the latest changes (represented by an **LSN** value) that have been successfully written to the data files.

See Also [buffer pool](#), [data files](#), [flush](#), [fuzzy checkpointing](#), [LSN](#).

#### checksum

In **InnoDB**, a validation mechanism to detect corruption when a **page** in a **tablespace** is read from disk into the InnoDB **buffer pool**. This feature is turned on and off by the [innodb\\_checksums \[1711\]](#) configuration option. In MySQL 5.6, you can enable a faster checksum algorithm by also specifying the configuration option [innodb\\_checksum\\_algorithm=crc32](#).

---

The [innochecksum](#) command helps to diagnose corruption problems by testing the checksum values for a specified **tablespace** file while the MySQL server is shut down.

MySQL also uses checksums for replication purposes. For details, see the configuration options [binlog\\_checksum](#) [2009], [master\\_verify\\_checksum](#) [2015], and [slave\\_sql\\_verify\\_checksum](#) [1995].  
See Also [buffer pool](#), [page](#), [tablespace](#).

#### child table

In a **foreign key** relationship, a child table is one whose rows refer (or point) to rows in another table with an identical value for a specific column. This is the table that contains the `FOREIGN KEY . . . REFERENCES` clause and optionally `ON UPDATE` and `ON DELETE` clauses. The corresponding row in the **parent table** must exist before the row can be created in the child table. The values in the child table can prevent delete or update operations on the parent table, or can cause automatic deletion or updates in the child table, based on the `ON CASCADE` option used when creating the foreign key.  
See Also [foreign key](#), [parent table](#).

#### clean page

A **page** in the InnoDB **buffer pool** where all changes made in memory have also been written (**flushed**) to the [data files](#). The opposite of a **dirty page**.  
See Also [buffer pool](#), [data files](#), [dirty page](#), [flush](#), [page](#).

#### clean shutdown

A **shutdown** that completes without errors and applies all changes to InnoDB tables before finishing, as opposed to a **crash** or a **fast shutdown**. Synonym for **slow shutdown**.  
See Also [crash](#), [fast shutdown](#), [shutdown](#), [slow shutdown](#).

#### client

A type of program that sends requests to a server, and interprets or processes the results. The client software might run only some of the time (such as a mail or chat program), and might run interactively (such as the `mysql` command processor).  
See Also [mysql](#), [server](#).

#### clustered index

The InnoDB term for a **primary key** index. InnoDB table storage is organized based on the values of the primary key columns, to speed up queries and sorts involving the primary key columns. For best performance, choose the primary key columns carefully based on the most performance-critical queries. Because modifying the columns of the clustered index is an expensive operation, choose primary columns that are rarely or never updated.

In the Oracle Database product, this type of table is known as an **index-organized table**.  
See Also [index](#), [primary key](#), [secondary index](#).

#### cold backup

A **backup** taken while the database is shut down. For busy applications and web sites, this might not be practical, and you might prefer a **warm backup** or a **hot backup**.  
See Also [backup](#), [hot backup](#), [warm backup](#).

#### column

A data item within a **row**, whose storage and semantics are defined by a data type. Each **table** and **index** is largely defined by the set of columns it contains.

Each column has a **cardinality** value. A column can be the **primary key** for its table, or part of the primary key. A column can be subject to a **unique constraint**, a **NOT NULL constraint**, or both. Values in different columns, even across different tables, can be linked by a **foreign key** relationship.

In discussions of MySQL internal operations, sometimes **field** is used as a synonym, while row is the preferred term when discussing **SQL**.  
See Also [cardinality](#), [foreign key](#), [index](#), [primary key](#), [row](#), [SQL](#), [table](#), [unique constraint](#).

---

#### column index

An **index** on a single column.

See Also [composite index](#), [index](#).

#### column prefix

When an index is created with a length specification, such as `CREATE INDEX idx ON t1 (c1(N))`, only the first N characters of the column value are stored in the index. Keeping the index prefix small makes the index compact, and the memory and disk I/O savings help performance. (Although making the index prefix too small can hinder query optimization by making rows with different values appear to the query optimizer to be duplicates.)

For columns containing binary values or long text strings, where sorting is not a major consideration and storing the entire value in the index would waste space, the index automatically uses the first N (typically 768) characters of the value to do lookups and sorts.

See Also [index](#).

#### commit

A **SQL** statement that ends a **transaction**, making permanent any changes made by the transaction. It is the opposite of **rollback**, which undoes any changes made in the transaction.

InnoDB uses an **optimistic** mechanism for commits, so that changes can be written to the data files before the commit actually occurs. This technique makes the commit itself faster, with the tradeoff that more work is required in case of a rollback.

By default, MySQL uses the **autocommit** setting, which automatically issues a commit following each SQL statement.

See Also [autocommit](#), [optimistic](#), [rollback](#), [SQL](#), [transaction](#).

#### compact row format

The default InnoDB **row format** since MySQL 5.0.3. Available for tables that use the **Antelope file format**. It has a more compact representation for nulls and variable-length fields than the prior default (**redundant row format**).

Because of the **B-tree** indexes that make row lookups so fast in InnoDB, there is little if any performance benefit to keeping all rows the same size.

See Also [Antelope](#), [file format](#), [redundant row format](#), [row format](#).

#### composite index

An **index** that includes multiple columns.

See Also [index](#), [index prefix](#).

#### compressed backup

The compression feature of the **MySQL Enterprise Backup** product makes a compressed copy of each tablespace, changing the extension from `.ibd` to `.ibz`. Compressing the backup data allows you to keep more backups on hand, and reduces the time to transfer backups to a different server. The data is uncompressed during the restore operation. When a compressed backup operation processes a table that is already compressed, it skips the compression step for that table, because compressing again would result in little or no space savings.

A set of files produced by the **MySQL Enterprise Backup** product, where each **tablespace** is compressed. The compressed files are renamed with a `.ibz` file extension.

Applying **compression** right at the start of the backup process helps to avoid storage overhead during the compression process, and to avoid network overhead when transferring the backup files to another server.

The process of **applying** the **binary log** takes longer, and requires uncompressing the backup files.

See Also [apply](#), [binary log](#), [compression](#), [hot backup](#), [MySQL Enterprise Backup](#), [tablespace](#).

#### compressed row format

A **row format** that enables data and index **compression** for InnoDB tables. It was introduced in the InnoDB Plugin, available as part of the **Barracuda** file format. Large fields are stored away from the page that holds the rest of the row data, as in **dynamic row format**. Both index pages and the large fields are compressed,

---

yielding memory and disk savings. Depending on the structure of the data, the decrease in memory and disk usage might or might not outweigh the performance overhead of uncompressing the data as it is used. See [Section 5.4.6, “Working with InnoDB Compressed Tables”](#) for usage details.  
See Also [Barracuda](#), [compression](#), [dynamic row format](#), [row format](#).

#### compression

A feature with wide-ranging benefits from using less disk space, performing less I/O, and using less memory for caching. InnoDB table and index data can be kept in a compressed format during database operation.

The data is uncompressed when needed for queries, and re-compressed when changes are made by **DML** operations. After you enable compression for a table, this processing is transparent to users and application developers. DBAs can consult **information\_schema** tables to monitor how efficiently the compression parameters work for the MySQL instance and for particular compressed tables.

When InnoDB table data is compressed, the compression applies to the **table** itself, any associated **index** data, and the pages loaded into the **buffer pool**. Compression does not apply to pages in the **undo buffer**.

The table compression feature requires using MySQL 5.5 or higher, or the InnoDB Plugin in MySQL 5.1 or earlier, and creating the table using the **Barracuda** file format and **compressed row format**, with the **innodb\_file\_per\_table** setting turned on. The compression for each table is influenced by the **KEY\_BLOCK\_SIZE** clause of the **CREATE TABLE** and **ALTER TABLE** statements. In MySQL 5.6 and higher, compression is also affected by the server-wide configuration options [innodb\\_compression\\_failure\\_threshold\\_pct \[1713\]](#), [innodb\\_compression\\_level \[1713\]](#), and [innodb\\_compression\\_pad\\_pct\\_max \[1713\]](#). See [Section 5.4.6, “Working with InnoDB Compressed Tables”](#) for usage details.

Another type of compression is the **compressed backup** feature of the **MySQL Enterprise Backup** product. See Also [Barracuda](#), [buffer pool](#), [compressed row format](#), [DML](#), [hot backup](#), [index](#), [INFORMATION\\_SCHEMA](#), [innodb\\_file\\_per\\_table](#), [plugin](#), [table](#), [undo buffer](#).

#### compression failure

Not actually an error, rather an expensive operation that can occur when using **compression** in combination with **DML** operations. It occurs when: updates to a compressed **page** overflow the area on the page reserved for recording modifications; the page is compressed again, with all changes applied to the table data; the re-compressed data does not fit on the original page, requiring MySQL to split the data into two new pages and compress each one separately. To check the frequency of this condition, query the table **INFORMATION\_SCHEMA.INNODB\_CMP** and check how much the value of the **COMPRESS\_OPS** column exceeds the value of the **COMPRESS\_OPS\_OK** column. Ideally, compression failures do not occur often; when they do, you can adjust the configuration options [innodb\\_compression\\_level \[1713\]](#), [innodb\\_compression\\_failure\\_threshold\\_pct \[1713\]](#), and [innodb\\_compression\\_pad\\_pct\\_max \[1713\]](#).

See Also [compression](#), [DML](#), [page](#).

#### concatenated index

See [composite index](#).

#### concurrency

The ability of multiple operations (in database terminology, **transactions**) to run simultaneously, without interfering with each other. Concurrency is also involved with performance, because ideally the protection for multiple simultaneous transactions works with a minimum of performance overhead, using efficient mechanisms for **locking**.

See Also [ACID](#), [locking](#), [transaction](#).

#### configuration file

The file that holds the **option** values used by MySQL at startup. Traditionally, on Linux and UNIX this file is named **my.cnf**, and on Windows it is named **my.ini**. You can set a number of options related to InnoDB under the **[mysqld]** section of the file.

Typically, this file is searched for in the locations **/etc/my.cnf** **/etc/mysql/my.cnf** **/usr/local/mysql/etc/my.cnf** and **~/my.cnf**. See [Section 4.2.3.3, “Using Option Files”](#) for details about the search path for this file.

---

When you use the **MySQL Enterprise Backup** product, you typically use two configuration files: one that specifies where the data comes from and how it is structured (which could be the original configuration file for your real server), and a stripped-down one containing only a small set of options that specify where the backup data goes and how it is structured. The configuration files used with the **MySQL Enterprise Backup** product must contain certain options that are typically left out of regular configuration files, so you might need to add some options to your existing configuration file for use with **MySQL Enterprise Backup**. See Also [my.cnf](#), [option file](#).

#### consistent read

A read operation that uses snapshot information to present query results based on a point in time, regardless of changes performed by other transactions running at the same time. If queried data has been changed by another transaction, the original data is reconstructed based on the contents of the **undo log**. This technique avoids some of the **locking** issues that can reduce **concurrency** by forcing transactions to wait for other transactions to finish.

With the **repeatable read** isolation level, the snapshot is based on the time when the first read operation is performed. With the **read committed** isolation level, the snapshot is reset to the time of each consistent read operation.

Consistent read is the default mode in which InnoDB processes **SELECT** statements in **READ COMMITTED** and **REPEATABLE READ** isolation levels. Because a consistent read does not set any locks on the tables it accesses, other sessions are free to modify those tables while a consistent read is being performed on the table.

For technical details about the applicable isolation levels, see [Section 14.2.3.3, “Consistent Nonlocking Reads”](#).

See Also [ACID](#), [concurrency](#), [isolation level](#), [locking](#), [MVCC](#), [READ COMMITTED](#), [READ UNCOMMITTED](#), [REPEATABLE READ](#), [SERIALIZABLE](#), [transaction](#), [undo log](#).

#### constraint

An automatic test that can block database changes to prevent data from becoming inconsistent. (In computer science terms, a kind of assertion related to an invariant condition.) Constraints are a crucial component of the **ACID** philosophy, to maintain data consistency. Constraints supported by MySQL include **FOREIGN KEY constraints** and **unique constraints**.

See Also [ACID](#), [foreign key](#), [relational](#), [unique constraint](#).

#### counter

A value that is incremented by a particular kind of **InnoDB** operation. Useful for measuring how busy a server is, troubleshooting the sources of performance issues, and testing whether changes (for example, to configuration settings or indexes used by queries) have the desired low-level effects. Different kinds of counters are available through **performance\_schema** tables and **information\_schema** tables, particularly [information\\_schema.innodb\\_metrics](#).

See Also [INFORMATION\\_SCHEMA](#), [metrics counter](#), [Performance Schema](#).

#### covering index

An **index** that includes all the columns retrieved by a query. Instead of using the index values as pointers to find the full table rows, the query returns values from the index structure, saving disk I/O. InnoDB can apply this optimization technique to more indexes than MyISAM can, because InnoDB **secondary indexes** also include the primary key columns. InnoDB cannot apply this technique for queries against tables modified by a transactions, until that transaction ends.

Any **column index** or **composite index** could act as a covering index, given the right query. Design your indexes and queries to take advantage of this optimization technique wherever possible.

See Also [column index](#), [composite index](#), [index](#), [secondary index](#).

#### crash

MySQL uses the term "crash" to refer generally to any unexpected [shutdown](#) operation where the server cannot do its normal cleanup. For example, a crash could happen due to a hardware fault on the database server machine or storage device; a power failure; a potential data mismatch that causes the MySQL server to

---

halt; a **fast shutdown** initiated by the DBA; or many other reasons. The robust, automatic **crash recovery** for **InnoDB** tables ensures that data is made consistent when the server is restarted, without any extra work for the DBA.

See Also [crash recovery](#), [fast shutdown](#), [InnoDB](#), [redo log](#), [shutdown](#).

#### crash recovery

The cleanup activities that occur when MySQL is started again after a **crash**. For **InnoDB** tables, changes from incomplete transactions are replayed using data from the **redo log**. Changes that were **committed** before the crash, but not yet written into the [data files](#), are reconstructed from the **doublewrite buffer**. When the database is shut down normally, this type of activity is performed during shutdown by the **purge** operation.

During normal operation, committed data can be stored in the **change buffer** for a period of time before being written to the data files. There is always a tradeoff between keeping the data files up-to-date, which introduces performance overhead during normal operation, and buffering the data, which can make shutdown and crash recovery take longer.

See Also [change buffer](#), [commit](#), [crash](#), [data files](#), [doublewrite buffer](#), [InnoDB](#), [purge](#), [redo log](#).

#### CRUD

Acronym for "create, read, update, delete", a common sequence of operations in database applications. Often denotes a class of applications with relatively simple database usage (basic **DDL**, **DML** and **query** statements in **SQL**) that can be implemented quickly in any language.

See Also [DDL](#), [DML](#), [query](#), [SQL](#).

#### cursor

An internal data structure that is used to represent the result set of a **query**, or other operation that performs a search using an SQL [WHERE](#) clause. It works like an iterator in other high-level languages, producing each value from the result set as requested.

Although usually SQL handles the processing of cursors for you, you might delve into the inner workings when dealing with performance-critical code.

See Also [query](#).

## D

#### data definition language

See [DDL](#).

#### data dictionary

Metadata that keeps track of InnoDB-related objects such as **tables**, **indexes**, and table **columns**. This metadata is physically located in the InnoDB **system tablespace**. For historical reasons, it overlaps to some degree with information stored in the **.frm files**.

Because the **MySQL Enterprise Backup** product always backs up the system tablespace, all backups include the contents of the data dictionary.

See Also [column](#), [.frm file](#), [hot backup](#), [index](#), [MySQL Enterprise Backup](#), [system tablespace](#), [table](#).

#### data directory

The directory under which each MySQL **instance** keeps the **data files** for InnoDB and the directories representing individual databases. Controlled by the [datadir \[472\]](#) configuration option.

See Also [data files](#), [instance](#).

#### data files

The files that physically contain the InnoDB **table** and **index** data. There can be a one-to-many relationship between data files and tables, as in the case of the **system tablespace**, which can hold multiple InnoDB tables as well as the **data dictionary**. There can also be a one-to-one relationship between data files and tables, as when the **file-per-table** setting is enabled, causing each newly created table to be stored in a separate **tablespace**.

See Also [data dictionary](#), [file-per-table](#), [index](#), [system tablespace](#), [table](#), [tablespace](#).

---

data manipulation language  
See [DML](#).

data warehouse

A database system or application that primarily runs large **queries**. The read-only or read-mostly data might be organized in **denormalized** form for query efficiency. Can benefit from the optimizations for **read-only transactions** in MySQL 5.6 and higher. Contrast with **OLTP**.

See Also [denormalized](#), [OLTP](#), [query](#), [read-only transaction](#).

database

Within the MySQL **data directory**, each database is represented by a separate directory. The InnoDB **system tablespace**, which can hold table data from multiple databases within a MySQL **instance**, is kept in its **data files** that reside outside the individual database directories. When **file-per-table** mode is enabled, the **.ibd files** representing individual InnoDB tables are stored inside the database directories.

For long-time MySQL users, a database is a familiar notion. Users coming from an Oracle Database background will find that the MySQL meaning of a database is closer to what Oracle Database calls a **schema**.

See Also [data files](#), [file-per-table](#), [.ibd file](#), [instance](#), [schema](#), [system tablespace](#).

DCL

Data control language, a set of **SQL** statements for managing privileges. In MySQL, consists of the [GRANT](#) and [REVOKE](#) statements. Contrast with **DDL** and **DML**.

See Also [DDL](#), [DML](#), [SQL](#).

DDL

Data definition language, a set of **SQL** statements for manipulating the database itself rather than individual table rows. Includes all forms of the [CREATE](#), [ALTER](#), and [DROP](#) statements. Also includes the [TRUNCATE](#) statement, because it works differently than a [DELETE FROM table\\_name](#) statement, even though the ultimate effect is similar.

DDL statements automatically **commit** the current **transaction**; they cannot be **rolled back**.

The InnoDB-related aspects of DDL include speed improvements for [CREATE INDEX](#) and [DROP INDEX](#) statements, and the way the **file-per-table** setting affects the behavior of the [TRUNCATE TABLE](#) statement.

Contrast with **DML** and **DCL**.

See Also [commit](#), [DCL](#), [DML](#), [file-per-table](#), [rollback](#), [SQL](#), [transaction](#).

deadlock

A situation where different **transactions** are unable to proceed, because each holds a **lock** that the other needs. Because both transactions are waiting for a resource to become available, neither will ever release the locks it holds.

A deadlock can occur when the transactions lock rows in multiple tables (through statements such as [UPDATE](#) or [SELECT ... FOR UPDATE](#)), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and **gaps**, with each transaction acquiring some locks but not others due to a timing issue.

To reduce the possibility of deadlocks, use transactions rather than [LOCK TABLE](#) statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of operations (such as [SELECT ... FOR UPDATE](#)) in each transaction; create indexes on the columns used in [SELECT ... FOR UPDATE](#) and [UPDATE ... WHERE](#) statements. The possibility of deadlocks is not affected by the **isolation level**, because the isolation level changes the behavior of read operations, while deadlocks occur because of write operations.

If a deadlock does occur, InnoDB detects the condition and **rolls back** one of the transactions (the **victim**). Thus, even if your application logic is perfectly correct, you must still handle the case where a transaction must be retried. To see the last deadlock in an InnoDB user transaction, use the command [SHOW ENGINE INNODB STATUS](#). If frequent deadlocks highlight a problem with transaction structure or application error

---

handling, run with the `innodb_print_all_deadlocks` [1741] setting enabled to print information about all deadlocks to the `mysqld` error log.

For background information on how deadlocks are automatically detected and handled, see [Section 14.2.3.9, “Deadlock Detection and Rollback”](#). For tips on avoiding and recovering from deadlock conditions, see [Section 14.2.3.10, “How to Cope with Deadlocks”](#).

See Also [concurrency](#), [gap](#), [isolation level](#), [lock](#), [locking](#), [rollback](#), [transaction](#), [victim](#).

#### deadlock detection

A mechanism that automatically detects when a **deadlock** occurs, and automatically **rolls back** one of the **transactions** involved (the **victim**).

See Also [deadlock](#), [rollback](#), [transaction](#), [victim](#).

#### delete

When InnoDB processes a `DELETE` statement, the rows are immediately marked for deletion and no longer are returned by queries. The storage is reclaimed sometime later, during the periodic garbage collection known as the **purge** operation, performed by a separate thread. For removing large quantities of data, related operations with their own performance characteristics are **truncate** and **drop**.

See Also [drop](#), [purge](#), [truncate](#).

#### delete buffering

The technique of storing index changes due to `DELETE` operations in the **insert buffer** rather than writing them immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally marks an index record for deletion.) It is one of the types of **change buffering**; the others are **insert buffering** and **purge buffering**.

See Also [change buffer](#), [change buffering](#), [insert buffer](#), [insert buffering](#), [purge buffering](#).

#### denormalized

A data storage strategy that duplicates data across different tables, rather than linking the tables with **foreign keys** and **join** queries. Typically used in **data warehouse** applications, where the data is not updated after loading. In such applications, query performance is more important than making it simple to maintain consistent data during updates. Contrast with **normalized**.

See Also [normalized](#).

#### descending index

A type of index available with some database systems, where index storage is optimized to process `ORDER BY column DESC` clauses. Currently, although MySQL allows the `DESC` keyword in the `CREATE TABLE` statement, it does not use any special storage layout for the resulting index.

See Also [index](#).

#### dirty page

A **page** in the InnoDB **buffer pool** that has been updated in memory, where the changes are not yet written (**flushed**) to the [data files](#). The opposite of a **clean page**.

See Also [buffer pool](#), [clean page](#), [data files](#), [flush](#), [page](#).

#### dirty read

An operation that retrieves unreliable data, data that was updated by another transaction but not yet **committed**. It is only possible with the **isolation level** known as **read uncommitted**.

This kind of operation does not adhere to the **ACID** principle of database design. It is considered very risky, because the data could be **rolled back**, or updated further before being committed; then, the transaction doing the dirty read would be using data that was never confirmed as accurate.

Its polar opposite is **consistent read**, where InnoDB goes to great lengths to ensure that a transaction does not read information updated by another transaction, even if the other transaction commits in the meantime.

See Also [ACID](#), [commit](#), [consistent read](#), [isolation level](#), [READ COMMITTED](#), [READ UNCOMMITTED](#), [rollback](#).

#### disk-based

A kind of database that primarily organizes data on disk storage (hard drives or equivalent). Data is brought back and forth between disk and memory to be operated upon. It is the opposite of an **in-memory database**.

---

Although InnoDB is disk-based, it also contains features such as **the buffer pool**, multiple buffer pool instances, and the **adaptive hash index** that allow certain kinds of workloads to work primarily from memory. See Also [adaptive hash index](#), [buffer pool](#), [in-memory database](#).

#### disk-bound

A type of **workload** where the primary **bottleneck** is CPU operations in memory. Typically involves read-intensive operations where the results can all be cached in the **buffer pool**.

See Also [bottleneck](#), [buffer pool](#), [disk-bound](#), [workload](#).

#### disk-bound

A type of **workload** where the primary **bottleneck** is disk I/O. (Also known as **I/O-bound**.) Typically involves frequent writes to disk, or random reads of more data than can fit into the **buffer pool**.

See Also [bottleneck](#), [buffer pool](#), [disk-bound](#), [workload](#).

#### DML

Data manipulation language, a set of **SQL** statements for performing insert, update, and delete operations. The **SELECT** statement is sometimes considered as a DML statement, because the **SELECT ... FOR UPDATE** form is subject to the same considerations for **locking** as **INSERT**, **UPDATE**, and **DELETE**.

DML statements for an InnoDB table operate in the context of a **transaction**, so their effects can be **committed** or **rolled back** as a single unit.

Contrast with **DDL** and **DCL**.

See Also [commit](#), [DCL](#), [DDL](#), [locking](#), [rollback](#), [SQL](#), [transaction](#).

#### document id

In the InnoDB **full-text search** feature, a special column in the table containing the **FULLTEXT index**, to uniquely identify the document associated with each **ilist** value. Its name is **FTS\_DOC\_ID** (uppercase required). The column itself must be of **BIGINT UNSIGNED NOT NULL** type, with a unique index named **FTS\_DOC\_ID\_INDEX**. Preferably, you define this column when creating the table. If InnoDB must add the column to the table while creating a **FULLTEXT** index, the indexing operation is considerably more expensive. See Also [full-text search](#), [FULLTEXT index](#), [ilist](#).

#### doublewrite buffer

InnoDB uses a novel file flush technique called doublewrite. Before writing **pages** to the **data files**, InnoDB first writes them to a contiguous area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer have completed, does InnoDB write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, InnoDB can later find a good copy of the page from the doublewrite buffer during **crash recovery**.

Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the buffer itself as a large sequential chunk, with a single **fsync()** call to the operating system.

To turn off the doublewrite buffer, specify the option **innodb\_doublewrite=0** [1715].

See Also [crash recovery](#), [data files](#), [page](#), [purge](#).

#### drop

A kind of **DDL** operation that removes a schema object, through a statement such as **DROP TABLE** or **DROP INDEX**. It maps internally to an **ALTER TABLE** statement. From an InnoDB perspective, the performance considerations of such operations involve the time that the **data dictionary** is locked to ensure that interrelated objects are all updated, and the time to update memory structures such as the **buffer pool**. For a **table**, the drop operation has somewhat different characteristics than a **truncate** operation (**TRUNCATE TABLE** statement).

See Also [buffer pool](#), [data dictionary](#), [DDL](#), [table](#), [truncate](#).

#### dynamic row format

A row format introduced in the InnoDB Plugin, available as part of the **Barracuda file format**. Because **TEXT** and **BLOB** fields are stored outside of the rest of the page that holds the row data, it is very efficient for rows

---

that include large objects. Since the large fields are typically not accessed to evaluate query conditions, they are not brought into the **buffer pool** as often, resulting in fewer I/O operations and better utilization of cache memory.

See Also [Barracuda](#), [buffer pool](#), [file format](#), [row format](#).

## E

early adopter

A stage similar to beta, when a software product is typically evaluated for performance, functionality, and compatibility in a non-mission-critical setting. InnoDB uses the **early adopter** designation rather than **beta**, through a succession of point releases leading up to a **GA** release.

See Also [beta](#), [GA](#).

error log

A type of **log** showing information about MySQL startup and critical runtime errors and **crash** information. For details, see [Section 5.2.2, “The Error Log”](#).

See Also [crash](#), [log](#).

eviction

The process of removing an item from a cache or other temporary storage area, such as the InnoDB **buffer pool**. Often, but not always, uses the **LRU** algorithm to determine which item to remove. When a **dirty page** is evicted, its contents are **flushed** to disk, and any **dirty neighbor** pages might be flushed also.

See Also [buffer pool](#), [dirty page](#), [flush](#), [LRU](#).

exclusive lock

A kind of **lock** that prevents any other **transaction** from locking the same row. Depending on the transaction **isolation level**, this kind of lock might block other transactions from writing to the same row, or might also block other transactions from reading the same row. The default InnoDB isolation level, **REPEATABLE READ**, enables higher **concurrency** by allowing transactions to read rows that have exclusive locks, a technique known as **consistent read**.

See Also [concurrency](#), [consistent read](#), [isolation level](#), [lock](#), [REPEATABLE READ](#), [shared lock](#), [transaction](#).

extent

A group of **pages** within a **tablespace** totaling 1 megabyte. With the default **page size** of 16KB, an extent contains 64 pages. In MySQL 5.6, the page size can also be 4KB or 8KB, in which case an extent contains more pages, still adding up to 1MB.

InnoDB features such as **segments**, **read-ahead** requests and the **doublewrite buffer** use I/O operations that read, write, allocate, or free data one extent at a time.

See Also [doublewrite buffer](#), [neighbor page](#), [page](#), [page size](#), [read-ahead](#), [segment](#), [tablespace](#).

## F

.frm file

A file containing the metadata, such as the table definition, of a MySQL table.

Although each InnoDB table has a `.frm` file, InnoDB maintains its own table metadata (the **data dictionary**) in the **system tablespace**; the `.frm` files are not needed for InnoDB to operate on InnoDB tables. Problems can occur if a **crash** happens while the `.frm` file is being written, leading to inconsistencies between the `.frm` file and the data dictionary,

For backups, you must always keep the full set of `.frm` files along with the backup data, to be able to restore tables that are altered or dropped after the backup. Files with this extension are always included in backups produced by the `mysqlbackup` command of the **MySQL Enterprise Backup** product. If you use the `ibbackup` command instead, you must copy the `.frm` files yourself.

These files are backed up by the **MySQL Enterprise Backup** product. These files must not be modified by an `ALTER TABLE` operation while the backup is taking place, which is why backups that include non-InnoDB

---

tables perform a `FLUSH TABLES WITH READ LOCK` operation to freeze such activity while backing up the `.frm` files. Restoring a backup can result in `.frm` files being created, changed, or removed to match the state of the database at the time of the backup.

See Also [crash](#), [data dictionary](#), [ibbackup command](#), [MySQL Enterprise Backup](#), [mysqlbackup command](#), [system tablespace](#).

#### Fast Index Creation

A capability first introduced in the InnoDB Plugin, now part of the MySQL server in 5.5 and higher, that speeds up creation of InnoDB **secondary indexes** by avoiding the need to completely rewrite the associated table. The speedup applies to dropping secondary indexes also.

Because index maintenance can add performance overhead to many data transfer operations, consider doing operations such as `ALTER TABLE ... ENGINE=INNODB` or `INSERT INTO ... SELECT * FROM ...` without any secondary indexes in place, and creating the indexes afterward.

In MySQL 5.6, this feature becomes more general: you can read and write to tables while an index is being created, and many more kinds of `ALTER TABLE` operations can be performed without copying the table, without blocking **DML** operations, or both. Thus in MySQL 5.6 and higher, we typically refer to this set of features as **online DDL** rather than Fast Index Creation.

See Also [DML](#), [index](#), [online DDL](#), [secondary index](#).

#### fast shutdown

The default **shutdown** procedure for InnoDB, based on the configuration setting `innodb_fast_shutdown=1` [1716]. To save time, certain **flush** operations are skipped. This type of shutdown is safe during normal usage, because the flush operations are performed during the next startup, using the same mechanism as in **crash recovery**. In cases where the database is being shut down for an upgrade or downgrade, do a **slow shutdown** instead to ensure that all relevant changes are applied to the **data files** during the shutdown.

See Also [crash recovery](#), [data files](#), [flush](#), [shutdown](#), [slow shutdown](#).

#### file format

The format used by InnoDB for each table, typically with the **file-per-table** setting enabled so that each table is stored in a separate `.ibd` file. Currently, the file formats available in InnoDB are known as **Antelope** and **Barracuda**. Each file format supports one or more **row formats**. The row formats available for Barracuda tables, **COMPRESSED** and **DYNAMIC**, enable important new storage features for InnoDB tables.

See Also [Antelope](#), [Barracuda](#), [file-per-table](#), [.ibd file](#), [ibdata file](#), [row format](#).

#### file-per-table

A general name for the setting controlled by the `innodb_file_per_table` [1718] option. That is a very important configuration option that affects many aspects of InnoDB file storage, availability of features, and I/O characteristics. In MySQL 5.6.7 and higher, it is enabled by default. Prior to MySQL 5.6.7, it is disabled by default.

For each table created while this setting is in effect, the data is stored in a separate `.ibd` file rather than in the `ibdata` files of the **system tablespace**. When table data is stored in individual files, you have more flexibility to choose nondefault **file formats** and **row formats**, which are required for features such as data **compression**. The `TRUNCATE TABLE` operation is also much faster, and the reclaimed space can be used by the operating system rather than remaining reserved for InnoDB.

The **MySQL Enterprise Backup** product is more flexible for tables that are in their own files. For example, tables can be excluded from a backup, but only if they are in separate files. Thus, this setting is suitable for tables that are backed up less frequently or on a different schedule.

See Also [compressed row format](#), [compression](#), [file format](#), [.ibd file](#), [ibdata file](#), [innodb\\_file\\_per\\_table](#), [row format](#), [system tablespace](#).

#### fill factor

In an InnoDB **index**, the proportion of a **page** that is taken up by index data before the page is split. The unused space when index data is first divided between pages allows for rows to be updated with longer string values without requiring expensive index maintenance operations. If the fill factor is too low, the index

---

consumes more space than needed, causing extra I/O overhead when reading the index. If the fill factor is too high, any update that increases the length of column values can cause extra I/O overhead for index maintenance. See [Section 14.2.3.12.4, “Physical Structure of an InnoDB Index”](#) for more information. See Also [index](#), [page](#).

#### fixed row format

This row format is used by the MyISAM storage engine, not by InnoDB. If you create an InnoDB table with the option `row_format=fixed`, InnoDB translates this option to use the **compact row format** instead, although the `fixed` value might still show up in output such as `SHOW TABLE STATUS` reports. See Also [compact row format](#), [row format](#).

#### flush

To write changes to the database files, that had been buffered in a memory area or a temporary disk storage area. The InnoDB storage structures that are periodically flushed include the **redo log**, the **undo log**, and the **buffer pool**.

Flushing can happen because a memory area becomes full and the system needs to free some space, because a **commit** operation means the changes from a transaction can be finalized, or because a **slow shutdown** operation means that all outstanding work should be finalized. When it is not critical to flush all the buffered data at once, InnoDB can use a technique called **fuzzy checkpointing** to flush small batches of pages to spread out the I/O overhead.

See Also [buffer pool](#), [commit](#), [fuzzy checkpointing](#), [neighbor page](#), [redo log](#), [slow shutdown](#), [undo log](#).

#### flush list

An internal InnoDB data structure that tracks **dirty pages** in the **buffer pool**: that is, **pages** that have been changed and need to be written back out to disk. This data structure is updated frequently by InnoDB's internal **mini-transactions**, and so is protected by its own **mutex** to allow concurrent access to the buffer pool.

See Also [buffer pool](#), [dirty page](#), [LRU](#), [mini-transaction](#), [mutex](#), [page](#), [page cleaner](#).

#### foreign key

A type of pointer relationship, between rows in separate InnoDB tables. The foreign key relationship is defined on one column in both the **parent table** and the **child table**.

In addition to enabling fast lookup of related information, foreign keys help to enforce **referential integrity**, by preventing any of these pointers from becoming invalid as data is inserted, updated, and deleted. This enforcement mechanism is a type of **constraint**. A row that points to another table cannot be inserted if the associated foreign key value does not exist in the other table. If a row is deleted or its foreign key value changed, and rows in another table point to that foreign key value, the foreign key can be set up to prevent the deletion, cause the corresponding column values in the other table to become **null**, or automatically delete the corresponding rows in the other table.

One of the stages in designing a **normalized** database is to identify data that is duplicated, separate that data into a new table, and set up a foreign key relationship so that the multiple tables can be queried like a single table, using a **join** operation.

See Also [child table](#), [FOREIGN KEY constraint](#), [join](#), [normalized](#), [NULL](#), [parent table](#), [referential integrity](#), [relational](#).

#### FOREIGN KEY constraint

The type of **constraint** that maintains database consistency through a **foreign key** relationship. Like other kinds of constraints, it can prevent data from being inserted or updated if data would become inconsistent; in this case, the inconsistency being prevented is between data in multiple tables. Alternatively, when a **DML** operation is performed, **FOREIGN KEY** constraints can cause data in **child rows** to be deleted, changed to different values, or set to **null**, based on the `ON CASCADE` option specified when creating the foreign key.

See Also [child table](#), [constraint](#), [DML](#), [foreign key](#), [NULL](#).

#### FTS

In most contexts, an acronym for **full-text search**. Sometimes in performance discussions, an acronym for **full table scan**.

---

See Also [full table scan](#), [full-text search](#).

#### full backup

A **backup** that includes all the **tables** in each MySQL **database**, and all the databases in a MySQL **instance**. Contrast with **partial backup**.

See Also [backup](#), [database](#), [instance](#), [partial backup](#), [table](#).

#### full table scan

An operation that requires reading the entire contents of a table, rather than just selected portions using an index. Typically performed either with small lookup tables, or in data warehousing situations with large tables where all available data is aggregated and analyzed. How frequently these operations occur, and the sizes of the tables relative to available memory, have implications for the algorithms used in query optimization and managing the buffer pool.

The purpose of **indexes** is to allow lookups for specific values or ranges of values within a large table, thus avoiding full table scans when practical.

See Also [buffer pool](#), [index](#), [LRU](#).

#### full-text search

The MySQL feature for finding words, phrases, Boolean combinations of words, and so on within table data, in a faster, more convenient, and more flexible way than using the SQL [LIKE](#) operator or writing your own application-level search algorithm. It uses the SQL function [MATCH\(\) \[1229\]](#) and **FULLTEXT indexes**.

See Also [FULLTEXT index](#).

#### FULLTEXT index

The special kind of **index** that holds the **search index** in the MySQL **full-text search** mechanism.

Represents the words from values of a column, omitting any that are specified as **stopwords**. Originally, only available for [MyISAM](#) tables. Starting in MySQL 5.6.4, it is also available for **InnoDB** tables.

See Also [full-text search](#), [index](#), [InnoDB](#), [search index](#), [stopword](#).

#### fuzzy checkpointing

A technique that **flushes** small batches of **dirty pages** from the **buffer pool**, rather than flushing all dirty pages at once which would disrupt database processing.

See Also [buffer pool](#), [dirty page](#), [flush](#).

## G

### GA

"Generally available", the stage when a software product leaves beta and is available for sale, official support, and production use.

See Also [beta](#), [early adopter](#).

### gap

A place in an InnoDB **index** data structure where new values could be inserted. When you lock a set of rows with a statement such as [SELECT ... FOR UPDATE](#), InnoDB can create locks that apply to the gaps as well as the actual values in the index. For example, if you select all values greater than 10 for update, a gap lock prevents another transaction from inserting a new value that is greater than 10. The **supremum record** and **infimum record** represent the gaps containing all values greater than or less than all the current index values.

See Also [concurrency](#), [gap lock](#), [index](#), [infimum record](#), [isolation level](#), [supremum record](#).

### gap lock

A **lock** on a **gap** between index records, or a lock on the gap before the first or after the last index record. For example, [SELECT c1 FOR UPDATE FROM t WHERE c1 BETWEEN 10 and 20;](#) prevents other transactions from inserting a value of 15 into the column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked. Contrast with **record lock** and **next-key lock**.

Gap locks are part of the tradeoff between performance and **concurrency**, and are used in some transaction **isolation levels** and not others.

---

See Also [gap](#), [infimum record](#), [lock](#), [next-key lock](#), [record lock](#), [supremum record](#).

general log

See [general query log](#).

general query log

A type of **log** used for diagnosis and troubleshooting of SQL statements processed by the MySQL server. Can be stored in a file or in a database table. You must enable this feature through the [general\\_log](#) [485] configuration option to use it. You can disable it for a specific connection through the [sql\\_log\\_off](#) [544] configuration option.

Records a broader range of queries than the **slow query log**. Unlike the **binary log**, which is used for replication, the general query log contains **SELECT** statements and does not maintain strict ordering. For more information, see [Section 5.2.3, "The General Query Log"](#).

See Also [binary log](#), [general query log](#), [log](#).

global\_transaction

A type of **transaction** involved in **XA** operations. It consists of several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends **ACID** properties "up a level" so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. For this type of distributed transaction, you must use the **SERIALIZABLE** isolation level to achieve ACID properties.

See Also [ACID](#), [SERIALIZABLE](#), [transaction](#), [XA](#).

group commit

An **InnoDB** optimization that performs some low-level I/O operations (**log write**) once for a set of **commit** operations, rather than flushing and syncing separately for each commit.

When the binlog is enabled, you typically also set the configuration option [sync\\_binlog=0](#), because group commit for the binary log is only supported if it is set to 0.

See Also [commit](#), [plugin](#), [XA](#).

## H

hash index

A type of **index** intended for queries that use equality operators, rather than range operators such as greater-than or [BETWEEN](#). It is available for MEMORY tables. Although hash indexes are the default for MEMORY tables for historic reasons, that storage engine also supports **B-tree** indexes, which are often a better choice for general-purpose queries.

MySQL includes a variant of this index type, the **adaptive hash index**, that is constructed automatically for InnoDB tables if needed based on runtime conditions.

See Also [adaptive hash index](#), [B-tree](#), [index](#), [InnoDB](#).

HDD

Acronym for "hard disk drive". Refers to storage media using spinning platters, usually when comparing and contrasting with **SSD**. Its performance characteristics can influence the throughput of a **disk-based** workload.

See Also [disk-based](#), [SSD](#).

heartbeat

A periodic message that is sent to indicate that a system is functioning properly. In a **replication** context, if the **master** stops sending such messages, one of the **slaves** can take its place. Similar techniques can be used between the servers in a cluster environment, to confirm that all of them are operating properly.

See Also [replication](#).

high-water mark

A value representing an upper limit, either a hard limit that should not be exceeded at runtime, or a record of the maximum value that was actually reached. Contrast with **low-water mark**.

See Also [low-water mark](#).

---

## history list

A list of **transactions** with delete-marked records scheduled to be processed by the **InnoDB purge** operation. Recorded in the **undo log**. The length of the history list is reported by the command `SHOW ENGINE INNODB STATUS`. If the history list grows longer than the value of the `innodb_max_purge_lag [1735]` configuration option, each **DML** operation is delayed slightly to allow the purge operation to finish **flushing** the deleted records.

Also known as **purge lag**.

See Also [flush](#), [purge](#), [purge lag](#), [rollback segment](#), [transaction](#), [undo log](#).

## hot

A condition where a row, table, or internal data structure is accessed so frequently, requiring some form of locking or mutual exclusion, that it results in a performance or scalability issue.

Although "hot" typically indicates an undesirable condition, a **hot backup** is the preferred type of backup.

See Also [hot backup](#).

## hot backup

A backup taken while the database and is running and applications are reading and writing to it. The backup involves more than simply copying data files: it must include any data that was inserted or updated while the backup was in process; it must exclude any data that was deleted while the backup was in process; and it must ignore any changes that were not committed.

The Oracle product that performs hot backups, of InnoDB tables especially but also tables from MyISAM and other storage engines, is known as **MySQL Enterprise Backup**.

The hot backup process consists of two stages. The initial copying of the data files produces a **raw backup**. The **apply** step incorporates any changes to the database that happened while the backup was running. Applying the changes produces a **prepared** backup; these files are ready to be restored whenever necessary. See Also [apply](#), [MySQL Enterprise Backup](#), [prepared backup](#), [raw backup](#).

## |

## .ibd file

Each InnoDB **table** created using the **file-per-table** mode goes into its own **tablespace** file, with a `.ibd` extension, inside the **database** directory. This file contains the table data and any **indexes** for the table. File-per-table mode, controlled by the `innodb_file_per_table` option, affects many aspects of InnoDB storage usage and performance, and is enabled by default in MySQL 5.6.7 and higher.

This extension does not apply to the **system tablespace**, which consists of the **ibdata files**.

When a `.ibd` file is included in a compressed backup by the **MySQL Enterprise Backup** product, the compressed equivalent is a `.ibz` file.

If a table is create with the `DATA DIRECTORY =` clause in MySQL 5.6 and higher, the `.ibd` file is located outside the normal database directory, and is pointed to by a `.isl` file.

See Also [database](#), [file-per-table](#), [ibdata file](#), [.ibz file](#), [index](#), [innodb\\_file\\_per\\_table](#), [.isl file](#), [MySQL Enterprise Backup](#), [system tablespace](#), [table](#), [tablespace](#).

## .ibz file

When the **MySQL Enterprise Backup** product performs a **compressed backup**, it transforms each **tablespace** file that is created using the **file-per-table** setting from a `.ibd` extension to a `.ibz` extension.

The compression applied during backup is distinct from the **compressed row format** that keeps table data compressed during normal operation. A compressed backup operation skips the compression step for a tablespace that is already in compressed row format, as compressing a second time would slow down the backup but produce little or no space savings.

See Also [compressed backup](#), [compressed row format](#), [file-per-table](#), [.ibd file](#), [MySQL Enterprise Backup](#), [tablespace](#).

---

## .isl file

A file that specifies the location of a **.ibd file** for an InnoDB table created with the `DATA DIRECTORY =` clause in MySQL 5.6 and higher. It functions like a symbolic link, without the platform restrictions of the actual symbolic link mechanism. You can store InnoDB **tablespaces** outside the **database** directory, for example, on an especially large or fast storage device depending on the usage of the table. For details, see [Section 5.4.1.2, “Specifying the Location of a Tablespace”](#).  
See Also [database](#), [.ibd file](#), [table](#), [tablespace](#).

## I/O-bound

See [disk-bound](#).

## ib-file set

The set of files managed by InnoDB within a MySQL database: the **system tablespace**, any **file-per-table** tablespaces, and the (typically 2) **redo log** files. Used sometimes in detailed discussions of InnoDB file structures and formats, to avoid ambiguity between the meanings of **database** between different DBMS products, and the non-InnoDB files that may be part of a MySQL database.  
See Also [database](#), [file-per-table](#), [redo log](#), [system tablespace](#).

## ibbackup command

The fundamental command-line tool of the **MySQL Enterprise Backup** product. It performs a **hot backup** operation for InnoDB tables. You use this command directly if all your data is in InnoDB tables, if all the important data that you need to back up is in InnoDB tables, or if you are running on the Windows platform. If you also need to back up tables from MyISAM or other storage engines, you use the **mysqlbackup command** instead (available on UNIX and Linux systems only).  
See Also [hot backup](#), [MySQL Enterprise Backup](#), [mysqlbackup command](#).

## ibbackup\_logfile

A supplemental backup file created by the **MySQL Enterprise Backup** product during a **hot backup** operation. It contains information about any data changes that occurred while the backup was running. The initial backup files, including [ibbackup\\_logfile](#), are known as a **raw backup**, because the changes that occurred during the backup operation are not yet incorporated. After you perform the **apply** step to the raw backup files, the resulting files do include those final data changes, and are known as a **prepared backup**. At this stage, the [ibbackup\\_logfile](#) file is no longer necessary.  
See Also [apply](#), [hot backup](#), [MySQL Enterprise Backup](#), [prepared backup](#), [raw backup](#).

## ibdata file

A set of files with names such as [ibdata1](#), [ibdata2](#), and so on, that make up the InnoDB **system tablespace**. These files contain metadata about InnoDB tables, (the **data dictionary**), and the storage areas for the **undo log**, the **change buffer**, and the **doublewrite buffer**. They also can contain some or all of the table data also (depending on whether the **file-per-table** mode is in effect when each table is created). When the **innodb\_file\_per\_table** option is enabled, data and indexes for newly created tables are stored in separate **.ibd files** rather than in the system tablespace.

The growth of the [ibdata](#) files is influenced by the [innodb\\_autoextend\\_increment \[1704\]](#) configuration option.

See Also [change buffer](#), [data dictionary](#), [doublewrite buffer](#), [file-per-table](#), [.ibd file](#), [innodb\\_file\\_per\\_table](#), [system tablespace](#), [undo log](#).

## ib\_logfile

A set of files, typically named [ib\\_logfile0](#) and [ib\\_logfile1](#), that form the **redo log**. Also sometimes referred to as the **log group**. These files record statements that attempt to change data in InnoDB tables. These statements are replayed automatically to correct data written by incomplete transactions, on startup following a crash.

This data cannot be used for manual recovery; for that type of operation, use the **binary log**.

See Also [binary log](#), [log group](#), [redo log](#).

## ilist

Within an InnoDB **FULLTEXT index**, the data structure consisting of a document ID and positional information for a token (that is, a particular word).

---

See Also [FULLTEXT index](#).

#### implicit row lock

A row lock that InnoDB acquires to ensure consistency, without you specifically requesting it.  
See Also [row lock](#).

#### in-memory database

A type of database system that maintains data in memory, to avoid overhead due to disk I/O and translation between disk blocks and memory areas. Some in-memory databases sacrifice durability (the "D" in the **ACID** design philosophy) and are vulnerable to hardware, power, and other types of failures, making them more suitable for read-only operations. Other in-memory databases do use durability mechanisms such as logging changes to disk or using non-volatile memory.

MySQL features that address the same kinds of memory-intensive processing include the InnoDB **buffer pool**, **adaptive hash index**, and **read-only transaction** optimization, the MEMORY storage engine, the MyISAM key cache, and the MySQL **query cache**.

See Also [ACID](#), [adaptive hash index](#), [buffer pool](#), [disk-based](#), [read-only transaction](#).

#### incremental backup

A type of **hot backup**, performed by the **MySQL Enterprise Backup** product, that only saves data changed since some point in time. Having a full backup and a succession of incremental backups lets you reconstruct backup data over a long period, without the storage overhead of keeping several full backups on hand. You can restore the full backup and then apply each of the incremental backups in succession, or you can keep the full backup up-to-date by applying each incremental backup to it, then perform a single restore operation.

The granularity of changed data is at the **page** level. A page might actually cover more than one row. Each changed page is included in the backup.

See Also [hot backup](#), [MySQL Enterprise Backup](#), [page](#).

#### index

A data structure that provides a fast lookup capability for **rows** of a **table**, typically by forming a tree structure (**B-tree**) representing all the values of a particular **column** or set of columns.

InnoDB tables always have a **clustered index** representing the **primary key**. They can also have one or more **secondary indexes** defined on one or more columns. Depending on their structure, secondary indexes can be classified as **partial**, **column**, or **composite** indexes.

Indexes are a crucial aspect of **query** performance. Database architects design tables, queries, and indexes to allow fast lookups for data needed by applications. The ideal database design uses a **covering index** where practical; the query results are computed entirely from the index, without reading the actual table data. Each **foreign key** constraint also requires an index, to efficiently check whether values exist in both the **parent** and **child** tables.

Although a B-tree index is the most common, a different kind of data structure is used for **hash indexes**, as in the **MEMORY** storage engine and the InnoDB **adaptive hash index**.

See Also [adaptive hash index](#), [B-tree](#), [child table](#), [clustered index](#), [column index](#), [composite index](#), [covering index](#), [foreign key](#), [hash index](#), [parent table](#), [partial index](#), [primary key](#), [query](#), [row](#), [secondary index](#), [table](#).

#### index cache

A memory area that holds the token data for InnoDB **full-text search**. It buffers the data to minimize disk I/O when data is inserted or updated in columns that are part of a **FULLTEXT index**. The token data is written to disk when the index cache becomes full. Each InnoDB **FULLTEXT** index has its own separate index cache, whose size is controlled by the configuration option `innodb_ft_cache_size` [1724].

See Also [full-text search](#), [FULLTEXT index](#).

#### index hint

Extended SQL syntax for overriding the **indexes** recommended by the optimizer. For example, the **FORCE INDEX**, **USE INDEX**, and **IGNORE INDEX** clauses. Typically used when indexed columns have unevenly distributed values, resulting in inaccurate **cardinality** estimates.

---

See Also [cardinality](#), [index](#).

#### index prefix

In an **index** that applies to multiple columns (known as a **composite index**), the initial or leading columns of the index. A query that references the first 1, 2, 3, and so on columns of a composite index can use the index, even if the query does not reference all the columns in the index.

See Also [composite index](#), [index](#).

#### index statistics

See [statistics](#).

#### infimum record

A **pseudo-record** in an **index**, representing the **gap** below the smallest value in that index. If a transaction has a statement such as `SELECT ... FOR UPDATE ... WHERE col < 10;`, and the smallest value in the column is 5, it is a lock on the infimum record that prevents other transactions from inserting even smaller values such as 0, -10, and so on.

See Also [gap](#), [index](#), [pseudo-record](#), [supremum record](#).

#### INFORMATION\_SCHEMA

The name of the **database** that provides a query interface to the MySQL **data dictionary**. (This name is defined by the ANSI SQL standard.) To examine information (metadata) about the database, you can query tables such as `INFORMATION_SCHEMA.TABLES` and `INFORMATION_SCHEMA.COLUMNS`, rather than using `SHOW` commands that produce unstructured output.

The information schema contains some tables that are specific to **InnoDB**, such as `INNODB_LOCKS` and `INNODB_TRX`. You use these tables not to see how the database is structured, but to get real-time information about the workings of InnoDB tables to help with performance monitoring, tuning, and troubleshooting. In particular, these tables provide information about MySQL features related to **compression**, and **transactions** and their associated **locks**.

See Also [compression](#), [data dictionary](#), [database](#), [InnoDB](#), [lock](#), [transaction](#).

#### innobackup command

A **backup** command from the former **InnoDB Hot Backup** product. It is superseded by the `mysqlbackup` command in the **MySQL Enterprise Backup** product.

See Also [backup](#), [InnoDB Hot Backup](#), [MySQL Enterprise Backup](#), [mysqlbackup command](#).

#### InnoDB

A MySQL component that combines high performance with **transactional** capability for reliability, robustness, and concurrent access. It embodies the **ACID** design philosophy. Represented as a **storage engine**; it handles tables created or altered with the `ENGINE=INNODB` clause. See [Section 14.2, “The InnoDB Storage Engine”](#) for architectural details and administration procedures, and [Section 8.5, “Optimizing for InnoDB Tables”](#) for performance advice.

In MySQL 5.5 and higher, InnoDB is the default storage engine for new tables and the `ENGINE=INNODB` clause is not required. In MySQL 5.1 only, many of the advanced InnoDB features require enabling the component known as the InnoDB Plugin. See [Section 14.2.1.1, “InnoDB as the Default MySQL Storage Engine”](#) for the considerations involved in transitioning to recent releases where InnoDB tables are the default.

InnoDB tables are ideally suited for **hot backups**. See [Section 23.2, “MySQL Enterprise Backup”](#) for information about the **MySQL Enterprise Backup** product for backing up MySQL servers without interrupting normal processing.

See Also [ACID](#), [hot backup](#), [storage engine](#), [transaction](#).

#### InnoDB Hot Backup

A licensed backup product, superseded in MySQL 5.1 and above by **MySQL Enterprise Backup**.

See Also [MySQL Enterprise Backup](#).

#### innodb\_autoinc\_lock\_mode

The `innodb_autoinc_lock_mode [1705]` option controls the algorithm used for **auto-increment locking**. When you have an auto-incrementing **primary key**, you can use statement-based replication only with

---

the setting `innodb_autoinc_lock_mode=1` [1705]. This setting is known as **consecutive** lock mode, because multi-row inserts within a transaction receive consecutive auto-increment values. If you have `innodb_autoinc_lock_mode=2`, which allows higher concurrency for insert operations, use row-based replication rather than statement-based replication. This setting is known as **interleaved** lock mode, because multiple multi-row insert statements running at the same time can receive autoincrement values that are interleaved. The setting `innodb_autoinc_lock_mode=0` is the previous (traditional) default setting and should not be used except for compatibility purposes.

See Also [auto-increment locking](#), [mixed-mode insert](#), [primary key](#).

#### innodb\_file\_format

The `innodb_file_format` [1716] option determines the **file format** for all InnoDB **tablespaces** created after you specify a value for this option. To create tablespaces other than the **system tablespace**, you must also use the **file-per-table** option. Currently, you can specify the **Antelope** and **Barracuda** file formats. See Also [Antelope](#), [Barracuda](#), [file format](#), [file-per-table](#), [innodb\\_file\\_per\\_table](#), [system tablespace](#), [tablespace](#).

#### innodb\_file\_per\_table

A very important configuration option that affects many aspects of InnoDB file storage, availability of features, and I/O characteristics. In MySQL 5.6.7 and higher, it is enabled by default. Prior to MySQL 5.6.7, it is disabled by default. The `innodb_file_per_table` [1718] option turns on **file-per-table** mode, which stores each newly created InnoDB table and its associated index in its own **.ibd file**, outside the **system tablespace**.

This option affects the performance and storage considerations for a number of SQL statements, such as `DROP TABLE` and `TRUNCATE TABLE`.

This option is needed to take full advantage of many other InnoDB features, such as such as table **compression**, or backups of named tables in **MySQL Enterprise Backup**.

This option was once static, but can now be set using the `SET GLOBAL` command.

For reference information, see `innodb_file_per_table` [1718]. For usage information, see [Section 5.4.1](#), “[Managing InnoDB Tablespaces](#)”.

See Also [compression](#), [file-per-table](#), [.ibd file](#), [MySQL Enterprise Backup](#), [system tablespace](#).

#### innodb\_lock\_wait\_timeout

The `innodb_lock_wait_timeout` [1729] option sets the balance between **waiting** for shared resources to become available, or giving up and handling the error, retrying, or doing alternative processing in your application. Rolls back any InnoDB transaction that waits more than a specified time to acquire a **lock**. Especially useful if **deadlocks** are caused by updates to multiple tables controlled by different storage engines; such deadlocks are not **detected** automatically.

See Also [deadlock](#), [deadlock detection](#), [lock](#), [wait](#).

#### innodb\_strict\_mode

The `innodb_strict_mode` [1749] option controls whether InnoDB operates in **strict mode**, where conditions that are normally treated as warnings, cause errors instead (and the underlying statements fail).

This mode is the default setting in MySQL 5.5.5 and higher.

See Also [strict mode](#).

#### insert

One of the primary **DML** operations in **SQL**. The performance of inserts is a key factor in **data warehouse** systems that load millions of rows into tables, and **OLTP** systems where many concurrent connections might insert rows into the same table, in arbitrary order. If insert performance is important to you, you should learn about **InnoDB** features such as the **insert buffer** used in **change buffering**, and **auto-increment** columns. See Also [auto-increment](#), [change buffering](#), [data warehouse](#), [DML](#), [InnoDB](#), [insert buffer](#), [OLTP](#), [SQL](#).

#### insert buffer

Former name for the **change buffer**. Now that **change buffering** includes delete and update operations as well as inserts, “change buffer” is the preferred term.

---

See Also [change buffer](#), [change buffering](#).

#### insert buffering

The technique of storing secondary index changes due to [INSERT](#) operations in the **insert buffer** rather than writing them immediately, so that the physical writes can be performed to minimize random I/O. It is one of the types of **change buffering**; the others are **delete buffering** and **purge buffering**.

Insert buffering is not used if the secondary index is **unique**, because the uniqueness of new values cannot be verified before the new entries are written out. Other kinds of change buffering do work for unique indexes. See Also [change buffer](#), [change buffering](#), [delete buffering](#), [insert buffer](#), [purge buffering](#), [unique index](#).

#### instance

A single **mysqld** daemon managing a **data directory** representing one or more **databases** with a set of **tables**. It is common in development, testing, and some **replication** scenarios to have multiple instances on the same **server** machine, each managing its own data directory and listening on its own port or socket. With one instance running a **disk-bound** workload, the server might still have extra CPU and memory capacity to run additional instances.

See Also [data directory](#), [database](#), [disk-bound](#), [mysqld](#), [replication](#), [server](#).

#### instrumentation

Modifications at the source code level to collect performance data for tuning and debugging. In MySQL, data collected by instrumentation is exposed through a SQL interface using the [INFORMATION\\_SCHEMA](#) and [PERFORMANCE\\_SCHEMA](#) databases.

See Also [INFORMATION\\_SCHEMA](#), [Performance Schema](#).

#### intention exclusive lock

See [intention lock](#).

#### intention lock

A kind of **lock** that applies to the table level, used to indicate what kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the first transaction to acquire an **intention exclusive** (IX) lock on a table prevents other transactions from acquiring any S or X locks on the table. Conversely, the first transaction to acquire an **intention shared** (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible. For more details on this locking mechanism, see [Section 14.2.3.2, “InnoDB Lock Modes”](#).

See Also [lock](#), [lock mode](#), [locking](#).

#### intention shared lock

See [intention lock](#).

#### inverted index

A data structure optimized for document retrieval systems, used in the implementation of InnoDB **full-text search**. The InnoDB **FULLTEXT index**, implemented as an inverted index, records the position of each word within a document, rather than the location of a table row. A single column value (a document stored as a text string) is represented by many entries in the inverted index.

See Also [full-text search](#), [FULLTEXT index](#), [ilist](#).

#### IOPS

Acronym for **I/O operations per second**. A common measurement for busy systems, particularly **OLTP** applications. If this value is near the maximum that the storage devices can handle, the application can become **disk-bound**, limiting **scalability**.

See Also [disk-bound](#), [OLTP](#), [scalability](#).

#### isolation level

One of the foundations of database processing. Isolation is the **I** in the acronym **ACID**; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple **transactions** are making changes and performing queries at the same time.

---

From highest amount of consistency and protection to the least, the isolation levels supported by InnoDB are: **SERIALIZABLE**, **REPEATABLE READ**, **READ COMMITTED**, and **READ UNCOMMITTED**.

With InnoDB tables, many users can keep the default isolation level (**REPEATABLE READ**) for all operations. Expert users might choose the **read committed** level as they push the boundaries of scalability with OLTP processing, or during data warehousing operations where minor inconsistencies do not affect the aggregate results of large amounts of data. The levels on the edges (**SERIALIZABLE** and **READ UNCOMMITTED**) change the processing behavior to such an extent that they are rarely used. See Also [ACID](#), [READ COMMITTED](#), [READ UNCOMMITTED](#), [REPEATABLE READ](#), [SERIALIZABLE](#), [transaction](#).

## J

join

A **query** that retrieves data from more than one table, by referencing columns in the tables that hold identical values. Ideally, these columns are part of an InnoDB **foreign key** relationship, which ensures **referential integrity** and that the join columns are **indexed**. Often used to save space and improve query performance by replacing repeated strings with numeric IDs, in a **normalized** data design. See Also [foreign key](#), [index](#), [normalized](#), [query](#), [referential integrity](#).

## K

KEY\_BLOCK\_SIZE

An option to specify the size of data pages within an InnoDB table that uses **compressed row format**. The default is 8 kilobytes. Lower values risk hitting internal limits that depend on the combination of row size and compression percentage. See Also [compressed row format](#).

## L

latch

A lightweight structure used by InnoDB to implement a **lock** for its own internal memory structures, typically held for a brief time measured in milliseconds or microseconds. A general term that includes both **mutexes** (for exclusive access) and **rw-locks** (for shared access). Certain latches are the focus of InnoDB performance tuning, such as the **data dictionary** mutex. Statistics about latch use and contention are available through the **Performance Schema** interface. See Also [data dictionary](#), [lock](#), [locking](#), [mutex](#), [Performance Schema](#), [rw-lock](#).

list

The InnoDB **buffer pool** is represented as a list of memory **pages**. The list is reordered as new pages are accessed and enter the buffer pool, as pages within the buffer pool are accessed again and are considered newer, and as pages that are not accessed for a long time are **evicted** from the buffer pool. The buffer pool is actually divided into **sublists**, and the replacement policy is a variation of the familiar **LRU** technique. See Also [buffer pool](#), [eviction](#), [LRU](#), [sublist](#).

lock

The high-level notion of an object that controls access to a resource, such as a table, row, or internal data structure, as part of a **locking** strategy. For intensive performance tuning, you might delve into the actual structures that implement locks, such as **mutexes** and **latches**. See Also [latch](#), [lock mode](#), [locking](#), [mutex](#).

lock escalation

An operation used in some database systems that converts many row locks into a single table lock, saving memory space but reducing concurrent access to the table. InnoDB uses a space-efficient representation for row locks, so that lock escalation is not needed. See Also [locking](#), [row lock](#), [table lock](#).

---

## lock mode

A shared (S) lock allows a transaction to read a row. Multiple transactions can acquire an S lock on that same row at the same time.

An exclusive (X) lock allows a transaction to update or delete a row. No other transaction can acquire any kind of lock on that same row at the same time.

**Intention locks** apply to the table level, and are used to indicate what kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the first transaction to acquire an intention exclusive (IX) lock on a table prevents other transactions from acquiring any S or X locks on the table. Conversely, the first transaction to acquire an intention shared (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible.

See Also [intention lock](#), [lock](#), [locking](#).

## locking

The system of protecting a **transaction** from seeing or changing data that is being queried or changed by other transactions. The locking strategy must balance reliability and consistency of database operations (the principles of the **ACID** philosophy) against the performance needed for good **concurrency**. Fine-tuning the locking strategy often involves choosing an **isolation level** and ensuring all your database operations are safe and reliable for that isolation level.

See Also [ACID](#), [concurrency](#), [isolation level](#), [latch](#), [lock](#), [mutex](#), [transaction](#).

## locking read

A **SELECT** statement that also performs a **locking** operation on an [InnoDB](#) table. Either `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`. It has the potential to produce a **deadlock**, depending on the **isolation level** of the transaction. The opposite of a **non-locking read**. Not allowed for global tables in a **read-only transaction**.

See Also [deadlock](#), [isolation level](#), [locking](#), [non-locking read](#), [read-only transaction](#).

## log

In the [InnoDB](#) context, "log" or "log files" typically refers to the **redo log** represented by the `ib_logfile*` files. Another log area, which is physically part of the **system tablespace**, is the **undo log**.

Other kinds of logs that are important in MySQL are the **error log** (for diagnosing startup and runtime problems), **binary log** (for working with replication and performing point-in-time restores), the **general query log** (for diagnosing application problems), and the **slow query log** (for diagnosing performance problems).

See Also [binary log](#), [error log](#), [general query log](#), [ib\\_logfile](#), [redo log](#), [slow query log](#), [system tablespace](#), [undo log](#).

## log buffer

The memory area that holds data to be written to the **log files** that make up the **redo log**. It is controlled by the `innodb_log_buffer_size` [1732] configuration option.

See Also [log file](#), [redo log](#).

## log file

One of the `ib_logfileN` files that make up the **redo log**. Data is written to these files from the **log buffer** memory area.

See Also [ib\\_logfile](#), [log buffer](#), [redo log](#).

## log group

The set of files that make up the **redo log**, typically named `ib_logfile0` and `ib_logfile1`. (For that reason, sometimes referred to collectively as **ib\_logfile**.)

See Also [ib\\_logfile](#), [redo log](#).

## logical

A type of operation that involves high-level, abstract aspects such as tables, queries, indexes, and other SQL concepts. Typically, logical aspects are important to make database administration and application development convenient and usable. Contrast with **physical**.

See Also [logical backup](#), [physical](#).

---

## logical backup

A **backup** that reproduces table structure and data, without copying the actual data files. For example, the [mysqldump](#) command produces a logical backup, because its output contains statements such as [CREATE TABLE](#) and [INSERT](#) that can re-create the data. Contrast with **physical backup**. A logical backup offers flexibility (for example, you could edit table definitions or insert statements before restoring), but can take substantially longer to **restore** than a physical backup.

See Also [backup](#), [mysqldump](#), [physical backup](#), [restore](#).

## loose\_

In MySQL 5.1, a prefix added to InnoDB configuration options when installing the InnoDB **Plugin** after server startup, so any new configuration options not recognized by the current level of MySQL do not cause a startup failure. MySQL processes configuration options that start with this prefix, but gives a warning rather than a failure if the part after the prefix is not a recognized option.

See Also [plugin](#).

## low-water mark

A value representing a lower limit, typically a threshold value at which some corrective action begins or becomes more aggressive. Contrast with **high-water mark**.

See Also [high-water mark](#).

## LRU

An acronym for "least recently used", a common method for managing storage areas. The items that have not been used recently are **evicted** when space is needed to cache newer items. InnoDB uses the LRU mechanism by default to manage the **pages** within the **buffer pool**, but makes exceptions in cases where a page might be read only a single time, such as during a **full table scan**. This variation of the LRU algorithm is called the **midpoint insertion strategy**. The ways in which the buffer pool management differs from the traditional LRU algorithm is fine-tuned by the options [innodb\\_old\\_blocks\\_pct](#) [1738], [innodb\\_old\\_blocks\\_time](#) [1738], and the new MySQL 5.6 options [innodb\\_lru\\_scan\\_depth](#) [1734] and [innodb\\_flush\\_neighbors](#) [1721].

See Also [buffer pool](#), [eviction](#), [full table scan](#), [midpoint insertion strategy](#).

## LSN

Acronym for "log sequence number". This arbitrary, ever-increasing value represents a point in time corresponding to operations recorded in the **redo log**. (This point in time is regardless of **transaction** boundaries; it can fall in the middle of one or more transactions.) It is used internally by InnoDB during **crash recovery** and for managing the buffer pool.

In the **MySQL Enterprise Backup** product, you can specify an LSN to represent the point in time from which to take an **incremental backup**. The relevant LSN is displayed by the output of the [ibbackup](#) command. Once you have the LSN corresponding to the time of a full backup, you can specify that value to take a subsequent incremental backup, whose output contains another LSN for the next incremental backup.

See Also [crash recovery](#), [incremental backup](#), [MySQL Enterprise Backup](#), [redo log](#), [transaction](#).

# M

## .MRG file

A file containing references to other tables, used by the [MERGE](#) storage engine. Files with this extension are always included in backups produced by the [mysqlbackup](#) command of the **MySQL Enterprise Backup** product.

See Also [MySQL Enterprise Backup](#), [mysqlbackup command](#).

## .MYD file

The file that MySQL uses to store data for a MyISAM table. Files with this extension are always included in backups produced by the [mysqlbackup](#) command of the **MySQL Enterprise Backup** product.

See Also [.MYI file](#), [MySQL Enterprise Backup](#), [mysqlbackup command](#).

## .MYI file

A file that MySQL uses to store indexes for a MyISAM table. Files with this extension are always included in backups produced by the [mysqlbackup](#) command of the **MySQL Enterprise Backup** product.

See Also [.MYD file](#), [MySQL Enterprise Backup](#), [mysqlbackup command](#).

---

## master server

Frequently shortened to "master". A database server machine in a **replication** scenario that processes the initial insert, update, and delete requests for data. These changes are propagated to, and repeated on, other servers known as **slave servers**.

See Also [replication](#), [slave server](#).

## master thread

An InnoDB **thread** that performs various tasks in the background. Most of these tasks are I/O related, such as writing changes from the **insert buffer** to the appropriate secondary indexes.

To improve **concurrency**, sometimes actions are moved from the master thread to separate background threads. For example, in MySQL 5.6 and higher, **dirty pages** are **flushed** from the **buffer pool** by the **page cleaner** thread rather than the master thread.

See Also [buffer pool](#), [dirty page](#), [flush](#), [insert buffer](#), [page cleaner](#), [thread](#).

## MDL

Acronym for "metadata lock".

See Also [metadata lock](#).

## memcached

A popular component of many MySQL and **NoSQL** software stacks, allowing fast reads and writes for single values and caching the results entirely in memory. Traditionally, applications required extra logic to write the same data to a MySQL database for permanent storage, or to read data from a MySQL database when it was not cached yet in memory. Now, applications can use the simple [memcached](#) protocol, supported by client libraries for many languages, to communicate directly with MySQL servers using **InnoDB** or MySQL Cluster tables. These NoSQL interfaces to MySQL tables allow applications to achieve higher read and write performance than by issuing SQL commands directly, and can simplify application logic and deployment configurations for systems that already incorporated [memcached](#) for in-memory caching.

The [memcached](#) interface to InnoDB tables is available in MySQL 5.6 and higher; see [Section 14.2.9, "InnoDB Integration with memcached"](#) for details. The [memcached](#) interface to MySQL Cluster tables is available in MySQL Cluster 7.2; see <http://dev.mysql.com/doc/ndbapi/en/ndbmemcache.html> for details. See Also [InnoDB](#), [NoSQL](#).

## merge

To apply changes to data cached in memory, such as when a page is brought into the **buffer pool**, and any applicable changes recorded in the **change buffer** are incorporated into the page in the buffer pool. The updated data is eventually written to the **tablespace** by the **flush** mechanism.

See Also [buffer pool](#), [change buffer](#), [flush](#), [tablespace](#).

## metadata lock

A type of **lock** that prevents **DDL** operations on a table that is being used at the same time by another **transaction**. For details, see [Section 8.10.4, "Metadata Locking"](#).

Enhancements to **online** operations, particularly in MySQL 5.6 and higher, are focused on reducing the amount of metadata locking. The objective is for DDL operations that do not change the table structure (such as [CREATE INDEX](#) and [DROP INDEX](#) for [InnoDB](#) tables) to proceed while the table is being queried, updated, and so on by other transactions.

See Also [DDL](#), [lock](#), [online](#), [transaction](#).

## metrics counter

A feature implemented by the [innodb\\_metrics](#) table in the **information\_schema**, in MySQL 5.6 and higher. You can query **counts** and totals for low-level InnoDB operations, and use the results for performance tuning in combination with data from the **performance\_schema**.

See Also [counter](#), [INFORMATION\\_SCHEMA](#), [Performance Schema](#).

## midpoint insertion strategy

The technique of initially bringing **pages** into the InnoDB **buffer pool** not at the "newest" end of the list, but instead somewhere in the middle. The exact location of this point can vary, based on the setting of the [innodb\\_old\\_blocks\\_pct \[1738\]](#) option. The intent is that blocks that are only read once, such as during a **full table scan**, can be aged out of the buffer pool sooner than with a strict **LRU** algorithm.

---

See Also [buffer pool](#), [full table scan](#), [LRU](#), [page](#).

#### mini-transaction

An internal phase of InnoDB processing, when making changes at the **physical** level to internal data structures during **DML** operations. A mini-transaction has no notion of **rollback**; multiple mini-transactions can occur within a single **transaction**. Mini-transactions write information to the **redo log** that is used during **crash recovery**. A mini-transaction can also happen outside the context of a regular transaction, for example during **purge** processing by background threads.

See Also [commit](#), [crash recovery](#), [DML](#), [physical](#), [purge](#), [redo log](#), [rollback](#), [transaction](#).

#### mixed-mode insert

An **INSERT** statement where **auto-increment** values are specified for some but not all of the new rows. For example, a multi-value **INSERT** could specify a value for the auto-increment column in some cases and **NULL** in other cases. InnoDB generates auto-increment values for the rows where the column value was specified as **NULL**. Another example is an **INSERT . . . ON DUPLICATE KEY UPDATE** statement, where auto-increment values might be generated but not used, for any duplicate rows that are processed as **UPDATE** rather than **INSERT** statements.

Can cause consistency issues between **master** and **slave** servers in a **replication** configuration. Can require adjusting the value of the **innodb\_autoinc\_lock\_mode** configuration option.

See Also [auto-increment](#), [innodb\\_autoinc\\_lock\\_mode](#), [master server](#), [replication](#), [slave server](#).

#### multi-core

A type of processor that can take advantage of multi-threaded programs, such as the MySQL server.

#### multiversion concurrency control

See [MVCC](#).

#### mutex

Informal abbreviation for "mutex variable". (Mutex itself is short for "mutual exclusion".) The low-level object that InnoDB uses to represent and enforce exclusive-access **locks** to internal in-memory data structures. Once the lock is acquired, any other process, thread, and so on is prevented from acquiring the same lock. Contrast with **rw-locks**, which allow shared access. Mutexes and rw-locks are known collectively as **latches**. See Also [latch](#), [lock](#), [Performance Schema](#), [Pthreads](#), [rw-lock](#).

#### MVCC

Acronym for "multiversion concurrency control". This technique lets InnoDB **transactions** with certain **isolation levels** to perform **consistent read** operations; that is, to query rows that are being updated by other transactions, and see the values from before those updates occurred. This is a powerful technique to increase **concurrency**, by allowing queries to proceed without waiting due to **locks** held by the other transactions.

This technique is not universal in the database world. Some other database products, and some other MySQL storage engines, do not support it.

See Also [ACID](#), [concurrency](#), [consistent read](#), [isolation level](#), [lock](#), [transaction](#).

#### my.cnf

The name, on UNIX or Linux systems, of the MySQL option file.

See Also [my.ini](#), [option file](#).

#### my.ini

The name, on Windows systems, of the MySQL option file.

See Also [my.cnf](#), [option file](#).

#### mysql

The **mysql** program is the command-line interpreter for the MySQL database. It processes **SQL** statements, and also MySQL-specific commands such as **SHOW TABLES**, by passing requests to the **mysqld** daemon.

See Also [mysqld](#), [SQL](#).

#### MySQL Enterprise Backup

A licensed product, superseding InnoDB Hot Backup, that performs **hot backups** of MySQL databases. It offers the most efficiency and flexibility when backing up **InnoDB** tables, but can also back up MyISAM and other kinds of tables.

---

See Also [hot backup](#), [InnoDB](#).

#### mysqlbackup command

A command-line tool of the **MySQL Enterprise Backup** product. It performs a **hot backup** operation for InnoDB tables, and a **warm backup** for MyISAM and other kinds of tables. See [Section 23.2, “MySQL Enterprise Backup”](#) for more information about this command.

See Also [hot backup](#), [ibbackup command](#), [MySQL Enterprise Backup](#), [warm backup](#).

#### mysqld

The `mysqld` program is the database engine for the MySQL database. It runs as a UNIX daemon or Windows service, constantly waiting for requests and performing maintenance work in the background.

See Also [mysql](#).

#### mysqldump

A command that performs a **logical backup** of some combination of databases, tables, and table data. The results are SQL statements that reproduce the original schema objects, data, or both. For substantial amounts of data, a **physical backup** solution such as **MySQL Enterprise Backup** is faster, particularly for the **restore** operation.

See Also [logical backup](#), [MySQL Enterprise Backup](#), [physical backup](#), [restore](#).

## N

#### natural key

A indexed column, typically a **primary key**, where the values have some real-world significance. Usually advised against because:

- If the value should ever change, there is potentially a lot of index maintenance to re-sort the **clustered index** and update the copies of the primary key value that are repeated in each **secondary index**.
- Even seemingly stable values can change in unpredictable ways that are difficult to represent correctly in the database. For example, one country can change into two or several, making the original country code obsolete. Or, rules about unique values might have exceptions. For example, even if taxpayer IDs are intended to be unique to a single person, a database might have to handle records that violate that rule, such as in cases of identity theft. Taxpayer IDs and other sensitive ID numbers also make poor primary keys, because they may need to be secured, encrypted, and otherwise treated differently than other columns.

Thus, it is typically better to use arbitrary numeric values to form a **synthetic key**, for example using an **auto-increment** column.

See Also [auto-increment](#), [primary key](#), [secondary index](#), [synthetic key](#).

#### neighbor page

Any **page** in the same **extent** as a particular page. When a page is selected to be **flushed**, any neighbor pages that are **dirty** are typically flushed as well, as an I/O optimization for traditional hard disks. In MySQL 5.6 and up, this behavior can be controlled by the configuration variable `innodb_flush_neighbors` [1721]; you might turn that setting off for SSD drives, which do not have the same overhead for writing smaller batches of data at random locations.

See Also [dirty page](#), [extent](#), [flush](#), [page](#).

#### next-key lock

A combination of a **record lock** on the index record and a [gap lock](#) on the gap before the index record.

See Also [gap lock](#), [locking](#), [record lock](#).

#### non-blocking I/O

An industry term that means the same as **asynchronous I/O**.

See Also [asynchronous I/O](#).

#### non-locking read

A **query** that does not use the `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE` clauses. The only kind of query allowed for global tables in a **read-only transaction**. The opposite of a **locking read**.

---

See Also [locking read](#), [query](#), [read-only transaction](#).

#### non-repeatable read

The situation when a query retrieves data, and a later query within the same **transaction** retrieves what should be the same data, but the queries return different results (changed by another transaction committing in the meantime).

This kind of operation goes against the **ACID** principle of database design. Within a transaction, data should be consistent, with predictable and stable relationships.

Among different **isolation levels**, non-repeatable reads are prevented by the **serializable read** and **repeatable read** levels, and allowed by the **consistent read**, and **read uncommitted** levels.

See Also [ACID](#), [consistent read](#), [isolation level](#), [READ UNCOMMITTED](#), [REPEATABLE READ](#), [SERIALIZABLE](#), [transaction](#).

#### normalized

A database design strategy where data is split into multiple tables, and duplicate values condensed into single rows represented by an ID, to avoid storing, querying, and updating redundant or lengthy values. It is typically used in **OLTP** applications.

For example, an address might be given a unique ID, so that a census database could represent the relationship **lives at this address** by associating that ID with each member of a family, rather than storing multiple copies of a complex value such as **123 Main Street, Anytown, USA**.

For another example, although a simple address book application might store each phone number in the same table as a person's name and address, a phone company database might give each phone number a special ID, and store the numbers and IDs in a separate table. This normalized representation could simplify large-scale updates when area codes split apart.

Normalization is not always recommended. Data that is primarily queried, and only updated by deleting entirely and reloading, is often kept in fewer, larger tables with redundant copies of duplicate values. This data representation is referred to as **denormalized**, and is frequently found in data warehousing applications.

See Also [denormalized](#), [foreign key](#), [OLTP](#), [relational](#).

#### NoSQL

A broad term for a set of data access technologies that do not use the **SQL** language as their primary mechanism for reading and writing data. Some NoSQL technologies act as key-value stores, only accepting single-value reads and writes; some relax the restrictions of the **ACID** methodology; still others do not require a pre-planned **schema**. MySQL users can combine NoSQL-style processing for speed and simplicity with SQL operations for flexibility and convenience, by using the **memcached** API to directly access some kinds of MySQL tables. The **memcached** interface to InnoDB tables is available in MySQL 5.6 and higher; see [Section 14.2.9, "InnoDB Integration with memcached"](#) for details. The **memcached** interface to MySQL Cluster tables is available in MySQL Cluster 7.2; see <http://dev.mysql.com/doc/ndbapi/en/ndbmemcache.html> for details.

See Also [ACID](#), [InnoDB](#), [memcached](#), [schema](#), [SQL](#).

#### NOT NULL constraint

A type of **constraint** that specifies that a **column** cannot contain any **NULL** values. It helps to preserve **referential integrity**, as the database server can identify data with erroneous missing values. It also helps in the arithmetic involved in query optimization, allowing the optimizer to predict the number of entries in an index on that column.

See Also [column](#), [constraint](#), [NULL](#), [primary key](#), [referential integrity](#).

#### NULL

A special value in **SQL**, indicating the absence of data. Any arithmetic operation or equality test involving a **NULL** value, in turn produces a **NULL** result. (Thus it is similar to the IEEE floating-point concept of NaN, "not a number".) Any aggregate calculation such as **AVG()** ignores rows with **NULL** values, when determining how many rows to divide by. The only test that works with **NULL** values uses the SQL idioms **IS NULL** or **IS NOT NULL**.

---

[NULL](#) values play a part in index operations, because for performance a database must minimize the overhead of keeping track of missing data values. Typically, [NULL](#) values are not stored in an index, because a query that tests an indexed column using a standard comparison operator could never match a row with a [NULL](#) value for that column. For the same reason, unique indexes do not prevent [NULL](#) values; those values simply are not represented in the index. Declaring a [NOT NULL](#) constraint on a column provides reassurance that there are no rows left out of the index, allowing for better query optimization (accurate counting of rows and estimation of whether to use the index).

Because the **primary key** must be able to uniquely identify every row in the table, a single-column primary key cannot contain any [NULL](#) values, and a multi-column primary key cannot contain any rows with [NULL](#) values in all columns.

Although the Oracle database allows a [NULL](#) value to be concatenated with a string, InnoDB treats the result of such an operation as [NULL](#).

See Also [index](#), [primary key](#), [SQL](#).

## O

### .OPT file

A file containing database configuration information. Files with this extension are always included in backups produced by the [mysqlbackup](#) command of the **MySQL Enterprise Backup** product.

See Also [MySQL Enterprise Backup](#), [mysqlbackup command](#).

### off-page column

A column containing variable-length data (such as [BLOB](#) and [VARCHAR](#)) that is too long to fit on a **B-tree** page. The data is stored in **overflow pages**. The [DYNAMIC](#) row format in the InnoDB **Barracuda** file format is more efficient for such storage than the older [COMPACT](#) row format.

See Also [B-tree](#), [Barracuda](#), [overflow page](#).

### OLTP

Acronym for "Online Transaction Processing". A database system, or a database application, that runs a workload with many **transactions**, with frequent writes as well as reads, typically affecting small amounts of data at a time. For example, an airline reservation system or an application that processes bank deposits. The data might be organized in **normalized** form for a balance between **DML** (insert/update/delete) efficiency and **query** efficiency. Contrast with **data warehouse**.

With its **row-level locking** and **transactional** capability, **InnoDB** is the ideal storage engine for MySQL tables used in OLTP applications.

See Also [data warehouse](#), [DML](#), [InnoDB](#), [query](#), [row lock](#), [transaction](#).

### online

A type of operation that involves no downtime, blocking, or restricted operation for the database. Typically applied to **DDL**. Operations that shorten the periods of restricted operation, such as **fast index creation**, have evolved into a wider set of **online DDL** operations in MySQL 5.6.

In the context of backups, a **hot backup** is an online operation and a **warm backup** is partially an online operation.

See Also [DDL](#), [Fast Index Creation](#), [hot backup](#), [online DDL](#), [warm backup](#).

### online DDL

A feature that improves the performance, concurrency, and availability of InnoDB tables during **DDL** (primarily [ALTER TABLE](#)) operations. See [Section 5.5, "Online DDL for InnoDB Tables"](#) for details.

The details vary according to the type of operation. In some cases, the table can be modified concurrently while the [ALTER TABLE](#) is in progress. The operation might be able to be performed without doing a table copy, or using a specially optimized type of table copy. Space usage is controlled by the [innodb\\_online\\_alter\\_log\\_max\\_size \[1739\]](#) configuration option.

This feature is an enhancement of the **Fast Index Creation** feature in MySQL 5.5 and the InnoDB Plugin for MySQL 5.1.

---

See Also [DDL](#), [Fast Index Creation](#), [online](#).

#### optimistic

A methodology that guides low-level implementation decisions for a relational database system. The requirements of performance and **concurrency** in a relational database mean that operations must be started or dispatched quickly. The requirements of consistency and **referential integrity** mean that any operation could fail: a transaction might be rolled back, a **DML** operation could violate a constraint, a request for a lock could cause a deadlock, a network error could cause a timeout. An optimistic strategy is one that assumes most requests or attempts will succeed, so that relatively little work is done to prepare for the failure case. When this assumption is true, the database does little unnecessary work; when requests do fail, extra work must be done to clean up and undo changes.

InnoDB uses optimistic strategies for operations such as **locking** and **commits**. For example, data changed by a transaction can be written to the data files before the commit occurs, making the commit itself very fast, but requiring more work to undo the changes if the transaction is rolled back.

The opposite of an optimistic strategy is a **pessimistic** one, where a system is optimized to deal with operations that are unreliable and frequently unsuccessful. This methodology is rare in a database system, because so much care goes into choosing reliable hardware, networks, and algorithms.

See Also [commit](#), [concurrency](#), [DML](#), [locking](#), [pessimistic](#).

#### optimizer

The MySQL component that determines the best **indexes** and **join** order to use for a **query**, based on characteristics and data distribution of the relevant **tables**.

See Also [index](#), [join](#), [query](#), [table](#).

#### option

A configuration parameter for MySQL, either stored in the **option file** or passed on the command line.

For the options that apply to **InnoDB** tables, each option name starts with the prefix `innodb_`.

See Also [InnoDB](#), [option file](#).

#### option file

The file that holds the configuration **options** for the MySQL instance. Traditionally, on Linux and UNIX this file is named `my.cnf`, and on Windows it is named `my.ini`.

See Also [configuration file](#), [my.cnf](#), [option](#).

#### overflow page

Separately allocated disk **pages** that hold variable-length columns (such as [BLOB](#) and [VARCHAR](#)) that are too long to fit on a **B-tree** page. The associated columns are known as **off-page columns**.

See Also [B-tree](#), [off-page column](#), [page](#).

## P

#### .PAR file

A file containing partition definitions. Files with this extension are always included in backups produced by the [mysqlbackup](#) command of the **MySQL Enterprise Backup** product.

See Also [MySQL Enterprise Backup](#), [mysqlbackup command](#).

#### page

A unit representing how much data InnoDB transfers at any one time between disk (the **data files**) and memory (the **buffer pool**). A page can contain one or more **rows**, depending on how much data is in each row. If a row does not fit entirely into a single page, InnoDB sets up additional pointer-style data structures so that the information about the row can be stored in one page.

One way to fit more data in each page is to use **compressed row format**. For tables that use BLOBs or large text fields, **compact row format** allows those large columns to be stored separately from the rest of the row, reducing I/O overhead and memory usage for queries that do not reference those columns.

When InnoDB reads or writes sets of pages as a batch to increase I/O throughput, it reads or writes an **extent** at a time.

---

All the InnoDB disk data structures within a MySQL instance share the same **page size**.  
See Also [buffer pool](#), [compact row format](#), [compressed row format](#), [data files](#), [extent](#), [page size](#), [row](#).

#### page cleaner

An InnoDB background **thread** that **flushes dirty pages** from the **buffer pool**. Prior to MySQL 5.6, this activity was performed by the **master thread**  
See Also [buffer pool](#), [dirty page](#), [flush](#), [master thread](#), [thread](#).

#### page size

For releases up to and including MySQL 5.5, the size of each InnoDB **page** is fixed at 16 kilobytes. This value represents a balance: large enough to hold the data for most rows, yet small enough to minimize the performance overhead of transferring unneeded data to memory. Other values are not tested or supported.

Starting in MySQL 5.6, the page size for an InnoDB **instance** can be either 4KB, 8KB, or 16KB, controlled by the [innodb\\_page\\_size](#) [1740] configuration option. You set the size when creating the MySQL instance, and it remains constant afterwards. The same page size applies to all InnoDB **tablespaces**, both the **system tablespace** and any separate tablespaces created in **file-per-table** mode.

Smaller page sizes can help performance with storage devices that use small block sizes, particularly for **SSD** devices in **disk-bound** workloads, such as for **OLTP** applications. As individual rows are updated, less data is copied into memory, written to disk, reorganized, locked, and so on.

See Also [disk-bound](#), [file-per-table](#), [instance](#), [OLTP](#), [page](#), [SSD](#), [system tablespace](#), [tablespace](#).

#### parent table

The table in a **foreign key** relationship that holds the initial column values pointed to from the **child table**. The consequences of deleting, or updating rows in the parent table depend on the [ON UPDATE](#) and [ON DELETE](#) clauses in the foreign key definition. Rows with corresponding values in the child table could be automatically deleted or updated in turn, or those columns could be set to [NULL](#), or the operation could be prevented.

See Also [child table](#), [foreign key](#).

#### partial backup

A **backup** that contains some of the **tables** in a MySQL database, or some of the databases in a MySQL instance. Contrast with **full backup**.

See Also [backup](#), [full backup](#), [table](#).

#### partial index

An **index** that represents only part of a column value, typically the first N characters (the **prefix**) of a long [VARCHAR](#) value.

See Also [index](#), [index prefix](#).

#### Performance Schema

The [performance\\_schema](#) schema, in MySQL 5.5 and up, presents a set of tables that you can query to get detailed information about the performance characteristics of many internal parts of the MySQL server.

See Also [latch](#), [mutex](#), [rw-lock](#).

#### persistent statistics

A feature in MySQL 5.6 that stores **index** statistics for InnoDB **tables** on disk, providing better **plan stability** for **queries**.

See Also [index](#), [optimizer](#), [plan stability](#), [query](#), [table](#).

#### pessimistic

A methodology that sacrifices performance or concurrency in favor of safety. It is appropriate if a high proportion of requests or attempts might fail, or if the consequences of a failed request are severe. InnoDB uses what is known as a pessimistic **locking** strategy, to minimize the chance of **deadlocks**. At the application level, you might avoid deadlocks by using a pessimistic strategy of acquiring all locks needed by a transaction at the very beginning.

Many built-in database mechanisms use the opposite **optimistic** methodology.

See Also [deadlock](#), [locking](#), [optimistic](#).

---

## phantom

A row that appears in the result set of a query, but not in the result set of an earlier query. For example, if a query is run twice within a **transaction**, and in the meantime, another transaction commits after inserting a new row or updating a row so that it matches the [WHERE](#) clause of the query.

This occurrence is known as a phantom read. It is harder to guard against than a **non-repeatable read**, because locking all the rows from the first query result set does not prevent the changes that cause the phantom to appear.

Among different **isolation levels**, phantom reads are prevented by the **serializable read** level, and allowed by the **repeatable read**, **consistent read**, and **read uncommitted** levels.

See Also [consistent read](#), [isolation level](#), [non-repeatable read](#), [READ UNCOMMITTED](#), [REPEATABLE READ](#), [SERIALIZABLE](#), [transaction](#).

## physical

A type of operation that involves hardware-related aspects such as disk blocks, memory pages, files, bits, disk reads, and so on. Typically, physical aspects are important during expert-level performance tuning and problem diagnosis. Contrast with **logical**.

See Also [logical](#), [physical backup](#).

## physical backup

A **backup** that copies the actual data files. For example, the [mysqlbackup](#) command of the **MySQL Enterprise Backup** product produces a physical backup, because its output contains data files that can be used directly by the `mysqld` server, resulting in a faster **restore** operation. Contrast with **logical backup**.

See Also [backup](#), [logical backup](#), [MySQL Enterprise Backup](#), [restore](#).

## PITR

Acronym for **point-in-time recovery**.

See Also [point-in-time recovery](#).

## plan stability

A property of a **query execution plan**, where the optimizer makes the same choices each time for a given **query**, so that performance is consistent and predictable.

See Also [query](#), [query execution plan](#).

## plugin

In MySQL 5.1 and earlier, a separately installable form of the **InnoDB** storage engine that includes features and performance enhancements not included in the **built-in** InnoDB for those releases.

For MySQL 5.5 and higher, the MySQL distribution includes the very latest InnoDB features and performance enhancements, known as InnoDB 1.1, and there is no longer a separate InnoDB Plugin.

This distinction is important mainly in MySQL 5.1, where a feature or bug fix might apply to the InnoDB Plugin but not the built-in InnoDB, or vice versa.

See Also [built-in](#), [InnoDB](#).

## point-in-time recovery

The process of restoring a **backup** to recreate the state of the database at a specific date and time.

Commonly abbreviated **PITR**. Because it is unlikely that the specified time corresponds exactly to the time of a backup, this technique usually requires a combination of a **physical backup** and a **logical backup**. For example, with the **MySQL Enterprise Backup** product, you restore the last backup that you took before the specified point in time, then replay changes from the **binary log** between the time of the backup and the PITR time.

See Also [backup](#), [logical backup](#), [MySQL Enterprise Backup](#), [physical backup](#), [PITR](#).

## prefix

See [index prefix](#).

## prepared backup

A set of backup files, produced by the **MySQL Enterprise Backup** product, after all the stages of applying **binary logs** and **incremental backups** are finished. The resulting files are ready to be **restored**. Prior to the apply steps, the files are known as a **raw backup**.

---

See Also [binary log](#), [hot backup](#), [incremental backup](#), [MySQL Enterprise Backup](#), [raw backup](#), [restore](#).

#### primary key

A set of columns -- and by implication, the index based on this set of columns -- that can uniquely identify every row in a table. As such, it must be a unique index that does not contain any [NULL](#) values.

InnoDB requires that every table has such an index (also called the **clustered index** or **cluster index**), and organizes the table storage based on the column values of the primary key.

When choosing primary key values, consider using arbitrary values (a **synthetic key**) rather than relying on values derived from some other source (a **natural key**).

See Also [clustered index](#), [index](#), [natural key](#), [synthetic key](#).

#### process

An instance of an executing program. The operating system switches between multiple running processes, allowing for a certain degree of **concurrency**. On most operating systems, processes can contain multiple **threads** of execution that share resources. Context-switching between threads is faster than the equivalent switching between processes.

See Also [concurrency](#), [thread](#).

#### pseudo-record

An artificial record in an index, used for **locking** key values or ranges that do not currently exist.

See Also [infimum record](#), [locking](#), [supremum record](#).

#### Pthreads

The POSIX threads standard, which defines an API for threading and locking operations on UNIX and Linux systems. On UNIX and Linux systems, InnoDB uses this implementation for **mutexes**.

See Also [mutex](#).

#### purge

A type of garbage collection performed by a separate thread, running on a periodic schedule. The purge includes these actions: removing obsolete values from indexes; physically removing rows that were marked for deletion by previous [DELETE](#) statements.

See Also [crash recovery](#), [delete](#), [doublewrite buffer](#).

#### purge buffering

The technique of storing index changes due to [DELETE](#) operations in the **insert buffer** rather than writing them immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally purges an index record that was previously marked for deletion.) It is one of the types of **change buffering**; the others are **insert buffering** and **delete buffering**.

See Also [change buffer](#), [change buffering](#), [delete buffering](#), [insert buffer](#), [insert buffering](#).

#### purge lag

Another name for the [InnoDB history list](#). Related to the [innodb\\_max\\_purge\\_lag](#) [1735] configuration option.

See Also [history list](#), [purge](#).

#### purge thread

A **thread** within the InnoDB process that is dedicated to performing the periodic **purge** operation. In MySQL 5.6 and higher, multiple purge threads are enabled by the [innodb\\_purge\\_threads](#) [1742] configuration option.

See Also [purge](#), [thread](#).

## Q

#### query

In **SQL**, an operation that reads information from one or more **tables**. Depending on the organization of data and the parameters of the query, the lookup might be optimized by consulting an **index**. If multiple tables are involved, the query is known as a **join**.

---

For historical reasons, sometimes discussions of internal processing for statements use "query" in a broader sense, including other types of MySQL statements such as **DDL** and **DML** statements.  
See Also [DDL](#), [DML](#), [index](#), [join](#), [SQL](#), [table](#).

#### query execution plan

The set of decisions made by the optimizer about how to perform a **query** most efficiently, including which **index** or indexes to use, and the order in which to **join** tables. **Plan stability** involves the same choices being made consistently for a given query.  
See Also [index](#), [join](#), [plan stability](#), [query](#).

#### query log

See [general query log](#).

#### quiesce

To reduce the amount of database activity, often in preparation for an operation such as an [ALTER TABLE](#), a **backup**, or a **shutdown**. Might or might not involve doing as much **flushing** as possible, so that **InnoDB** does not continue doing background I/O.

In MySQL 5.6 and higher, the syntax [FLUSH TABLES ... FOR EXPORT](#) writes some data to disk for **InnoDB** tables that make it simpler to back up those tables by copying the data files.  
See Also [backup](#), [flush](#), [InnoDB](#), [shutdown](#).

## R

### RAID

Acronym for "Redundant Array of Inexpensive Drives". Spreading I/O operations across multiple drives enables greater **concurrency** at the hardware level, and improves the efficiency of low-level write operations that otherwise would be performed in sequence.  
See Also [concurrency](#).

#### random dive

A technique for quickly estimating the number of different values in a column (the column's cardinality). **InnoDB** samples pages at random from the index and uses that data to estimate the number of different values. This operation occurs when each table is first opened.

Originally, the number of sampled pages was fixed at 8; now, it is determined by the setting of the [innodb\\_stats\\_sample\\_pages \[1748\]](#) parameter.

The way the random pages are picked depends on the setting of the [innodb\\_use\\_legacy\\_cardinality\\_algorithm](#) parameter. The default setting (OFF) has better randomness than in older releases.  
See Also [cardinality](#).

#### raw backup

The initial set of backup files produced by the **MySQL Enterprise Backup** product, before the changes reflected in the **binary log** and any **incremental backups** are applied. At this stage, the files are not ready to **restore**. After these changes are applied, the files are known as a **prepared backup**.  
See Also [binary log](#), [hot backup](#), [ibbackup\\_logfile](#), [incremental backup](#), [MySQL Enterprise Backup](#), [prepared backup](#), [restore](#).

### READ COMMITTED

An **isolation level** that uses a **locking** strategy that relaxes some of the protection between **transactions**, in the interest of performance. Transactions cannot see uncommitted data from other transactions, but they can see data that is committed by another transaction after the current transaction started. Thus, a transaction never sees any bad data, but the data that it does see may depend to some extent on the timing of other transactions.

When a transaction with this isolation level performs [UPDATE ... WHERE](#) or [DELETE ... WHERE](#) operations, other transactions might have to wait. The transaction can perform [SELECT ... FOR UPDATE](#), and [LOCK IN SHARE MODE](#) operations without making other transactions wait.

---

See Also [ACID](#), [isolation level](#), [locking](#), [REPEATABLE READ](#), [SERIALIZABLE](#), [transaction](#).

## READ UNCOMMITTED

The **isolation level** that provides the least amount of protection between transactions. Queries employ a **locking** strategy that allows them to proceed in situations where they would normally wait for another transaction. However, this extra performance comes at the cost of less reliable results, including data that has been changed by other transactions and not committed yet (known as **dirty read**). Use this isolation level only with great caution, and be aware that the results might not be consistent or reproducible, depending on what other transactions are doing at the same time. Typically, transactions with this isolation level do only queries, not insert, update, or delete operations.

See Also [ACID](#), [dirty read](#), [isolation level](#), [locking](#), [transaction](#).

## read view

An internal snapshot used by the **MVCC** mechanism of InnoDB. Certain **transactions**, depending on their **isolation level**, see the data values as they were at the time the transaction (or in some cases, the statement) started. Isolation levels that use a read view are **REPEATABLE READ**, **READ COMMITTED**, and **READ UNCOMMITTED**.

See Also [isolation level](#), [MVCC](#), [READ COMMITTED](#), [READ UNCOMMITTED](#), [REPEATABLE READ](#), [transaction](#).

## read-ahead

A type of I/O request that prefetches a group of **pages** (an entire **extent**) into the **buffer pool** asynchronously, in anticipation that these pages will be needed soon. The linear read-ahead technique prefetches all the pages of one extent based on access patterns for pages in the preceding extent, and is part of all MySQL versions starting with the InnoDB Plugin for MySQL 5.1. The random read-ahead technique prefetches all the pages for an extent once a certain number of pages from the same extent are in the buffer pool. Random read-ahead is not part of MySQL 5.5, but is re-introduced in MySQL 5.6 under the control of the [innodb\\_random\\_read\\_ahead](#) configuration option.

See Also [buffer pool](#), [extent](#), [page](#).

## read-only transaction

A type of transaction that can be optimized for InnoDB tables by eliminating some of the bookkeeping involved with creating a **read view** for each transaction. Can only perform **non-locking read** queries. It can be started explicitly with the syntax `START TRANSACTION READ ONLY`, or automatically under certain conditions. See [Section 14.2.4.2.3, "Optimizations for Read-Only Transactions"](#) for details.

See Also [non-locking read](#), [read view](#), [transaction](#).

## record lock

A **lock** on an index record. For example, `SELECT c1 FOR UPDATE FROM t WHERE c1 = 10;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10. Contrast with **gap lock** and **next-key lock**.

See Also [gap lock](#), [lock](#), [next-key lock](#).

## redo

The data, in units of records, recorded in the **redo log** when **DML** statements make changes to InnoDB tables. It is used during **crash recovery** to correct data written by incomplete **transactions**. The ever-increasing **LSN** value represents the cumulative amount of redo data that has passed through the redo log.

See Also [crash recovery](#), [DML](#), [LSN](#), [redo log](#), [transaction](#).

## redo log

A disk-based data structure used during **crash recovery**, to correct data written by incomplete **transactions**. During normal operation, it encodes requests to change InnoDB table data, which result from SQL statements or low-level API calls through NoSQL interfaces. Modifications that did not finish updating the **data files** before an unexpected **shutdown** are replayed automatically.

The redo log is physically represented as a set of files, typically named `ib_logfile0` and `ib_logfile1`. The data in the redo log is encoded in terms of records affected; this data is collectively referred to as **redo**. The passage of data through the redo logs is represented by the ever-increasing **LSN** value. The original 4GB limit on maximum size for the redo log is raised to 512GB in MySQL 5.6.

---

The disk layout of the redo log is influenced by the configuration options [innodb\\_log\\_file\\_size \[1732\]](#), [innodb\\_log\\_group\\_home\\_dir \[1733\]](#), and (rarely) [innodb\\_log\\_files\\_in\\_group \[1733\]](#).

The performance of redo log operations is also affected by the **log buffer**, which is controlled by the [innodb\\_log\\_buffer\\_size \[1732\]](#) configuration option.

See Also [crash recovery](#), [data files](#), [ib\\_logfile](#), [log buffer](#), [LSN](#), [redo](#), [shutdown](#), [transaction](#).

#### redundant row format

The oldest InnoDB row format, available for tables using the **Antelope file format**. Prior to MySQL 5.0.3, it was the only row format available in InnoDB. In MySQL 5.0.3 and later, the default is **compact row format**. You can still specify redundant row format for compatibility with older InnoDB tables.

See Also [Antelope](#), [compact row format](#), [file format](#), [row format](#).

#### referential integrity

The technique of maintaining data always in a consistent format, part of the **ACID** philosophy. In particular, data in different tables is kept consistent through the use of **foreign key constraints**, which can prevent changes from happening or automatically propagate those changes to all related tables. Related mechanisms include the **unique constraint**, which prevents duplicate values from being inserted by mistake, and the **NOT NULL constraint**, which prevents blank values from being inserted by mistake.

See Also [ACID](#), [FOREIGN KEY constraint](#), [NOT NULL constraint](#), [unique constraint](#).

#### relational

An important aspect of modern database systems. The database server encodes and enforces relationships such as one-to-one, one-to-many, many-to-one, and uniqueness. For example, a person might have zero, one, or many phone numbers in an address database; a single phone number might be associated with several family members. In a financial database, a person might be required to have exactly one taxpayer ID, and any taxpayer ID could only be associated with one person.

The database server can use these relationships to prevent bad data from being inserted, and to find efficient ways to look up information. For example, if a value is declared to be unique, the server can stop searching as soon as the first match is found, and it can reject attempts to insert a second copy of the same value.

At the database level, these relationships are expressed through SQL features such as **columns** within a table, unique and **NOT NULL constraints**, **foreign keys**, and different kinds of join operations. Complex relationships typically involve data split between more than one table. Often, the data is **normalized**, so that duplicate values in one-to-many relationships are stored only once.

In a mathematical context, the relations within a database are derived from set theory. For example, the **OR** and **AND** operators of a **WHERE** clause represent the notions of union and intersection.

See Also [ACID](#), [constraint](#), [foreign key](#), [normalized](#).

#### relevance

In the **full-text search** feature, a number signifying the similarity between the search string and the data in the **FULLTEXT index**. For example, when you search for a single word, that word is typically more relevant for a row where it occurs several times in the text than a row where it appears only once.

See Also [full-text search](#), [FULLTEXT index](#).

#### REPEATABLE READ

The default **isolation level** for InnoDB. It prevents any rows that are queried from being changed by other transactions, thus blocking **non-repeatable reads** but not **phantom** reads. It uses a moderately strict **locking** strategy so that all queries within a transaction see data from the same snapshot, that is, the data as it was at the time the transaction started.

When a transaction with this isolation level performs **UPDATE ... WHERE**, **DELETE ... WHERE**, **SELECT ... FOR UPDATE**, and **LOCK IN SHARE MODE** operations, other transactions might have to wait.

See Also [ACID](#), [consistent read](#), [isolation level](#), [locking](#), [phantom](#), [SERIALIZABLE](#), [transaction](#).

#### replication

The practice of sending changes from a **master database**, to one or more **slave databases**, so that all databases have the same data. This technique has a wide range of uses, such as load-balancing for better scalability, disaster recovery, and testing software upgrades and configuration changes. The changes can be sent between the database by methods called **row-based replication** and **statement-based replication**.

---

See Also [row-based replication](#), [statement-based replication](#).

#### restore

The process of putting a set of backup files from the **MySQL Enterprise Backup** product in place for use by MySQL. This operation can be performed to fix a corrupted database, to return to some earlier point in time, or (in a **replication** context) to set up a new **slave database**. In the **MySQL Enterprise Backup** product, this operation is performed by the `copy-back` option of the `mysqlbackup` command.

See Also [hot backup](#), [MySQL Enterprise Backup](#), [mysqlbackup command](#), [prepared backup](#), [replication](#).

#### rollback

A **SQL** statement that ends a **transaction**, undoing any changes made by the transaction. It is the opposite of **commit**, which makes permanent any changes made in the transaction.

By default, MySQL uses the **autocommit** setting, which automatically issues a commit following each SQL statement. You must change this setting before you can use the rollback technique.

See Also [ACID](#), [commit](#), [transaction](#).

#### rollback segment

The storage area containing the **undo log**, part of the **system tablespace**.

See Also [system tablespace](#), [undo log](#).

#### row

The logical data structure defined by a set of **columns**. A set of rows makes up a **table**. Within InnoDB **data files**, each **page** can contain one or more rows.

Although InnoDB uses the term **row format** for consistency with MySQL syntax, the row format is a property of each table and applies to all rows in that table.

See Also [column](#), [data files](#), [page](#), [row format](#), [table](#).

#### row format

The disk storage format for a **row** from an InnoDB **table**. As InnoDB gains new capabilities such as compression, new row formats are introduced to support the resulting improvements in storage efficiency and performance.

Each table has its own row format, specified through the `ROW_FORMAT` option. To see the row format for each InnoDB table, issue the command `SHOW TABLE STATUS`. Because all the tables in the system tablespace share the same row format, to take advantage of other row formats typically requires setting the `innodb_file_per_table [1718]` option, so that each table is stored in a separate tablespace.

See Also [compact row format](#), [compressed row format](#), [dynamic row format](#), [fixed row format](#), [redundant row format](#), [row](#), [table](#).

#### row lock

A **lock** that prevents a row from being accessed in an incompatible way by another **transaction**. Other rows in the same table can be freely written to by other transactions. This is the type of **locking** done by **DML** operations on **InnoDB** tables.

Contrast with **table locks** used by MyISAM, or during **DDL** operations on InnoDB tables that cannot be done with **online DDL**; those locks block concurrent access to the table.

See Also [DDL](#), [DML](#), [InnoDB](#), [lock](#), [locking](#), [online DDL](#), [table lock](#), [transaction](#).

#### row-based replication

A form of **replication** where events are propagated from the **master** server specifying how to change individual rows on the **slave** server. It is safe to use for all settings of the `innodb_autoinc_lock_mode [1705]` option.

See Also [auto-increment locking](#), [innodb\\_autoinc\\_lock\\_mode](#), [replication](#), [statement-based replication](#).

#### row-level locking

The **locking** mechanism used for **InnoDB** tables, relying on **row locks** rather than **table locks**. Multiple **transactions** can modify the same table concurrently. Only if two transactions try to modify the same row does one of the transactions wait for the other to complete (and release its row locks).

See Also [InnoDB](#), [locking](#), [row lock](#), [table lock](#), [transaction](#).

---

rw-lock

The low-level object that InnoDB uses to represent and enforce shared-access **locks** to internal in-memory data structures. Once the lock is acquired, any other process, thread, and so on can read the data structure, but no one else can write to it. Contrast with **mutexes**, which enforce exclusive access. Mutexes and rw-locks are known collectively as **latches**.

See Also [latch](#), [lock](#), [mutex](#), [Performance Schema](#).

## S

savepoint

Savepoints help to implement nested **transactions**. They can be used to provide scope to operations on tables that are part of a larger transaction. For example, scheduling a trip in a reservation system might involve booking several different flights; if a desired flight is unavailable, you might **roll back** the changes involved in booking that one leg, without rolling back the earlier flights that were successfully booked.

See Also [rollback](#), [transaction](#).

scalability

The ability to add more work and issue more simultaneous requests to a system, without a sudden drop in performance due to exceeding the limits of system capacity. Software architecture, hardware configuration, application coding, and type of workload all play a part in scalability. When the system reaches its maximum capacity, popular techniques for increasing scalability are **scale up** (increasing the capacity of existing hardware or software) and **scale out** (adding new servers and more instances of MySQL). Often paired with **availability** as critical aspects of a large-scale deployment.

See Also [availability](#), [scale out](#), [scale up](#).

scale out

A technique for increasing **scalability** by adding new servers and more instances of MySQL. For example, setting up replication, MySQL Cluster, connection pooling, or other features that spread work across a group of servers. Contrast with **scale up**.

See Also [scalability](#), [scale up](#).

scale up

A technique for increasing **scalability** by increasing the capacity of existing hardware or software.

For example, increasing the memory on a server and adjusting memory-related parameters such as [innodb\\_buffer\\_pool\\_size](#) [1708] and [innodb\\_buffer\\_pool\\_instances](#) [1706]. Contrast with **scale out**.

See Also [scalability](#), [scale out](#).

schema

Conceptually, a schema is a set of interrelated database objects, such as tables, table columns, data types of the columns, indexes, foreign keys, and so on. These objects are connected through SQL syntax, because the columns make up the tables, the foreign keys refer to tables and columns, and so on. Ideally, they are also connected logically, working together as part of a unified application or flexible framework. For example, the **information\_schema** and **performance\_schema** databases use "schema" in their names to emphasize the close relationships between the tables and columns they contain.

In MySQL, physically, a **schema** is synonymous with a **database**. You can substitute the keyword [SCHEMA](#) instead of [DATABASE](#) in MySQL SQL syntax, for example using [CREATE SCHEMA](#) instead of [CREATE DATABASE](#).

Some other database products draw a distinction. For example, in the Oracle Database product, a **schema** represents only a part of a database: the tables and other objects owned by a single user.

See Also [database](#), [ib-file set](#), [INFORMATION\\_SCHEMA](#), [Performance Schema](#).

search index

In MySQL, **full-text search** queries use a special kind of index, the **FULLTEXT** index. In MySQL 5.6.4 and up, [InnoDB](#) and [MyISAM](#) tables both support [FULLTEXT](#) indexes; formerly, these indexes were only available for [MyISAM](#) tables.

See Also [full-text search](#), [FULLTEXT index](#).

---

## secondary index

A type of InnoDB **index** that represents a subset of table columns. An InnoDB table can have zero, one, or many secondary indexes. (Contrast with the **clustered index**, which is required for each InnoDB table, and stores the data for all the table columns.)

A secondary index can be used to satisfy queries that only require values from the indexed columns. For more complex queries, it can be used to identify the relevant rows in the table, which are then retrieved through lookups using the clustered index.

Creating and dropping secondary indexes has traditionally involved significant overhead from copying all the data in the InnoDB table. The **fast index creation** feature of the InnoDB Plugin makes both `CREATE INDEX` and `DROP INDEX` statements much faster for InnoDB secondary indexes.

See Also [clustered index](#), [Fast Index Creation](#), [index](#).

## segment

A division within an InnoDB **tablespace**. If a tablespace is analogous to a directory, the segments are analogous to files within that directory. A segment can grow. New segments can be created.

For example, within a **file-per-table** tablespace, the table data is in one segment and each associated index is in its own segment. The **system tablespace** contains many different segments, because it can hold many tables and their associated indexes. The system tablespace also includes up to 128 **rollback segments** making up the **undo log**.

Segments grow and shrink as data is inserted and deleted. When a segment needs more room, it is extended by one **extent** (1 megabyte) at a time. Similarly, a segment releases one extent's worth of space when all the data in that extent is no longer needed.

See Also [extent](#), [file-per-table](#), [rollback segment](#), [system tablespace](#), [tablespace](#), [undo log](#).

## selectivity

A property of data distribution, the number of distinct values in a column (its **cardinality**) divided by the number of records in the table. High selectivity means that the column values are relatively unique, and can be retrieved efficiently through an index. If you (or the query optimizer) can predict that a test in a `WHERE` clause only matches a small number (or proportion) of rows in a table, the overall **query** tends to be efficient if it evaluates that test first, using an index.

See Also [cardinality](#), [query](#).

## semi-consistent read

A type of read operation used for `UPDATE` statements, that is a combination of **read committed** and **consistent read**. When an `UPDATE` statement examines a row that is already locked, InnoDB returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again, and this time InnoDB either locks it or waits for a lock on it. This type of read operation can only happen when the transaction has the read committed **isolation level**, or when the `innodb_locks_unsafe_for_binlog [1729]` option is enabled.

See Also [consistent read](#), [isolation level](#), [READ COMMITTED](#).

## SERIALIZABLE

The **isolation level** that uses the most conservative locking strategy, to prevent any other transactions from inserting or changing data that was read by this transaction, until it is finished. This way, the same query can be run over and over within a transaction, and be certain to retrieve the same set of results each time. Any attempt to change data that was committed by another transaction since the start of the current transaction, cause the current transaction to wait.

This is the default isolation level specified by the SQL standard. In practice, this degree of strictness is rarely needed, so the default isolation level for InnoDB is the next most strict, **repeatable read**.

See Also [ACID](#), [consistent read](#), [isolation level](#), [locking](#), [REPEATABLE READ](#), [transaction](#).

## server

A type of program that runs continuously, waiting to receive and act upon requests from another program (the client). Because often an entire computer is dedicated to running one or more server programs (such as

---

a database server, a web server, an application server, or some combination of these), the term **server** can also refer to the computer that runs the server software.

See Also [client](#), [mysqld](#).

#### shared lock

A kind of **lock** that allows other **transactions** to read the locked object, and to also acquire other shared locks on it, but not to write to it. The opposite of **exclusive lock**.

See Also [exclusive lock](#), [lock](#), [transaction](#).

#### shared tablespace

Another way of referring to the **system tablespace**.

See Also [system tablespace](#).

#### sharp checkpoint

The process of **flushing** to disk all **dirty** buffer pool pages whose redo entries are contained in certain portion of the **redo log**. Occurs before InnoDB reuses a portion of a log file; the log files are used in a circular fashion. Typically occurs with write-intensive **workloads**.

See Also [dirty page](#), [flush](#), [redo log](#), [workload](#).

#### shutdown

The process of stopping the MySQL server. By default, this process does cleanup operations for **InnoDB** tables, so it can **slow** to shut down, but fast to start up later. If you skip the cleanup operations, it is **fast** to shut down but must do the cleanup during the next restart.

The shutdown mode is controlled by the [innodb\\_fast\\_shutdown \[1716\]](#) option.

See Also [fast shutdown](#), [InnoDB](#), [slow shutdown](#), [startup](#).

#### slave server

Frequently shortened to "slave". A database **server** machine in a **replication** scenario that receives changes from another server (the **master**) and applies those same changes. Thus it maintains the same contents as the master, although it might lag somewhat behind.

In MySQL, slave servers are commonly used in disaster recovery, to take the place of a master servers that fails. They are also commonly used for testing software upgrades and new settings, to ensure that database configuration changes do not cause problems with performance or reliability.

Slave servers typically have high workloads, because they process all the **DML** (write) operations relayed from the master, as well as user queries. To ensure that slave servers can apply changes from the master fast enough, they frequently have fast I/O devices and sufficient CPU and memory to run multiple database instances on the same slave server. For example, the master server might use hard drive storage while the slave servers use **SSDs**.

See Also [DML](#), [replication](#), [server](#), [SSD](#).

#### slow query log

A type of **log** used for performance tuning of SQL statements processed by the MySQL server. The log information is stored in a file. You must enable this feature to use it. You control which categories of "slow" SQL statements are logged. For more information, see [Section 5.2.5, "The Slow Query Log"](#).

See Also [general query log](#), [log](#).

#### slow shutdown

A type of shutdown that does additional [InnoDB](#) flushing operations before completing. Also known as a **clean shutdown**. Specified by the configuration parameter [innodb\\_fast\\_shutdown=0 \[1716\]](#) or the command `SET GLOBAL innodb_fast_shutdown=0;`. Although the shutdown itself can take longer, that time will be saved on the subsequent startup.

See Also [clean shutdown](#), [fast shutdown](#), [shutdown](#).

#### snapshot

A representation of data at a particular time, which remains the same even as changes are **committed** by other **transactions**. Used by certain **isolation levels** to allow **consistent reads**.

See Also [commit](#), [consistent read](#), [isolation level](#), [transaction](#).

---

## space ID

An identifier used to uniquely identify an **InnoDB tablespace** within a MySQL instance. The space ID for the **system tablespace** is always zero; this same ID applies to all tables within the system tablespace. Each tablespace file created in **file-per-table** mode also has its own space ID.

Prior to MySQL 5.6, this hardcoded value presented difficulties in moving **InnoDB** tablespace files between MySQL instances. Starting in MySQL 5.6, you can copy tablespace files between instances by using the **transportable tablespace** feature involving the statements `FLUSH TABLES ... FOR EXPORT`, `ALTER TABLE ... DISCARD TABLESPACE`, and `ALTER TABLE ... IMPORT TABLESPACE`. The information needed to adjust the space ID is conveyed in the **.cfg file** which you copy along with the tablespace. See [Section 14.2.4.2.34, "Improved Tablespace Management"](#) for details.

See Also [.cfg file](#), [file-per-table](#), [.ibd file](#), [system tablespace](#), [tablespace](#), [transportable tablespace](#).

## spin

A type of **wait** operation that continuously tests whether a resource becomes available. This technique is used for resources that are typically held only for brief periods, where it is more efficient to wait in a "busy loop" than to put the thread to sleep and perform a context switch. If the resource does not become available within a short time, the spin loop ceases and another wait technique is used.

See Also [latch](#), [lock](#), [mutex](#), [wait](#).

## SQL

The Structured Query Language that is standard for performing database operations. Often divided into the categories **DDL**, **DML**, and **queries**. MySQL includes some additional statement categories such as **replication**. See [Chapter 9, Language Structure](#) for the building blocks of SQL syntax, [Chapter 11, Data Types](#) for the data types to use for MySQL table columns, [Chapter 13, SQL Statement Syntax](#) for details about SQL statements and their associated categories, and [Chapter 12, Functions and Operators](#) for standard and MySQL-specific functions to use in queries.

See Also [DDL](#), [DML](#), [query](#), [replication](#).

## SSD

Acronym for "solid-state drive". A type of storage device with different performance characteristics than a traditional hard disk drive (**HDD**): smaller storage capacity, faster for random reads, no moving parts, and with a number of considerations affecting write performance. Its performance characteristics can influence the throughput of a **disk-bound** workload.

See Also [disk-bound](#), [SSD](#).

## startup

The process of starting the MySQL server. Typically done by one of the programs listed in [Section 4.3, "MySQL Server and Server-Startup Programs"](#). The opposite of **shutdown**.

See Also [shutdown](#).

## statement-based replication

A form of **replication** where SQL statements are sent from the **master** server and replayed on the **slave** server. It requires some care with the setting for the `innodb_autoinc_lock_mode [1705]` option, to avoid potential timing problems with **auto-increment locking**.

See Also [auto-increment locking](#), [innodb\\_autoinc\\_lock\\_mode](#), [replication](#), [row-based replication](#).

## statistics

Estimated values relating to each **InnoDB table** and **index**, used to construct an efficient **query execution plan**. The main values are the **cardinality** (number of distinct values) and the total number of table rows or index entries. The statistics for the table represent the data in its **primary key** index. The statistics for a **secondary index** represent the rows covered by that index.

The values are estimated rather than counted precisely because at any moment, different **transactions** can be inserting and deleting rows from the same table. To keep the values from being recalculated frequently, you can enable **persistent statistics**, where the values are stored in **InnoDB** system tables, and refreshed only when you issue an `ANALYZE TABLE` statement.

You can control how **NULL** values are treated when calculating statistics through the `innodb_stats_method [1746]` configuration option.

---

Other types of statistics are available for database objects and database activity through the **INFORMATION\_SCHEMA** and **PERFORMANCE\_SCHEMA** tables.

See Also [cardinality](#), [index](#), [INFORMATION\\_SCHEMA](#), [NULL](#), [Performance Schema](#), [persistent statistics](#), [primary key](#), [query execution plan](#), [secondary index](#), [table](#), [transaction](#).

#### stemming

The ability to search for different variations of a word based on a common root word, such as singular and plural, or past, present, and future verb tense. This feature is currently supported in MyISAM **full-text search** feature but not in **FULLTEXT indexes** for InnoDB tables.

See Also [full-text search](#), [FULLTEXT index](#).

#### stopword

In a **FULLTEXT index**, a word that is considered common or trivial enough that it is omitted from the **search index** and ignored in search queries. Different configuration settings control stopwords processing for [InnoDB](#) and [MyISAM](#) tables. See [Section 12.9.4, “Full-Text Stopwords”](#) for details.

See Also [FULLTEXT index](#), [search index](#).

#### storage engine

A component of the MySQL database that performs the low-level work of storing, updating, and querying data. In MySQL 5.5 and higher, **InnoDB** is the default storage engine for new tables, superseding MyISAM. Different storage engines are designed with different tradeoffs between factors such as memory usage versus disk usage, read speed versus write speed, and speed versus robustness. Each storage engine manages specific tables, so we refer to [InnoDB tables](#), [MyISAM tables](#), and so on.

The **MySQL Enterprise Backup** product is optimized for backing up InnoDB tables. It can also back up tables handled by MyISAM and other storage engines.

See Also [InnoDB](#), [MySQL Enterprise Backup](#), [table type](#).

#### strict mode

The general name for the setting controlled by the [innodb\\_strict\\_mode \[1749\]](#) option. Turning on this setting causes certain conditions that are normally treated as warnings, to be considered errors. For example, certain invalid combinations of options related to **file format** and **row format**, that normally produce a warning and continue with default values, now cause the `CREATE TABLE` operation to fail.

MySQL also has something called strict mode.

See Also [file format](#), [innodb\\_strict\\_mode](#), [row format](#).

#### sublist

Within the list structure that represents the buffer pool, pages that are relatively old and relatively new are represented by different portions of the list. A set of parameters control the size of these portions and the dividing point between the new and old pages.

See Also [buffer pool](#), [eviction](#), [list](#), [LRU](#).

#### supremum record

A **pseudo-record** in an index, representing the **gap** above the largest value in that index. If a transaction has a statement such as `SELECT ... FOR UPDATE ... WHERE col > 10;`, and the largest value in the column is 20, it is a lock on the supremum record that prevents other transactions from inserting even larger values such as 50, 100, and so on.

See Also [gap](#), [infimum record](#), [pseudo-record](#).

#### surrogate key

Synonym name for **synthetic key**.

See Also [synthetic key](#).

#### synthetic key

A indexed column, typically a **primary key**, where the values are assigned arbitrarily. Often done using an **auto-increment** column. By treating the value as completely arbitrary, you can avoid overly restrictive rules and faulty application assumptions. For example, a numeric sequence representing employee numbers might have a gap if an employee was approved for hiring but never actually joined. Or employee number 100 might have a later hiring date than employee number 500, if they left the company and later rejoined. Numeric

---

values also produce shorter values of predictable length. For example, storing numeric codes meaning "Road", "Boulevard", "Expressway", and so on is more space-efficient than repeating those strings over and over.

Also known as a **surrogate key**. Contrast with **natural key**.

See Also [auto-increment](#), [natural key](#), [primary key](#), [surrogate key](#).

## system tablespace

A small set of data files (the **ibdata** files) containing the metadata for InnoDB-related objects (the **data dictionary**), and the storage areas for the **undo log**, the **change buffer**, and the **doublewrite buffer**. Depending on the setting of the [innodb\\_file\\_per\\_table](#) [1718], when tables are created, it might also contain table and index data for some or all InnoDB tables. The data and metadata in the system tablespace apply to all the **databases** in a MySQL **instance**.

Prior to MySQL 5.6.7, the default was to keep all InnoDB tables and indexes inside the system tablespace, often causing this file to become very large. Because the system tablespace never shrinks, storage problems could arise if large amounts of temporary data were loaded and then deleted. In MySQL 5.6.7 and higher, the default is **file-per-table** mode, where each table and its associated indexes are stored in a separate **.ibd file**. This new default makes it easier to use InnoDB features that rely on the **Barracuda** file format, such as table **compression** and the **DYNAMIC** row format.

In MySQL 5.6 and higher, setting a value for the [innodb\\_undo\\_tablespaces](#) [1753] option splits the **undo log** into one or more separate tablespace files. These files are still considered part of the system tablespace.

Keeping all table data in the system tablespace or in separate **.ibd** files has implications for storage management in general. The **MySQL Enterprise Backup** product might back up a small set of large files, or many smaller files. On systems with thousands of tables, the filesystem operations to process thousands of **.ibd** files can cause bottlenecks.

See Also [Barracuda](#), [change buffer](#), [compression](#), [data dictionary](#), [database](#), [doublewrite buffer](#), [dynamic row format](#), [file-per-table](#), [.ibd file](#), [ibdata file](#), [innodb\\_file\\_per\\_table](#), [instance](#), [MySQL Enterprise Backup](#), [tablespace](#), [undo log](#).

## T

### .TRG file

A file containing **trigger** parameters. Files with this extension are always included in backups produced by the [mysqlbackup](#) command of the **MySQL Enterprise Backup** product.

See Also [MySQL Enterprise Backup](#), [mysqlbackup command](#), [.TRN file](#).

### .TRN file

A file containing trigger namespace information. Files with this extension are always included in backups produced by the [mysqlbackup](#) command of the **MySQL Enterprise Backup** product.

See Also [MySQL Enterprise Backup](#), [mysqlbackup command](#), [.TRG file](#).

## table

Each MySQL table is associated with a particular **storage engine**. **InnoDB** tables have particular **physical** and **logical** characteristics that affect performance, **scalability**, **backup**, administration, and application development.

In terms of file storage, each InnoDB table is either part of the single big InnoDB **system tablespace**, or in a separate **.ibd** file if the table is created in **file-per-table** mode. The **.ibd** file holds data for the table and all its **indexes**, and is known as a **tablespace**.

InnoDB tables created in file-per-table mode can use the **Barracuda** file format. Barracuda tables can use the **DYNAMIC row format** or the **COMPRESSED row format**. These relatively new settings enable a number of InnoDB features, such as **compression**, **fast index creation**, and **off-page columns**

For backward compatibility with MySQL 5.1 and earlier, InnoDB tables inside the system tablespace must use the **Antelope** file format, which supports the **compact row format** and the **redundant row format**.

---

The **rows** of an InnoDB table are organized into an index structure known as the **clustered index**, with entries sorted based on the **primary key** columns of the table. Data access is optimized for queries that filter and sort on the primary key columns, and each index contains a copy of the associated primary key columns for each entry. Modifying values for any of the primary key columns is an expensive operation. Thus an important aspect of InnoDB table design is choosing a primary key with columns that are used in the most important queries, and keeping the primary key short, with rarely changing values.

See Also [Antelope](#), [backup](#), [Barracuda](#), [clustered index](#), [compact row format](#), [compressed row format](#), [compression](#), [dynamic row format](#), [Fast Index Creation](#), [file-per-table](#), [.ibd file](#), [index](#), [off-page column](#), [primary key](#), [redundant row format](#), [row](#), [system tablespace](#), [tablespace](#).

#### table lock

A lock that prevents any other **transaction** from accessing a table. InnoDB makes considerable effort to make such locks unnecessary, by using techniques such as **online DDL**, **row locks** and **consistent reads** for processing **DML** statements and **queries**. You can create such a lock through SQL using the `LOCK TABLE` statement; one of the steps in migrating from other database systems or MySQL storage engines is to remove such statements wherever practical.

See Also [consistent read](#), [DML](#), [lock](#), [locking](#), [online DDL](#), [query](#), [row lock](#), [table](#), [transaction](#).

#### table scan

See [full table scan](#).

#### table statistics

See [statistics](#).

#### table type

Obsolete synonym for **storage engine**. We refer to [InnoDB](#) tables, [MyISAM](#) tables, and so on.

See Also [InnoDB](#), [storage engine](#).

#### tablespace

A data file that can hold data for one or more InnoDB **tables** and associated **indexes**. The **system tablespace** contains the tables that make up the **data dictionary**, and prior to MySQL 5.6 holds all the other InnoDB tables by default. Turning on the [innodb\\_file\\_per\\_table \[1718\]](#) option, the default in MySQL 5.6 and higher, allows newly created tables to each have their own tablespace, with a separate **data file** for each table.

Using multiple tablespaces, by turning on the [innodb\\_file\\_per\\_table \[1718\]](#) option, is vital to using many MySQL features such as table compression and transportable tablespaces, and managing disk usage. See [Section 5.4.1, “Managing InnoDB Tablespaces”](#) and [Section 14.2.4.2.34, “Improved Tablespace Management”](#) for details.

Tablespaces created by the built-in InnoDB storage engine are upward compatible with the InnoDB Plugin. Tablespaces created by the InnoDB Plugin are downward compatible with the built-in InnoDB storage engine, if they use the **Antelope** file format.

MySQL Cluster also groups its tables into tablespaces. See [MySQL Cluster Disk Data Objects](#) for details.

See Also [Antelope](#), [Barracuda](#), [compressed row format](#), [data dictionary](#), [data files](#), [file-per-table](#), [index](#), [innodb\\_file\\_per\\_table](#), [system tablespace](#), [table](#).

#### tablespace dictionary

A representation of the **data dictionary** metadata for a table, within the InnoDB **tablespace**. This metadata can be checked against the **.frm file** for consistency when the table is opened, to diagnose errors resulting from out-of-date **.frm** files. This information is present for InnoDB tables that are part of the **system tablespace**, as well as for tables that have their own **.ibd file** because of the **file-per-table** option.

See Also [data dictionary](#), [file-per-table](#), [.frm file](#), [.ibd file](#), [system tablespace](#), [tablespace](#).

#### temporary table

A table whose data does not need to be truly permanent. For example, temporary tables might be used as storage areas for intermediate results in complicated calculations or transformations; this intermediate data would not need to be recovered after a crash. Database products can take various shortcuts to improve the

---

performance of operations on temporary tables, by being less scrupulous about writing data to disk and other measures to protect the data across restarts.

Sometimes, the data itself is removed automatically at a set time, such as when the transaction ends or when the session ends. With some database products, the table itself is removed automatically too.  
See Also [table](#).

#### text collection

The set of columns included in a **FULLTEXT index**.  
See Also [FULLTEXT index](#).

#### thread

A unit of processing that is typically more lightweight than a **process**, allowing for greater **concurrency**.  
See Also [concurrency](#), [master thread](#), [process](#), [Pthreads](#).

#### torn page

An error condition that can occur due to a combination of I/O device configuration and hardware failure. If data is written out in chunks smaller than the InnoDB **page size** (by default, 16KB), a hardware failure while writing could result in only part of a page being stored to disk. The InnoDB **doublewrite buffer** guards against this possibility.  
See Also [doublewrite buffer](#).

#### TPS

Acronym for "**transactions per second**", a unit of measurement sometimes used in benchmarks. Its value depends on the **workload** represented by a particular benchmark test, combined with factors that you control such as the hardware capacity and database configuration.  
See Also [transaction](#), [workload](#).

#### transaction

Transactions are atomic units of work that can be committed or rolled back. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

Database transactions, as implemented by InnoDB, have properties that are collectively known by the acronym **ACID**, for atomicity, consistency, isolation, and durability.  
See Also [ACID](#), [commit](#), [isolation level](#), [lock](#), [rollback](#).

#### transaction ID

An internal field associated with each row. This field is physically changed by INSERT, UPDATE, and DELETE operations to record which transaction has locked the row.  
See Also [implicit row lock](#).

#### transportable tablespace

A feature that allows a **tablespace** to be moved from one instance to another. Traditionally, this has not been possible for InnoDB tablespaces because all table data was part of the **system tablespace**. In MySQL 5.6 and higher, the `FLUSH TABLES ... FOR EXPORT` syntax prepares an InnoDB table for copying to another server; running `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` on the other server brings the copied data file into the other instance. A separate `.cfg` file, copied along with the `.ibd` file, is used to update the table metadata (for example the **space ID**) as the tablespace is imported. See [Section 14.2.4.2.34, "Improved Tablespace Management"](#) for usage information.  
See Also [.ibd file](#), [space ID](#), [system tablespace](#), [tablespace](#).

#### troubleshooting

Resources for troubleshooting InnoDB reliability and performance issues include: the Information Schema tables.

#### truncate

A **DDL** operation that removes the entire contents of a table, while leaving the table and related indexes intact. Contrast with **drop**. Although conceptually it has the same result as a `DELETE` statement with no

---

**WHERE** clause, it operates differently behind the scenes: InnoDB creates a new empty table, drops the old table, then renames the new table to take the place of the old one. Because this is a DDL operation, it cannot be **rolled back**.

If the table being truncated contains foreign keys that reference another table, the truncation operation uses a slower method of operation, deleting one row at a time so that corresponding rows in the referenced table can be deleted as needed by any **ON DELETE CASCADE** clause. (MySQL 5.5 and higher do not allow this slower form of truncate, and return an error instead if foreign keys are involved. In this case, use a **DELETE** statement instead.

See Also [DDL](#), [drop](#), [foreign key](#), [rollback](#).

#### tuple

A technical term designating an ordered set of elements. It is an abstract notion, used in formal discussions of database theory. In the database field, tuples are usually represented by the columns of a table row. They could also be represented by the result sets of queries, for example, queries that retrieved only some columns of a table, or columns from joined tables.

See Also [cursor](#).

#### two-phase commit

An operation that is part of a distributed **transaction**, under the **XA** specification. (Sometimes abbreviated as 2PC.) When multiple databases participate in the transaction, either all databases **commit** the changes, or all databases **roll back** the changes.

See Also [commit](#), [rollback](#), [transaction](#), [XA](#).

## U

#### undo

Data that is maintained throughout the life of a **transaction**, recording all changes so that they can be undone in case of a **rollback** operation. It is stored in the **undo log**, also known as the **rollback segment**, either within the **system tablespace** or in separate **undo tablespaces**.

See Also [rollback](#), [rollback segment](#), [system tablespace](#), [transaction](#), [undo log](#), [undo tablespace](#).

#### undo buffer

See [undo log](#).

#### undo log

A storage area that holds copies of data modified by active **transactions**. If another transaction needs to see the original data (as part of a **consistent read** operation), the unmodified data is retrieved from this storage area.

By default, this area is physically part of the **system tablespace**. In MySQL 5.6 and higher, you can use the [innodb\\_undo\\_tablespaces \[1753\]](#) and [innodb\\_undo\\_directory \[1752\]](#) configuration options to split it into one or more separate **tablespace** files, the **undo tablespaces**, optionally stored on another storage device such as an **SSD**.

The undo log is split into separate portions, the **insert undo buffer** and the **update undo buffer**. Collectively, these parts are also known as the **rollback segment**, a familiar term for Oracle DBAs.

See Also [consistent read](#), [rollback segment](#), [SSD](#), [system tablespace](#), [transaction](#), [undo tablespace](#).

#### undo tablespace

One of a set of files containing the **undo log**, when the undo log is separated from the **system tablespace** by the [innodb\\_undo\\_tablespaces \[1753\]](#) and [innodb\\_undo\\_directory \[1752\]](#) configuration options. Only applies to MySQL 5.6 and higher.

See Also [system tablespace](#), [undo log](#).

#### unique constraint

A kind of **constraint** that asserts that a column cannot contain any duplicate values. In terms of **relational algebra**, it is used to specify 1-to-1 relationships. For efficiency in checking whether a value can be inserted

---

(that is, the value does not already exist in the column), a unique constraint is supported by an underlying **unique index**.

See Also [constraint](#), [relational](#), [unique index](#).

#### unique index

An index on a column or set of columns that have a **unique constraint**. Because the index is known not to contain any duplicate values, certain kinds of lookups and count operations are more efficient than in the normal kind of index. Most of the lookups against this type of index are simply to determine if a certain value exists or not. The number of values in the index is the same as the number of rows in the table, or at least the number of rows with non-null values for the associated columns.

The **insert buffering** optimization does not apply to unique indexes. As a workaround, you can temporarily set `unique_checks=0` while doing a bulk data load into an InnoDB table.

See Also [cardinality](#), [insert buffering](#), [unique constraint](#), [unique key](#).

#### unique key

The set of columns (one or more) comprising a **unique index**. When you can define a `WHERE` condition that matches exactly one row, and the query can use an associated unique index, the lookup and error handling can be performed very efficiently.

See Also [cardinality](#), [unique constraint](#), [unique index](#).

## V

#### victim

The transaction that is automatically chosen to be rolled back when a **deadlock** is detected. InnoDB rolls back the transaction that has updated the fewest rows.

See Also [deadlock](#), [deadlock detection](#), [innodb\\_lock\\_wait\\_timeout](#).

## W

#### wait

When an operation, such as acquiring a **lock**, **mutex**, or **latch**, cannot be completed immediately, InnoDB pauses and tries again. The mechanism for pausing is elaborate enough that this operation has its own name, the **wait**. Individual threads are paused using a combination of internal InnoDB scheduling, operating system `wait()` calls, and short-duration **spin** loops.

On systems with heavy load and many transactions, you might use the output from the `SHOW INNODB STATUS` command to determine whether threads are spending too much time waiting, and if so, how you can improve **concurrency**.

See Also [concurrency](#), [latch](#), [lock](#), [mutex](#), [spin](#).

#### warm backup

A **backup** taken while the database is running, but that restricts some database operations during the backup process. For example, tables might become read-only. For busy applications and web sites, you might prefer a **hot backup**.

See Also [backup](#), [cold backup](#), [hot backup](#).

#### warm up

To run a system under a typical **workload** for some time after startup, so that the **buffer pool** and other memory regions are filled as they would be under normal conditions.

This process happens naturally over time when a MySQL server is restarted or subjected to a new workload. Starting in MySQL 5.6, you can speed up the warmup process by setting the configuration variables `innodb_buffer_pool_dump_at_shutdown=ON` [1705] and `innodb_buffer_pool_load_at_startup=ON` [1707], to bring the contents of the buffer pool back into memory after a restart. Typically, you run a workload for some time to warm up the buffer pool before running performance tests, to ensure consistent results across multiple runs; otherwise, performance might be artificially low during the first run.

---

See Also [buffer pool](#), [workload](#).

## Windows

The built-in **InnoDB** storage engine and the **InnoDB Plugin** are supported on all the same Microsoft Windows versions as the MySQL server. The **MySQL Enterprise Backup** product has more comprehensive support for Windows systems than the **InnoDB Hot Backup** product that it supercedes.

See Also [InnoDB](#), [InnoDB Hot Backup](#), [MySQL Enterprise Backup](#), [plugin](#).

## workload

The combination and volume of **SQL** and other database operations, performed by a database application during typical or peak usage. You can subject the database to a particular workload during performance testing to identify **bottlenecks**, or during capacity planning.

See Also [bottleneck](#), [disk-bound](#), [disk-bound](#), [SQL](#).

## write combining

An optimization technique that reduces write operations when **dirty pages** are **flushed** from the **InnoDB buffer pool**. If a row in a page is updated multiple times, or multiple rows on the same page are updated, all of those changes are stored to the data files in a single write operation rather than one write for each change.

See Also [buffer pool](#), [dirty page](#), [flush](#).

## X

### XA

A standard interface for coordinating distributed **transactions**, allowing multiple databases to participate in a transaction while maintaining **ACID** compliance. For full details, see [Section 13.3.7, “XA Transactions”](#).

XA Distributed Transaction support is turned on by default. If you are not using this feature, you can disable the `innodb_support_xa` [1749] configuration option, avoiding the performance overhead of an extra fsync for each transaction.

See Also [commit](#), [transaction](#), [two-phase commit](#).

## Y

### young

A characteristic of a **page** in the **InnoDB buffer pool** meaning it has been accessed recently, and so is moved within the buffer pool data structure, so that it will not be **flushed** soon by the **LRU** algorithm. This term is used in some **information schema** column names of tables related to the buffer pool.

See Also [buffer pool](#), [flush](#), [INFORMATION\\_SCHEMA](#), [LRU](#), [page](#).

## C Function Index

### **my\_init()**

Section 21.8.11.1, “my\_init()”  
Section 21.8.11.3, “mysql\_thread\_init()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_affected\_rows()**

Section 13.2.1, “CALL Syntax”  
Section 13.2.5, “INSERT Syntax”  
Section 21.8.6.1, “mysql\_affected\_rows()”  
Section 21.8.6.46, “mysql\_next\_result()”  
Section 21.8.6.48, “mysql\_num\_rows()”  
Section 21.8.10.1, “mysql\_stmt\_affected\_rows()”  
Section 21.8.6.72, “mysql\_use\_result()”  
Section 13.2.8, “REPLACE Syntax”  
Section 21.8.4, “C API Data Structures”  
Section 21.8.5, “C API Function Overview”  
Section 12.14, “Information Functions”  
Section 21.8.14.2, “What Results You Can Get from a Query”

### **mysql\_autocommit()**

Section 21.8.6.2, “mysql\_autocommit()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_change\_user()**

Section 21.8.6.3, “mysql\_change\_user()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_character\_set\_name()**

Section 21.8.6.4, “mysql\_character\_set\_name()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_client\_find\_plugin()**

Section 21.8.13.1, “mysql\_client\_find\_plugin()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_client\_register\_plugin()**

Section 21.8.13.2,  
“mysql\_client\_register\_plugin()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_close()**

Section 21.8.6.5, “mysql\_close()”  
Section 21.8.6.6, “mysql\_commit()”  
Section 21.8.6.7, “mysql\_connect()”  
Section 21.8.6.36, “mysql\_init()”  
Section 21.8.6.58, “mysql\_rollback()”  
Section 21.8.5, “C API Function Overview”  
Section C.5.2.11, “Communication Errors and Aborted Connections”

### **mysql\_commit()**

Section 21.8.6.6, “mysql\_commit()”

Section 21.8.5, “C API Function Overview”

### **mysql\_connect()**

Section 21.8.11.1, “my\_init()”  
Section 21.8.6.5, “mysql\_close()”  
Section 21.8.6.7, “mysql\_connect()”  
Section 21.8.6.49, “mysql\_options()”  
Section 21.8.11.3, “mysql\_thread\_init()”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.3.2, “Writing C API Threaded Client Programs”

### **mysql\_create\_db()**

Section 21.8.6.8, “mysql\_create\_db()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_data\_seek()**

Section 21.8.6.9, “mysql\_data\_seek()”  
Section 21.8.6.59, “mysql\_row\_seek()”  
Section 21.8.6.72, “mysql\_use\_result()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_debug()**

Section 21.8.6.10, “mysql\_debug()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_drop\_db()**

Section 21.8.6.11, “mysql\_drop\_db()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_dump\_debug\_info()**

Section 21.8.6.12, “mysql\_dump\_debug\_info()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_eof()**

Section 21.8.6.13, “mysql\_eof()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_errno()**

Section 21.8.13.1, “mysql\_client\_find\_plugin()”  
Section 21.8.13.2,  
“mysql\_client\_register\_plugin()”  
Section 21.8.6.7, “mysql\_connect()”  
Section 21.8.6.13, “mysql\_eof()”  
Section 21.8.6.14, “mysql\_errno()”  
Section 21.8.6.22, “mysql\_field\_count()”  
Section 21.8.13.3, “mysql\_load\_plugin()”  
Section 21.8.6.47, “mysql\_num\_fields()”  
Section 21.8.6.67, “mysql\_sqlstate()”  
Section 21.8.6.70, “mysql\_store\_result()”  
Section 21.8.6.72, “mysql\_use\_result()”  
Section 21.8.6, “C API Function Descriptions”  
Section 21.8.5, “C API Function Overview”  
Section 13.6.7.5.1, “Signal Condition Information Items”  
Section 6.3.11.2, “The Audit Log File”

---

Section C.2, “Types of Error Values”  
Section 21.8.14.1, “Why `mysql_store_result()`  
Sometimes Returns `NULL` After `mysql_query()`  
Returns Success”  
Section 22.2.4.8, “Writing Audit Plugins”

## **mysql\_error()**

Section 21.8.13.1, “`mysql_client_find_plugin()`”  
Section 21.8.13.2,  
“`mysql_client_register_plugin()`”  
Section 21.8.6.7, “`mysql_connect()`”  
Section 21.8.6.13, “`mysql_eof()`”  
Section 21.8.6.15, “`mysql_error()`”  
Section 21.8.13.3, “`mysql_load_plugin()`”  
Section 21.8.6.70, “`mysql_store_result()`”  
Section 21.8.6.72, “`mysql_use_result()`”  
Section 21.8.6, “C API Function Descriptions”  
Section 21.8.5, “C API Function Overview”  
Section 13.6.7.5.1, “Signal Condition Information Items”  
Section C.2, “Types of Error Values”  
Section 21.8.14.1, “Why `mysql_store_result()`  
Sometimes Returns `NULL` After `mysql_query()`  
Returns Success”  
Section 22.2.4.8, “Writing Audit Plugins”

## **mysql\_escape\_string()**

Section 21.8.6.16, “`mysql_escape_string()`”  
Section 21.8.5, “C API Function Overview”  
Section 6.1.7, “Client Programming Security  
Guidelines”

## **mysql\_fetch\_field()**

Section 21.8.6.17, “`mysql_fetch_field()`”

Section 21.8.4, “C API Data Structures”  
Section 21.8.5, “C API Function Overview”

### **mysql\_list\_processes()**

Section 21.8.6.43, “mysql\_list\_processes()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_list\_tables()**

Section 21.8.6.44, “mysql\_list\_tables()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_load\_plugin()**

Section 21.8.13.3, “mysql\_load\_plugin()”  
Section 21.8.13.4, “mysql\_load\_plugin\_v()”  
Section 21.8.5, “C API Function Overview”  
Section 22.2.4.2.3, “Client Plugin Descriptors”

### **mysql\_load\_plugin\_v()**

Section 21.8.13.3, “mysql\_load\_plugin()”  
Section 21.8.13.4, “mysql\_load\_plugin\_v()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_more\_results()**

Section 21.8.6.45, “mysql\_more\_results()”  
Section 21.8.6.46, “mysql\_next\_result()”  
Section 21.8.10.17, “mysql\_stmt\_next\_result()”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.16, “C API Support for Multiple Statement Execution”

### **mysql\_next\_result()**

Section 13.2.1, “CALL Syntax”  
Section 21.8.6.45, “mysql\_more\_results()”  
Section 21.8.6.46, “mysql\_next\_result()”  
Section 21.8.6.53, “mysql\_real\_connect()”  
Section 21.8.6.65, “mysql\_set\_server\_option()”  
Section 21.8.6.70, “mysql\_store\_result()”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.16, “C API Support for Multiple Statement Execution”

### **mysql\_num\_fields()**

Section 21.8.6.18, “mysql\_fetch\_field\_direct()”  
Section 21.8.6.21, “mysql\_fetch\_row()”  
Section 21.8.6.47, “mysql\_num\_fields()”

Section 21.8.10.23,  
“mysql\_stmt\_result\_metadata()”  
Section 21.8.5, “C API Function Overview”

### **mysql\_num\_rows()**

Section 21.8.6.1, “mysql\_affected\_rows()”  
Section 21.8.6.9, “mysql\_data\_seek()”  
Section 21.8.6.48, “mysql\_num\_rows()”  
Section 21.8.6.70, “mysql\_store\_result()”  
Section 21.8.6.72, “mysql\_use\_result()”  
Section 21.8.4, “C API Data Structures”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.14.2, “What Results You Can Get from a Query”

### **mysql\_options()**

Section C.5.2.9, “MySQL server has gone away”  
Section 21.8.6.49, “mysql\_options()”  
Section 21.8.6.50, “mysql\_options4()”  
Section 21.8.6.51, “mysql\_ping()”  
Section 21.8.6.53, “mysql\_real\_connect()”  
Section 21.8.10.11, “mysql\_stmt\_fetch()”  
Section 21.8.13, “C API Client Plugin Functions”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.8, “C API Prepared Statement Data Structures”  
Section 22.2.4.2.3, “Client Plugin Descriptors”  
Section 10.1.4, “Connection Character Sets and Collations”  
Section 21.8.15, “Controlling Automatic Reconnection Behavior”  
Section 6.3.6, “Password Expiration and Sandbox Mode”  
Section 20.9.7, “Performance Schema Connection Attribute Tables”  
Section 22.2.2, “Plugin API Components”  
Section 6.1.6, “Security Issues with LOAD DATA LOCAL”  
Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”  
Section 6.3.1, “User Names and Passwords”  
Section 5.6.4, “Using Client Programs in a Multiple-Server Environment”  
Section 22.2.4.9.3, “Using the Authentication Plugins”

### **mysql\_options4()**

Section 21.8.6.49, “mysql\_options()”  
Section 21.8.6.50, “mysql\_options4()”  
Section 21.8.5, “C API Function Overview”  
Section 20.9.7, “Performance Schema Connection Attribute Tables”

### **mysql\_ping()**

Section C.5.2.9, “MySQL server has gone away”  
Section 21.8.6.51, “mysql\_ping()”  
Section 21.8.6.71, “mysql\_thread\_id()”  
Section 21.8.5, “C API Function Overview”

---

Section 21.8.15, “Controlling Automatic Reconnection Behavior”

## **mysql\_plugin\_options()**

Section 21.8.13.5, “mysql\_plugin\_options()”  
Section 21.8.5, “C API Function Overview”

## **mysql\_query()**

Section 13.2.1, “CALL Syntax”  
Section 21.8.6.1, “mysql\_affected\_rows()”  
Section 21.8.6.8, “mysql\_create\_db()”  
Section 21.8.6.11, “mysql\_drop\_db()”  
Section 21.8.6.17, “mysql\_fetch\_field()”  
Section 21.8.6.38, “mysql\_kill()”  
Section 21.8.6.46, “mysql\_next\_result()”  
Section 21.8.6.52, “mysql\_query()”  
Section 21.8.6.53, “mysql\_real\_connect()”  
Section 21.8.6.55, “mysql\_real\_query()”  
Section 21.8.6.57, “mysql\_reload()”  
Section 21.8.6.64, “mysql\_set\_local\_infile\_handler()”  
Section 21.8.6.65, “mysql\_set\_server\_option()”  
Section 21.8.6.70, “mysql\_store\_result()”  
Section 21.8.6.72, “mysql\_use\_result()”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.16, “C API Support for Multiple Statement Execution”  
Section 21.8.14.3, “How to Get the Unique ID for the Last Inserted Row”  
Section 21.8.14.1, “Why mysql\_store\_result() Sometimes Returns NULL After mysql\_query() Returns Success”  
Section 21.8.3.2, “Writing C API Threaded Client Programs”

## **mysql\_real\_connect()**

Section 13.2.1, “CALL Syntax”  
Section 21.8.6.1, “mysql\_affected\_rows()”  
Section 21.8.6.3, “mysql\_change\_user()”  
Section 21.8.6.7, “mysql\_connect()”  
Section 21.8.6.36, “mysql\_init()”  
Section 21.8.6.46, “mysql\_next\_result()”  
Section 21.8.6.49, “mysql\_options()”  
Section 21.8.6.53, “mysql\_real\_connect()”  
Section 21.8.6.65, “mysql\_set\_server\_option()”  
Section 21.8.6.67, “mysql\_sqlstate()”  
Section 21.8.6.68, “mysql\_ssl\_set()”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.16, “C API Support for Multiple Statement Execution”  
Chapter 12, *Functions and Operators*  
Section 12.14, “Information Functions”  
Section 6.3.6, “Password Expiration and Sandbox Mode”  
Section 5.1.4, “Server System Variables”  
Section 13.5, “SQL Syntax for Prepared Statements”  
Section 18.2.1, “Stored Routine Syntax”

Section 5.6.4, “Using Client Programs in a Multiple-Server Environment”  
Section 6.3.9.3, “Using SSL Connections”

## **mysql\_real\_escape\_string()**

Section 21.8.6.16, “mysql\_escape\_string()”  
Section 21.8.6.54, “mysql\_real\_escape\_string()”  
Section 21.8.6.62, “mysql\_set\_character\_set()”  
Section 21.8.5, “C API Function Overview”  
Section 6.1.7, “Client Programming Security Guidelines”  
Section 12.18.4.4, “Populating Spatial Columns”  
Section 9.1.1, “String Literals”

## **mysql\_real\_query()**

Section 13.2.1, “CALL Syntax”  
Section 14.9.1, “FEDERATED Storage Engine Overview”  
Section 21.8.6.1, “mysql\_affected\_rows()”  
Section 21.8.6.46, “mysql\_next\_result()”  
Section 21.8.6.52, “mysql\_query()”  
Section 21.8.6.53, “mysql\_real\_connect()”  
Section 21.8.6.55, “mysql\_real\_query()”  
Section 21.8.6.65, “mysql\_set\_server\_option()”  
Section 21.8.6.70, “mysql\_store\_result()”  
Section 21.8.6.72, “mysql\_use\_result()”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.16, “C API Support for Multiple Statement Execution”

## **mysql\_refresh()**

Section 21.8.6.56, “mysql\_refresh()”  
Section 21.8.5, “C API Function Overview”

## **mysql\_reload()**

Section 21.8.6.57, “mysql\_reload()”  
Section 21.8.5, “C API Function Overview”

## **mysql\_rollback()**

Section 21.8.6.58, “mysql\_rollback()”  
Section 21.8.5, “C API Function Overview”

## **mysql\_row\_seek()**

Section 21.8.6.59, “mysql\_row\_seek()”  
Section 21.8.6.60, “mysql\_row\_tell()”  
Section 21.8.6.70, “mysql\_store\_result()”  
Section 21.8.6.72, “mysql\_use\_result()”  
Section 21.8.5, “C API Function Overview”

## **mysql\_row\_tell()**

Section 21.8.6.59, “mysql\_row\_seek()”  
Section 21.8.6.60, “mysql\_row\_tell()”  
Section 21.8.6.70, “mysql\_store\_result()”  
Section 21.8.6.72, “mysql\_use\_result()”  
Section 21.8.5, “C API Function Overview”

## **mysql\_select\_db()**

Section 21.8.6.61, “mysql\_select\_db()”

---

Section 21.8.5, “C API Function Overview”

## **mysql\_server\_end()**

Section 21.8.12.2, “mysql\_server\_end()”

Section 21.8.5, “C API Function Overview”

## **mysql\_server\_init()**

Section 21.8.11.1, “my\_init()”

Section 21.8.12.1, “mysql\_server\_init()”

Section 21.8.11.3, “mysql\_thread\_init()”

Section 21.8.5, “C API Function Overview”

## **mysql\_set\_character\_set()**

Section 21.8.6.26,

“mysql\_get\_character\_set\_info()”

Section 21.8.6.54, “mysql\_real\_escape\_string()”

Section 21.8.6.62, “mysql\_set\_character\_set()”

Section 21.8.5, “C API Function Overview”

## **mysql\_set\_local\_infile\_defaults()**

Section 21.8.6.63,

“mysql\_set\_local\_infile\_default()”

Section 21.8.5, “C API Function Overview”

## **mysql\_set\_local\_infile\_handler()**

Section 21.8.6.63,

“mysql\_set\_local\_infile\_default()”

Section 21.8.6.64,

“mysql\_set\_local\_infile\_handler()”

Section 21.8.5, “C API Function Overview”

## **mysql\_set\_server\_option()**

Section 21.8.6.65, “mysql\_set\_server\_option()”

Section 21.8.5, “C API Function Overview”

Section 21.8.16, “C API Support for Multiple Statement Execution”

## **mysql\_shutdown()**

Section 21.8.6.66, “mysql\_shutdown()”

Section 21.8.5, “C API Function Overview”

## **mysql\_sqlstate()**

Section 21.8.6.14, “mysql\_errno()”

Section 21.8.6.67, “mysql\_sqlstate()”

Section 21.8.5, “C API Function Overview”

Section 13.6.7.5.1, “Signal Condition Information Items”

Section C.2, “Types of Error Values”

## **mysql\_ssl\_set()**

Section 21.8.6.53, “mysql\_real\_connect()”

Section 21.8.6.68, “mysql\_ssl\_set()”

Section 21.8.5, “C API Function Overview”

Section 6.3.9.3, “Using SSL Connections”

## **mysql\_stat()**

Section 21.8.6.69, “mysql\_stat()”

Section 21.8.5, “C API Function Overview”

## **mysql\_stmt\_affected\_rows()**

Section 21.8.10.1, “mysql\_stmt\_affected\_rows()”

Section 21.8.10.10, “mysql\_stmt\_execute()”

Section 21.8.10.17, “mysql\_stmt\_next\_result()”

Section 21.8.10.18, “mysql\_stmt\_num\_rows()”

Section 21.8.9, “C API Prepared Statement Function Overview”

## **mysql\_stmt\_attr\_get()**

Section 21.8.10.2, “mysql\_stmt\_attr\_get()”

Section 21.8.9, “C API Prepared Statement Function Overview”

## **mysql\_stmt\_attr\_set()**

Section 21.8.10.3, “mysql\_stmt\_attr\_set()”

Section 21.8.10.10, “mysql\_stmt\_execute()”

Section 21.8.10.11, “mysql\_stmt\_fetch()”

Section 21.8.10.28, “mysql\_stmt\_store\_result()”

Section 21.8.4, “C API Data Structures”

Section 21.8.9, “C API Prepared Statement Function Overview”

Section 21.8.8.2, “C API Prepared Statement Type Conversions”

Section E.3, “Restrictions on Server-Side Cursors”

## **mysql\_stmt\_bind\_param()**

Section 21.8.10.4, “mysql\_stmt\_bind\_param()”

Section 21.8.10.10, “mysql\_stmt\_execute()”

Section 21.8.10.21, “mysql\_stmt\_prepare()”

Section 21.8.10.26,

“mysql\_stmt\_send\_long\_data()”

Section 21.8.8, “C API Prepared Statement Data Structures”

Section 21.8.9, “C API Prepared Statement Function Overview”

Section 21.8.18, “C API Prepared Statement Handling of Date and Time Values”

## **mysql\_stmt\_bind\_result()**

Section 21.8.10.5, “mysql\_stmt\_bind\_result()”

Section 21.8.10.11, “mysql\_stmt\_fetch()”

Section 21.8.10.12, “mysql\_stmt\_fetch\_column()”

Section 21.8.10.17, “mysql\_stmt\_next\_result()”

Section 21.8.10.28, “mysql\_stmt\_store\_result()”

Section 21.8.8, “C API Prepared Statement Data Structures”

Section 21.8.9, “C API Prepared Statement Function Overview”

Section 21.8.18, “C API Prepared Statement Handling of Date and Time Values”

## **mysql\_stmt\_close()**

Section 21.8.10.6, “mysql\_stmt\_close()”

Section 21.8.10.15, “mysql\_stmt\_init()”

---

Section 21.8.8, “C API Prepared Statement Data Structures”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_data\_seek()**

Section 21.8.10.7, “mysql\_stmt\_data\_seek()”  
Section 21.8.10.24, “mysql\_stmt\_row\_seek()”  
Section 21.8.10.28, “mysql\_stmt\_store\_result()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_errno()**

Section 21.8.10.8, “mysql\_stmt\_errno()”  
Section 21.8.10.11, “mysql\_stmt\_fetch()”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section C.2, “Types of Error Values”

### **mysql\_stmt\_error()**

Section 21.8.10.9, “mysql\_stmt\_error()”  
Section 21.8.10.11, “mysql\_stmt\_fetch()”  
Section 21.8.10.21, “mysql\_stmt\_prepare()”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section C.2, “Types of Error Values”

### **mysql\_stmt\_execute()**

Section 21.8.10.1, “mysql\_stmt\_affected\_rows()”  
Section 21.8.10.3, “mysql\_stmt\_attr\_set()”  
Section 21.8.10.10, “mysql\_stmt\_execute()”  
Section 21.8.10.11, “mysql\_stmt\_fetch()”  
Section 21.8.10.17, “mysql\_stmt\_next\_result()”  
Section 21.8.10.26,  
“mysql\_stmt\_send\_long\_data()”  
Section 21.8.10.28, “mysql\_stmt\_store\_result()”  
Section 21.8.8, “C API Prepared Statement Data Structures”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section 21.8.18, “C API Prepared Statement Handling of Date and Time Values”  
Section 21.8.8.2, “C API Prepared Statement Type Conversions”  
Section 8.9.3.1, “How the Query Cache Operates”

### **mysql\_stmt\_fetch()**

Section 21.8.10.5, “mysql\_stmt\_bind\_result()”  
Section 21.8.10.10, “mysql\_stmt\_execute()”  
Section 21.8.10.11, “mysql\_stmt\_fetch()”  
Section 21.8.10.23,  
“mysql\_stmt\_result\_metadata()”  
Section 21.8.10.25, “mysql\_stmt\_row\_tell()”  
Section 21.8.10.28, “mysql\_stmt\_store\_result()”  
Section 21.8.8, “C API Prepared Statement Data Structures”

Section 21.8.9, “C API Prepared Statement Function Overview”  
Section 21.8.8.2, “C API Prepared Statement Type Conversions”

### **mysql\_stmt\_fetch\_column()**

Section 21.8.10.11, “mysql\_stmt\_fetch()”  
Section 21.8.10.12, “mysql\_stmt\_fetch\_column()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_field\_count()**

Section 21.8.10.13, “mysql\_stmt\_field\_count()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_free\_result()**

Section 21.8.10.3, “mysql\_stmt\_attr\_set()”  
Section 21.8.10.14, “mysql\_stmt\_free\_result()”  
Section 21.8.10.17, “mysql\_stmt\_next\_result()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_init()**

Section 21.8.10.10, “mysql\_stmt\_execute()”  
Section 21.8.10.15, “mysql\_stmt\_init()”  
Section 21.8.10.21, “mysql\_stmt\_prepare()”  
Section 21.8.8, “C API Prepared Statement Data Structures”  
Section 21.8.10, “C API Prepared Statement Function Descriptions”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section 21.8.7, “C API Prepared Statements”

### **mysql\_stmt\_insert\_id()**

Section 21.8.10.16, “mysql\_stmt\_insert\_id()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_next\_result()**

Section 13.2.1, “CALL Syntax”  
Section 21.8.10.17, “mysql\_stmt\_next\_result()”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section 21.8.19, “C API Support for Prepared CALL Statements”

### **mysql\_stmt\_num\_rows()**

Section 21.8.10.7, “mysql\_stmt\_data\_seek()”  
Section 21.8.10.18, “mysql\_stmt\_num\_rows()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_param\_count()**

Section 21.8.10.10, “mysql\_stmt\_execute()”

---

Section 21.8.10.19, “mysql\_stmt\_param\_count()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_param\_metadata()**

Section 21.8.10.20,  
“mysql\_stmt\_param\_metadata()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_prepare()**

Section 21.8.10.4, “mysql\_stmt\_bind\_param()”  
Section 21.8.10.10, “mysql\_stmt\_execute()”  
Section 21.8.10.13, “mysql\_stmt\_field\_count()”  
Section 21.8.10.21, “mysql\_stmt\_prepare()”  
Section 21.8.10.22, “mysql\_stmt\_reset()”  
Section 21.8.10.23,  
“mysql\_stmt\_result\_metadata()”  
Section 21.8.8, “C API Prepared Statement Data Structures”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section 21.8.18, “C API Prepared Statement Handling of Date and Time Values”  
Section 8.9.4, “Caching of Prepared Statements and Stored Programs”  
Section 8.9.3.1, “How the Query Cache Operates”  
Section 13.5, “SQL Syntax for Prepared Statements”

### **mysql\_stmt\_reset()**

Section 21.8.10.3, “mysql\_stmt\_attr\_set()”  
Section 21.8.10.22, “mysql\_stmt\_reset()”  
Section 21.8.10.26,  
“mysql\_stmt\_send\_long\_data()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_result\_metadata()**

Section 21.8.10.11, “mysql\_stmt\_fetch()”  
Section 21.8.10.23,  
“mysql\_stmt\_result\_metadata()”  
Section 21.8.10.28, “mysql\_stmt\_store\_result()”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section 21.8.8.2, “C API Prepared Statement Type Conversions”

### **mysql\_stmt\_row\_seek()**

Section 21.8.10.24, “mysql\_stmt\_row\_seek()”  
Section 21.8.10.25, “mysql\_stmt\_row\_tell()”  
Section 21.8.10.28, “mysql\_stmt\_store\_result()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_row\_tell()**

Section 21.8.10.24, “mysql\_stmt\_row\_seek()”

Section 21.8.10.25, “mysql\_stmt\_row\_tell()”  
Section 21.8.10.28, “mysql\_stmt\_store\_result()”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_stmt\_send\_long\_data()**

Section 21.8.10.22, “mysql\_stmt\_reset()”  
Section 21.8.10.26,  
“mysql\_stmt\_send\_long\_data()”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section 5.1.4, “Server System Variables”

### **mysql\_stmt\_sqlstate()**

Section 21.8.10.27, “mysql\_stmt\_sqlstate()”  
Section 21.8.9, “C API Prepared Statement Function Overview”  
Section C.2, “Types of Error Values”

### **mysql\_stmt\_store\_result()**

Section 21.8.10.3, “mysql\_stmt\_attr\_set()”  
Section 21.8.10.7, “mysql\_stmt\_data\_seek()”  
Section 21.8.10.11, “mysql\_stmt\_fetch()”  
Section 21.8.10.18, “mysql\_stmt\_num\_rows()”  
Section 21.8.10.24, “mysql\_stmt\_row\_seek()”  
Section 21.8.10.25, “mysql\_stmt\_row\_tell()”  
Section 21.8.10.28, “mysql\_stmt\_store\_result()”  
Section 21.8.4, “C API Data Structures”  
Section 21.8.9, “C API Prepared Statement Function Overview”

### **mysql\_store\_result()**

Section C.5.2.14, “Commands out of sync”  
Section 14.9.1, “FEDERATED Storage Engine Overview”  
Section 21.8.6.1, “mysql\_affected\_rows()”  
Section 21.8.6.9, “mysql\_data\_seek()”  
Section 21.8.6.13, “mysql\_eof()”  
Section 21.8.6.17, “mysql\_fetch\_field()”  
Section 21.8.6.21, “mysql\_fetch\_row()”  
Section 21.8.6.22, “mysql\_field\_count()”  
Section 21.8.6.25, “mysql\_free\_result()”  
Section 21.8.6.46, “mysql\_next\_result()”

Section 4.5.1, “mysql — The MySQL Command-Line Tool”  
Section 21.8.14.2, “What Results You Can Get from a Query”

---

Section 21.8.14.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”  
Section 21.8.3.2, “Writing C API Threaded Client Programs”

### **mysql\_thread\_end()**

Section 21.8.11.2, “`mysql_thread_end()`”  
Section 21.8.5, “C API Function Overview”  
Section 21.7, “libmysqld, the Embedded MySQL Server Library”  
Section 21.8.3.2, “Writing C API Threaded Client Programs”

### **mysql\_thread\_id()**

Section 21.8.6.51, “`mysql_ping()`”  
Section 21.8.6.71, “`mysql_thread_id()`”  
Section 21.8.5, “C API Function Overview”  
Section 21.8.15, “Controlling Automatic Reconnection Behavior”

### **mysql\_thread\_init()**

Section 21.8.11.1, “`my_init()`”  
Section 21.8.11.2, “`mysql_thread_end()`”  
Section 21.8.11.3, “`mysql_thread_init()`”  
Section 21.8.5, “C API Function Overview”  
Section 21.7, “libmysqld, the Embedded MySQL Server Library”  
Section 21.8.3.2, “Writing C API Threaded Client Programs”

### **mysql\_thread\_safe()**

Section 21.8.11.4, “`mysql_thread_safe()`”  
Section 21.8.5, “C API Function Overview”

### **mysql\_use\_result()**

Section C.5.2.14, “Commands out of sync”  
Section 21.8.6.9, “`mysql_data_seek()`”  
Section 21.8.6.13, “`mysql_eof()`”  
Section 21.8.6.21, “`mysql_fetch_row()`”  
Section 21.8.6.25, “`mysql_free_result()`”  
Section 21.8.6.46, “`mysql_next_result()`”  
Section 21.8.6.47, “`mysql_num_fields()`”  
Section 21.8.6.48, “`mysql_num_rows()`”  
Section 21.8.6.59, “`mysql_row_seek()`”  
Section 21.8.6.60, “`mysql_row_tell()`”  
Section 21.8.10.10, “`mysql_stmt_execute()`”  
Section 21.8.6.70, “`mysql_store_result()`”  
Section 21.8.6.72, “`mysql_use_result()`”  
Section C.5.2.8, “Out of memory”  
Section 21.8.4, “C API Data Structures”  
Section 21.8.5, “C API Function Overview”  
Section 4.5.1, “`mysql` — The MySQL Command-Line Tool”  
Section 21.8.14.2, “What Results You Can Get from a Query”

Section 21.8.3.2, “Writing C API Threaded Client Programs”

### **mysql\_warning\_count()**

Section 21.8.6.46, “`mysql_next_result()`”  
Section 21.8.6.73, “`mysql_warning_count()`”  
Section 13.7.5.41, “`SHOW WARNINGS` Syntax”  
Section 21.8.5, “C API Function Overview”  
Section C.2, “Types of Error Values”
